Data

A scalar or an array of entity structures.

Keywords

None

Examples

In the following example, we create a new shapefile, define a new entity, and then use the PutEntity method to insert it into the new file:

```
PRO ex_shapefile_putentity

; Create the new shapefile and define the entity type to Point.
mynewshape=OBJ_NEW('IDLffShape',
DIALOG_PICKFILE(FILE='shape_entity.shp', /WRITE), $
    /UPDATE, ENTITY_TYPE=1)
```

```
; Create structure for new entity.
entNew = {IDL_SHAPE_ENTITY}

; Define the values for the new entity.
entNew.SHAPE_TYPE = 1
entNew.BOUNDS[0] = -104.87270
entNew.BOUNDS[1] = 39.768040
entNew.BOUNDS[2] = 0.00000000
entNew.BOUNDS[3] = 0.00000000
entNew.BOUNDS[4] = -104.87270
entNew.BOUNDS[5] = 39.768040
entNew.BOUNDS[6] = 0.00000000
entNew.BOUNDS[7] = 0.00000000

; Add the new entity to new shapefile.
mynewshape->PutEntity, entNew

; Close the shapefile
mynewshape->Close

; Close the shapefile.
OBJ_DESTROY, mynewshape

END
```

IDLffShape::SetAttributes

The IDLffShape::SetAttributes procedure method sets the attributes for a specified entity in a Shapefile object.

Syntax

Obj->[IDLffShape::]SetAttributes, *Index*, *Attribute_Num*, *Value*

or

Obj->[IDLffShape::]SetAttributes, *Index*, *Value*

Arguments

Attribute_Num

The field number in the attribute structure for the attribute whose value is being set. This value is 0-based.

Attributes

An Attribute structure whose fields match the fields in the attribute table. If *Attributes* is an array, the entities specified in *Index*, up to the size of the Attributes array, are set. Using this feature, all the attribute values of a set of entities can be set for a Shapefile.

The type of this Attribute structure must match the type that is generated internally for Attribute table. To get a copy of this structure, either get the attribute set for an entity or get the definition using the ATTRIBUTE_STRUCTURE keyword of the IDLffShape::GetProperty method.

Index

A scalar or array of integers specifying the entity in which you want to set the attributes. If *Index* is a scalar, then it specifies the starting point at which to start writing the attributes as given by the *Value* argument. If *Index* is an array with the same number of elements as *Value*, then *Index* specifies the indices of the attributes to write. When writing new attributes, the attributes must be written in order, starting at index 0, with no gaps. When overwriting existing attributes, the attributes may be written in any order.

Value

If *Attribute_Num* is present, then *Value* is the value (or array of values) of the field within the attribute. If the value is not of the correct type, type conversion is attempted.

If *Attribute_Num* is not present, then *Value* is an *Attribute* structure (or array of structures) whose fields match the fields in the attribute table. The type of this *Attribute* structure must match the type that is generated internally for *Attribute* table. To get a copy of this structure, either get the attribute set for an entity or get the definition using the ATTRIBUTE_STRUCTURE keyword of the IDLffShape::GetProperty method. If *Value* is an array, the attributes specified in *Index* are set. Using this feature, all the attribute values of a set of entities can be set for a Shapefile.

Keywords

None

Examples

For an example of SetAttributes, see "Creating New Shapefiles" on page 3389. In this example you will create a new shapefile, define the attributes for the new file, define a new entity, define some attributes, insert the new entity, and then use the SetAttributes method to insert the attributes into the new file.

IDLffXMLDOM Classes

IDL's XML Document Object Model (DOM) support comprises the following IDL object classes. For more information on using the XML DOM classes, see Chapter 21, "Using the XML DOM Object Classes" (*Application Programming*). For more information on XML, see "About XML" (Chapter 20, *Application Programming*).

- "IDLffXMLDOMAttr" on page 3421
- "IDLffXMLDOMCDATASection" on page 3430
- "IDLffXMLDOMCharacterData" on page 3434
- "IDLffXMLDOMComment" on page 3447
- "IDLffXMLDOMDocument" on page 3451
- "IDLffXMLDOMDocumentFragment" on page 3489
- "IDLffXMLDOMDocumentType" on page 3494
- "IDLffXMLDOMElement" on page 3501
- "IDLffXMLDOMEntity" on page 3514
- "IDLffXMLDOMEntityReference" on page 3521
- "IDLffXMLDOMNamedNodeMap" on page 3525
- "IDLffXMLDOMNode" on page 3536
- "IDLffXMLDOMNodeIterator" on page 3564
- "IDLffXMLDOMNodeList" on page 3571
- "IDLffXMLDOMNotation" on page 3577
- "IDLffXMLDOMProcessingInstruction" on page 3583
- "IDLffXMLDOMText" on page 3590
- "IDLffXMLDOMTreeWalker" on page 3596

IDLffXMLDOMAttr

The IDLffXMLDOMAttr object represents an attribute that is part of an element object. Typically, the allowable values for the attribute are defined in a DTD.

Attribute objects are subclasses of the IDLffXMLDOMNode abstract superclass, but are not actually child nodes of the elements they describe and are not considered as part of the DOM tree. Therefore, an attribute object does not have a parent or siblings, and so the ParentNode(), NextSibling(), and PreviousSibling() methods always return a null object reference. The DOM takes the view that attributes are properties of elements, rather than having a separate identity.

An attribute's value may be explicitly assigned or may take on a default value as described by a DTD. If neither of these alternatives is true, the attribute does not exist in the element. Use the IDLffXMLDOMAttr::GetSpecified method to determine if the value was explicitly specified or has taken on the default value.

If the value of an attribute may contain entity references, then the attribute node may have either text or entity-reference child nodes.

Superclasses

IDLffXMLDOMNode

Creation

See IDLffXMLDOMAttr::Init.

Properties

Objects of this class have no properties of their own, but do have properties inherited from any superclasses.

Methods

This class has the following methods:

- IDLffXMLDOMAttr::Cleanup
- IDLffXMLDOMAttr::GetName
- IDLffXMLDOMAttr::GetSpecified
- IDLffXMLDOMAttr::GetValue

- IDLffXMLDOMAttr::Init
- IDLffXMLDOMAttr::SetValue

In addition, this class inherits the methods of any superclasses.

Version History

6.1	Introduced

IDLffXMLDOMAttr Properties

Objects of this class have no properties of their own, but do have properties inherited from any superclasses.

Objects of this class inherit:

- IDLffXMLDOMNode

IDLffXMLDOMAttr::Cleanup

The IDLffXMLDOMAttr::Cleanup procedure method destroys both the object (that is, the accessing object in the IDL tree) and any objects created by that object. It does not modify the actual DOM tree.

This class should not be subclassed by a user class because the classes that create objects, such as IDLffXMLDOMDocument, will not be aware of any user-defined classes.

Syntax

OBJ_DESTROY, *Obj*

Arguments

None

Keywords

None

Version History

6.1	Introduced

IDLffXMLDOMAttr::GetName

The IDLffXMLDOMAttr::GetName function method returns the name of the attribute node.

Syntax

Result = Obj->[IDLffXMLDOMAttr::]GetName()

Return Value

Returns a scalar string containing the name of the attribute node.

Arguments

None

Keywords

None

Version History

6.1	Introduced

IDLffXMLDOMAttr::GetSpecified

The IDLffXMLDOMAttr::GetSpecified function method returns a scalar integer indicating how the value of the attribute node was set.

Syntax

Result = Obj->[IDLffXMLDOMAttr::]GetSpecified()

Return Value

Returns 1 if the value of the attribute node was explicitly set in the XML document or was set programmatically with the IDLffXMLDOMAttr::SetValue method. Returns 0 if the attribute's value was established from the default value declared in the document's DTD.

Arguments

None

Keywords

None

Version History

6.1	Introduced

IDLffXMLDOMAttr::GetValue

The IDLffXMLDOMAttr::GetValue function method returns the value of the attribute node.

Syntax

Result = Obj->[IDLffXMLDOMAttr::]GetValue()

Return Value

Returns a scalar string containing the value of the attribute node.

Arguments

None

Keywords

None

Version History

6.1	Introduced

IDLffXMLDOMAttr::Init

The IDLffXMLDOMAttr::Init function method initializes the object, but this class should not be instantiated directly. Instead, methods such as IDLffXMLDOMNode::GetAttributes are used to create objects of this class.

This class should not be subclassed by a user class because the classes that create objects, such as IDLffXMLDOMDocument, will not be aware of any user-defined classes.

IDLffXMLDOMAttr::SetValue

The IDLffXMLDOMAttr::SetValue procedure method sets the value of the attribute node, using the *Value* argument.

Syntax

Obj->[IDLffXMLDOMAttr::]SetValue, *Value*

Arguments

Value

A scalar string used to set the value of the attribute node.

Keywords

None

Version History

6.1	Introduced

IDLffXMLDOMCDATASection

The IDLffXMLDOMCDATASection object is used to escape blocks of text containing characters that would otherwise be regarded as markup. The only delimiter that is recognized in a CDATA section is the "]]>" string that ends the CDATA section. CDATA sections cannot be nested. The primary purpose is for including material such as XML fragments without needing to escape all the delimiters.

There are no methods specific to this class except Cleanup and Init.

Superclasses

IDLffXMLDOMNode

IDLffXMLDOMCharacterData

IDLffXMLDOMText

Creation

See IDLffXMLDOMCDATASection::Init.

Properties

Objects of this class have no properties of their own, but do have properties inherited from any superclasses.

Methods

This class has the following methods:

- IDLffXMLDOMCDATASection::Cleanup
- IDLffXMLDOMCDATASection::Init

In addition, this class inherits the methods of any superclasses.

Keywords

None

Version History

6.1	Introduced

IDLffXMLDOMCDATASection::Init

The IDLffXMLDOMCDATASection::Init function method initializes the object, but this class should not be instantiated directly. Instead, methods such as IDLffXMLDOMNode::GetFirstChild are used to create objects of all classes except IDLffXMLDOMDocument.

This class should not be subclassed by a user class because the classes that create objects, such as IDLffXMLDOMDocument, will not be aware of any user-defined classes.

IDLffXMLDOMCharacterData

The IDLffXMLDOMCharacterData class extends the IDLffXMLDOMNode class with a set of methods for accessing character data in the DOM tree. This is an abstract class in the sense that there will never be an instance of this class, but its methods are available to its subclasses.

Superclasses

IDLffXMLDOMNode

Creation

See IDLffXMLDOMCharacterData::Init.

Properties

Objects of this class have no properties of their own, but do have properties inherited from any superclasses.

Methods

This class has the following methods:

- IDLffXMLDOMCharacterData::AppendData
- IDLffXMLDOMCharacterData::Cleanup
- IDLffXMLDOMCharacterData::DeleteData
- IDLffXMLDOMCharacterData::GetData
- IDLffXMLDOMCharacterData::GetLength
- IDLffXMLDOMCharacterData::Init
- IDLffXMLDOMCharacterData::InsertData
- IDLffXMLDOMCharacterData::ReplaceData
- IDLffXMLDOMCharacterData::SetData
- IDLffXMLDOMCharacterData::SubstringData

In addition, this class inherits the methods of any superclasses.

Version History

6.1	Introduced

IDLffXMLDOMCharacterData Properties

Objects of this class have no properties of their own, but do have properties inherited from any superclasses.

Objects of this class inherit:

- IDLffXMLDOMNode

IDLffXMLDOMCharacterData::AppendData

The IDLffXMLDOMCharacterData::AppendData procedure method appends a string to the character data in the node.

Syntax

Obj->[IDLffXMLDOMCharacterData::]AppendData, *String*

Arguments

String

A scalar string to be added at the end of the character data.

Keywords

None

Version History

6.1	Introduced

IDLffXMLDOMCharacterData::Cleanup

The IDLffXMLDOMCharacterData::Cleanup procedure method destroys both the object (that is, the accessing object in the IDL tree) and any objects created by that object. It does not modify the actual DOM tree.

This class should not be subclassed by a user class because the classes that create objects, such as IDLffXMLDOMDocument, will not be aware of any user-defined classes.

Syntax

OBJ_DESTROY, *Obj*

Arguments

None

Keywords

None

Version History

6.1	Introduced

IDLffXMLDOMCharacterData::DeleteData

The IDLffXMLDOMCharacterData::DeleteData procedure method deletes a number of characters from the character data in the node, starting at an offset.

Syntax

Obj->[IDLffXMLDOMCharacterData::]DeleteData, *Offset*, *Count*

Arguments

Offset

A scalar value that indicates where to begin deleting characters.

Count

A scalar number of characters to delete.

Keywords

None

Version History

6.1	Introduced

IDLffXMLDOMCharacterData::GetData

The IDLffXMLDOMCharacterData::GetData function method returns the character data in the node.

Syntax

Result = Obj->[IDLffXMLDOMCharacterData::]GetData()

Return Value

Returns a scalar string containing the character data in the node.

Arguments

None

Keywords

None

Version History

6.1	Introduced

IDLffXMLDOMCharacterData::GetLength

The IDLffXMLDOMCharacterData::GetLength function method returns the number of characters in the node.

Syntax

Result = Obj->[IDLffXMLDOMCharacterData::]GetLength()

Return Value

Returns a scalar string containing the number of characters in the node. This value may be zero.

Arguments

None

Keywords

None

Version History

6.1	Introduced

IDLffXMLDOMCharacterData::Init

The IDLffXMLDOMCharacterData::Init function method initializes the object, but this class should not be instantiated directly. Instead, methods such as IDLffXMLDOMNode::GetFirstChild are used to create objects of all classes except IDLffXMLDOMDocument.

This class should not be subclassed by a user class because the classes that create objects, such as IDLffXMLDOMDocument, will not be aware of any user-defined classes.

IDLffXMLDOMCharacterData::InsertData

The IDLffXMLDOMCharacterData::InsertData procedure method inserts a string in the node's character data at a specified offset.

Syntax

Obj->[IDLffXMLDOMCharacterData::]InsertData, *Offset*, *String*

Arguments

Offset

A scalar value that indicates where in the character data to begin inserting the string contained in *String*.

String

A scalar string to be inserted in the character data at the point indicated by *Offset*.

Keywords

None

Version History

6.1	Introduced

IDLffXMLDOMCharacterData::ReplaceData

The IDLffXMLDOMCharacterData::ReplaceData procedure method replaces a number of characters, starting at an offset in the node's character data, with a string.

Syntax

Obj->[IDLffXMLDOMCharacterData::]ReplaceData, *Offset*, *Count*, *String*

Arguments

Offset

A scalar value that indicates where in the character data to begin replacement.

Count

A scalar number of characters in the character data to replace.

String

A scalar string to be inserted in the character data at the point indicated by *Offset*.

Keywords

None

Version History

6.1	Introduced

IDLffXMLDOMCharacterData::SetData

The IDLffXMLDOMCharacterData::SetData procedure method sets the node's character data to a string.

Syntax

Obj->[IDLffXMLDOMCharacterData::]SetData, *String*

Arguments

String

A scalar string to be set in the node.

Keywords

None

Version History

6.1	Introduced

IDLffXMLDOMCharacterData::SubstringData

The IDLffXMLDOMCharacterData::SubstringData function method returns a string composed of a substring of the node's character data.

Syntax

Result = Obj->[IDLffXMLDOMCharacterData::]SubstringData(*Offset, Count)*

Return Value

Returns a string containing a substring of the node's character data that starts at *Offset* and has a length specified by *Count*.

Arguments

Offset

A scalar value that indicates where in the character data to begin the substring.

Count

A scalar length of the substring.

Keywords

None

Version History

6.1	Introduced

IDLffXMLDOMComment

The IDLffXMLDOMComment class represents the content of a comment, the characters between the starting "<!--" and the ending "-->".

There are no methods specific to this class except Cleanup and Init.

Superclasses

IDLffXMLDOMNode

IDLffXMLDOMCharacterData

Creation

See IDLffXMLDOMComment::Init.

Properties

Objects of this class have no properties of their own, but do have properties inherited from its superclasses.

Methods

This class has the following methods:

- IDLffXMLDOMComment::Cleanup
- IDLffXMLDOMComment::Init

In addition, this class inherits the methods of any superclasses.

Version History

IDLffXMLDOMComment::Init

The IDLffXMLDOMComment::Init function method initializes the object, but this class should not be instantiated directly. Instead, methods such as IDLffXMLDOMNode::GetFirstChild are used to create objects of all classes except IDLffXMLDOMDocument.

This class should not be subclassed by a user class because the classes that create objects, such as IDLffXMLDOMDocument, will not be aware of any user-defined classes.

IDLffXMLDOMDocument

The IDLffXMLDOMDocument class represents the entire XML document as the root of the document tree and by providing the primary access to the document's data.

This class is also the class factory for DOM tree nodes such as IDLffXMLDOMText since all DOM tree nodes must belong to a specific document. To this end, this class includes methods that create DOM tree nodes of all the various types.

Note that nodes created with these factory methods belong to the document, but are not part of the DOM tree structure until they are inserted into the DOM tree. See the relevant methods in the IDLffXMLDOMNode class for details on inserting nodes into the DOM tree.

Superclasses

IDLffXMLDOMNode

Creation

See IDLffXMLDOMDocument::Init.

Properties

Objects of this class have the following properties. See "IDLffXMLDOMDocument Properties" on page 3453 for details on individual properties.

- NODE_DESTRUCTION_POLICY

Methods

This class has the following methods:

- IDLffXMLDOMDocument::Cleanup
- IDLffXMLDOMDocument::CreateAttribute
- IDLffXMLDOMDocument::CreateCDATASection
- IDLffXMLDOMDocument::CreateComment
- IDLffXMLDOMDocument::CreateElement
- IDLffXMLDOMDocument::CreateDocumentFragment

- IDLffXMLDOMDocument::CreateEntityReference
- IDLffXMLDOMDocument::CreateNodeIterator
- IDLffXMLDOMDocument::CreateProcessingInstruction
- IDLffXMLDOMDocument::CreateTextNode
- IDLffXMLDOMDocument::CreateTreeWalker
- IDLffXMLDOMDocument::GetDoctype
- IDLffXMLDOMDocument::GetDocumentElement
- IDLffXMLDOMDocument::GetElementsByTagName
- IDLffXMLDOMDocument::GetProperty
- IDLffXMLDOMDocument::Init
- IDLffXMLDOMDocument::Load
- IDLffXMLDOMDocument::Save
- IDLffXMLDOMDocument::SetProperty

In addition, this class inherits the methods of any superclasses.

Version History

6.1	Introduced
6.2	Added NODE_DESTRUCTION_POLICY property.
	Added CreateNodeIterator, CreateTreeWalker, GetProperty and SetProperty methods.

IDLffXMLDOMDocument Properties

IDLffXMLDOMDocument objects have the following properties in addition to properties inherited from any superclasses. Properties with the word "Yes" in the "Get" column of the property table can be retrieved via IDLffXMLDOMDocument::GetProperty. Properties with the word "Yes" in the "Init" column of the property table can be set via IDLffXMLDOMDocument::Init. Properties with the word "Yes" in the "Set" column in the property table can be set via IDLffXMLDOMDocument::SetProperty.

Note ───

For a discussion of the property description tables shown below, see "About Object Property Descriptions" on page 3135.

──

Objects of this class have the following properties.

• NODE_DESTRUCTION_POLICY

In addition, objects of this class inherit properties from the following superclass:

• IDLffXMLDOMNode

NODE_DESTRUCTION_POLICY

A scalar integer that specifies the node destruction policy for all node objects created directly or indirectly by a document object. The property value is not changed if you attempt to set it to other than one of the supported values:

0	When OBJ_DESTROY destroys a node object, it also destroys all node objects that the node created. These nodes, in turn, destroy all the nodes that they created, and so on. This is the default property value.
1	OBJ_DESTROY destroys only the node object for which it is called.

The destruction policy used for node destruction is obtained from the document object's property at the time a node object is destroyed. Thus, the document object's node destruction policy property can be changed between node destructions to use a specific destruction policy for certain nodes.

For all values of this property, all of the nodes created directly or indirectly by the document object are destroyed when the document object itself is destroyed.

For example, consider the following code:

```
oChild = oElement->getFirstChild()
oParent = oElement->getParentNode()
OBJ_DESTROY, oElement
```

If NODE_DESTRUCTION_POLICY has a value of 0 when OBJ_DESTROY is called, all three nodes, `oChild`, `oParent`, and `oElement`, are destroyed. If the property has a value of 1 when OBJ_DESTROY is called, only `oElement` is destroyed.

Property Type	Integer		
Name String	*not displayed*		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** No

IDLffXMLDOMDocument::Cleanup

The IDLffXMLDOMDocument::Cleanup procedure method destroys both the object (that is, the accessing object in the IDL tree) and any objects created by that object. It does not modify the actual DOM tree.

Syntax

OBJ_DESTROY, *Obj*

or

Obj->[IDLffXMLDOMDocument::]Cleanup   *(In a lifecycle method only.)*

Arguments

None

Keywords

None

Version History

6.1	Introduced

IDLffXMLDOMDocument::CreateAttribute

The IDLffXMLDOMDocument::CreateAttribute function method creates and names an attribute node that is owned by the document. The new attribute can be set in an Element node with the IDLffXMLDOMElement::SetAttributeNode method.

Syntax

Result = Obj->[IDLffXMLDOMDocument::]CreateAttribute(*Name*)

Return Value

Returns an object reference to the new IDLffXMLDOMAttr node.

Arguments

Name

A scalar string containing the attribute name.

Keywords

None

Version History

6.1	Introduced

IDLffXMLDOMDocument::CreateCDATASection

The IDLffXMLDOMDocument::CreateCDATASection function method creates a CDATASection node that is owned by the document and stores a string in the CDATASection node.

Syntax

Result = Obj->[IDLffXMLDOMDocument::]CreateCDATASection(*String*)

Return Value

Returns an object reference to the new IDLffXMLDOMCDATASection node.

Arguments

String

A scalar string to put in the new CDATASection node.

Keywords

None

Version History

6.1	Introduced

IDLffXMLDOMDocument::CreateComment

The IDLffXMLDOMDocument::CreateComment function method creates a comment node that is owned by the document and stores a string in the comment node.

Syntax

Result = Obj->[IDLffXMLDOMDocument::]CreateComment(*String*)

Return Value

Returns an object reference to the new IDLffXMLDOMComment node.

Arguments

String

A scalar string to put in the new comment node.

Keywords

None

Version History

6.1	Introduced

IDLffXMLDOMDocument::CreateDocumentFragment

The IDLffXMLDOMDocument::CreateDocumentFragment function method creates a document-fragment node that is owned by the document.

Syntax

Result = Obj->[IDLffXMLDOMDocument::]CreateDocumentFragment()

Return Value

Returns an object reference to the new IDLffXMLDOMDocumentFragment node.

Arguments

None

Keywords

None

Version History

6.1	Introduced

IDLffXMLDOMDocument::CreateElement

The IDLffXMLDOMDocument::CreateElement function method creates an element node that is owned by the document and sets the element's name to a tag name.

Syntax

Result = Obj->[IDLffXMLDOMDocument::]CreateElement(*TagName*)

Return Value

Returns an object reference to the new IDLffXMLDOMElement node.

Arguments

TagName

A scalar string that contains the name of the element.

Keywords

None

Version History

6.1	Introduced

IDLffXMLDOMDocument::CreateEntityReference

The IDLffXMLDOMDocument::CreateEntityReference function method creates and names an entity reference node that is owned by the document.

Syntax

Result = Obj->[IDLffXMLDOMDocument::]CreateEntityReference(*Name*)

Return Value

Returns an object reference to the new IDLffXMLDOMEntityReference node.

Arguments

Name

A scalar string that contains the entity reference name.

Keywords

None

Version History

6.1	Introduced

IDLffXMLDOMDocument::CreateNodeIterator

The IDLffXMLDOMDocument::CreateNodeIterator function method is used to create an instance of an IDLffXMLDOMNodeIterator object. This function returns an object reference to that instance.

Please note the following exceptions in node iteration:

- Attributes are never children of DOM nodes, so they are not visited by the node iterator. Showing attributes is only meaningful when the iterator root node is an attribute.

- Entities are not part of the DOM tree, so they are not visited by the node iterator. Showing entities is only meaningful when the iterator root node is an entity.

- Notations are not part of the DOM tree, so they are not visited by the node iterator. Showing notations is only meaningful when the iterator root node is a notation.

Syntax

Result = Obj->[IDLffXMLDOMDocument::]CreateNodeIterator(*RootNode*
   [, FILTER_NAME=*string*] [, FILTER_USERDATA=*variable*]
   [, WHAT_TO_SHOW=*value*])

Arguments

RootNode

An object reference to an object that is a subclass of IDLffXMLDOMNode that refers to a node in the DOM tree. The iterator's current position is set immediately before this node. If this object reference is NULL, the iterator's current position is set immediately before the document node.

Keywords

FILTER_NAME

Set this keyword to a scalar string containing the name of an IDL function that is called each time the iterator is about to visit a node. The purpose of this function is to allow the iterator to ask the IDL application if it should visit a particular node, and hence return it in response to an IDLffXMLDOMNodeIterator::NextNode or

IDLffXMLDOMNodeIterator::PreviousNode method call. The code in this function should analyze the incoming node and then return a value that instructs the iterator to accept or reject the node.

If this keyword is not specified, the node iterator visits every node.

Nodes that are accepted are returned by IDLffXMLDOMNodeIterator::NextNode and IDLffXMLDOMNodeIterator::PreviousNode. Nodes that are rejected are not returned by these methods.

The filter function is called by the iterator for the given node after the determinations are made with respect to the WHAT_TO_SHOW setting. Therefore, the filter function is not called for nodes that are rejected by the WHAT_TO_SHOW property.

The filter function specified by FILTER_NAME must have the following parameters:

- **Node Object** — an object reference to an instance of an IDLffXMLDOMNode subclass. This parameter is required and is supplied by the iterator on every call.

- **USERDATA** — an optional keyword parameter set by the iterator to a variable containing a copy of the data provided in the FILTER_USERDATA keyword. If FILTER_USERDATA is not specified, USERDATA is not passed by the iterator.

The function must return one of three scalar integer values:

Value	Function
1	ACCEPT: this node is visited by the node iterator
2	REJECT: this node is not visited by the node iterator
3	SKIP: this node is not visited by the node iterator (same as REJECT)

Table 30-20: Return Values for CreateNodeIterator's Filter Function

SKIP and REJECT have the same meanings for a node iterator, but have different meanings for a tree walker. This makes it possible for a single filter function to be used with either a node iterator or tree walker. If the function returns a value that is not supported, the iterator visits the node, as if the return value was 1 (ACCEPT). If the function returns a value that cannot be converted to a scalar, IDL throws an error.

The function should not destroy the node object passed as the first parameter.

FILTER_USERDATA

Set this keyword to an IDL variable containing data to pass to the filter function each time the iterator calls the filter function. The iterator creates a copy of this variable to pass on each call.

Supplying this keyword without FILTER_NAME produces no effect on the iterator.

WHAT_TO_SHOW

Set this keyword to a scalar unsigned integer containing a bitmask, where each bit indicates types of nodes that the iterator visits. If this keyword is not specified, the node iterator visits every node.

Type	Value (Hex)	Value (Decimal)
ALL	'ffff'xu	65535U
Element	'0001'xu	1U
Attribute	'0002'xu	2U
Text	'0004'xu	4U

Notation	'0800'xu	2048U

Table 30-21: Bitmasks for CreateNodeIterator's WHAT_TO_SHOW Keyword

The node iterator performs the WHAT_TO_SHOW test for a node before calling any user-provided filter function.

Version History

6.2	Introduced

IDLffXMLDOMDocument::CreateProcessingInstruction

The IDLffXMLDOMDocument::CreateProcessingInstruction function method creates a processing-instruction node that is owned by the document and stores two strings in the processing-instruction node.

Syntax

Result = Obj->[IDLffXMLDOMDocument::]CreateProcessingInstruction(*Target*, *Data*)

Return Value

Returns an object reference to the new IDLffXMLDOMProcessingInstruction node.

Arguments

Target

A scalar string to store in the processing-instruction target.

Data

A scalar string to store in the processing-instruction data.

Keywords

None

Version History

6.1	Introduced

IDLffXMLDOMDocument::CreateTextNode

The IDLffXMLDOMDocument::CreateTextNode function method creates a text node that is owned by the document and stores a string in the text node.

Syntax

Result = Obj->[IDLffXMLDOMDocument::]CreateTextNode(*String)*

Return Value

Returns an object reference to the new IDLffXMLDOMText node.

Arguments

String

A scalar string to put in the new text node.

Keywords

None

Version History

6.1	Introduced

IDLffXMLDOMDocument::CreateTreeWalker

The IDLffXMLDOMDocument::CreateTreeWalker function method is used to create an instance of an IDLffXMLDOMTreeWalker object. This function returns an object reference to that instance.

Please note the following exceptions in tree-walking:

- Attributes are never children of DOM nodes, so they are not visited by the tree walker. Showing attributes is only meaningful when the walker root node is an attribute.

- Entities are not part of the DOM tree, so they are not visited by the tree walker. Showing entities is only meaningful when the walker root node is an entity.

- Notations are not part of the DOM tree, so they are not visited by the tree walker. Showing notations is only meaningful when the walker root node is a notation.

Syntax

Result = Obj->[IDLffXMLDOMDocument::]CreateTreeWalker(*RootNode*
    [, FILTER_NAME=*string*] [, FILTER_USERDATA=*variable*]
    [, WHAT_TO_SHOW=*value*])

Arguments

RootNode

An object reference to an object that is a subclass of IDLffXMLDOMNode that refers to a node in the DOM tree. The tree walkers's current position is set at this node. If the object reference is NULL, the walker's current position is set to the document node.

Keywords

FILTER_NAME

Set this keyword to a scalar string containing the name of an IDL function that is called each time the tree walker is about to visit a node. The purpose of this function is to allow the walker to ask the IDL application if it should visit a particular node, and hence return it in response to a call to one of the tree walker's navigation methods (e.g., IDLffXMLDOMTreeWalker::NextNode). The code in this function

should analyze the incoming node and then return a value that instructs the walker to accept or reject the node.

If this keyword is not specified, the tree walker visits every node.

The various tree-walker movement methods return nodes that are accepted by the filter function. The movement methods do not return nodes that are rejected or skipped by the filter function. The walker does not consider nodes that are children of a rejected node, but does consider children of nodes that are skipped.

The tree walker calls the filter function for the given node after making determinations with respect to the WHAT_TO_SHOW setting. However, unlike the node iterator, the walker still calls the filter function for nodes not meeting the WHAT_TO_SHOW criteria. This is required so that the filter function can direct the walker to either REJECT or SKIP a node whose type is not in the WHAT_TO_SHOW list. If the filter function returns ACCEPT for a node not meeting the WHAT_TO_SHOW criteria, the walker SKIPs the node. That is, a filter function cannot override the rejection of a node because of the WHAT_TO_SHOW setting; it can only direct the walker to REJECT or SKIP such a node.

The filter function specified by FILTER_NAME must have the following parameters:

- **Node Object** — an object reference to an instance of an IDLffXMLDOMNode subclass. This parameter is required and is supplied by the tree walker on every call.

- **USERDATA** — an optional keyword parameter set by the tree walker to a variable containing a copy of the data provided in the FILTER_USERDATA keyword. If FILTER_USERDATA is not specified, USERDATA is not passed by the walker.

The function must return one of three scalar integer values:

Value	Function
1	ACCEPT: the tree walker visits this node
2	REJECT: the tree walker does not visit this node or its children
3	SKIP: the tree walker does not visit this node, but considers the node's children for visiting

Table 30-22: Return Values for CreateTreeWalker's Filter Function

If the function returns a value that is not supported, the tree walker visits the node, as if the return value were 1 (ACCEPT). If the function returns a value that cannot be converted to a scalar, IDL throws an error.

The function should not destroy the node object passed as the first parameter.

FILTER_USERDATA

Set this keyword to an IDL variable containing data to pass to the filter function each time the tree walker calls the filter function.

Supplying this keyword without FILTER_NAME produces no effect on the tree walker.

WHAT_TO_SHOW

Set this keyword to a scalar unsigned integer containing a bitmask, where each bit indicates types of nodes that the tree walker visits. If this keyword is not specified, the walker visits every node.

Type	Value (Hex)	Value (Decimal)
ALL	'ffff'xu	65535U
Element	'0001'xu	1U
Attribute	'0002'xu	2U
Text	'0004'xu	4U
CDATA Section	'0008'xu	8U
Entity Reference	'0010'xu	16U
Entity	'0020'xu	32U
Processing Instruction	'0040'xu	64U
Comment	'0080'xu	128U
Document	'0100'xu	256U
Document Type	'0200'xu	512U
Document Fragment	'0400'xu	1024U
Notation	'0800'xu	2048U

Table 30-23: Bitmasks for CreateTreeWalker's WHAT_TO_SHOW Keyword

The tree walker performs the WHAT_TO_SHOW test for a node before calling any user-provided filter function.

Version History

6.2	Introduced

IDLffXMLDOMDocument::GetDoctype

The IDLffXMLDOMDocument::GetDoctype function method creates an instance of IDLffXMLDOMDocumentType and returns its object reference.

Syntax

Result = Obj->[IDLffXMLDOMDocument::]GetDoctype()

Return Value

Returns an object reference to the new instance of IDLffXMLDOMDocumentType, or a null object reference if a document does not have a DTD.

Arguments

None

Keywords

None

Version History

6.1	Introduced

IDLffXMLDOMDocument::GetDocumentElement

The IDLffXMLDOMDocument::GetDocumentElement function method creates an instance of an IDLffXMLDOMElement and returns its object reference. The IDLffXMLDOMElement object refers to the node that is the root element of the document.

Syntax

Result = Obj->[IDLffXMLDOMDocument::]GetDocumentElement()

Return Value

Returns an object reference to the new instance of IDLffXMLDOMElement.

Arguments

None

Keywords

None

Version History

6.1	Introduced

IDLffXMLDOMDocument::GetElementsByTagName

The IDLffXMLDOMDocument::GetElementsByTagName function method creates an IDLffXMLDOMNodeList object containing all element nodes in the document tree with the specified tag name and returns an object reference to the IDLffXMLDOMNodeList object. The nodes are placed in the node list in the order that they are encountered during a preorder traversal of the tree.

Syntax

Result = Obj->[IDLffXMLDOMDocument::]GetElementsByTagName(*TagName*)

Return Value

Returns an object reference to the IDLffXMLDOMNodeList object.

The returned node list is "live," in that any changes made to the document tree after the node list was returned will be immediately reflected in the node list.

If no nodes matching the specified tag name are found, an IDLffXMLDOMNodeList object is still returned, but contains no nodes.

Arguments

TagName

A scalar string containing the tag name that is used to match the elements. The value "*" matches all tags only; it is not a wildcard expression, and you cannot use it to make partial matches.

Keywords

None

Version History

6.1	Introduced

IDLffXMLDOMDocument::GetProperty

The IDLffXMLDOMDocument::GetProperty procedure method is used to get the values of various properties of the document object.

Syntax

Obj->[IDLffXMLDOMDocument::]GetProperty [, *PROPERTY=variable*]

Arguments

None

Keywords

Any property listed under "IDLffXMLDOMDocument Properties" on page 3453 that contains the word "Yes" in the "Get" column of the property table can be retrieved using this method. To retrieve the value of a property, specify the property name as a keyword set equal to a named variable that will contain the value of the property.

Version History

6.2	Introduced

IDLffXMLDOMDocument::Init

The IDLffXMLDOMDocument::Init function method initializes the object. It can also load and parse an XML document, using the same keywords that IDLffXMLDOMDocument::Load does. (For more information on loading, see that method's description.)

Syntax

Obj = OBJ_NEW('IDLffXMLDOMDocument'
   [, /EXCLUDE_IGNORABLE_WHITESPACE]
   [, /EXPAND_ENTITY_REFERENCES]
   [, FILENAME=*string* / STRING=*string*] [, MSG_ERROR=*string*]
   [, MSG_FATAL=*string*] [, MSG_WARNING=*string*] [, /QUIET]
   [, SCHEMA_CHECKING=*value*] [, VALIDATION_MODE=*value*])

or

Result = *Obj*->[IDLffXMLDOMDocument::]Init(
   [, /EXCLUDE_IGNORABLE_WHITESPACE]
   [, /EXPAND_ENTITY_REFERENCES]
   [, FILENAME=*string* / STRING=*string*] [, MSG_ERROR=*string*]
   [, MSG_FATAL=*string*] [, MSG_WARNING=*string*] [, /QUIET]
   [, SCHEMA_CHECKING=*value*] [, VALIDATION_MODE=*value*])   *(In a lifecycle method only.)*

Return Value

Returns an object reference to the newly created object when this method is called indirectly, as part of the call to the OBJ_NEW function.

Returns 1 if initialization was successful or 0 otherwise, when this method is called directly within a subclass Init method.

Arguments

None

Keywords

Note

> Any property listed under "IDLffXMLDOMDocument Properties" on page 3453 that contains the word "Yes" in the "Init" column of the property table can be initialized during object creation using this method. To initialize the value of a property, specify the property name as a keyword set equal to the appropriate property value.

EXCLUDE_IGNORABLE_WHITESPACE

Set this keyword to prevent text nodes containing ignorable white space from being inserted into the DOM tree. The default action is to include these nodes in the DOM tree. Note that in order for the parser to distinguish between ignorable and non-ignorable white space, validation must be turned on with the VALIDATION_MODE keyword and there must be a DTD. This keyword has no effect if VALIDATION_MODE is 0 or if there is no DTD for the XML document.

EXPAND_ENTITY_REFERENCES

Set this keyword to cause the parser to replace entity references with their fully expanded substitution text. If entity references are not expanded, the DOM parser creates entity-reference nodes in the DOM tree. The children of the entity-reference nodes are read-only and are elements containing the entity values. If entity references are expanded, the DOM parser creates no entity-reference nodes in the DOM tree and instead creates read-write nodes that correspond to the fully expanded substitution text.

FILENAME

Set this keyword to a scalar string containing the name of the XML file to load and parse.

The FILENAME keyword can also specify a URL. In this case, the object reads the XML data from the specified URL over the network and builds the document tree without the XML data needing to be present in a local file.

Setting both the FILENAME and STRING keywords causes an error.

The following example reads XML from an RSS feed containing weather information for Denver, Colorado:

```
FUNCTION filter, oNode
   name = oNode->getNodeName()
```

```
       IF name EQ 'title' OR name EQ 'description' THEN $
          RETURN, 1 ; accept
       RETURN, 3 ;; skip
   END

   PRO weather
      oDoc = OBJ_NEW( 'IDLffXMLDOMDocument', $
         FILENAME='http://weather.gov/data/current_obs/KDEN.rss' )
      oNodeIterator = oDoc->createNodeIterator( OBJ_NEW(), $
         FILTER_NAME='filter' )

      oNode = oNodeIterator->nextNode()
      WHILE OBJ_VALID( oNode ) DO BEGIN
         ; Assuming only one text node per element
         PRINT, (oNode->GetFirstChild())->getNodeValue()
         oNode = oNodeIterator->nextNode()
      ENDWHILE
      PRINT
      OBJ_DESTROY, oDoc
   END
```

MSG_ERROR

Set this keyword to a scalar string that contains the name of an IDL procedure that will be called when the parser generates an error message. The following procedure parameters are required:

- Filename – A scalar string containing the name of the file being parsed

- Line number – A scalar integer containing the line number in the file where the parsing error occurred

- Column number – A scalar integer containing the column number in the file where the parsing error occurred

- Message – A scalar string containing the parser error message

MSG_FATAL

Set this keyword to a scalar string that contains the name of an IDL procedure that will be called when the parser generates a fatal error message. The required procedure parameters are the same as for MSG_ERROR.

MSG_WARNING

Set this keyword to a scalar string that contains the name of an IDL procedure that will be called when the parser generates a warning message. The required procedure parameters are the same as for MSG_ERROR.

QUIET

Set this keyword to prevent IDL from printing out informational parser warnings and error messages. The default action is to report all parser warnings and errors with messages. If an error more severe than a warning is encountered, IDL issues an additional single message after parsing is complete and returns to the interpreter, regardless of this keyword's setting.

SCHEMA_CHECKING

Set this keyword to an integer value to indicate the type of validation the parser should perform. XML schemas describe the structure and allowed contents of an XML document. Schemas are more robust than, and are envisioned as a replacement for, DTDs. By default, the parser will validate the parsed XML file against the specified schema, if one is provided. If no schema is provided, no validation occurs. Possible values are:

0	No schema checking is performed.
1	Schema checking is performed only if a schema is provided. This is the default value.
2	Full schema constraint checking is performed if a schema is provided. This feature checks the schema grammar itself for additional errors.

STRING

Set this keyword equal to a scalar string containing the XML Document text. Setting the STRING keyword avoids the need for file input/output operations. As a result, setting both the FILENAME and STRING keywords causes an error.

If the XML Document text contains references to local files, IDL's current working directory should be set to the directory containing those files. To avoid the need to manage the current working directory, use this keyword with self-contained XML documents. For example, placing DTD information in a DOCTYPE element in the document text avoids the need for an external file reference.

VALIDATION_MODE

Set this keyword to one of the following values:

0	The parser does not report validation errors.
1	The parser reports validation errors only if a DTD is specified. This is the default value.
2	The parser always reports validation errors.

This keyword ignores all other values.

Version History

6.1	Introduced
6.2	Added SCHEMA_CHECKING keyword
6.4	Added STRING keyword

IDLffXMLDOMDocument::Load

The IDLffXMLDOMDocument::Load procedure method loads XML data from the source specified by the FILENAME keyword. The XML parser then parses the data, using any related DTD or schema specifications. The results of the parse are used to construct a DOM document tree that can then be accessed through this document object.

If the FILENAME keyword is not specified, the other keywords have no effect and the DOM document tree is unchanged. If it is specified, then any existing DOM document tree is destroyed, and the results of the parsing operation are used to create a new DOM document tree.

Note —————————————————————————————————————

This method invalidates all object references to node objects created with the previous document.

———

IDL issues messages for any parser warnings or errors unless the QUIET keyword is set. If a parsing error that is more severe than a warning is encountered during parsing, IDL issues a single additional message after parsing and returns to the interpreter, even if QUIET is set. The IDL CATCH facility can intercept this message. If this message is issued, the document tree is empty, containing no nodes.

Syntax

Obj->[IDLffXMLDOMDocument::]Load
   [, /EXCLUDE_IGNORABLE_WHITESPACE]
   [, /EXPAND_ENTITY_REFERENCES]
   [, FILENAME=*string* / STRING=*string*] [, MSG_ERROR=*string*]
   [, MSG_FATAL=*string*] [, MSG_WARNING=*string*] [, /QUIET]
   [, SCHEMA_CHECKING=*value*] [, VALIDATION_MODE=*value*]

Arguments

None

Keywords

EXCLUDE_IGNORABLE_WHITESPACE

Set this keyword to prevent text nodes containing ignorable white space from being inserted into the DOM tree. The default action is to include these nodes in the DOM

tree. Note that in order for the parser to distinguish between ignorable and non-ignorable white space, validation must be turned on with the VALIDATION_MODE keyword and there must be a DTD. This keyword has no effect if VALIDATION_MODE is 0 or if there is no DTD for the XML document.

EXPAND_ENTITY_REFERENCES

Set this keyword to cause the parser to replace entity references with their fully expanded substitution text. If entity references are not expanded, the DOM parser creates entity-reference nodes in the DOM tree. The children of the entity-reference nodes are read-only and are elements containing the entity values. If entity references are expanded, the DOM parser creates no entity-reference nodes in the DOM tree and instead creates read-write nodes that correspond to the fully expanded substitution text.

FILENAME

Set this keyword equal to a scalar string containing the name of the XML file to load and parse. If this keyword is not specified, the other keywords have no effect and the DOM document tree is unchanged. If it is specified, then any existing DOM document tree is destroyed, and the results of the parsing operation are used to create a new DOM document tree.

The keyword string can also specify a URL. In this case, the object reads the XML data from the specified URL over the network and builds the document tree without the XML data needing to be present in a local file.

Setting both the FILENAME and STRING keywords causes an error.

The following example reads XML from an RSS feed containing weather information for Denver, Colorado:

```
FUNCTION filter, oNode
   name = oNode->getNodeName()
   IF name EQ 'title' OR name EQ 'description' THEN $
      RETURN, 1 ; accept
   RETURN, 3 ;; skip
END

PRO weather
   oDoc = OBJ_NEW( 'IDLffXMLDOMDocument', $
      FILENAME='http://weather.gov/data/current_obs/KDEN.rss' )
   oNodeIterator = oDoc->createNodeIterator( OBJ_NEW(), $
      FILTER_NAME='filter' )

   oNode = oNodeIterator->nextNode()
   WHILE OBJ_VALID( oNode ) DO BEGIN
```

```
      ; Assuming only one text node per element
      PRINT, (oNode->GetFirstChild())->getNodeValue()
      oNode = oNodeIterator->nextNode()
  ENDWHILE
  PRINT
  OBJ_DESTROY, oDoc
END
```

MSG_ERROR

Set this keyword to a scalar string that contains the name of an IDL procedure that will be called when the parser generates an error message. The following procedure parameters are required:

- **Filename** – A scalar string containing the name of the file being parsed
- **Line number** – A scalar integer containing the line number in the file where the parsing error occurred
- **Column number** – A scalar integer containing the column number in the file where the parsing error occurred
- **Message** – A scalar string containing the parser error message

MSG_FATAL

Set this keyword to a scalar string that contains the name of an IDL procedure that will be called when the parser generates a fatal error message. The required procedure parameters are the same as for MSG_ERROR.

MSG_WARNING

Set this keyword to a scalar string that contains the name of an IDL procedure that will be called when the parser generates a warning message. The required procedure parameters are the same as for MSG_ERROR.

QUIET

Set this keyword to prevent IDL from printing out informational parser warnings and error messages. The default action is to report all parser warnings and errors with messages. If an error more severe than a warning is encountered, IDL issues an additional single message after parsing is complete and returns to the interpreter, regardless of this keyword's setting.

SCHEMA_CHECKING

Set this keyword to an integer value to indicate the type of validation the parser should perform. XML schemas describe the structure and allowed contents of an XML document. Schemas are more robust than, and are envisioned as a replacement for, DTDs. By default, the parser will validate the parsed XML file against the specified schema, if one is provided. If no schema is provided, no validation occurs.

Possible values are:

0	No schema checking is performed.
1	Schema checking is performed only if a schema is provided. This is the default value.
2	Full schema constraint checking is performed if a schema is provided. This feature checks the schema grammar itself for additional errors.

STRING

Set this keyword equal to a scalar string containing the XML Document text. Setting the STRING keyword avoids the need for file input/output operations. As a result, setting both the FILENAME and STRING keywords causes an error.

If the XML Document text contains references to local files, IDL's current working directory should be set to the directory containing those files. To avoid the need to manage the current working directory, use this keyword with self-contained XML documents. For example, placing DTD information in a DOCTYPE element in the document text avoids the need for an external file reference.

VALIDATION_MODE

Set this keyword to one of the following values:

0	The parser does not report validation errors.
1	The parser reports validation errors only if a DTD is specified. This is the default value.
2	The parser always reports validation errors.

This keyword ignores all other values.

Version History

6.1	Introduced
6.2	Added SCHEMA_CHECKING keyword
6.4	Added STRING keyword

IDLffXMLDOMDocument::Save

The IDLffXMLDOMDocument::Save procedure method serializes the current DOM document belonging to this document object and writes it to the output source specified by the FILENAME keyword.

Syntax

Obj->[IDLffXMLDOMDocument::]Save [, ENCODING=*string*]
   [, /EXPAND_ENTITY_REFERENCES]
   [, FILENAME=*string* / STRING=*variable*] [, /PRETTY_PRINT]

Arguments

None

Keywords

ENCODING

Set this keyword to a scalar string specifying the encoding to be used when the XML DOM document is written to a file. If this keyword is not specified and the document was loaded with the IDLffXMLDOMDocument::Init or IDLffXMLDOMDocument::Load methods from a file, the document is written to a file using the same encoding used to load the file. If this keyword is not specified and the document was created programatically, the document is written to the file using UTF-8 encoding.

Note ──

For the list of supported XML encodings, see "About XML" (Chapter 20, *Application Programming*).

──

If an encoding is specified that is not supported, no error is reported and this method writes an empty file.

EXPAND_ENTITY_REFERENCES

Set this keyword to cause the parser to replace entity references with their fully expanded substitution text as the DOM tree is written to the output file. The DOM tree itself is not changed. The default behavior is to write the entity references to the output file.

FILENAME

Set this keyword to the name of the XML file in which to store the XML data. If FILENAME is not set or is set to "" (null string), this method will return without storing any data on the file system.

FILENAME can contain a directory path (e.g., `'C:\ITT\test.xml'`). IDL throws an error and stops if any of the following conditions are true:

- The directory does not exist
- The directory exists, but is not writable
- The file exists, but is not writable

Setting both the FILENAME and STRING keywords causes an error.

PRETTY_PRINT

Set this keyword to format the output by adding white space to produce a pretty-printed, indented, reader-friendly form.

STRING

Set this keyword to a named variable that will contain the string data representing the XML DOM document currently represented in this object. Setting the STRING keyword avoids the need for file input/output operations. As a result, setting the FILENAME and STRING keywords causes an error.

Version History

6.1	Introduced
6.2	Added ENCODING keyword
6.4	Added STRING keyword

IDLffXMLDOMDocument::SetProperty

The IDLffXMLDOMDocument::SetProperty procedure method is used to set the values of various properties of the parser.

Syntax

Obj->[IDLffXMLDOMDocument::]SetProperty [, *PROPERTY=variable*]

Arguments

None

Keywords

Any property listed under "IDLffXMLDOMDocument Properties" on page 3453 that contains the word "Yes" in the "Set" column of the property table can be set using this method. To set the value of a property, specify the property name as a keyword set equal to the appropriate property value.

Version History

6.2	Introduced

IDLffXMLDOMDocumentFragment

The IDLffXMLDOMDocumentFragment class references a document-fragment node.

It is very common to want to be able to extract a portion of a document's tree or to create a new fragment of a document. Imagine implementing a user command such as "cut" or rearranging a document by moving fragments around. It is desirable to have an object that can hold such fragments, and it is quite natural to use a node for this purpose. While it is true that a document object could fill this role, it can potentially be a heavyweight object, depending on the underlying implementation. What you need for this purpose, instead, is a very lightweight object, and the document-fragment node is such an object.

Furthermore, various operations such as inserting nodes as children of another node may take document-fragment objects as arguments; this results in all the child nodes of the document-fragment node being moved to the child list of this node.

The children of a document-fragment node are zero or more nodes representing the roots of any sub-trees defining the structure of the document. Document-fragment nodes do not need to be well-formed XML documents (although they do need to follow the rules imposed upon well-formed XML parsed entities, which can have multiple root nodes). For example, a document-fragment node might have only one child, and that child node could be a text node. Such a structure model represents neither an HTML document nor a well-formed XML document.

When a document-fragment node is inserted into a document tree (or, indeed, any other node that may take children), the children of the document-fragment node and not the document-fragment node itself are inserted into the node. This insertion process makes the document-fragment node very useful when you want to create nodes that are siblings. Because the document-fragment node acts as the parent of these nodes, you use the standard methods from the node object, such as InsertBefore() and AppendChild().

There are no methods specific to this class except Cleanup and Init.

Superclasses

IDLffXMLDOMNode

Creation

See IDLffXMLDOMDocumentFragment::Init.

Properties

Objects of this class have no properties of their own, but do have properties inherited from any superclasses.

Methods

This class has the following methods:

- IDLffXMLDOMDocumentFragment::Cleanup
- IDLffXMLDOMDocumentFragment::Init

In addition, this class inherits the methods of any superclasses.

Version History

6.1	Introduced

IDLffXMLDOMDocumentFragment Properties

Objects of this class have no properties of their own, but do have properties inherited from any superclasses.

Objects of this class inherit:

• IDLffXMLDOMNode

IDLffXMLDOMDocumentFragment::Cleanup

The IDLffXMLDOMDocumentFragment::Cleanup procedure method destroys both the object (that is, the accessing object in the IDL tree) and any objects created by that object. It does not modify the actual DOM tree.

This class should not be subclassed by a user class because the classes that create objects, such as IDLffXMLDOMDocument, will not be aware of any user-defined classes.

Syntax

Version History

6.1	Introduced

IDLffXMLDOMDocumentFragment::Init

The IDLffXMLDOMDocumentFragment::Init function method initializes the object, but this class should not be instantiated directly. Instead, methods such as IDLffXMLDOMDocument::CreateDocumentFragment are used to create objects of this class.

This class should not be subclassed by a user class because the classes that create objects, such as IDLffXMLDOMDocument, will not be aware of any user-defined classes.

IDLffXMLDOMDocumentType

The IDLffXMLDOMDocumentType class references a document-type node. Each document has a `doctype` attribute whose value is stored in a document-type object or is null.

Superclasses

IDLffXMLDOMNode

Creation

See IDLffXMLDOMDocumentType::Init.

Properties

Objects of this class have no properties of their own, but do have properties inherited from any superclasses.

Methods

This class has the following methods:

- IDLffXMLDOMDocumentType::Cleanup
- IDLffXMLDOMDocumentType::GetEntities
- IDLffXMLDOMDocumentType::GetName
- IDLffXMLDOMDocumentType::GetNotations
- IDLffXMLDOMDocumentType::Init

In addition, this class inherits the methods of any superclasses.

6.1	Introduced

IDLffXMLDOMDocumentType::Init

The IDLffXMLDOMDocumentType::Init function method initializes the object, but this class should not be instantiated directly. Instead, methods such as IDLffXMLDOMNode::GetFirstChild are used to create objects of all classes except IDLffXMLDOMDocument.

This class should not be subclassed by a user class because the classes that create objects, such as IDLffXMLDOMDocument, will not be aware of any user-defined classes.

IDLffXMLDOMElement

The IDLffXMLDOMElement class references an element node, which is one of the most common node types in an XML document.

Elements can have attributes associated with them, which can be obtained with the IDLffXMLDOMNode::GetAttributes method. The IDLffXMLDOMElement class also has methods for getting an attribute object or an attribute value by its name.

Superclasses

IDLffXMLDOMNode

Creation

See IDLffXMLDOMElement::Init.

Properties

Objects of this class have no properties of their own, but do have properties inherited from any superclasses.

Methods

This class has the following methods:

- IDLffXMLDOMElement::Cleanup
- IDLffXMLDOMElement::GetAttribute
- IDLffXMLDOMElement::GetAttributeNode
- IDLffXMLDOMElement::GetElementsByTagName
- IDLffXMLDOMElement::GetTagName
- IDLffXMLDOMElement::Init
- IDLffXMLDOMElement::RemoveAttribute
- IDLffXMLDOMElement::RemoveAttributeNode
- IDLffXMLDOMElement::SetAttribute
- IDLffXMLDOMElement::SetAttributeNode

In addition, this class inherits the methods of any superclasses.

Version History

6.1	Introduced

IDLffXMLDOMElement Properties

Objects of this class have no properties of their own, but do have properties inherited from any superclasses.

Objects of this class inherit:

• IDLffXMLDOMNode

IDLffXMLDOMElement::Cleanup

The IDLffXMLDOMElement::Cleanup procedure method destroys both the object (that is, the accessing object in the IDL tree) and any objects created by that object. It does not modify the actual DOM tree.

This class should not be subclassed by a user class because the classes that create objects, such as IDLffXMLDOMDocument, will not be aware of any user-defined classes.

Syntax

OBJ_DESTROY, *Obj*

Arguments

None

Keywords

None

Version History

6.1	Introduced

IDLffXMLDOMElement::GetAttribute

The IDLffXMLDOMElement::GetAttribute function method returns the value of the attribute specified by *Name*.

Syntax

Result = Obj->[IDLffXMLDOMElement::]GetAttribute(*Name*)

Return Value

Returns a scalar string containing the value of the attribute specified by *Name*.

Arguments

Name

A scalar string used to specify the name of the attribute for which to get the value.

Keywords

None

Version History

6.1	Introduced

IDLffXMLDOMElement::GetAttributeNode

The IDLffXMLDOMElement::GetAttributeNode function method creates an IDLffXMLDOMAttr object and returns its object reference.

Syntax

Result = Obj->[IDLffXMLDOMElement::]GetAttributeNode(*Name*)

Return Value

Returns an object reference to the IDLffXMLDOMAttr object. The object refers to the attribute node specified by name. If this node does not exist, this function returns a null object reference.

Arguments

Name

A scalar string used to specify the attribute node to get.

Keywords

None

Version History

6.1	Introduced

IDLffXMLDOMElement::GetElementsByTagName

The IDLffXMLDOMElement::GetElementsByTagName function method creates an IDLffXMLDOMNodeList object containing all descendant element nodes in the document tree with the specified tag name and returns an object reference to the IDLffXMLDOMNodeList object. The nodes are placed in the node list in the order that they are encountered during a preorder traversal of the tree.

Syntax

Result = Obj->[IDLffXMLDOMElement::]GetElementsByTagName(*TagName*)

Return Value

Returns an object reference to the IDLffXMLDOMNodeList object.

The returned node list is "live," in that any changes made to the document tree after the node list was returned will be immediately reflected in the node list.

If no nodes matching the specified tag name are found, an IDLffXMLDOMNodeList is still returned, but contains no nodes.

Arguments

TagName

A scalar string containing the tag name that is used to match the elements. The value "*" matches all tags only; it is not a wildcard expression, and you cannot use it to make partial matches.

Keywords

None

Version History

6.1	Introduced

IDLffXMLDOMElement::GetTagName

The IDLffXMLDOMElement::GetTagName function method returns the name of the element.

Syntax

Result = Obj->[IDLffXMLDOMElement::]GetTagName()

Return Value

Returns a scalar string containing the name of the element.

Argument

None

Keywords

None

Version History

6.1	Introduced

IDLffXMLDOMElement::Init

The IDLffXMLDOMElement::Init function method initializes the object, but this class should not be instantiated directly. Instead, methods such as IDLffXMLDOMNode::GetFirstChild are used to create objects of all classes except IDLffXMLDOMDocument.

This class should not be subclassed by a user class because the classes that create objects, such as IDLffXMLDOMDocument, will not be aware of any user-defined classes.

IDLffXMLDOMElement::RemoveAttribute

The IDLffXMLDOMElement::RemoveAttribute procedure method removes a specified attribute from the element node.

Syntax

Result = Obj->[IDLffXMLDOMElement::]RemoveAttribute(*Name*)

Arguments

Name

A scalar string that contains the name of the attribute to remove from the element.

Keywords

None

Version History

6.1	Introduced

IDLffXMLDOMElement::RemoveAttributeNode

The IDLffXMLDOMElement::RemoveAttributeNode function method removes a specified attribute node from the element node.

Syntax

Result = Obj->[IDLffXMLDOMElement::]RemoveAttributeNode(*OldAttr*)

Return Value

Returns an object reference to an IDLffXMLDOMAttr node referring to the attribute node that was removed.

Arguments

OldAttr

An object reference to an IDLffXMLDOMAttr object that refers to an attribute node to be removed from the element node.

Keywords

None

Version History

6.1	Introduced

IDLffXMLDOMElement::SetAttribute

The IDLffXMLDOMElement::SetAttribute procedure method adds a new attribute to the element node.

Syntax

Obj->[IDLffXMLDOMElement::]SetAttribute, *Name*, *Value*

Arguments

Name

A scalar string that contains the name of the attribute.

Value

A scalar string that contains the value of the attribute.

Keywords

None

Version History

6.1	Introduced

IDLffXMLDOMElement::SetAttributeNode

The IDLffXMLDOMElement::SetAttributeNode function method adds an attribute node to the element node.

Syntax

Result = Obj->[IDLffXMLDOMElement::]SetAttributeNode(*NewAttr*)

Return Value

Returns an object reference to an IDLffXMLDOMAttr node, if an old attribute is replaced by the new. This method returns a null object reference if no attribute was replaced by this method.

Arguments

NewAttr

An object reference to an IDLffXMLDOMAttr object that refers to an attribute node that is to be set in the element node.

Keywords

None

Version History

6.1	Introduced

IDLffXMLDOMEntity

The IDLffXMLDOMEntity class references an entity, either parsed or unparsed, in an XML document. Entities are placeholders in XML and are inserted into documents by entity references. Entity nodes have no parents. Entity nodes and their descendants are read-only.

Superclasses

IDLffXMLDOMNode

Creation

See IDLffXMLDOMEntity::Init.

Properties

Objects of this class have no properties of their own, but do have properties inherited from any superclasses.

Methods

This class has the following methods:

- IDLffXMLDOMEntity::Cleanup
- IDLffXMLDOMEntity::GetNotationName
- IDLffXMLDOMEntity::GetPublicId
- IDLffXMLDOMEntity::GetSystemId
- IDLffXMLDOMEntity::Init

In addition, this class inherits the methods of any superclasses.

Version History

6.1	Introduced

IDLffXMLDOMEntity Properties

Objects of this class have no properties of their own, but do have properties inherited from any superclasses.

Objects of this class inherit:

- IDLffXMLDOMNode

IDLffXMLDOMEntity::Cleanup

The IDLffXMLDOMEntity::Cleanup procedure method destroys both the object (that is, the accessing object in the IDL tree) and any objects created by that object. It does not modify the actual DOM tree.

This class should not be subclassed by a user class because the classes that create objects, such as IDLffXMLDOMDocument, will not be aware of any user-defined classes.

Syntax

OBJ_DESTROY, *Obj*

Arguments

Keywords

None

Version History

6.1	Introduced

IDLffXMLDOMEntity::GetNotationName

The IDLffXMLDOMEntity::GetNotationName function method returns the name of the notation for the entity.

Syntax

Result = Obj->[IDLffXMLDOMEntity::]GetNotationName()

Return Value

Returns a scalar string containing the name of the notation for the unparsed entity, or an empty string if the entity is parsed.

Arguments

None

Keywords

None

Version History

6.1	Introduced

IDLffXMLDOMEntity::GetPublicId

The IDLffXMLDOMEntity::GetPublicId function method returns the public ID of the entity, if it is specified.

Syntax

Result = Obj->[IDLffXMLDOMEntity::]GetPublicId()

Return Value

Returns a scalar string containing the public ID of the entity, or an empty string if the public ID is not specified.

Arguments

None

Keywords

None

Version History

6.1	Introduced

IDLffXMLDOMEntity::GetSystemId

The IDLffXMLDOMEntity::GetSystemId function method returns the system ID of the entity, if it is specified.

Syntax

Result = Obj->[IDLffXMLDOMEntity::]GetSystemId()

Return Value

Returns a scalar string containing the system ID of the entity, or an empty string if the system ID is not specified.

Arguments

None

Keywords

None

Version History

6.1	Introduced

IDLffXMLDOMEntity::Init

The IDLffXMLDOMEntity::Init function method initializes the object, but this class should not be instantiated directly. Instead, methods such as IDLffXMLDOMDocumentType::GetEntities coupled with IDLffXMLDOMNamedNodeMap::GetNamedItem are used to create objects of this class.

This class should not be subclassed by a user class because the classes that create objects, such as IDLffXMLDOMDocument, will not be aware of any user-defined classes.

IDLffXMLDOMEntityReference

The IDLffXMLDOMEntityReference class references entity reference nodes. Entity references in the source XML file are meant to be substituted by the entity contents upon parsing. Any entity reference nodes left in the document tree may exist because the entity was not found, or the parser was instructed to not expand entity references.

Entity references are read-only.

There are no methods specific to this class except Cleanup and Init.

Superclasses

IDLffXMLDOMNode

Creation

See IDLffXMLDOMEntityReference::Init.

Properties

Objects of this class have no properties of their own, but do have properties inherited from any superclasses.

Methods

This class has the following methods:

- IDLffXMLDOMEntityReference::Cleanup
- IDLffXMLDOMEntityReference::Init

In addition, this class inherits the methods of any superclasses.

Version History

6.1	Introduced

IDLffXMLDOMEntityReference Properties

Objects of this class have no properties of their own, but do have properties inherited from any superclasses.

Objects of this class inherit:

Version History

6.1	Introduced

IDLffXMLDOMEntityReference::Init

The IDLffXMLDOMEntityReference::Init function method initializes the object, but this class should not be instantiated directly. Instead, methods such as IDLffXMLDOMNode::GetFirstChild are used to create objects of all classes except IDLffXMLDOMDocument.

This class should not be subclassed by a user class because the classes that create objects, such as IDLffXMLDOMDocument, will not be aware of any user-defined classes.

IDLffXMLDOMNamedNodeMap

The IDLffXMLDOMNamedNodeMap class is a container for nodes (see IDLffXMLDOMNode and its subclasses) and uses the node's name to access the nodes in the container.

For example, consider this XML:

```
<show title="My Title" date="Nov 12, 1999" author="Me">
```

The entire line is a DOM element node. A GetAttributes call returns a NamedNodeMap that contains three attribute node objects. The attribute node object containing the date, for example, has a node name of 'date' and a node value of 'Nov 12, 1999'.

The benefit of the named node map is that the nodes are accessed by their node names. Thus, to access the date node, you would use the string 'date' and would not have to worry about its position in the list.

Superclasses

IDLffXMLDOMNode

Creation

See IDLffXMLDOMNamedNodeMap::Init.

Properties

Objects of this class have no properties of their own, but do have properties inherited from any superclasses.

Methods

This class has the following methods:

- IDLffXMLDOMNamedNodeMap::Cleanup
- IDLffXMLDOMNamedNodeMap::GetLength
- IDLffXMLDOMNamedNodeMap::GetNamedItem
- IDLffXMLDOMNamedNodeMap::Init
- IDLffXMLDOMNamedNodeMap::Item

- IDLffXMLDOMNamedNodeMap::RemoveNamedItem

- IDLffXMLDOMNamedNodeMap::SetNamedItem

In addition, this class inherits the methods of any superclasses.

Version History

6.1	Introduced

IDLffXMLDOMNamedNodeMap Properties

Objects of this class have no properties of their own, but do have properties inherited from any superclasses.

Objects of this class inherit:

• IDLffXMLDOMNode

IDLffXMLDOMNamedNodeMap::Cleanup

The IDLffXMLDOMNamedNodeMap::Cleanup procedure method destroys both the object (that is, the accessing object in the IDL tree) and any objects created by that object. It does not modify the actual DOM tree.

This class should not be subclassed by a user class because the classes that create objects, such as IDLffXMLDOMDocument, will not be aware of any user-defined classes.

Syntax

OBJ_DESTROY, *Obj*

Arguments

None

Keywords

None

Version History

6.1	Introduced

IDLffXMLDOMNamedNodeMap::GetLength

The IDLffXMLDOMNamedNodeMap::GetLength function method returns the number of nodes in the named node map.

Syntax

Result = Obj->[IDLffXMLDOMNamedNodeMap::]GetLength()

Return Value

Returns an integer containing the number of nodes in the named node map.

Arguments

None

Keywords

None

Version History

6.1	Introduced

IDLffXMLDOMNamedNodeMap::GetNamedItem

The IDLffXMLDOMNamedNodeMap::GetNamedItem function method returns an object reference to an instance of a subclass of IDLffXMLDOMNode that refers to the node from the named node map that corresponds to the supplied name.

Syntax

Result = Obj->[IDLffXMLDOMNamedNodeMap::]GetNamedItem(*Name*)

Return Value

Returns an object reference to an instance of a subclass of IDLffXMLDOMNode that refers to the node from the named node map that corresponds to the supplied name. If the node is not found, this function returns a null object reference.

Arguments

Name

A scalar string that contains the name used to locate the node.

Keywords

None

Version History

6.1	Introduced

IDLffXMLDOMNamedNodeMap::Init

The IDLffXMLDOMNamedNodeMap::Init function method initializes the object, but this class should not be instantiated directly. Instead, the IDLffXMLDOMNode::GetAttributes method is used to create objects of this class.

This class should not be subclassed by a user class because the classes that create objects, such as IDLffXMLDOMDocument, will not be aware of any user-defined classes.

IDLffXMLDOMNamedNodeMap::Item

The IDLffXMLDOMNamedNodeMap::Item function method returns an object reference to an instance of a subclass of IDLffXMLDOMNode that refers to the node from the named node map that corresponds to an index.

Syntax

Result = Obj->[IDLffXMLDOMNamedNodeMap::]Item(*Index*)

Return Value

Returns an object reference to an instance of a subclass of IDLffXMLDOMNode that refers to the node from the named node map that corresponds to the supplied index. If the node at the specified index does not exist, a null object reference is returned.

Arguments

Index

An integer that contains the index into the named node map.

Keywords

None

Version History

6.1	Introduced

IDLffXMLDOMNamedNodeMap::RemoveNamedItem

The IDLffXMLDOMNamedNodeMap::RemoveNamedItem function method removes the node from the named node map that corresponds to a name.

Syntax

Result = Obj->[IDLffXMLDOMNamedNodeMap::]RemoveNamedItem(*Name*)

Return Value

Returns an object reference to an instance of a subclass of IDLffXMLDOMNode that refers to the removed node if it exists. If the node does not exist, this function returns a null object reference.

Arguments

Name

A scalar string that contains the name used to locate the node.

Keywords

None

Version History

6.1	Introduced

IDLffXMLDOMNamedNodeMap::SetNamedItem

The IDLffXMLDOMNamedNodeMap::SetNamedItem function method adds a node to the named node map. After adding the node, the node can be accessed using the node's name attribute. If a node with the same name is already present in the map, then the node in the map is replaced by this new node.

Some node types have fixed name tags due to the nature of the node type. For example, an IDLffXMLDOMText node's name tag always has the value "#text" because it always contains text in its value tag. For a list of other nodes with fixed name tags see "IDLffXMLDOMNode::GetNodeName Return Values" on page 3547. (The fixed names are the names in quotation marks.)

Note ──

You cannot place nodes with fixed name tags into a named node map because it uses the nodes' name tags to search for a requested node.

──

Syntax

Result = Obj->[IDLffXMLDOMNamedNodeMap::]SetNamedItem(*Node*)

Return Value

Returns an object reference to an instance of a subclass of IDLffXMLDOMNode that references the node that was replaced, if the method replaces a node in the map. Otherwise, the method returns a null object reference.

Arguments

Node

An object reference to an instance of a subclass of IDLffXMLDOMNode that refers to the node to add to the map.

Keywords

None

Version History

6.1	Introduced

IDLffXMLDOMNode

The IDLffXMLDOMNode class is an abstract class used as a superclass for other IDLffXMLDOM node classes.

Because this class is an abstract class, there will never be an instance of this class. Rather, this class's functionality described here is accessed through an instance of one of its subclasses.

An object instance of this class is a reference to a corresponding node in the DOM document tree. Use the appropriate methods for this class, defined below, to access and manipulate the DOM data.

This class keeps track of any objects it creates (e.g., via the IDLffXMLDOMNode::GetFirstChild method) and destroys these objects when it is destroyed.

Superclasses

None

Creation

See IDLffXMLDOMNode::Init.

Properties

Objects of this class have no properties of their own, but do have properties inherited from any superclasses.

Methods

This class has the following methods:

- IDLffXMLDOMNode::AppendChild
- IDLffXMLDOMNode::Cleanup
- IDLffXMLDOMNode::CloneNode
- IDLffXMLDOMNode::GetAttributes
- IDLffXMLDOMNode::GetChildNodes
- IDLffXMLDOMNode::GetFirstChild

- IDLffXMLDOMNode::GetLastChild
- IDLffXMLDOMNode::GetNextSibling
- IDLffXMLDOMNode::GetNodeName
- IDLffXMLDOMNode::GetNodeType
- IDLffXMLDOMNode::GetNodeValue
- IDLffXMLDOMNode::GetOwnerDocument
- IDLffXMLDOMNode::GetParentNode
- IDLffXMLDOMNode::GetPreviousSibling
- IDLffXMLDOMNode::HasChildNodes
- IDLffXMLDOMNode::Init
- IDLffXMLDOMNode::InsertBefore
- IDLffXMLDOMNode::RemoveChild
- IDLffXMLDOMNode::ReplaceChild
- IDLffXMLDOMNode::SetNodeValue

In addition, this class inherits the methods of any superclasses.

Version History

6.1	Introduced

IDLffXMLDOMNode Properties

Objects of this class have no properties of their own, but do have properties inherited from any superclasses.

IDLffXMLDOMNode::AppendChild

The IDLffXMLDOMNode::AppendChild function method adds a new node to the end of the calling node's children list.

If the new child node is already in the tree, it is first removed.

The ownership of the IDL object to which the *NewChild* object reference refers is changed so that it is no longer owned by its previous owner and becomes owned by the calling object. Therefore, destroying the calling object destroys the new child as well.

Syntax

Result = Obj->[IDLffXMLDOMNode::]AppendChild(*NewChild*)

Return Value

Returns an object reference to the new child node.

Arguments

NewChild

An object reference to an instance of an IDLffXMLDOMNode subclass that refers to the node that is being added.

Keywords

None

Version History

6.1	Introduced

IDLffXMLDOMNode::Cleanup

The IDLffXMLDOMNode::Cleanup procedure method destroys both the object (that is, the accessing object in the IDL tree) and any objects created by that object. It does not modify the actual DOM tree.

This class should not be subclassed by a user class because the classes that create objects, such as IDLffXMLDOMDocument, will not be aware of any user-defined classes.

Syntax

OBJ_DESTROY, *Obj*

Arguments

None

Keywords

None

Version History

6.1	Introduced

IDLffXMLDOMNode::CloneNode

The IDLffXMLDOMNode::CloneNode function method creates a copy of the calling node (i.e., an instance of an IDLffXMLDOMNode subclass) and returns the object reference to the cloned node. The class of the cloned node is the same as the class of the calling node. The cloned node has no parent.

Cloning an element node copies all attributes and their values and does not copy child nodes unless the DEEP keyword is set. Cloning any other type of node simply copies the node.

Syntax

Result = Obj->[IDLffXMLDOMNode::]CloneNode([, /DEEP])

Return Value

Returns an object reference to the cloned node.

Arguments

None

Keywords

DEEP

Set this keyword to cause all of a node's children to be cloned along with the calling node. By default, only the calling node is cloned.

Version History

6.1	Introduced

IDLffXMLDOMNode::GetAttributes

The IDLffXMLDOMNode::GetAttributes function method creates an instance of an IDLffXMLDOMNamedNodeMap and returns an object reference to that object. The named node map can then be used to access the attributes of an element object.

Syntax

Result = Obj->[IDLffXMLDOMNode::]GetAttributes()

Return Value

Returns an object reference to the new IDLffXMLDOMNamedNodeMap object. If the calling object is not an IDLffXMLDOMElement, a null object reference is returned.

Arguments

None

Keywords

None

Version History

6.1	Introduced

IDLffXMLDOMNode::GetChildNodes

The IDLffXMLDOMNode::GetChildNodes function method creates an instance of an IDLffXMLDOMNodeList object, which can then be used to access the child nodes. If there are no children, the node list object contains no nodes.

The contents of the node list object are updated as changes are made to the tree, such as children being added or removed from the calling node's children list.

Syntax

Result = Obj->[IDLffXMLDOMNode::]GetChildNodes()

Return Value

Returns an object reference to the new IDLffXMLDOMNodeList object.

Arguments

None

Keywords

None

Version History

6.1	Introduced

IDLffXMLDOMNode::GetFirstChild

The IDLffXMLDOMNode::GetFirstChild function method creates an instance of one of the IDLffXMLDOMNode subclasses and returns an object reference to that object, which refers to the first child of the calling node in the DOM tree. The type of the object corresponds to the type of the first child node.

Syntax

Result = Obj->[IDLffXMLDOMNode::]GetFirstChild()

Return Value

Returns an object reference to the new IDLffXMLDOMNode subclass object if there is a child in the DOM tree. If there are no children, a null object reference is returned.

Arguments

None

Keywords

None

Version History

6.1	Introduced

IDLffXMLDOMNode::GetLastChild

The IDLffXMLDOMNode::GetLastChild function method creates an instance of one of the IDLffXMLDOMNode subclasses and returns an object reference to that object, which refers to the last child of the calling node in the DOM tree. The type of the object corresponds to the type of the last child node.

Syntax

Result = Obj->[IDLffXMLDOMNode::]GetLastChild()

Return Value

Returns an object reference to the new IDLffXMLDOMNode subclass object if there is a child in the DOM tree. If there are no children, a null object reference is returned.

Arguments

None

Keywords

None

Version History

6.1	Introduced

IDLffXMLDOMNode::GetNextSibling

The IDLffXMLDOMNode::GetNextSibling function method creates an instance of one of the IDLffXMLDOMNode subclasses and returns an object reference to that object, which refers to the next sibling of the calling node in the DOM tree. The type of the object corresponds to the type of the next sibling node.

Syntax

Result = Obj->[IDLffXMLDOMNode::]GetNextSibling()

Return Value

Returns an object reference to the new IDLffXMLDOMNode subclass object if there is a next sibling in the DOM tree. If there is no sibling, a null object reference is returned.

Arguments

None

Keywords

None

Version History

6.1	Introduced

IDLffXMLDOMNode::GetNodeName

The IDLffXMLDOMNode::GetNodeName function method returns the name of the node, depending on the calling node's subclass type.

Syntax

Result = Obj->[IDLffXMLDOMNode::]GetNodeName()

Return Value

Returns a scalar string whose value depends on the subclass type:

Subclass	Return Value
IDLffXMLDOMAttr	attribute name
IDLffXMLDOMCDATASection	"#cdata-section"
IDLffXMLDOMComment	"#comment"
IDLffXMLDOMDocument	"#document"
IDLffXMLDOMDocumentFragment	"#document-fragment"
IDLffXMLDOMDocumentType	document type name
IDLffXMLDOMElement	tag name
IDLffXMLDOMEntity	entity name
IDLffXMLDOMEntityReference	name of entity reference
IDLffXMLDOMNotation	notation name
IDLffXMLDOMProcessingInstruction	target
IDLffXMLDOMText	"#text"

Table 30-24: IDLffXMLDOMNode::GetNodeName Return Values

Arguments

None

Keywords

None

Version History

6.1	Introduced

IDLffXMLDOMNode::GetNodeType

The IDLffXMLDOMNode::GetNodeType function method returns the subclass type of the calling node.

Syntax

Result = Obj->[IDLffXMLDOMNode::]GetNodeType()

Return Value

Returns an integer whose value depends on the subclass type:

Subclass	Return Value
IDLffXMLDOMAttr	2
IDLffXMLDOMCDATASection	4
IDLffXMLDOMComment	8
IDLffXMLDOMDocument	9
IDLffXMLDOMDocumentFragment	11
IDLffXMLDOMDocumentType	10
IDLffXMLDOMElement	1
IDLffXMLDOMEntity	6
IDLffXMLDOMEntityReference	5
IDLffXMLDOMNotation	12
IDLffXMLDOMProcessingInstruction	7
IDLffXMLDOMText	3

Table 30-25: IDLffXMLDOMNode::GetNodeType Return Values

Arguments

None

Keywords

None

Version History

6.1	Introduced

IDLffXMLDOMNode::GetNodeValue

The IDLffXMLDOMNode::GetNodeValue function method returns the value of the calling node, depending on its subclass type.

Syntax

Result = Obj->[IDLffXMLDOMNode::]GetNodeValue()

Return Value

Returns a scalar string whose value depends on the subclass type:

Subclass	Return Value
IDLffXMLDOMAttr	attribute value
IDLffXMLDOMCDATASection	content of the CDATA section
IDLffXMLDOMComment	content of the comment
IDLffXMLDOMDocument	empty string
IDLffXMLDOMDocumentFragment	empty string
IDLffXMLDOMDocumentType	empty string
IDLffXMLDOMElement	empty string
IDLffXMLDOMEntity	empty string
IDLffXMLDOMEntityReference	empty string
IDLffXMLDOMNotation	empty string
IDLffXMLDOMProcessingInstruction	entire content excluding the target
IDLffXMLDOMText	content of the text node

Table 30-26: IDLffXMLDOMNode::GetNodeValue Return Values

Arguments

None

Keywords

None

Version History

6.1	Introduced

IDLffXMLDOMNode::GetOwnerDocument

The IDLffXMLDOMNode::GetOwnerDocument function method returns an object reference to the IDLffXMLDOMDocument used to create the node.

Syntax

Result = Obj->[IDLffXMLDOMNode::]GetOwnerDocument()

Return Value

Returns an object reference to the IDLffXMLDOMDocument used to create the node. If the calling node is an IDLffXMLDOMDocument, the method returns a null object reference.

Arguments

None

Keywords

None

Version History

6.1	Introduced

IDLffXMLDOMNode::GetParentNode

The IDLffXMLDOMNode::GetParentNode function method creates an instance of one of the IDLffXMLDOMNode subclasses and returns an object reference to that object, which refers to the parent node in the DOM tree. The type of the created object corresponds to the type of the parent node.

All node classes except IDLffXMLDOMAttr, IDLffXMLDOMDocument, IDLffXMLDOMDocumentFragment, and IDLffXMLDOMEntity may have parents.

A node that has just been created and not yet added to the tree does not have a parent.

Syntax

Result = Obj->[IDLffXMLDOMNode::]GetParentNode()

Return Value

Returns an object reference to the new object, which refers to the calling node's parent in the DOM tree. The type of the new object corresponds to the type of the parent node. If there is no parent, a null object reference is returned.

Arguments

None

Keywords

None

Version History

6.1	Introduced

IDLffXMLDOMNode::GetPreviousSibling

The IDLffXMLDOMNode::GetPreviousSibling function method creates an instance of one of the IDLffXMLDOMNode subclasses and returns an object reference to that object, which refers to the previous sibling of the calling node in the DOM tree. The type of the object corresponds to the type of the previous sibling node.

Syntax

Result = Obj->[IDLffXMLDOMNode::]GetPreviousSibling()

Return Value

Returns an object reference to the new IDLffXMLDOMNode subclass object if there is a previous sibling in the DOM tree. If there is no sibling, a null object reference is returned.

Arguments

None

Keywords

None

Version History

6.1	Introduced

IDLffXMLDOMNode::HasChildNodes

The IDLffXMLDOMNode::HasChildNodes returns a value indicating whether the calling node has children.

Syntax

Result = Obj->[IDLffXMLDOMNode::]HasChildNodes()

Return Value

Returns 1 if the calling node has children, or 0 otherwise.

Arguments

None

Keywords

None

Version History

6.1	Introduced

IDLffXMLDOMNode::Init

The IDLffXMLDOMNode::Init function method initializes the object, but this class should not be instantiated directly. Instead, methods such as IDLffXMLDOMNode::GetFirstChild are used to create objects of all classes except IDLffXMLDOMDocument.

This class should not be subclassed by a user class because the classes that create objects, such as IDLffXMLDOMDocument, will not be aware of any user-defined classes.

IDLffXMLDOMNode::InsertBefore

The IDLffXMLDOMNode::InsertBefore function method inserts a new node into the calling node's children list at the location before a reference node.

If the reference node is not specified or is a null object reference, the new node is inserted at the end of the list of children.

If the new node is an IDLffXMLDOMDocumentFragment, all of its children are inserted in the same order before the reference node.

If the new node is already in the tree, it is first removed.

The ownership of the IDL object to which the *NewChild* object reference refers is changed so that it is no longer owned by its previous owner and becomes owned by the calling object. Therefore, destroying the calling object destroys the new child as well.

Syntax

Result = *Obj*->[IDLffXMLDOMNode::]InsertBefore(*NewChild* [, *RefChild*])

Return Value

Returns an object reference to the new child node.

Arguments

NewChild

An object reference to an instance of an IDLffXMLDOMNode subclass that refers to the node to insert.

RefChild

An object reference to an instance of an IDLffXMLDOMNode subclass that refers to the reference node. The new child node is inserted before the reference node. The reference node must be a child of the calling node.

Keywords

None

Version History

6.1	Introduced

IDLffXMLDOMNode::RemoveChild

The IDLffXMLDOMNode::RemoveChild function method removes an existing child node from the calling node's child list.

The ownership of the IDL object to which the *OldChild* object reference refers is transferred from this calling object to the document object. The old child node has no parent after it is replaced. The document object becomes the new owner of the old child node, which is destroyed when the document object is destroyed.

Syntax

Result = Obj->[IDLffXMLDOMNode::]RemoveChild(*OldChild*)

Return Value

Returns an object reference to the old child node.

Arguments

OldChild

An object reference to an instance of an IDLffXMLDOMNode subclass that refers to the node that is being removed. The old child node must be a child of the calling node.

Keywords

None

Version History

6.1	Introduced

IDLffXMLDOMNode::ReplaceChild

The IDLffXMLDOMNode::ReplaceChild function method replaces an existing child node with a new child node into the calling node's child list.

If the new child node is an IDLffXMLDOMDocumentFragment, the old child node is replaced by all the IDLffXMLDOMDocumentFragment children, which are inserted in the same order.

If the new child node is already in the tree, it is first removed.

The ownership of the IDL object to which the *NewChild* object reference refers is changed so that it is no longer owned by its previous owner and becomes owned by the calling object. Therefore, destroying the calling object destroys the new child as well.

The ownership of the IDL object to which the *OldChild* object reference refers is transferred from this calling object to the document object. The old child node has no parent after it is replaced. The document object becomes the new owner of the old child node, which is destroyed when the document object is destroyed.

Syntax

Result = Obj->[IDLffXMLDOMNode::]ReplaceChild(*NewChild*, *OldChild*)

Return Value

Returns an object reference to the old child node.

Arguments

NewChild

An object reference to an instance of an IDLffXMLDOMNode subclass that refers to the node to put into the tree, replacing the old child node.

OldChild

An object reference to an instance of an IDLffXMLDOMNode subclass that refers to the node that is being replaced. The old child node must be a child of the calling node.

Keywords

Version History

6.1	Introduced

IDLffXMLDOMNode::SetNodeValue

The IDLffXMLDOMNode::SetNodeValue procedure method sets the node's value to the contents of a string.

Note ⎯⎯⎯⎯⎯⎯⎯⎯⎯⎯⎯⎯⎯⎯⎯⎯⎯⎯⎯⎯⎯⎯⎯⎯⎯⎯⎯⎯⎯⎯

This method is applicable only to the following node types: Attribute, Text, CDATA, Comment, and ProcessingInstruction. For all other node types, the method does nothing. For more information, see "IDLffXMLDOMNode::GetNodeValue Return Values" on page 3551.

Syntax

Obj->[IDLffXMLDOMNode::]SetNodeValue, *NodeValue*

Arguments

NodeValue

A scalar string value used to set the node's value.

Keywords

None

Version History

6.1	Introduced

IDLffXMLDOMNodeIterator

The IDLffXMLDOMNodeIterator class is used to navigate a DOM tree by creating a node object for accessing a DOM node and then destroying that node object as the iterator moves to another DOM node. The iterator creates an object and returns an object reference to that object each time the iterator moves, destroying the object that it last returned when the iterator last moved. This process lets the application visit the nodes in a DOM tree efficiently and easily.

The iterator moves back and forth through a document in a depth-first document-order traversal that corresponds to the order of the starting tags in an XML document. The node iterator is conceptually a "current" node pointer into the DOM tree. The pointer is positioned between nodes, so there is no concept of a current node. Instead, nodes on either side of the iterator's current position are referred to as the next and previous nodes. When the iterator moves, it returns either the next node or the previous node, depending on the direction it moves. The iterator is then positioned after the next node or before the previous node, again depending on the direction.

When the iterator is positioned at the start of a list of nodes, it has a next node, but no previous node. When the iterator is positioned at the end of a list of nodes, it has a previous node, but no next node.

The node specified when the iterator is created is the root node for the iterator. The iterator is positioned before the root node when the iterator is created. The nodes following the root node are the root node's children, if any. The iterator cannot move to siblings or to the parent of the root node. The root node therefore represents the top node of the subtree visible to the iterator.

The iterator never destroys the IDLffXMLDOMDocument objects that it might return. The iterator can only return an IDLffXMLDOMDocument object if an IDLffXMLDOMDocument object is the root node.

Objects of this class are created with the IDLffXMLDOMDocument::CreateNodeIterator method.

Superclasses

None

Creation

See IDLffXMLDOMNodeIterator::Init.

Properties

Objects of this class have no properties of their own, but do have properties inherited from any superclasses.

Methods

This class has the following methods:

- IDLffXMLDOMNodeIterator::Cleanup
- IDLffXMLDOMNodeIterator::Init
- IDLffXMLDOMNodeIterator::NextNode
- IDLffXMLDOMNodeIterator::PreviousNode

In addition, this class inherits the methods of any superclasses.

Version History

6.2	Introduced

IDLffXLMDOMNodeIterator Properties

Objects of this class have no properties of their own, but do have properties inherited from any superclasses.

IDLffXMLDOMNodeIterator::Cleanup

The IDLffXMLDOMNodeIterator::Cleanup procedure method performs cleanup on the node-iterator object. As part of this cleanup, the method destroys any other objects that were created by the iterator object. In particular, the node object returned when the iterator was last moved is destroyed. The destruction of the iterator object does not affect any corresponding nodes in the DOM tree.

This class should not be subclassed by a user class because the classes that create objects, such as IDLffXMLDOMDocument, will not be aware of any user-defined classes.

Syntax

OBJ_DESTROY, *Obj*

Arguments

None

Keywords

None

Version History

6.2	Introduced

IDLffXMLDOMNodeIterator::Init

The IDLffXMLDOMNodeIterator::Init function method initializes the object, but this class should not be instantiated directly. Instead, use the IDLffXMLDOMDocument::CreateNodeIterator method to create instances of this class.

This class should not be subclassed by a user class because the classes that create objects, such as IDLffXMLDOMDocument, will not be aware of any user-defined classes.

IDLffXMLDOMNodeIterator::NextNode

The IDLffXMLDOMNodeIterator::NextNode function method creates an object that is a subclass of IDLffXMLDOMNode and returns the object reference to that object. The object refers to the node in the DOM tree that appears after the iterator's current position in document-order traversal. The iterator's current position is then updated to the position immediately after the node returned by this method.

This method destroys the object returned by the most recent previous invocation of IDLffXMLDOMNodeIterator::NextNode or IDLffXMLDOMNodeIterator::PreviousNode.

Syntax

Result = Obj->[IDLffXMLDOMNodeIterator::]NextNode()

Return Value

Returns the object reference to the object that refers to the next node in the DOM tree.

If the iterator is positioned after the last node in the subtree under the iterator's root node, this method returns a null object reference, and the iterator's position does not change.

The first time this method is called after the iterator is created, the return value is the iterator's root node.

Arguments

None

Keywords

None

Version History

6.2	Introduced

IDLffXMLDOMNodeIterator::PreviousNode

The IDLffXMLDOMNodeIterator::PreviousNode function method creates an object that is a subclass of IDLffXMLDOMNode and returns the object reference to that object. The object refers to the node in the DOM tree that appears before the iterator's current position in document-order traversal. The iterator's current position is then updated to the position immediately before the node returned by this method.

This method destroys the object returned by the most recent previous invocation of IDLffXMLDOMNodeIterator::NextNode or IDLffXMLDOMNodeIterator::PreviousNode.

Syntax

Result = Obj->[IDLffXMLDOMNodeIterator::]PreviousNode()

Return Value

Returns the object reference to the object that refers to the previous node in the DOM tree.

If the iterator is positioned before the iterator's root node, this method returns a null object reference, and the iterator's position does not change. This is the situation immediately after an iterator's creation.

IDLffXMLDOMNodeList::GetLength

The IDLffXMLDOMNodeList::GetLength returns the number of nodes in the node list.

Syntax

Result = *Obj*->[IDLffXMLDOMNodeList::]GetLength()

Return Value

Returns an integer containing the number of nodes in the node list.

Arguments

None

Keywords

None

Version History

6.1	Introduced

IDLffXMLDOMNodeList::Init

The IDLffXMLDOMNodeList::Init function method initializes the object, but this class should not be instantiated directly. Instead, methods such as IDLffXMLDOMNode::GetFirstChild are used to create objects of all classes except IDLffXMLDOMDocument.

This class should not be subclassed by a user class because the classes that create objects, such as IDLffXMLDOMDocument, will not be aware of any user-defined classes.

IDLffXMLDOMNodeList::Item

The IDLffXMLDOMNodeList::Item returns an object reference to an instance of a subclass of IDLffXMLDOMNode that refers to an indexed node from the node list.

Syntax

Result = Obj->[IDLffXMLDOMNodeList::]Item(*Index*)

Return Value

Returns an object reference to an instance of a subclass of IDLffXMLDOMNode that refers to the node from the node list that corresponds to the supplied index. If the node at the specified index does not exist, a null object reference is returned.

Arguments

Index

An integer that contains the index into the node list.

Version History

6.1	Introduced

IDLffXMLDOMProcessingInstruction::Init

The IDLffXMLDOMProcessingInstruction::Init function method initializes the object, but this class should not be instantiated directly. Instead, methods such as IDLffXMLDOMNode::GetFirstChild are used to create objects of all classes except IDLffXMLDOMDocument.

This class should not be subclassed by a user class because the classes that create objects, such as IDLffXMLDOMDocument, will not be aware of any user-defined classes.

IDLffXMLDOMProcessingInstruction::SetData

The IDLffXMLDOMProcessingInstruction::SetData procedure method sets the content of the processing instruction.

Syntax

Obj->[IDLffXMLDOMProcessingInstruction::]SetData, *Content*

Arguments

Content

A scalar string containing the data to set in the processing instruction.

Keywords

None

Version History

6.1	Introduced

IDLffXMLDOMText

The IDLffXMLDOMText class references a text node in an XML document.

Superclasses

IDLffXMLDOMNode

IDLffXMLDOMCharacterData

Creation

See IDLffXMLDOMText::Init.

Properties

Objects of this class have no properties of their own, but do have properties inherited from any superclasses.

Methods

This class has the following methods:

- IDLffXMLDOMText::Cleanup
- IDLffXMLDOMText::Init
- IDLffXMLDOMText::IsIgnorableWhitespace
- IDLffXMLDOMText::SplitText

In addition, this class inherits the methods of any superclasses.

Version History

This class should not be subclassed by a user class because the classes that create objects, such as IDLffXMLDOMDocument, will not be aware of any user-defined classes.

IDLffXMLDOMText::IsIgnorableWhitespace

The IDLffXMLDOMText::IsIgnorableWhitespace function method indicates whether the text node contains ignorable whitespace.

In order for the parser to distinguish between ignorable and non-ignorable white space, validation must be performed during parsing with a DTD or schema.

Syntax

Result = Obj->[IDLffXMLDOMText::]IsIgnorableWhitespace()

Return Value

Returns 1 if the text node contains ignorable whitespace, or 0 if the text node contains whitespace that is not ignorable.

Arguments

None

Keywords

None

Version History

6.1	Introduced

IDLffXMLDOMText::SplitText

The IDLffXMLDOMText::SplitText function method breaks a text node into two nodes, splitting the text at the specified offset. Both nodes are kept in the same tree as siblings. The method both modifies its caller and creates an instance of a new IDLffXMLDOMText object, which contains the text following the offset point. When the offset is equal to the length of the string, the new node has no value data.

Syntax

Result = Obj->[IDLffXMLDOMText::]SplitText(*Offset*)

Return Value

Returns an object reference to the new IDLffXMLDOMText object.

Arguments

Offset

An integer containing the offset into the string at which to split it.

Keywords

None

Version History

6.1	Introduced

IDLffXMLDOMTreeWalker

The IDLffXMLDOMTreeWalker class is used to navigate a DOM tree by creating a node object for accessing a DOM node and then destroying that node object as the tree walker is moved to another DOM node. The walker creates an object and returns an object reference to that object each time the walker moves, destroying the object that it last returned when the walker last moved. This process lets the application visit the nodes in a DOM tree efficiently and easily.

The tree walker is conceptually a "current" node pointer into the DOM tree. When the walker moves, it returns an object reference to a newly created instance of a node that represents the DOM node where the walker is now positioned.

The node specified when the tree walker is created is the root node for the walker. The walker is positioned at the root node when the walker is created. The walker cannot move to an ancestor of the root node. The root node, its children, and all of its siblings and their children compose the subtree visible to the walker.

The tree walker never destroys the IDLffXMLDOMDocument objects that it might return. The walker can only return an IDLffXMLDOMDocument object if an IDLffXMLDOMDocument object is the root node.

Objects of this class are created with the IDLffXMLDOMDocument::CreateTreeWalker method.

Superclasses

None

Creation

See IDLffXMLDOMTreeWalker::Init.

Properties

Objects of this class have no properties of their own, but do have properties inherited from any superclasses.

Methods

This class has the following methods:

- IDLffXMLDOMTreeWalker::Cleanup

- IDLffXMLDOMTreeWalker::FirstChild
- IDLffXMLDOMTreeWalker::GetCurrentNode
- IDLffXMLDOMTreeWalker::Init
- IDLffXMLDOMTreeWalker::LastChild
- IDLffXMLDOMTreeWalker::NextNode
- IDLffXMLDOMTreeWalker::NextSibling
- IDLffXMLDOMTreeWalker::ParentNode
- IDLffXMLDOMTreeWalker::PreviousNode
- IDLffXMLDOMTreeWalker::PreviousSibling
- IDLffXMLDOMTreeWalker::SetCurrentNode

In addition, this class inherits the methods of any superclasses.

Version History

6.2	Introduced

IDLffXMLDOMTreeWalker Properties

Objects of this class have no properties of their own, but do have properties inherited from any superclasses.

IDLffXMLDOMTreeWalker::Cleanup

The IDLffXMLDOMTreeWalker::Cleanup procedure method performs cleanup on the tree-walker object. As part of this cleanup, the method destroys any other objects that were created by the walker object. The destruction of the walker object does not affect any corresponding nodes in the DOM tree.

This class should not be subclassed by a user class because the classes that create objects, such as IDLffXMLDOMDocument, will not be aware of any user-defined classes.

Syntax

6.2	Introduced

IDLffXMLDOMTreeWalker::FirstChild

The IDLffXMLDOMTreeWalker::FirstChild function method creates an object that is a subclass of IDLffXMLDOMNode and returns the object reference to that object. The object refers to the node in the DOM tree that is the first child of the node to which the walker is currently pointing.

If the current node has no visible children, this method returns a null object reference, and the current node does not change. Otherwise, the DOM tree node to which the returned object refers becomes the current node in the tree walker.

This method destroys the object returned by the most recent previous invocation of any of the following navigation methods:

- IDLffXMLDOMTreeWalker::FirstChild
- IDLffXMLDOMTreeWalker::GetCurrentNode
- IDLffXMLDOMTreeWalker::LastChild
- IDLffXMLDOMTreeWalker::NextNode
- IDLffXMLDOMTreeWalker::NextSibling
- IDLffXMLDOMTreeWalker::ParentNode
- IDLffXMLDOMTreeWalker::PreviousNode
- IDLffXMLDOMTreeWalker::PreviousSibling

A node object returned by this method is destroyed when the tree walker is destroyed.

Syntax

Result = Obj->[IDLffXMLDOMTreeWalker::]FirstChild()

Return Value

Returns an object reference to the first child of the node in the DOM tree to which the tree walker is pointing, or a null object reference if the current node has no visible children.

Arguments

None

Keywords

None

Version History

6.2	Introduced

IDLffXMLDOMTreeWalker::GetCurrentNode

The IDLffXMLDOMTreeWalker::GetCurrentNode function method creates an object that is a subclass of IDLffXMLDOMNode and returns the object reference to that object. The object refers to the node in the DOM tree to which the walker is currently pointing.

This method destroys the object returned by the most recent previous invocation of any of the following navigation methods:

- IDLffXMLDOMTreeWalker::FirstChild
- IDLffXMLDOMTreeWalker::GetCurrentNode
- IDLffXMLDOMTreeWalker::LastChild
- IDLffXMLDOMTreeWalker::NextNode
- IDLffXMLDOMTreeWalker::NextSibling
- IDLffXMLDOMTreeWalker::ParentNode
- IDLffXMLDOMTreeWalker::PreviousNode
- IDLffXMLDOMTreeWalker::PreviousSibling

A node object returned by this method is destroyed when the tree walker is destroyed.

Syntax

Result = Obj->[IDLffXMLDOMTreeWalker::]GetCurrentNode()

Return Value

Returns the object reference to the object that refers to the tree walker's current position in the DOM tree.

Arguments

None

Keywords

None

Version History

6.2	Introduced

IDLffXMLDOMTreeWalker::Init

The IDLffXMLDOMTreeWalker::Init function method initializes the object, but this class should not be instantiated directly. Instead, use the IDLffXMLDOMDocument::CreateTreeWalker method to create instances of this class.

This class should not be subclassed by a user class because the classes that create objects, such as IDLffXMLDOMDocument, will not be aware of any user-defined classes.

IDLffXMLDOMTreeWalker::LastChild

The IDLffXMLDOMTreeWalker::LastChild function method creates an object that is a subclass of IDLffXMLDOMNode and returns the object reference to that object. The object refers to the node in the DOM tree that is the last child of the node to which the walker is currently pointing.

If the current node has no visible children, this method returns a null object reference, and the current node does not change. Otherwise, the DOM tree node to which the returned object refers becomes the current node in the tree walker.

This method destroys the object returned by the most recent previous invocation of any of the following navigation methods:

- IDLffXMLDOMTreeWalker::FirstChild
- IDLffXMLDOMTreeWalker::GetCurrentNode
- IDLffXMLDOMTreeWalker::LastChild
- IDLffXMLDOMTreeWalker::NextNode
- IDLffXMLDOMTreeWalker::NextSibling
- IDLffXMLDOMTreeWalker::ParentNode
- IDLffXMLDOMTreeWalker::PreviousNode
- IDLffXMLDOMTreeWalker::PreviousSibling

A node object returned by this method is destroyed when the tree walker is destroyed.

Syntax

Result = Obj->[IDLffXMLDOMTreeWalker::]LastChild()

Return Value

Returns an object reference to the last child of the node in the DOM tree to which the tree walker is pointing, or a null object reference if the current node has no visible children.

Arguments

None

Keywords

None

Version History

6.2	Introduced

IDLffXMLDOMTreeWalker::NextNode

The IDLffXMLDOMTreeWalker::NextNode function method creates an object that is a subclass of IDLffXMLDOMNode and returns the object reference to that object. The object refers to the node in the DOM tree that is visited next after the walker's current node in document-order traversal.

If the current node has no next node or the search for the next node looks above the tree walker's root node, this method returns a null object reference, and the current node does not change. Otherwise, the DOM tree node to which the returned object refers becomes the current node in the tree walker.

This method destroys the object returned by the most recent previous invocation of any of the following navigation methods:

- IDLffXMLDOMTreeWalker::FirstChild
- IDLffXMLDOMTreeWalker::GetCurrentNode
- IDLffXMLDOMTreeWalker::LastChild
- IDLffXMLDOMTreeWalker::NextNode
- IDLffXMLDOMTreeWalker::NextSibling
- IDLffXMLDOMTreeWalker::ParentNode
- IDLffXMLDOMTreeWalker::PreviousNode
- IDLffXMLDOMTreeWalker::PreviousSibling

A node object returned by this method is destroyed when the tree walker is destroyed.

Syntax

Result = Obj->[IDLffXMLDOMTreeWalker::]NextNode()

Return Value

Returns an object reference to the next node in the DOM tree in the tree walker's document-order traversal, or a null object reference if the current node has no next node or the search for the next node looks above the walker's root node.

Arguments

None

Keywords

None

Version History

6.2	Introduced

IDLffXMLDOMTreeWalker::NextSibling

The IDLffXMLDOMTreeWalker::NextSibling function method creates an object that is a subclass of IDLffXMLDOMNode and returns the object reference to that object. The object refers to the node in the DOM tree that is the next sibling of the node to which the walker is currently pointing.

If the current node has no visible next sibling, this method returns a null object reference, and the current node does not change. Otherwise, the DOM tree node to which the returned object refers becomes the current node in the tree walker.

This method destroys the object returned by the most recent previous invocation of any of the following navigation methods:

- IDLffXMLDOMTreeWalker::FirstChild
- IDLffXMLDOMTreeWalker::GetCurrentNode
- IDLffXMLDOMTreeWalker::LastChild
- IDLffXMLDOMTreeWalker::NextNode
- IDLffXMLDOMTreeWalker::NextSibling
- IDLffXMLDOMTreeWalker::ParentNode
- IDLffXMLDOMTreeWalker::PreviousNode
- IDLffXMLDOMTreeWalker::PreviousSibling

A node object returned by this method is destroyed when the tree walker is destroyed.

Syntax

Result = *Obj*->[IDLffXMLDOMTreeWalker::]NextSibling()

Return Value

Returns an object reference to the next sibling of the node in the DOM tree to which the tree walker is pointing, or a null object reference if the current node has no visible next sibling.

Arguments

None

Keywords

None

Version History

6.2	Introduced

IDLffXMLDOMTreeWalker::ParentNode

The IDLffXMLDOMTreeWalker::ParentNode function method creates an object that is a subclass of IDLffXMLDOMNode and returns the object reference to that object. The object refers to the node in the DOM tree that is the parent of the node to which the walker is currently pointing.

If the search for a parent node attempts to look above the tree walker's root node or no visible ancestor node is found, this method returns a null object reference, and the current node does not change. Otherwise, the DOM tree node to which the returned object refers becomes the current node in the tree walker.

This method destroys the object returned by the most recent previous invocation of any of the following navigation methods:

- IDLffXMLDOMTreeWalker::FirstChild
- IDLffXMLDOMTreeWalker::GetCurrentNode
- IDLffXMLDOMTreeWalker::LastChild
- IDLffXMLDOMTreeWalker::NextNode
- IDLffXMLDOMTreeWalker::NextSibling
- IDLffXMLDOMTreeWalker::ParentNode
- IDLffXMLDOMTreeWalker::PreviousNode
- IDLffXMLDOMTreeWalker::PreviousSibling

A node object returned by this method is destroyed when the tree walker is destroyed.

Syntax

Result = Obj->[IDLffXMLDOMTreeWalker::]ParentNode()

Return Value

Returns the object reference to the parent of the node in the DOM tree to which the tree walker is pointing, or a null object reference if the search cannot find a visible ancestor node or attempts to look above the walker's root node.

Arguments

None

Keywords

None

Version History

6.2	Introduced

IDLffXMLDOMTreeWalker::PreviousNode

The IDLffXMLDOMTreeWalker::PreviousNode function method creates an object that is a subclass of IDLffXMLDOMNode and returns the object reference to that object. The object refers to the node in the DOM tree that is visited before the walker's current node in document-order traversal.

If the current node has no previous node or the search for the previous node looks above the tree walker's root node, this method returns a null object reference, and the current node does not change. Otherwise, the DOM tree node to which the returned object refers becomes the current node in the tree walker.

This method destroys the object returned by the most recent previous invocation of any of the following navigation methods:

- IDLffXMLDOMTreeWalker::FirstChild
- IDLffXMLDOMTreeWalker::GetCurrentNode
- IDLffXMLDOMTreeWalker::LastChild
- IDLffXMLDOMTreeWalker::NextNode
- IDLffXMLDOMTreeWalker::NextSibling
- IDLffXMLDOMTreeWalker::ParentNode
- IDLffXMLDOMTreeWalker::PreviousNode
- IDLffXMLDOMTreeWalker::PreviousSibling

A node object returned by this method is destroyed when the tree walker is destroyed.

Syntax

Result = Obj->[IDLffXMLDOMTreeWalker::]PreviousNode()

Return Value

Returns an object reference to the previous node in the DOM tree in the tree walker's document-order traversal, or a null object reference if the current node has no previous node or the search for the previous node looks above the walker's root node.

Arguments

None

Keywords

None

Version History

6.2	Introduced

IDLffXMLDOMTreeWalker::PreviousSibling

The IDLffXMLDOMTreeWalker::PreviousSibling function method creates an object that is a subclass of IDLffXMLDOMNode and returns the object reference to that object. The object refers to the node in the DOM tree that is the previous sibling of the node to which the walker is currently pointing.

If the current node has no visible previous sibling, this method returns a null object reference, and the current node does not change. Otherwise, the DOM tree node to which the returned object refers becomes the current node in the tree walker.

This method destroys the object returned by the most recent previous invocation of any of the following navigation methods:

- IDLffXMLDOMTreeWalker::FirstChild
- IDLffXMLDOMTreeWalker::GetCurrentNode
- IDLffXMLDOMTreeWalker::LastChild
- IDLffXMLDOMTreeWalker::NextNode
- IDLffXMLDOMTreeWalker::NextSibling
- IDLffXMLDOMTreeWalker::ParentNode
- IDLffXMLDOMTreeWalker::PreviousNode
- IDLffXMLDOMTreeWalker::PreviousSibling

A node object returned by this method is destroyed when the tree walker is destroyed.

Syntax

Result = Obj->[IDLffXMLDOMTreeWalker::]PreviousSibling()

Return Value

Returns an object reference to the previous sibling of the node in the DOM tree to which the tree walker is pointing, or a null object reference if the current node has no visible previous sibling.

Arguments

None

Keywords

None

Version History

6.2	Introduced

IDLffXMLDOMTreeWalker::SetCurrentNode

The IDLffXMLDOMTreeWalker::SetCurrentNode procedure method sets the tree walker's current node to the specified node. You can use this method to position the walker at a particular node in the DOM tree.

Syntax

Obj->[IDLffXMLDOMTreeWalker::]SetCurrentNode, *CurrentNode*

Arguments

CurrentNode

An object reference to an object belonging to a subclass of IDLffXMLDOMNode. For example:

```
oTop = oDocument->GetDocumentElement()
oWalker = oDocument->CreateTreeWalker( oTop )
oNode = oWalker->GetFirstChild()
oNode = oWalker->GetNextSibling()
; Move walker back to the top.
oWalker->SetCurrentNode, oTop
```

Keywords

None

Version History

6.2	Introduced

IDLffXMLSAX

An IDLffXMLSAX object uses an XML SAX level 2 parser. The XML parser allows you to read an XML file and store arbitrary data from the file in IDL variables. The parser object's methods are *callbacks*. These methods are called automatically when the parser encounters different types of XML elements or attributes.

Note ───

To use the XML parser, you *must* write a subclass of this object class, overriding the object methods as necessary to process the data in a specific XML file or files. See Chapter 20, "Using the XML Parser Object Class" (*Application Programming*) for further information and examples.

──

The IDLffXMLSAX object encapsulates the Xerces validating XML parser; see `http://xml.apache.org` for details.

Note ───

For more information on XML, see "About XML" (Chapter 20, *Application Programming*).

──

Superclasses

None

Subclasses

You *must* write a subclass of this object, overriding object methods as necessary to retrieve information from the XML file.

Creation

See "IDLffXMLSAX::Init" on page 3644

Properties

Objects of this class have the following properties. See "IDLffXMLSAX Properties" on page 3621 for details on individual properties.

- FILENAME
- NAMESPACE_PREFIXES

- PARSER_LOCATION
- PARSER_PUBLICID
- PARSER_URI
- SCHEMA_CHECKING
- VALIDATION_MODE

Methods

This class has the following methods:

- IDLffXMLSAX::AttributeDecl
- IDLffXMLSAX::Characters
- IDLffXMLSAX::Cleanup
- IDLffXMLSAX::Comment
- IDLffXMLSAX::ElementDecl
- IDLffXMLSAX::EndCDATA
- IDLffXMLSAX::EndDocument
- IDLffXMLSAX::EndDTD
- IDLffXMLSAX::EndElement
- IDLffXMLSAX::EndEntity
- IDLffXMLSAX::EndPrefixMapping
- IDLffXMLSAX::Error
- IDLffXMLSAX::ExternalEntityDecl
- IDLffXMLSAX::FatalError
- IDLffXMLSAX::GetProperty
- IDLffXMLSAX::IgnorableWhitespace
- IDLffXMLSAX::Init
- IDLffXMLSAX::InternalEntityDecl
- IDLffXMLSAX::NotationDecl
- IDLffXMLSAX::ParseFile
- IDLffXMLSAX::ProcessingInstruction

- IDLffXMLSAX::SetProperty
- IDLffXMLSAX::SkippedEntity
- IDLffXMLSAX::StartCDATA
- IDLffXMLSAX::StartDocument
- IDLffXMLSAX::StartDTD
- IDLffXMLSAX::StartElement
- IDLffXMLSAX::StartEntity
- IDLffXMLSAX::StartPrefixmapping
- IDLffXMLSAX::StopParsing
- IDLffXMLSAX::UnparsedEntityDecl
- IDLffXMLSAX::Warning

Version History

5.6	Introduced

IDLffXMLSAX Properties

IDLffXMLSAX objects have the following properties in addition to properties inherited from any superclasses. Properties with the word "Yes" in the "Get" column of the property table can be retrieved via IDLffXMLSAX::GetProperty. Properties with the word "Yes" in the "Init" column of the property table can be set via IDLffXMLSAX::Init. Properties with the word "Yes" in the "Set" column in the property table can be set via IDLffXMLSAX::SetProperty.

Note ————————————————————————————————

For a discussion of the property description tables shown below, see "About Object Property Descriptions" on page 3135.

——

Objects of this class have the following properties.

- FILENAME
- NAMESPACE_PREFIXES
- PARSER_LOCATION
- PARSER_PUBLICID
- PARSER_URI
- SCHEMA_CHECKING
- VALIDATION_MODE

FILENAME

A string containing the filename of the XML file being parsed.

Note ————————————————————————————————

This property is only available during a parse operation.

——

Property Type	String		
Name String	*not displayed*		
Get: Yes	**Set:** No	**Init:** No	**Registered:** No

NAMESPACE_PREFIXES

A Boolean value indicating whether namespace prefixes are enabled. Namespace prefixes are enabled if this property is set to true. By default, namespace prefixes are disabled.

Property Type	Boolean		
Name String	*not displayed*		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** No

PARSER_LOCATION

A two-element array containing the approximate location of the parser within the entity being parsed. The first element of the array is set to the line number and the second element is set to the column number.

Note ───────────────────────────────────────
This property is only available during a parse operation.
──

Property Type	Array		
Name String	*not displayed*		
Get: Yes	**Set:** No	**Init:** No	**Registered:** No

PARSER_PUBLICID

A string containing the Public ID for the entity being parsed, if it is available. If the Public ID is not available, an empty string is returned.

Note ───────────────────────────────────────
This property is only available during a parse operation.
──

Property Type	String		
Name String	*not displayed*		
Get: Yes	**Set:** No	**Init:** No	**Registered:** No

PARSER_URI

A string containing the base URI (System ID) for the entity being parsed, if it is available. If the value is available, it is always an absolute URI. If the System ID is not available, an empty string is returned.

Note

This property can be used to identify the document or external entity in diagnostics, or to resolve relative URIs. However, it is only available during a parse operation.

Property Type	String		
Name String	*not displayed*		
Get: Yes	**Set:** No	**Init:** No	**Registered:** No

SCHEMA_CHECKING

An integer value to indicating the type of validation the parser should perform. XML *Schemas* describe the structure and allowed contents of an XML document. Schemas are more robust than, and are envisioned as a replacement for, DTDs. By default, the parser will validate the parsed XML file against the specified schema, if one is provided. If no schema is provided, no validation will occur. Possible values are:

0	No validation.
1	Validate only if a schema is provided. This is the default value.
2	Perform full schema constraint checking, if a schema is provided. This feature checks the schema grammar itself for additional errors. It does not affect the level of checking performed on document instances that use schema grammars.

Property Type	Integer		
Name String	*not displayed*		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** No

VALIDATION_MODE

An integer value indicating the type of XML validation that the parser should perform. XML *Document Type Definitions* (DTDs) describe the structure and allowed contents of an XML document. By default, the parser will validate the parsed XML file against the specified DTD, if one is provided; if no DTD specification is provided, no validation will occur. Possible values are:

0	No validation.
1	Validate only if a DTD is provided. This is the default value.
2	Always perform validation. If this option is in force and no DTD is provided, every XML element in the document will generate an error.

Property Type	Integer		
Name String	*not displayed*		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** No

IDLffXMLSAX::AttributeDecl

The IDLffXMLSAX::AttributeDecl procedure method is called when the parser detects an `<!ATTLIST ...>` declaration in a DTD. This method is called once for each attribute declared by the tag.

Syntax

Obj->[IDLffXMLSAX::]AttributeDecl, *eName*, *aName*, *Type*, *Mode*, *Value*

Arguments

eName

A string containing the name of the element for which the attribute is being declared.

aName

A string containing the name of the attribute being declared.

Type

A string that specifying the type of attribute being defined. Possible values are:

- 'CDATA'
- 'ID'
- 'IDREF'
- 'IDREFS'
- 'NMTOKEN'
- 'NMTOKENS'
- 'ENTITY'
- 'ENTITIES'

or two types of enumerated values. Enumerated values are encoded with parenthesized strings such as `(a|b|c)` to indicate that strings a, b, or c are permissible. If the string is an enumeration of notation names, the string `"NOTATION "` (note the space after the second "N") precedes the parenthesized string.

Mode

A string specifying restrictions on the value of the attribute. Possible values are:

- '#IMPLIED' - the application determines the value

- '#REQUIRED' - the value must be given; defaulting is not permitted

- '#FIXED' - only one value is permitted

- '' - a null string (the value specified by the *Value* argument is used as the default)

Value

A string containing the default value for the attribute. If *Value* contains a null string, no default value was specified.

Keywords

None

Version History

5.6	Introduced

IDLffXMLSAX::Characters

The IDLffXMLSAX::Characters procedure method is called when the parser detects text in the parsed document.

Syntax

Obj->[IDLffXMLSAX::]Characters, *Chars*

Arguments

Chars

A string containing the text detected by the parser.

Keywords

None

Version History

5.6	Introduced

IDLffXMLSAX::Cleanup

The IDLffXMLSAX::Cleanup procedure method performs all cleanup on the object.

Note ───

Cleanup methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation and destruction. In most cases, you cannot call the Cleanup method directly. However, one exception to this rule does exist. If you write your own subclass of this class, you can call the Cleanup method from within the Init or Cleanup method of the subclass.

───

Syntax

OBJ_DESTROY, *Obj*

or

Obj->[IDLffXMLSAX::]Cleanup   *(In a lifecycle method only.)*

Arguments

None

Keywords

None

Version History

5.6	Introduced

IDLffXMLSAX::Comment

The IDLffXMLSAX::Comment procedure method is called when the parser detects a comment section of the form `<!-- ... -->`.

Syntax

Obj->[IDLffXMLSAX::]Comment, *Comment*

Arguments

Comment

A string containing the text within the detected comment section, without the delimiting characters ("`<!--`" and "`-->`").

Keywords

None

Version History

5.6	Introduced

IDLffXMLSAX::ElementDecl

The IDLffXMLSAX::ElementDecl procedure method is called when the parser detects an `<!ELEMENT ...>` declaration in the DTD.

Syntax

Obj->[IDLffXMLSAX::]ElementDecl, *Name*, *Model*

Arguments

Name

A string containing the name of the element.

Model

A string containing the *content model* (sometimes called the *content specification*) for the element, with all whitespace removed.

Keywords

None

Version History

5.6	Introduced

IDLffXMLSAX::EndCDATA

The IDLffXMLSAX::EndCDATA procedure method is called when the parser detects the end of a `<![CDATA[...]]>` text section.

Syntax

Obj->[IDLffXMLSAX::]EndCDATA

Arguments

None

Keywords

None

Version History

5.6	Introduced

IDLffXMLSAX::EndDocument

The IDLffXMLSAX::EndDocument procedure method is called when the parser detects the end of the XML document.

Syntax

Obj->[IDLffXMLSAX::]EndDocument

Arguments

None

Keywords

None

Version History

5.6	Introduced

IDLffXMLSAX::EndDTD

The IDLffXMLSAX::EndDTD procedure method is called when the parser detects the end of a Document Type Definition (DTD).

Syntax

Obj->[IDLffXMLSAX::]EndDTD

Arguments

None

Keywords

None

Version History

5.6	Introduced

IDLffXMLSAX::EndElement

The IDLffXMLSAX::EndElement procedure method is called when the parser detects the end of an element.

Syntax

Obj->[IDLffXMLSAX::]EndElement, *URI*, *Local*, *qName*

Arguments

URI

A string containing the namespace URI with which the element is associated, if any.

Note

A URI (or Uniform Resource Identifier) refers to the generic set of all names and addresses which are short strings which refer to objects.

Local

A string containing the element name with any prefix removed, if the element is associated with a namespace URI. If the element is not associated with a namespace URI, this variable will contain an empty string.

qName

A string containing the element name found in the XML file.

Note

If the element is associated with a namespace URI, this variable may contain an empty string.

Keywords

None

Version History

5.6	Introduced

IDLffXMLSAX::EndEntity

The IDLffXMLSAX::EndEntity procedure method is called when the parser detects the end of an internal or external entity expansion.

Syntax

Obj->[IDLffXMLSAX::]EndEntity, *Name*

Arguments

Name

A string containing the name of the entity.

Keywords

None

Version History

5.6	Introduced

IDLffXMLSAX::EndPrefixMapping

The IDLffXMLSAX::EndPrefixMapping procedure method is called when a previously declared prefix mapping goes out of scope.

Syntax

Obj->[IDLffXMLSAX::]EndPrefixMapping, *Prefix*

Arguments

Prefix

A string containing the namespace prefix that is going out of scope.

Keywords

None

Version History

5.6	Introduced

IDLffXMLSAX::Error

The IDLffXMLSAX::Error procedure method is called when the parser detects an error that is not expected to be fatal. This method prints an IDL error string to the IDL output log and allows the parser to continue processing.

For example, a violation of XML validity constraints is generally a non-fatal error.

Note ──

This method will cause error messages to be printed to the IDL output log. If you would like your application to hide error messages from the user (or display them in some other fashion), override this method in your subclass of the IDLffXMLSAX object class. If you do override this method, the error message will not be printed to the output log unless you explicitly call the superclass method.

──

Syntax

Obj->[IDLffXMLSAX::]Error, *SystemID*, *LineNumber*, *ColumnNumber*, *Message*

Arguments

SystemID

A string containing the URI of the associated text.

LineNumber

A longword integer representing the line number that contains the error.

ColumnNumber

A longword integer representing the column number that contains the error.

Message

A string containing the error message sent to the IDL output log.

Keywords

None

Version History

5.6	Introduced

IDLffXMLSAX::ExternalEntityDecl

The IDLffXMLSAX::ExternalEntityDecl procedure method is called when the parser detects an `<!ENTITY ...>` declarations in the DTD for a parsed external entity.

Syntax

Obj->[IDLffXMLSAX::]ExternalEntityDecl, *Name*, *PublicID*, *SystemID*

Arguments

Name

A string containing the entity name.

PublicID

A string containing the Public ID for the entity.

Note ──

If this value is not specified in the entity declaration, this variable will contain an empty string.

──

SystemID

A string containing the System ID for the entity, provided as an absolute URI.

Keywords

None

Version History

5.6	Introduced

IDLffXMLSAX::FatalError

The IDLffXMLSAX::FatalError procedure method is called when the parser detects a fatal error. When called, parsing will normally stop, but may sometimes continue long enough to report further errors. This method prints an IDL error string to the IDL output log.

Syntax

Obj->[IDLffXMLSAX::]FatalError, *SystemID*, *LineNumber*, *ColumnNumber*, *Message*

Arguments

SystemID

A string containing the URI of the associated text.

LineNumber

A longword integer representing the line number that contains the error.

ColumnNumber

A longword integer representing the column number that contains the error.

Message

A string containing the error message sent to the IDL output log.

Keywords

None

Version History

5.6	Introduced

IDLffXMLSAX::GetProperty

The IDLffXMLSAX::GetProperty procedure method is used to get the values of various properties of the parser.

Syntax

Obj->[IDLffXMLSAX::]GetProperty [, *PROPERTY=variable*]

Arguments

None

Keywords

Any property listed under "IDLffXMLSAX Properties" on page 3621 that contains the word "Yes" in the "Get" column of the properties table can be retrieved using this method. To retrieve the value of a property, specify the property name as a keyword set equal to a named variable that will contain the value of the property.

Version History

5.6	Introduced

IDLffXMLSAX::IgnorableWhitespace

The IDLffXMLSAX::IgnorableWhitespace procedure method is called when the parser detects whitespace that separates elements in an element content model.

Syntax

Obj->[IDLffXMLSAX::]IgnorableWhitespace, *Chars*

Arguments

Chars

A string containing the whitespace detected by the parser. Whitespace can consist of spaces, tabs, or newline characters in any combination.

Keywords

None

Version History

5.6	Introduced

IDLffXMLSAX::Init

The IDLffXMLSAX::Init function method initializes an XML parser object.

Note ──

Init methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation. In most cases, you cannot call the Init method directly. However, one exception to this rule does exist. If you write your own subclass of this class, you can call the Init method from within the Init method of the subclass.

──

Syntax

Obj = OBJ_NEW('IDLffXMLSAX' [, *PROPERTY=value*])

or

Result = Obj->[IDLffXMLSAX::]Init([, *PROPERTY=value*])   *(In a lifecycle method only.)*

Return Value

When this method is called indirectly, as part of the call to the OBJ_NEW function, the return value is an object reference to the newly-created object.

When called directly within a subclass Init method, the return value is 1 if initialization was successful, or zero otherwise.

Arguments

None

Keywords

Any property listed under "IDLffXMLSAX Properties" on page 3621 that contains the word "Yes" in the "Init" column of the properties table can be initialized during object creation using this method. To initialize the value of a property, specify the property name as a keyword set equal to the appropriate property value.

Version History

5.6	Introduced

IDLffXMLSAX::InternalEntityDecl

The IDLffXMLSAX::InternalEntityDecl procedure method is called when the parser detects an `<!ENTITY ...>` declaration in a DTD for (parsed) internal entities. The entity can be either a general entity or a parameter entity.

Syntax

Obj->[IDLffXMLSAX::]InternalEntityDecl, *Name*, *Value*

Arguments

Name

A string containing the entity name. Names that start with the "`%`" character are parameter entities; all others are general entities.

Value

A string containing the entity value. The entity value can contain arbitrary XML content, which will be reparsed when the entity is expanded.

Keywords

None

Version History

5.6	Introduced

IDLffXMLSAX::NotationDecl

The IDLffXMLSAX::NotationDecl procedure method is called when the parser detects a `<!NOTATION ...>` declaration in a DTD.

Syntax

Obj->[IDLffXMLSAX::]NotationDecl, *Name*, *PublicID*, *SystemID*

Arguments

Name

A string containing the notation name.

PublicID

A string containing the Public ID for the notation.

Note

If this value is not specified in the notation declaration, this variable will contain an empty string.

SystemID

A string containing the System ID for the notation, provided as an absolute URI.

Note

If this value is not specified in the notation declaration, this variable will contain an empty string.

Keywords

None

Version History

5.6	Introduced

IDLffXMLSAX::ParseFile

The IDLffXMLSAX::ParseFile procedure method parses the specified XML file. During the parsing operation, different object methods are called as different items within the XML file are detected. When this method returns, the parse operation is complete.

Syntax

Obj->[IDLffXMLSAX::]ParseFile, *Input* [, /URL] [, /XML_STRING]

Arguments

Input

A string containing the full path name of the file to be parsed. If the XML_STRING keyword is set, *Input* should be a string containing the XML data to be parsed. If the URL keyword is set, *Input* should be a Uniform Resource Locator.

Keywords

URL

Set this keyword to indicate that *Input* is a Uniform Resource Locator containing the XML data to be parsed rather than the name of an XML file.

XML_STRING

Set this keyword to indicate that *Input* is a string array containing XML data to be parsed rather than the name of an XML file.

Version History

5.6	Introduced
6.4	Added URL and XML_STRING keywords

IDLffXMLSAX::ProcessingInstruction

The IDLffXMLSAX::ProcessingInstruction procedure method is called when the parser detects a processing instruction.

Syntax

Obj->[IDLffXMLSAX::]ProcessingInstruction, *Target*, *Data*

Arguments

Target

A string specifying the target, which is the application that should process the instruction.

Data

A string specifying the data to be passed to the application specified by *Target*.

Keywords

None

Version History

5.6	Introduced

IDLffXMLSAX::SetProperty

The IDLffXMLSAX::SetProperty procedure method is used to set the values of various properties of the parser.

Syntax

Obj->[IDLffXMLSAX::]SetProperty [, *PROPERTY=value*]

Arguments

None

Keywords

Any property listed under "IDLffXMLSAX Properties" on page 3621 that contains the word "Yes" in the "Set" column of the properties table can be set using this method. To set the value of a property, specify the property name as a keyword set equal to the appropriate property value.

Version History

5.6	Introduced

IDLffXMLSAX::SkippedEntity

The IDLffXMLSAX::SkippedEntity procedure method is called when the parser skips an entity and validation is not being performed. This method is rarely called by SAX parsers.

Syntax

Obj->[IDLffXMLSAX::]SkippedEntity, *Name*

Arguments

Name

A string containing the name of the entity that was skipped.

Keywords

None

Version History

5.6	Introduced

IDLffXMLSAX::StartCDATA

The IDLffXMLSAX::StartCDATA procedure method is called when the parser detects the beginning of a <![CDATA[...]]> text section.

Syntax

Obj->[IDLffXMLSAX::]StartCDATA

Arguments

None

Keywords

None

Version History

5.6	Introduced

IDLffXMLSAX::StartDocument

The IDLffXMLSAX::StartDocument procedure method is called when the parser begins processing a document, and before any data is processed.

Syntax

Obj->[IDLffXMLSAX::]StartDocument

Arguments

None

Keywords

None

Version History

5.6	Introduced

IDLffXMLSAX::StartDTD

The IDLffXMLSAX::StartDTD procedure method is called when the parser detects the beginning of a Document Type Definition (DTD).

Syntax

Obj->[IDLffXMLSAX::]StartDTD, *Name*, *PublicID*, *SystemID*

Arguments

Name

A string containing the declared name of the root element for the document.

PublicID

A string containing the *normalized* version of the Public ID (a URI) declared for the external subset, or an empty string if no external subset was declared. *Normalization* involves removal of unnecessary "." and ". ." segments from the URI.

SystemID

A string containing the System ID (a URI) of the external subset, or an empty string if no external subset was declared.

Note ──

This URI has not been resolved into an absolute URI.

──

Keywords

None

Version History

5.6	Introduced

IDLffXMLSAX::StartElement

The IDLffXMLSAX::StartElement procedure method is called when the parser detects the beginning of an element.

Syntax

Obj->[IDLffXMLSAX::]StartElement, *URI*, *Local*, *qName* [, *attName*, *attValue*]

Arguments

URI

A string containing the namespace URI with which the element is associated, if any.

Local

A string containing the element name with any prefix removed, if the element is associated with a namespace URI. If the element is not associated with a namespace URI, this variable will contain an empty string.

qName

A string containing the element name found in the XML file.

Note
If the element is associated with a namespace URI, this variable may contain an empty string.

attrName

A string array representing the names of the attributes associated with the element, if any.

attrValue

A string array representing the values of each attribute associated with the element, if any. The returned array will have the same number of elements as the array returned in the *attrName* keyword variable.

Keywords

None

Version History

5.6	Introduced

IDLffXMLSAX::StartEntity

The IDLffXMLSAX::StartEntity procedure method is called when the parser detects the start of an internal or external entity expansion.

Syntax

Obj->[IDLffXMLSAX::]StartEntity, *Name*

Arguments

Name

A string containing the name of the entity.

Keywords

None

Version History

5.6	Introduced

IDLffXMLSAX::StartPrefixmapping

The IDLffXMLSAX::StartPrefixMapping procedure method is called when the parser detects the beginning of a namespace declaration.

Syntax

Obj->[IDLffXMLSAX::]StartPrefixmapping, *Prefix*, *URI*

Arguments

Prefix

A string containing the prefix, which is being mapped. If the variable specified by *Prefix* contains an empty string, the mapping is for the default element namespace.

URI

A string containing the URI of the prefix namespace.

Keywords

None

Version History

5.6	Introduced

IDLffXMLSAX::StopParsing

Call the IDLffXMLSAX::StopParsing procedure method during a parse operation to halt the operation and cause the ParseFile method to return. This may be useful when parsing large XML files and the desired information is known to have been returned.

Syntax

Obj->[IDLffXMLSAX::]StopParsing

Arguments

None

Keywords

None

Version History

5.6	Introduced

IDLffXMLSAX::UnparsedEntityDecl

The IDLffXMLSAX::UnparsedEntityDecl procedure method is called when the parser detects an `<!ENTITY ...>` declaration that includes the NDATA keyword, indicating that the entity is not meant to be parsed. The value of the NDATA keyword generally specifies the name of a *notation*, which in turn specifies the type of data.

Syntax

Obj->[IDLffXMLSAX::]UnparsedEntityDecl, *Name*, *PublicID*, *SystemID*, *Notation*

Arguments

Name

A string containing the name of the unparsed entity.

PublicID

A string containing the Public ID of the notation specified by the entity's NDATA keyword, or an empty string if no Public ID was declared.

SystemID

A string containing the System ID of the notation specified by the entity's NDATA keyword. This value is normally an absolute URI.

Notation

A string containing the name of the notation specified by the entity's NDATA keyword.

Keywords

None

Version History

5.6	Introduced

IDLffXMLSAX::Warning

The IDLffXMLSAX::Warning procedure method is called when the parser detects a problem during processing. This method prints an IDL error string to the IDL output log and allows the parser to continue processing.

Note —————————————————————————————

This method will cause error messages to be printed to the IDL output log. If you would like your application to hide error messages from the user (or display them in some other fashion), override this method in your subclass of the IDLffXMLSAX object class. If you do override this method, the error message will not be printed to the output log unless you explicitly call the superclass method.

Syntax

Obj->[IDLffXMLSAX::]Warning, *SystemID*, *LineNumber*, *ColumnNumber*, *Message*

Arguments

SystemID

A string containing the URI of the text that generated the error.

LineNumber

A longword integer representing the line number that contains the error.

ColumnNumber

A longword integer representing the column number that contains the error.

Message

A string containing the error message.

Keywords

None

5.6	Introduced

Chapter 31
iTools Object Classes

This chapter describes IDL's built-in iTool object classes.

IDLitCommand

The IDLitCommand class provides a dynamic data dictionary storage system. Its methods and properties allow the iTool developer to store information about the execution of an iTool operation on a single target object. It provides a tag-based mechanism for storing and retrieving this information, which allows the iTool developer to easily implement undo and redo functionality for an operation.

This class is written in the IDL language. Its source code can be found in the file `idlitcommand__define.pro` in the `lib/itools/framework` subdirectory of the IDL distribution.

Superclasses

IDLitComponent

Note ───

See the "iTools Object Model Diagram" (Chapter 2, *iTool Developer's Guide*) for a visual representation of the iTools object model hierarchy.

───

Creation

See "IDLitCommand::Init" on page 3674.

Properties

Objects of this class have the following properties. See "IDLitCommand Properties" on page 3666 for details on individual properties.

- SKIP_REDO
- SKIP_UNDO
- TARGET_IDENTIFIER
- OPERATION_IDENTIFIER

In addition, objects of this class inherit the properties of the superclass of this class.

Methods

This class has the following methods:

- IDLitCommand::AddItem

- IDLitCommand::Cleanup
- IDLitCommand::GetItem
- IDLitCommand::GetProperty
- IDLitCommand::GetSize
- IDLitCommand::Init
- IDLitCommand::SetProperty

In addition, this class inherits the methods of its superclass.

Examples

See "Creating a New Generalized Operation" (Chapter 7, *iTool Developer's Guide*) for examples using this class and its methods.

Version History

6.0	Introduced
6.2	Added SKIP_REDO, SKIP_UNDO properties

IDLitCommand Properties

IDLitCommand objects have the following properties in addition to properties inherited from any superclasses. Properties with the word "Yes" in the "Get" column of the property table can be retrieved via IDLitCommand::GetProperty. Properties with the word "Yes" in the "Init" column of the property table can be set via IDLitCommand::Init. Properties with the word "Yes" in the "Set" column in the property table can be set via IDLitCommand::SetProperty.

Note ───
For a discussion of the property description tables shown below, see "About Object Property Descriptions" on page 3135.
───

Objects of this class have the following properties.

- SKIP_REDO
- SKIP_UNDO
- TARGET_IDENTIFIER
- OPERATION_IDENTIFIER

In addition, objects of this class inherit:

- IDLitComponent

SKIP_REDO

A Boolean value that determines whether the command object will be skipped when performing a Redo operation on the command set that contains this command. If this property is set to True (1), the command object will be skipped. The default is False (0), which includes this command during the Redo operation.

The SKIP_REDO property is useful when you have a command that needs to be Undone, but not Redone.

Property Type	Boolean		
Name String	*not displayed*		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** No

SKIP_UNDO

A Boolean value that determines whether the command object will be skipped when performing an Undo operation on the command set that contains this command. If this property is set to True (1), the command object will be skipped. The default is False (0), which includes this command during the Undo operation.

The SKIP_UNDO property is useful when you have a command that needs to be Redone, but not Undone.

Property Type	Boolean		
Name String	*not displayed*		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** No

TARGET_IDENTIFIER

The iTool identifier of the *target* object for this command. This is the item on which the operation associated with the command will execute.

Property Type	String		
Name String	*not displayed*		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** No

OPERATION_IDENTIFIER

The iTool identifier for the *operation* associated with this command. When an undo-redo operation takes place, the command object is passed to this operation.

Property Type	String		
Name String	*not displayed*		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** No

IDLitCommand::AddItem

The IDLitCommand::AddItem function method adds the specified data item to the data dictionary associated with this object.

Note ──

If a data item with the specified identifying string is already in the data dictionary, the new value is not added unless the OVERWRITE keyword is set, in which case the old value is discarded.

───

Syntax

Result = Obj->[IDLitCommand::]AddItem(*StrItem, Item*[, /OVERWRITE])

Return Value

Returns 1 if the item was successfully added to the data dictionary, or 0 if the new value was not added.

Arguments

StrItem

A scalar string used to identify the data specified by the *Item* argument in the data dictionary. This string is treated in a case-insensitive manner.

Item

A data item of any IDL data type.

Keywords

OVERWRITE

Normally, if an item already exists in the data dictionary of an IDLitCommand object, it is not overwritten. If this keyword is set, the original value will be overwritten.

Note ————————————————————————————

If the item being replaced uses dynamic memory (that is, if it is a pointer or object reference), the memory must be released by calling PTR_FREE or OBJ_DESTROY before overwriting the value.

Version History

6.0	Introduced

IDLitCommand::Cleanup

The IDLitCommand::Cleanup procedure method performs all cleanup on the object.

Note —————————————————————————————

Cleanup methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation and destruction. This means that in most cases, you cannot call the Cleanup method directly. There is one exception to this rule: if you write your own subclass of this class, you can call the Cleanup method from within the Init or Cleanup method of the subclass.

Syntax

OBJ_DESTROY, *Obj*

or

Obj->[IDLitCommand::]Cleanup()   *(In a lifecycle method only.)*

Arguments

None

Keywords

None

Version History

6.0	Introduced

IDLitCommand::GetItem

The IDLitCommand::GetItem function method retrieves the specified item from the data dictionary associated with this object.

Syntax

Result = Obj->[IDLitCommand::]GetItem(*StrItem, Item*)

Return Value

Returns 1 if the *Item* is retrieved successfully, or 0 if *Item* is not found in the data dictionary.

Arguments

StrItem

A scalar string used to identify the data to be retrieved from the data dictionary. This string is treated in a case-insensitive manner.

Item

A named IDL variable that will contain the IDLitData object retrieved from the data dictionary.

Keywords

None

Version History

6.0	Introduced

IDLitCommand::GetProperty

The IDLitCommand::GetProperty procedure method retrieves the value of a property or group of properties of a command object.

Syntax

Obj->[IDLitCommand::]GetProperty[, *PROPERTY=variable*]

Arguments

None

Keywords

Any property listed under "IDLitCommand Properties" on page 3666 that contains the word "Yes" in the "Get" column of the properties table can be retrieved using this method. To retrieve the value of a property, specify the property name as a keyword set equal to a named variable that will contain the value of the property.

Any keyword not recognized is passed to this object's super-class.

Version History

6.0	Introduced

IDLitCommand::GetSize

The IDLitCommand::GetSize function method returns an approximate value for the amount of memory being used by the items in the data dictionary associated with this object.

Syntax

Result = Obj->[IDLitCommand::]GetSize([, /KILOBYTES])

Return Value

Returns the number of bytes of memory used by the data dictionary associated with this object. The returned value is an approximation.

Arguments

None

Keywords

KILOBYTES

Set this keyword to return the number of kilobytes of memory being used by the data dictionary. By default, this function returns the number of bytes of memory being used.

Version History

6.0	Introduced

IDLitCommand::Init

The IDLitCommand::Init function method initializes the object and allows specification of items associated with it.

Note ───

Init methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation. This means that in most cases, you cannot call the Init method directly. There is one exception to this rule: if you write your own subclass of this class, you can call the Init method from within the Init method of the subclass.

───

Syntax

Obj = OBJ_NEW('IDLitCommand' [, *PROPERTY=value*])

or

Result = Obj->[IDLitCommand::]Init([, *PROPERTY=value*])   *(In a lifecycle method only.*)

Return Value

When this method is called indirectly, as part of the call to the OBJ_NEW function, the return value is an object reference to the newly-created object.

When called directly within a subclass Init method, the return value is 1 if initialization was successful, or zero otherwise.

Arguments

None

Keywords

Any property listed under "IDLitCommand Properties" on page 3666 that contains the word "Yes" in the "Init" column of the properties table can be initialized during object creation using this method. To initialize the value of a property, specify the property name as a keyword set equal to the appropriate property value.

All other keywords are passed to the superclass of this object (IDLitComponent).

Version History

6.0	Introduced

IDLitCommand::SetProperty

The IDLitCommand::SetProperty procedure method sets the value of a property or group of properties for the command object.

Syntax

Obj->[IDLitCommand::]SetProperty[, *PROPERTY=value*]

Arguments

None

Keywords

Any property listed under "IDLitCommand Properties" on page 3666 that contains the word "Yes" in the "Set" column of the properties table can be set using this method. To set the value of a property, specify the property name as a keyword set equal to the appropriate property value.

Version History

6.0	Introduced

IDLitCommandSet

The IDLitCommandSet class stores a collection of IDLitCommand objects, allowing a group of commands to be managed as a single item. Command sets are useful as containers for IDLitCommand objects generated by the application of an iTool operation to multiple target items; the generated command set objects are used to provide undo/redo functionality to the iTool system.

This class is written in the IDL language. Its source code can be found in the file idlitcommandset__define.pro in the lib/itools/framework subdirectory of the IDL distribution.

Superclasses

IDL_Container

IDLitCommand

Note —————————————————————————————
See the "iTools Object Model Diagram" (Chapter 2, *iTool Developer's Guide*) for a visual representation of the iTools object model hierarchy.

Creation

See "IDLitCommandSet::Init" on page 3682.

Properties

Objects of this class have no properties of their own, but do have properties inherited from any superclasses.

Methods

This class has the following methods:

- IDLitCommandSet::Cleanup
- IDLitCommandSet::GetSize
- IDLitCommandSet::Init

In addition, this class inherits the methods of its superclasses.

Examples

See "Creating a New Generalized Operation" (Chapter 7, *iTool Developer's Guide*) for examples using this class and its methods.

Version History

6.0	Introduced

IDLitCommandSet Properties

Objects of this class have no properties of their own, but do have properties inherited from any superclasses.

Objects in this class inherit:

- IDL_Container
- IDLitCommand

IDLitCommandSet::Cleanup

The IDLitCommandSet::Cleanup procedure method performs all cleanup on the object.

Note

Cleanup methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation and destruction. This means that in most cases, you cannot call the Cleanup method directly. There is one exception to this rule: if you write your own subclass of this class, you can call the Cleanup method from within the Init or Cleanup method of the subclass.

Syntax

OBJ_DESTROY, Obj

or

Obj->[IDLitCommandSet::]Cleanup()   *(In a lifecycle method only.)*

Arguments

None

Keywords

None

Version History

6.0	Introduced

IDLitCommandSet::GetSize

The IDLitCommandSet::GetSize function method returns an approximate value for the amount of memory being used by the items contained by this command set. When called, the method will call the GetSize method on all of the command objects that it contains and generate a sum of the values.

Syntax

Result = Obj->[IDLitCommand::]GetSize([/KILOBYTES])

Return Value

Returns the number of bytes of memory used by the data dictionary associated with this object. The returned value is an approximation.

Arguments

None

Keywords

KILOBYTES

Set this keyword to return the number of kilobytes of memory being used. By default, this function returns the number of bytes of memory being used.

Version History

6.0	Introduced

IDLitCommandSet::Init

The IDLitCommandSet::Init function method initializes the object.

Note

Init methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation. This means that in most cases, you cannot call the Init method directly. There is one exception to this rule: if you write your own subclass of this class, you can call the Init method from within the Init method of the subclass.

Syntax

Obj = OBJ_NEW('IDLitCommandSet')

or

Result = Obj->[IDLitCommandSet::]Init()   *(In a lifecycle method only.)*

Return Value

When this method is called indirectly, as part of the call to the OBJ_NEW function, the return value is an object reference to the newly-created object.

When called directly within a subclass Init method, the return value is 1 if initialization was successful, or zero otherwise.

Arguments

None

Keywords

All keywords are passed to the superclass of this object (IDLitCommand).

Version History

6.0	Introduced

IDLitComponent

The IDLitComponent class is the base component from which all iTool components should subclass. The IDLitComponent class provides support for property descriptors and property registration, and defines properties that are common to all iTool component objects.

Note ──

This class is now a superclass of all the atomic graphical (IDLgr*) object classes.

──

Superclasses

None

Note ──

See the "iTools Object Model Diagram" (Chapter 2, *iTool Developer's Guide*) for a visual representation of the iTools object model hierarchy.

──

Creation

See "IDLitComponent::Init" on page 3698.

Properties

Objects of this class have the following properties. See "IDLitComponent Properties" on page 3685 for details on individual properties.

- COMPONENT_VERSION
- DESCRIPTION
- HELP
- ICON
- IDENTIFIER
- NAME
- PRIVATE
- UVALUE

Methods

This class has the following methods:

- IDLitComponent::Cleanup
- IDLitComponent::EditUserDefProperty
- IDLitComponent::GetFullIdentifier
- IDLitComponent::GetProperty
- IDLitComponent::GetPropertyAttribute
- IDLitComponent::GetPropertyByIdentifier
- IDLitComponent::Init
- IDLitComponent::NotifyBridge
- IDLitComponent::QueryProperty
- IDLitComponent::RegisterProperty
- IDLitComponent::Restore
- IDLitComponent::SetProperty
- IDLitComponent::SetPropertyAttribute
- IDLitComponent::SetPropertyByIdentifier
- IDLitComponent::UpdateComponentVersion

Version History

6.0	Introduced
6.1	Added COMPONENT_VERSION property
6.3	Added IDLitComponent::NotifyBridge

IDLitComponent Properties

IDLitComponent objects have the following properties. Properties with the word "Yes" in the "Get" column of the property table can be retrieved via IDLitComponent::GetProperty. Properties with the word "Yes" in the "Init" column of the property table can be set via IDLitComponent::Init. Properties with the word "Yes" in the "Set" column in the property table can be set via IDLitComponent::SetProperty.

Note
For a discussion of the property description tables shown below, see "About Object Property Descriptions" on page 3135.

Objects of this class have the following properties.

- COMPONENT_VERSION
- DESCRIPTION
- HELP
- ICON
- IDENTIFIER
- NAME
- PRIVATE
- UVALUE

COMPONENT_VERSION

A integer value representing the version of the component object. This value is set automatically and is intended to aid in determining how a component object should be restored by the Restore method.

Property Type	Integer		
Name String	*not displayed*		
Get: Yes	**Set:** No	**Init:** No	**Registered:** No

DESCRIPTION

A string giving the full name or description of this object.

Property Type	STRING		
Name String	Description		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** Yes

HELP

A scalar string representing the help topic associated with this object. If this property is not set, or is set to a null string, then the object class name will be used as the default help topic.

Property Type	String		
Name String	*not displayed*		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** No

ICON

A string specifying the name of an icon to be associated with this object. Typically, this property is the name of a bitmap file used when displaying this object in a tree view. See "System Resources" (Chapter 2, *iTool Developer's Guide*) for details.

Property Type	String		
Name String	*not displayed*		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** No

IDENTIFIER

A string containing the *object identifier* for this object. If this property is not specified, then the NAME property is used as the identifier. See "iTool Object

Identifiers" (Chapter 2, *iTool Developer's Guide*) for details about how identifiers are named.

Property Type	String		
Name String	*not displayed*		
Get: Yes	Set: Yes	Init: Yes	Registered: No

NAME

A string giving the human-readable name of this object.

Property Type	STRING		
Name String	Name		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

PRIVATE

A boolean value that indicates whether the object should be marked as private. Objects marked private (and all of their children) are not displayed in the graphical iTool browser windows.

Property Type	Boolean		
Name String	*not displayed*		
Get: Yes	Set: Yes	Init: Yes	Registered: No

UVALUE

A value of any type containing any information you wish.

Note

Object references or pointers contained in the UVALUE property are *not* automatically cleaned up when the IDLitComponent object is destroyed.

Property Type	User Defined		
Name String	*not displayed*		
Get: Yes	Set: Yes	Init: Yes	Registered: No

IDLitComponent::Cleanup

The IDLitComponent::Cleanup procedure method performs all cleanup on the object, and should be called by the Cleanup method of a subclass.

Note ————————————————————————————————————

Cleanup methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation and destruction. This means that in most cases, you cannot call the Cleanup method directly. There is one exception to this rule: if you write your own subclass of this class, you can call the Cleanup method from within the Init or Cleanup method of the subclass.

——

Syntax

OBJ_DESTROY, *Obj*

or

Obj->[IDLitComponent::]Cleanup   *(In a lifecycle method only.)*

Arguments

None

Keywords

None

Version History

6.0	Introduced

IDLitComponent::EditUserDefProperty

The IDLitComponent::EditUserDefProperty function method defines the interface that is displayed when a user selects the "Edit" button on a user-defined property in the property sheet interface. Typically, this method will display an interactive dialog that allows the user to change the value of the property.

Note ──

An iTool object class that includes a user-defined property *must* implement this method if the property is displayed in a property sheet — that is, if the property is registered and not hidden. If an iTool object class has no user-defined properties that are displayed in a property sheet, there is no need to supply an EditUserDefProperty method.

──

See "User Defined Property Types" (Chapter 4, *iTool Developer's Guide*) for a discussion of how the property sheet interface displays user-defined properties.

Syntax

Result = Obj->[IDLitComponent::]EditUserDefProperty(*iTool*, *PropertyIdentifier*)

Return Value

Returns a 1 if the property value was changed, or a 0 if the property value was not changed.

Note ──

If the return value is 1, the property sheet interface automatically updates the displayed property value using the value of the property's USERDEF attribute. If the return value is 0, no update takes place.

──

Arguments

iTool

An object reference to the current iTool object.

PropertyIdentifier

A string containing the property identifier of the user-defined property.

Tip ——————————————————————————————

Since there can only be one EditUserDefProperty method for each class, you can use the *PropertyIdentifier* argument to determine which user-defined property is being edited.

———————————————————————————————————

Keywords

None

Example

The following is the EditUserDefProperty method of the IDLitOpConvolution operation class. Selecting and editing the Kernel property of this operation displays a dialog that allows the user to edit a convolution kernel.

```
FUNCTION IDLitopConvolution::EditUserDefProperty, oTool, $
   identifier

CASE identifier OF

   'KERNEL': RETURN, oTool->DoUIService('ConvolKernel', self)

   ELSE:

ENDCASE

RETURN, 0

END
```

This method simply checks the property identifier to determine whether it matches the string `'KERNEL'`. If it does, it returns the value returned by the DoUIService method; otherwise it returns zero. In this case, the DoUIService method actually handles the modification of the property value. See "User Defined Property Types" (Chapter 4, *iTool Developer's Guide*) for additional discussion.

Version History

6.0	Introduced

IDLitComponent::GetFullIdentifier

The IDLitComponent::GetFullIdentifier function method navigates the iTool object container hierarchy of the object on which it is called and retrieves the fully-qualified object identifier. The full identifier is constructed by recursively retrieving the parent object reference and prepending this to the identifier, separated by / characters. The parent must inherit from the IDLitContainer class. The full identifier string has the following form:

```
/.../GRANDPARENTID/PARENTID/OBJID
```

If the *Objref* argument is specified, the function returns the object identifier path relative to the specified object.

See "iTool Object Identifiers" (Chapter 2, *iTool Developer's Guide*) for additional discussion of object identifiers.

Syntax

Result = Obj->[IDLitComponent::]GetFullIdentifier([*Objref*])

Return Value

Returns a string containing the object identifier.

Note
The full object identifier of a top-level *container* object is "/" even if the top-level container's IDENTIFIER property is set to some other value. If the top-level object is *not* a container object, the full object identifier is a null string (" ") even if the top-level object's IDENTIFIER property is set to some other value.

Arguments

Objref

An object reference to an iTool component object. If this argument is specified, the returned value is a relative object identifier, beginning with *Objref*. If this argument is not specified, the returned value is a fully-qualified object identifier.

Keywords

None

Version History

6.0	Introduced

IDLitComponent::GetProperty

The IDLitComponent::GetProperty procedure method retrieves the value of an IDLitComponent property or properties.

Syntax

Obj->[IDLitComponent::]GetProperty[, *PROPERTY=variable*] [, /NO_COPY]

Arguments

None

Keywords

Any property listed under "IDLitComponent Properties" on page 3685 that contains that contains the word "Yes" in the "Get" column of the properties table can be retrieved using this method. To retrieve the value of a property, specify the property name as a keyword set equal to a named variable that will contain the value of the property.

NO_COPY

Note ───

This keyword only has an effect when getting the UVALUE property.

───

Usually, when getting the UVALUE property, IDL makes a copy of the data being transferred. Although this technique is fine for small data, it can have a significant memory cost when the data being copied is large.

If the NO_COPY keyword is set, IDL handles the GetProperty operation differently. Rather than copy the source data, it takes the data away from the source and attaches it directly to the destination. This feature can be used to obtain the information from the UVALUE property without the memory copying that would otherwise occur. However, it has the side effect of causing the source variable to become undefined; in a call to the GetProperty method, this means that the UVALUE property of the IDLitComponent object becomes undefined.

Version History

6.0	Introduced
6.4	Added NO_COPY keyword

IDLitComponent::GetPropertyAttribute

The IDLitComponent::GetPropertyAttribute procedure method retrieves property attribute values for a registered property.

Syntax

Obj->[IDLitComponent::]GetPropertyAttribute, *PropertyIdentifier*
  [, TYPE=*variable*]

Arguments

PropertyIdentifier

A string containing the property identifier of the registered property.

Keywords

Any keywords to the RegisterProperty method followed by the word "Get" can be retrieved. In addition, the following keyword is available:

TYPE

Set this argument to a named variable that returns the TYPE code as an integer, as specified under the *Type* argument to IDLitComponent::RegisterProperty.

Version History

6.0	Introduced

IDLitComponent::GetPropertyByIdentifier

The IDLitComponent::GetPropertyByIdentifier function method retrieves the value of an IDLitComponent property.

Tip ───

The IDLitComponent::GetPropertyByIdentifier method is similar to the IDLitComponent::GetProperty method, but is useful for cases where the *property identifier* is defined at runtime.

───

Syntax

Result = Obj->[IDLitComponent::]GetPropertyByIdentifier(*PropertyIdentifier*, *Value*)

Return Value

Returns 1 if the property value is defined, or 0 if the property value is undefined.

Arguments

PropertyIdentifier

A string containing the property identifier of the property. *PropertyIdentifier* does not need to be a registered property, but must be a valid keyword name for the GetProperty method of the component.

Value

A named variable that will contain the value of the property. If the property value is currently undefined, then the contents of the variable specified by *Value* will not be modified.

Keywords

None

Version History

6.0	Introduced

IDLitComponent::Init

The IDLitComponent::Init function method initializes the IDLitComponent object, and should be called by the Init method of a subclass.

Note

Init methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation. This means that in most cases, you cannot call the Init method directly. There is one exception to this rule: if you write your own subclass of this class, you can call the Init method from within the Init method of the subclass.

Syntax

Obj = OBJ_NEW('IDLitComponent'[, *PROPERTY=value*])

or

Result = Obj->[IDLitComponent::]Init([, *PROPERTY=value*])   *(In a lifecycle method only.)*

Return Value

When this method is called indirectly, as part of the call to the OBJ_NEW function, the return value is an object reference to the newly-created object.

When called directly within a subclass Init method, the return value is 1 if initialization was successful, or zero otherwise.

Arguments

None

Keywords

Any property listed under "IDLitComponent Properties" on page 3685 that contains the word "Yes" in the "Init" column of the properties table can be initialized during object creation using this method. To initialize the value of a property, specify the property name as a keyword set equal to the appropriate property value.

Version History

6.0	Introduced

IDLitComponent::NotifyBridge

The IDLitComponent::NotifyBridge procedure method is used to broadcast a notification message to the Export Bridge object that is wrapping the IDLitComponent object. If this method is called on an object that is not connected to the Export Bridge, the method quietly returns.

For more information on the Export Bridge, see "Exporting from IDL" (*IDL Connectivity Bridges*).

Syntax

Obj->IDLitComponent::NotifyBridge, *IdMessage*, *Value*

Arguments

IdMessage

A scalar string that will uniquely identify the message being sent.

Value

A scalar string that is associated with the message being sent.

Keywords

None

Version History

6.3	Introduced

IDLitComponent::QueryProperty

The IDLitComponent::QueryProperty function method checks whether a property identifier is registered, or retrieves a list of all registered properties.

Syntax

Result = Obj->[IDLitComponent::]QueryProperty([*PropertyIdentifier*])

Return Value

Returns a 1 if *PropertyIdentifier* is a scalar string that corresponds to a valid registered property, or a 0 otherwise. If *PropertyIdentifier* is an array, the result is an array of 1s and 0s.

If *PropertyIdentifier* is not specified, *Result* is a string array containing the identifiers of all registered properties.

Arguments

PropertyIdentifier

A scalar string or string array containing property identifiers.

Keywords

None

Version History

6.0	Introduced

IDLitComponent::RegisterProperty

The IDLitComponent::RegisterProperty procedure method registers a property as belonging to the component. Only registered properties are displayed in the graphical property sheet interface for the object.

Syntax

Obj->[IDLitComponent::]RegisterProperty, *PropertyIdentifier*[, *Type*]
   [, /BOOLEAN] [, /COLOR] [, DESCRIPTION=*string*]
   [, ENUMLIST=*stringvector*] [, /FLOAT] [, /HIDE] [, /INTEGER]
   [, /LINESTYLE] [, NAME=*string*] [, /SENSITIVE] [, /STRING] [, /SYMBOL]
   [, /THICKNESS] [, /UNDEFINED] [, USERDEF=*string*]
   [, VALID_RANGE=*vector*]

Arguments

PropertyIdentifier

A scalar string containing the property identifier. GetProperty and SetProperty methods accept this string as a keyword.

Type

An optional integer argument representing the property type. Values recognized by Property Sheets are:

- 0 = USERDEF
- 1 = BOOLEAN
- 2 = INTEGER
- 3 = FLOAT
- 4 = STRING
- 5 = COLOR
- 6 = LINESTYLE
- 7 = SYMBOL
- 8 = THICKNESS
- 9 = ENUMLIST

If *Type* is not supplied, then one of the type keywords must be set instead.

Keywords

Some of the following keywords correspond to *attributes* of the property being registered. Keywords followed by the word "Get" indicate attributes that can be retrieved by the IDLitComponent::GetPropertyAttribute method. Keywords followed by the word "Set" indicate attributes that can be set by the IDLitComponent::SetPropertyAttribute method.

Some of the following keywords correspond to iTool property data types, which can also be specified via the *Type* argument. Note that if both the *Type* argument and one of the corresponding keywords are set, the keyword value will be honored.

BOOLEAN

Set this keyword to indicate that the property type is BOOLEAN. Properties of type BOOLEAN must accept an integer value of either 0 ("False") or 1 ("True"). Setting this keyword is equivalent to setting the TYPE argument equal to 1.

COLOR

Set this keyword to indicate that the property type is COLOR. Properties of type COLOR must accept a three-element integer array containing an RGB triplet. Setting this keyword is equivalent to setting the TYPE argument equal to 5.

DESCRIPTION

(Get, Set)

Set this keyword to a string containing the description of this property.

Note

Do not confuse the DESCRIPTION *property attribute* with the DESCRIPTION *property*. The DESCRIPTION property attribute is *not* displayed in the graphical property sheet interface.

ENUMLIST

(Get, Set)

Set this keyword equal to an array of strings to be displayed in the dropdown menu displayed by a property of type ENUMLIST. The default is a scalar null string. Properties of type ENUMLIST report their value as an integer between 0 and *n*-1, where *n* is the number of elements in the enumerated list. Setting this keyword implies that the TYPE argument is equal to 9.

FLOAT

Set this keyword to indicate that the property type is FLOAT. Properties of type FLOAT must accept a scalar double-precision floating-point value. Setting this keyword is equivalent to setting the TYPE argument equal to 3.

HIDE

(Get, Set)

Set this keyword to hide the given property when displaying the graphical property sheet interface. By default, all registered properties are displayed.

INTEGER

Set this keyword to indicate that the property type is INTEGER. Properties of type INTEGER must accept a scalar integer value. Setting this keyword is equivalent to setting the TYPE argument equal to 2.

LINESTYLE

Set this keyword to indicate that the property type is LINESTYLE. Properties of type LINESTYLE must accept an integer specifying a pre-defined linestyle, as described under the LINESTYLE property of the IDLgrPolyline class. Setting this keyword is equivalent to setting the TYPE argument equal to 6.

NAME

(Get, Set)

Set this keyword to a string giving the human-readable name for the property. The NAME string will be used when displaying the graphical property sheet interface. If NAME is not set, the value of the *PropertyIdentifier* argument is used.

Note ───
Do not confuse the NAME *property attribute* with the NAME *property.*
───

SENSITIVE

(Get, Set)

Set this keyword to zero to make the given property insensitive in the graphical property sheet interface. By default, registered properties are sensitive.

STRING

Set this keyword to indicate that the property type is STRING. Properties of type STRING must accept a scalar string of any length. Setting this keyword is equivalent to setting the TYPE argument equal to 4.

SYMBOL

Set this keyword to indicate that the property type is SYMBOL. Properties of type SYMBOL must accept an integer specifying one of the pre-defined symbol types described under IDLgrSymbol::Init. Setting this keyword is equivalent to setting the TYPE argument equal to 7.

THICKNESS

Set this keyword to indicate that the property type is THICKNESS. Properties of type THICKNESS must accept an integer between 1 and 10 specifying the line thickness in points. Setting this keyword is equivalent to setting the TYPE argument equal to 8.

UNDEFINED

(Get, Set)

Set this keyword to indicate that the property should appear as a blank cell when displayed in the graphical property sheet interface. This is useful in situations where properties of multiple objects are displayed in the property sheet (either because multiple objects are selected, or because the objects have been grouped).

Note —————————————————————————————————————

It is the iTool developer's responsibility to set this property attribute back to zero. Use the SET_DEFINED field of the WIDGET_PROPERTYSHEET event structure to determine when to set the UNDEFINED attribute back to zero.

———

USERDEF

(Get, Set)

Set this keyword to a string that represents a user-defined property. Properties of type USERDEF can accept and return variables of any type. When the actual property value changes, it is assumed that the string value of the USERDEF attribute will also be modified to reflect the new property value. Setting this keyword implies that the TYPE argument is equal to 0.

VALID_RANGE

(Get, Set)

For INTEGER or FLOAT types, set this keyword to a two- or three-element vector specifying the [*minimum*, *maximum*] or [*minimum*, *maximum*, *increment*] for valid values of the property.

What is displayed for the property sheet number cell depends upon the following:

- If this attribute is not specified — the property sheet displays an editable text field where masked editing is enforced, and the range is that of the data type. The only accepted keystrokes are the ten digits and the plus and minus signs. If the float type is specified, the decimal, and "d" and "e" (scientific exponent notation tokens) are also allowed.

- If a range is specified without an increment — the property sheet displays a spinner control that allows the user to click, or click and hold the up or down buttons to change the value. For an integer type, the increment is one. For a float type, the increment equals approximately 1/100 of the range. For example, a range of 100 results in an increment of 1. A value is snapped to the nearest allowable value when a value outside the range, or not equal to an incremental value, is entered. The editable text field (featuring masked editing) also allows the user to enter a numerical value.

- If a range and increment are specified — the property sheet displays a slider with a marker that can be repositioned to change the value. A value is snapped to the nearest allowable value when a value outside the range, or not equal to an incremental value, is entered. The increment value must be positive and will be converted to an integer for INTEGER types. Specifying an increment of 0 (zero) is the same as specifying a range without an increment. The editable text field (featuring masked editing) also allows the user to enter a numerical value.

The following code creates properties containing various number cells:

```
; Number cell with no explicit range.
self->RegisterProperty, 'integer1', /INTEGER , $
   NAME = 'Integer1', description = 'Integer'

; Number cell with spinner control and explicit range.
self->RegisterProperty, 'integer2', /INTEGER , $
   NAME = 'Integer2', VALID_RANGE = [ -100, 100 ]

; Number cell with slider control, explicit range, and
; increment.
self->RegisterProperty, 'float1', /FLOAT, $
   NAME = 'Float1', VALID_RANGE = [ -20.0D, 5.0D, 0.5D ]
```

Version History

6.0	Introduced
6.1	Added spinner control functionality to VALID_RANGE keyword

IDLitComponent::Restore

The IDLitComponent::Restore procedure method performs any transitional work required after an object of this class has been restored from a SAVE file, to ensure that its state is appropriate for the current version.

Note ───

This method is designed to be implemented by a subclass of IDLitComponent, to perform any transition work necessary when a component object is restored.

───

Syntax

Obj->[IDLitComponent::]Restore

Arguments

None

Keywords

None

Version History

6.1	Introduced

See Also

IDLitComponent::UpdateComponentVersion, IDL_Savefile, SAVE, RESTORE

IDLitComponent::SetProperty

The IDLitComponent::SetProperty procedure method sets the value of an
IDLitComponent property or properties.

Syntax

Obj->[IDLitComponent::]SetProperty[, *PROPERTY=value*] [, /NO_COPY]

Arguments

None

Keywords

Any property listed under "IDLitComponent Properties" on page 3685 that contains
the word "Yes" in the "Set" column of the properties table can be set using this
method. To set the value of a property, specify the property name as a keyword set
equal to the appropriate property value.

NO_COPY

Note

This keyword only has an effect when setting the UVALUE property.

Usually, when setting the UVALUE property, IDL makes a copy of the data being
transferred. Although this technique is fine for small data, it can have a significant
memory cost when the data being copied is large.

If the NO_COPY keyword is set, IDL handles the SetProperty operation differently.
Rather than copy the source data, it takes the data away from the source and attaches
it directly to the destination. This feature can be used to obtain the information from
the UVALUE property without the memory copying that would otherwise occur.
However, it has the side effect of causing the source variable to become undefined; in
a call to the SetProperty method, this means that the variable passed in as UVALUE
becomes undefined.

Version History

6.0	Introduced
6.4	Added NO_COPY keyword.

IDLitComponent::SetPropertyAttribute

The IDLitComponent::SetPropertyAttribute procedure method sets one or more property attributes for a registered property.

Syntax

Obj->[IDLitComponent::]SetPropertyAttribute , *PropertyIdentifier*

Arguments

PropertyIdentifier

A string containing the property identifier of the registered property.

Keywords

Any keywords to the IDLitComponent::RegisterProperty method followed by the word "Set" can be set.

Version History

6.0	Introduced

IDLitComponent::SetPropertyByIdentifier

The IDLitComponent::SetPropertyByIdentifier procedure method sets the value of an IDLitComponent property.

Tip ——

The IDLitComponent::SetPropertyByIdentifier method is similar to the IDLitComponent::SetProperty method, but is useful for cases where the *PropertyIdentifier* is defined at runtime, and avoids the overhead of creating an _EXTRA structure to pass to SetProperty.

——

Syntax

Obj->[IDLitComponent::]SetPropertyByIdentifier, *PropertyIdentifier*, *Value*

Arguments

PropertyIdentifier

A string containing the property identifier of the property. *PropertyIdentifier* does not need to be a registered property, but must be a valid keyword name for the SetProperty method of the component.

Value

The new value for the property.

Keywords

None

Version History

6.0	Introduced

IDLitComponent::UpdateComponentVersion

The IDLitComponent::UpdateComponentVersion procedure method updates the value of the COMPONENT_VERSION property for the specified object to match the version associated with the current release of IDL. This method is intended for use after calling the Restore method on a component object, so that the object can be identified as having been restored.

Syntax

Obj->[IDLitComponent::]UpdateComponentVersion

Arguments

None

Keywords

None

Version History

6.1	Introduced

See Also

IDLitComponent::Restore

IDLitContainer

The IDLitContainer class is a specialization of the IDL_Container class designed to manage collections of IDLitComponent objects and provide methods to work with the iTools *identifier* system. IDLitContainer object methods allow you to add, retrieve, and remove values from a IDLitContainer-based hierarchy using either object references or iTool identifiers.

This class is written in the IDL language. Its source code can be found in the file `idlitcontainer__define.pro` in the `lib/itools/framework` subdirectory of the IDL distribution.

Superclasses

IDL_Container

IDLitComponent

Note ───

See the "iTools Object Model Diagram" (Chapter 2, *iTool Developer's Guide*) for a visual representation of the iTools object model hierarchy.

───

Creation

See "IDLitContainer::Init" on page 3725.

Properties

Objects of this class have no properties of their own, but do have properties inherited from any superclasses.

Methods

This class has the following methods:

- IDLitContainer::Add
- IDLitContainer::AddByIdentifier
- IDLitContainer::Cleanup
- IDLitContainer::FindIdentifiers
- IDLitContainer::Get

- IDLitContainer::GetByIdentifier
- IDLitContainer::Init
- IDLitContainer::Remove
- IDLitContainer::RemoveByIdentifier

In addition, this class inherits the methods of its superclasses.

Version History

6.0	Introduced

IDLitContainer Properties

Objects of this class have no properties of their own, but do have properties inherited from any superclasses.

Objects in this class inherit:

- IDL_Container
- IDLitComponent

IDLitContainer::Add

The IDLitContainer::Add procedure method adds items to the container object.

Syntax

Obj->[IDLitContainer::]Add, *Components*[, /NO_NOTIFY]

Arguments

Components

An object reference (or array of object references) to the IDLitComponent object or objects to be added to the container. When this method is called, the IDENTIFIER properties of objects specified by *Components* are validated, verifying that no items in the container have the same value. If an object with the same identifier already exists in the container, a unique identifier is created by appending a number to the original value.

Keywords

NO_NOTIFY

Normally, when an item is added to a container object that inherits from both the IDLitContainer class and the IDLitIMessaging class, an ADDITEMS notification message is broadcast to all iTool components registered as monitoring this container. If this keyword is set, no message is sent.

Version History

6.0	Introduced

IDLitContainer::AddByIdentifier

The IDLitContainer::AddByIdentifier procedure method adds an object to the container hierarchy in the position specified by the *Identifier* argument.

Syntax

Obj->[IDLitContainer::]AddByIdentifier, *Identifier*, *Item*
    [, FOLDER_CLASSNAME=*string*]

Arguments

Identifier

An object identifier specifying the location in the container hierarchy where *Item* should be added. *Identifier* can be either a fully-qualified object identifier (beginning with a "/" character) or a relative to the container on which this method is called. If *Identifier* is a null string (`' '`), Item is added to the root of the container object.

See "iTool Object Identifiers" (Chapter 2, *iTool Developer's Guide*) for a discussion of object identifier strings.

Item

An object reference to the iTool component object being added to the container.

Keywords

FOLDER_CLASSNAME

If the container hierarchy specified by *Identifier* contains subfolders that do not exist, the necessary subfolders are created automatically. By default, the created subfolders are of the same class as the calling method (IDLitContainer or one of its subclasses). To create subfolders of a different class, set the FOLDER_CLASSNAME keyword equal to a string specifying the name of the class to be used.

Version History

6.0	Introduced
6.2	Added FOLDER_CLASSNAME keyword

IDLitContainer::Cleanup

The IDLitContainer::Cleanup procedure method performs all cleanup on the object.

Note

Cleanup methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation and destruction. This means that in most cases, you cannot call the Cleanup method directly. There is one exception to this rule: if you write your own subclass of this class, you can call the Cleanup method from within the Init or Cleanup method of the subclass.

Syntax

OBJ_DESTROY, *Obj*

or

Obj->[IDLitContainer::]Cleanup   *(In a lifecycle method only.)*

Arguments

None

Keywords

None

Version History

6.0	Introduced

IDLitContainer::FindIdentifiers

The IDLitContainer::FindIdentifiers function method allows you to retrieve the full identifiers for items within an iTool container.

Warning ──

The FindIdentifiers method recurses through the entire object hierarchy of the specified object, which may be slow for large container hierarchies. If you find it necessary to call FindIdentifiers multiple times, it may be more efficient to use a single call with one or more wildcards ("*") to return all relevant identifiers, and then perform the necessary searches using the returned list.

──

Syntax

Result = Obj->[IDLitContainer::]FindIdentifiers([*Pattern*] [, COUNT=*variable*] [, /LEAF_NODES])

Return Value

Returns a scalar string or string array containing the full object identifiers for all items matching the *Pattern*. If no object identifiers are matched, the function returns a scalar null string.

Arguments

Pattern

A string specifying a search pattern to be used for filtering the returned object identifiers. Only object identifiers that match *Pattern* are returned. Matching is case insensitive. If *Pattern* is not supplied, identifiers for all objects within the object on which this method is called are returned. See STRMATCH for a description of the rules used when matching patterns.

Note ──

Objects for which the PRIVATE property contains a True value are not included in the *Result*. Only objects that subclass from IDLitComponent can be marked as private.

──

Keywords

COUNT

Set this keyword equal to a named variable that will contain the number of identifiers in *Result*.

LEAF_NODES

Set this keyword to return only leaf nodes. Leaf nodes are objects which are either not a container, or are an empty container.

Note

If all of the objects within a container are marked as PRIVATE, then that container is considered a leaf node. Only objects that subclass from IDLitComponent can be marked as private.

Version History

6.1	Introduced

See Also

IDLitTool::FindIdentifiers

IDLitContainer::Get

The IDLitContainer::Get function method retrieves items from the container.

Syntax

Result = Obj->[IDLitContainer::]Get([, /ALL] [, COUNT=*variable*] [, ISA=*string* or *array of strings*] [, POSITION=*index* or *array of indices*] [, /SKIP_PRIVATE])

Return Value

Returns an object reference or array of object references to the iTool components stored in the container. Unless either the ALL keyword or the POSITION keyword is specified, the first object in the container is returned. If no objects are found in the container, the return value is -1.

Arguments

None

Keywords

ALL

Set this keyword to return an array of object references to all of the objects in the container.

COUNT

Set this keyword equal to a named variable that will contain the number of objects selected by the function.

ISA

Set this keyword equal to a class name or vector of class names. This keyword is used in conjunction with the ALL keyword. The ISA keyword filters the array returned by the ALL keyword, returning only the objects that inherit from the class or classes specified by the ISA keyword.

Note
This keyword is ignored if the ALL keyword is not provided.

POSITION

Set this keyword equal to a scalar or array containing the zero-based indices of the positions of the objects to return.

SKIP_PRIVATE

Set this keyword to ignore any components for which the PRIVATE property is set to true. This keyword is ignored unless the ALL keyword is also set.

Version History

6.0	Introduced

IDLitContainer::GetByIdentifier

The IDLitContainer::GetByIdentifier function method retrieves an object from a container hierarchy using the specified identifier to locate the object.

Syntax

Result = Obj->[IDLitContainer::]GetByIdentifier(*Identifier*)

Return Value

Returns an object reference to the object that was requested from the hierarchy, or a null object reference if no object was located.

Arguments

Identifier

The object identifier of the object that should be retrieved from the container hierarchy. *Identifier* can be either a fully-qualified object identifier (beginning with a "/" character) or a relative to the container on which this method is called.

See "iTool Object Identifiers" (Chapter 2, *iTool Developer's Guide*) for a discussion of object identifier strings.

Keywords

None

Version History

6.0	Introduced

IDLitContainer::Init

The IDLitContainer::Init function method initializes the object.

Note ───

Init methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation. This means that in most cases, you cannot call the Init method directly. There is one exception to this rule: if you write your own subclass of this class, you can call the Init method from within the Init method of the subclass.

───

Syntax

Obj = OBJ_NEW('IDLitContainer')

or

Result = Obj->[IDLitContainer::]Init()   *(In a lifecycle method only.)*

Return Value

When this method is called indirectly, as part of the call to the OBJ_NEW function, the return value is an object reference to the newly-created object.

When called directly within a subclass Init method, the return value is 1 if initialization was successful, or zero otherwise.

Arguments

None

Keywords

None

Version History

6.0	Introduced

IDLitContainer::Remove

The IDLitContainer::Remove procedure method removes items from the container.

Syntax

Obj->[IDLitContainer::]Remove, *Components* [, /NO_NOTIFY]

Arguments

Components

An object reference (or array of object references) to the objects to be removed from the container.

Keywords

NO_NOTIFY

Normally, when an item is removed from a container object that inherits from both the IDLitContainer class and the IDLitIMessaging class, a REMOVEITEMS notification message is broadcast to all iTool components registered as monitoring this container. If this keyword is set, no message is sent.

Version History

6.0	Introduced

IDLitContainer::RemoveByIdentifier

The IDLitContainer::RemoveByIdentifier function method removes an object from a container hierarchy using the specified identifier to locate the object.

Syntax

Result = Obj->[IDLitContainer::]RemoveByIdentifier(*Identifier*)

Return Value

Returns an object reference to the object that was removed from the hierarchy, or a null object reference if no object was removed.

Arguments

Identifier

The object identifier of the object that should be removed from the container hierarchy. The *Identifier* argument can be either a fully-qualified object identifier (beginning with a "/" character) or a relative to the container on which this method is called.

See "iTool Object Identifiers" (Chapter 2, *iTool Developer's Guide*) for a discussion of object identifier strings.

Keywords

None

Version History

6.0	Introduced

IDLitData

The IDLitData class provides a generic data storage object that can hold data items of any IDL data type. The IDLitData class provides typing and data change notification functionality, and when coupled with the IDLitDataContainer object forms the base element for the construction of composite data types.

The IDLitData class implements the iTools *notifier interface*, which provides a mechanism by which observers of a data item can be alerted when the state of the information contained in the data object changes.

This class is written in the IDL language. Its source code can be found in the file `idlitdata__define.pro` in the `lib/itools/framework` subdirectory of the IDL distribution.

Superclasses

IDLitComponent

Note

See the "iTools Object Model Diagram" (Chapter 2, *iTool Developer's Guide*) for a visual representation of the iTools object model hierarchy.

Creation

See "IDLitData::Init" on page 3740.

Properties

Objects of this class have the following properties. See "IDLitData Properties" on page 3730 for details on individual properties.

- HIDE
- READ_ONLY
- TYPE

In addition, objects of this class inherit the properties of the superclass.

Methods

This class has the following methods:

- IDLitData::AddDataObserver
- IDLitData::Cleanup
- IDLitData::Copy
- IDLitData::GetByType
- IDLitData::GetData
- IDLitData::GetProperty
- IDLitData::GetSize
- IDLitData::Init
- IDLitData::NotifyDataChange
- IDLitData::NotifyDataComplete
- IDLitData::RemoveDataObserver
- IDLitData::SetData
- IDLitData::SetProperty

In addition, this class inherits the methods of its superclasses.

Examples

See Chapter 3, "Data Management" (*iTool Developer's Guide*) for examples using this class and its methods.

Version History

6.0	Introduced
6.2	Removed NO_COPY property as it should only be documented as a keyword

IDLitData Properties

IDLitData objects have the following properties in addition to properties inherited from any superclasses. Properties with the word "Yes" in the "Get" column of the property table can be retrieved via IDLitData::GetProperty. Properties with the word "Yes" in the "Init" column of the property table can be set via IDLitData::Init. Properties with the word "Yes" in the "Set" column in the property table can be set via IDLitData::SetProperty.

Note ──
For a discussion of the property description tables shown below, see "About Object Property Descriptions" on page 3135.
──

Objects of this class have the following properties.

- HIDE
- READ_ONLY
- TYPE

In addition, objects of this class inherit:

- IDLitComponent

HIDE

A Boolean value that controls the visibility of the data with respect to queries performed by the IDLitDataContainer methods GetData, SetData and GetIdentifiers. If the HIDE property has a True value, the data object is not found by these methods and the methods behave as if the data object did not exist.

Property Type	BOOLEAN		
Name String	HIDE		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** Yes

READ_ONLY

A Boolean value that controls the ability to modify the data with the SetData method. If the READ_ONLY property has a True value, an attempt to use SetData on the object fails. IDL prints an informational message in this case.

Property Type	BOOLEAN		
Name String	READ_ONLY		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

TYPE

A scalar string containing the type of the data object. The default value of this property is NULL (' ') and cannot be changed after the class is instantiated. Subclasses of this class set the value of this property to a value that reflects the type of data that the subclass is implementing.

Property Type	STRING		
Name String	TYPE		
Get: Yes	Set: No	Init: Yes	Registered: Yes

IDLitData::AddDataObserver

The IDLitData::AddDataObserver procedure method specifies an object (the *Observer*) that will be notified when the contents of the data object are changed.

The object specified as the *Observer* must implement three methods that form the data observer interface:

- OnDataChange
- OnDataComplete
- OnDataDelete

The OnDataChange method is called when the contents of a data object are changed, and the OnDataComplete method is called when the change messages are completed. This two-part notification process is used to allow observers of data to transact the change event and minimize the required system updates (such as graphic redrawing). The OnDataDelete method is called when the data item is deleted.

Syntax

Obj->[IDLitData::]AddDataObserver, *Observer*

Arguments

Observer

An object reference to an iTool component object that implements the data observer interface methods. When the contained data value changes, the *Observer* is notified of this change.

Keywords

None

Version History

6.0	Introduced

IDLitData::Cleanup

The IDLitData::Cleanup procedure method performs all cleanup operations on the object, and should be called by the Cleanup method of any subclass of this class. This method removes all data stored in the IDLitData object.

Note ———————————————————————————————————

Cleanup methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation and destruction. This means that in most cases, you cannot call the Cleanup method directly. There is one exception to this rule: if you write your own subclass of this class, you can call the Cleanup method from within the Init or Cleanup method of the subclass.

Syntax

OBJ_DESTROY, *Obj*

or

Obj->[IDLitData::]Cleanup   *(In a lifecycle method only.)*

Arguments

None

Keywords

None

Version History

6.0	Introduced

IDLitData::Copy

The IDLitData::Copy function method returns an exact copy of the data object and its contents, including registered property values.

The following values are *not* copied:

- Values of unregistered properties.
- Values of properties registered after the data object is created.
- Property attribute values.

Note ———

If an object has been added to the data object, only the object reference to the added object is copied.

Syntax

Result = Obj->[IDLitData::]Copy()

Return Value

Returns a copy of the object on which it is called. If the copy operation fails, a null object is returned.

Arguments

None

Keywords

None

Version History

6.0	Introduced

IDLitData::GetByType

The IDLitData::GetByType function method returns all contained objects of the specified iTool data type.

Syntax

Result = Obj->[IDLitData::]GetByType(*Type*[, COUNT=*variable*])

Return Value

Returns an object array containing references to the contained data objects that are of the iTool data type specified by *Type*. If no objects matching *Type* exist, a null object reference is returned.

Arguments

Type

A string containing the iTool data type to search for in the data hierarchy rooted by this data container.

Keywords

COUNT

Set this keyword equal to a named variable that will contain the number of valid objects returned by this method.

Version History

6.0	Introduced

IDLitData::GetData

The IDLitData::GetData function method retrieves the data stored in the object.

Syntax

Result = Obj->[*IDLitData*::]GetData(*Data*[, *Identifier*] [, NAN=*variable*]
  [, /NO_COPY])

Return Value

Returns a 1 if the operation succeeds, and 0 if it fails.

Arguments

Data

A named variable that will contain the data retrieved from the data object. If the
GetData method fails, the variable is not modified.

Identifier

A string argument that is not used by this method, but is accepted for parameter
compatibility with the IDLitDataContainer::GetData method. If a value for this
argument is supplied, the method does not retrieve any data and returns the value 0.

Keywords

NAN

Set this keyword to a named variable that will contain 1 if *Data* contains any non-
finite values (either NaN or Infinity), or 0 otherwise.

NO_COPY

Set this keyword to move the data from the data object to the variable specified by the
Data argument, leaving the data value of the data object undefined.

Version History

6.0	Introduced

IDLitData::GetProperty

The IDLitData::GetProperty procedure method retrieves the value of an IDLitData property, and should be called by the GetProperty method of any subclass of this class.

Syntax

Obj->[IDLitData::]GetProperty[, *PROPERTY=variable*]

Arguments

None

Keywords

Any property listed under "IDLitData Properties" on page 3730 that contains the word "Yes" in the "Get" column of the properties table can be retrieved using this method. To retrieve the value of a property, specify the property name as a keyword set equal to a named variable that will contain the value of the property.

Version History

6.0	Introduced

IDLitData::GetSize

The IDLitData::GetSize function method returns an approximate value for the amount of memory being used by the data object.

Syntax

Result = Obj->[IDLitData::]GetSize()

Return Value

Returns the number of bytes of memory used by the data object. The returned value is an approximation.

Arguments

None

Keywords

None

Version History

6.0	Introduced

IDLitData::Init

The IDLitData::Init function method initializes the IDLitData object.

Note ───────────────────────────────────────

Init methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation. This means that in most cases, you cannot call the Init method directly. There is one exception to this rule: if you write your own subclass of this class, you can call the Init method from within the Init method of the subclass.

───

Syntax

Obj = OBJ_NEW('IDLitData'[, *Data*] [, *PROPERTY=value*])

or

Result = Obj->[IDLitData::]Init([*Data*] [, *PROPERTY=value*])   *(In a lifecycle method only.)*

Return Value

When this method is called indirectly, as part of the call to the OBJ_NEW function, the return value is an object reference to the newly-created object.

When called directly within a subclass Init method, the return value is 1 if initialization was successful, or zero otherwise.

Arguments

Data

An IDL variable of any type that is stored in the data object.

Keywords

Any property listed under "IDLitData Properties" on page 3730 that contains the word "Yes" in the "Init" column of the properties table can be initialized during object creation using this method. To initialize the value of a property, specify the property name as a keyword set equal to the appropriate property value.

Version History

6.0	Introduced

IDLitData::NotifyDataChange

The IDLitData::NotifyDataChange procedure method is called when a data object has been changed; it is part of the notification process that allows data updates to be reflected by visualizations that use the data. It works in conjunction with the NotifyDataComplete method to provide a two-pass change notification system that minimizes the number of operations performed when a data object changes.

When NotifyDataChange is called, the OnDataChange methods of all observers of the data object (usually visualizations) are automatically called. This causes the observers to perform any necessary updates *without committing those updates*. When the NotifyDataComplete method is called, the observers' OnDataComplete methods are called to commit the updates. This two-pass system allows visualizations to be notified that the data has changed without forcing an immediate redraw of the iTool window; when the NotifyDataComplete method is called, all visualizations can be redrawn at once.

Every call to the NotifyDataChange method must have an accompanying NotifyDataComplete call; without the call to NotifyDataComplete, no updates will take place.

Note ───

If the data object is being changed by an operation based on the IDLitDataOperation class, the call to NotifyDataChange is handled automatically. The only time you will need to call this method directly is if the operation that modifies the data is based on the more generic IDLitOperation class.

───

Syntax

Obj->[IDLitData::]NotifyDataChange

Arguments

None

Keywords

None

Version History

6.0	Introduced

IDLitData::NotifyDataComplete

The IDLitData::NotifyDataComplete procedure method is called after a data object has been changed; it is part of the notification process that allows data updates to be reflected by visualizations that use the data. It works in conjunction with the NotifyDataChange method to provide a two-pass change notification system that minimizes the number of operations performed when a data object changes.

When NotifyDataChange is called, the OnDataChange methods of all observers of the data object (usually visualizations) are automatically called. This causes the observers to perform any necessary updates *without committing those updates*. When the NotifyDataComplete method is called, the observers' OnDataComplete methods are called to commit the updates. This two-pass system allows visualizations to be notified that the data has changed without forcing an immediate redraw of the iTool window; when the NotifyDataComplete method is called, all visualizations can be redrawn at once.

Every call to the NotifyDataChange method must have an accompanying NotifyDataComplete call; without the call to NotifyDataComplete, no updates will take place.

Note

If the data object is being changed by an operation based on the IDLitDataOperation class, the call to NotifyDataChange is handled automatically. The only time you will need to call this method directly is if the operation that modifies the data is based on the more generic IDLitOperation class.

Syntax

Obj->[IDLitData::]NotifyDataComplete

Arguments

None

Keywords

None

Version History

6.0	Introduced

IDLitData::RemoveDataObserver

The IDLitData::RemoveDataObserver method unregisters an object that has been registered as an *observer* of this data object. After this method is called, the Observer will no longer be notified when the contents of the data object change. If the specified *Observer* doesn't exist, this method will return quietly.

Syntax

Obj->[IDLitData::]RemoveDataObserver, *Observer*

Arguments

Observer

An object reference to an iTool component object that was previously registered as an observer of this data object.

Keywords

None

Version History

6.0	Introduced

IDLitData::SetData

The IDLitData::SetData function method copies the data from an IDL variable or expression into the data object, and notifies all its observers that the data has changed.

Syntax

Result = Obj->[IDLitData::]SetData(*Data*[, *Identifier*] [, /NO_COPY] [, /NULL])

Return Value

Returns a 1 if the operation succeeds, and 0 if it fails.

Arguments

Data

An IDL variable or expression whose value is copied into the data object.

Identifier

A string argument that is not used by this method. It is accepted by this method only for parameter compatibility with IDLitDataContainer::SetData. If a value for this argument is supplied, the method does not retrieve any data and returns the value 0.

Keywords

NO_COPY

Set this keyword to move the data into the specified IDLitData object without creating an additional copy. This leaves the original IDL variable named by the *Data* argument undefined.

NULL

Set this keyword to remove any data stored in the IDLitData object, leaving it empty. If this keyword is set, the *Data* argument is ignored.

Version History

6.0	Introduced

IDLitData::SetProperty

The IDLitData::SetProperty procedure method sets the value of an IDLitData property, and should be called by the SetProperty method of any subclass of this class.

Syntax

Obj->[IDLitData::]SetProperty[, *PROPERTY=value*]

Arguments

None

Keywords

Any property listed under "IDLitData Properties" on page 3730 that contains the word "Yes" in the "Set" column of the properties table can be set using this method. To set the value of a property, specify the property name as a keyword set equal to the appropriate property value.

Version History

6.0	Introduced

IDLitDataContainer

The IDLitDataContainer class is used to store collections of IDLitData and IDLitDataContainer objects to form hierarchical data structures. Objects can be added to and removed from an IDLitDataContainer at any time, allowing for the dynamic creation of composite data types.

Objects stored in an IDLitDataContainer hierarchy are referenced using iTool *object identifiers*. Object identifiers are simple scalar strings assigned to the IDENTIFIER property of an object when it is created. For a complete discussion of object identifiers and their role in the iTool system, see "iTool Object Identifiers" (Chapter 2, *iTool Developer's Guide*).

This class is written in the IDL language. Its source code can be found in the file idlitdatacontainer__define.pro in the lib/itool/framework subdirectory of the IDL distribution.

Superclasses

IDLitContainer

IDLitData

Note ─────────────
See the "iTools Object Model Diagram" (Chapter 2, *iTool Developer's Guide*) for a visual representation of the iTools object model hierarchy.
─────────────

Creation

See "IDLitDataContainer::Init" on page 3758.

Properties

Objects of this class have no properties of their own, but do have properties inherited from any superclasses.

Methods

This class has the following methods:

- IDLitDataContainer::Add
- IDLitDataContainer::Cleanup

- IDLitDataContainer::GetData
- IDLitDataContainer::GetIdentifiers
- IDLitDataContainer::GetProperty
- IDLitDataContainer::Init
- IDLitDataContainer::SetData
- IDLitDataContainer::SetProperty

In addition, this class inherits the methods of its superclasses.

Examples

See Chapter 3, "Data Management" (*iTool Developer's Guide*) for examples using this class and its methods.

Version History

6.0	Introduced

IDLitDataContainer Properties

Objects of this class have no properties of their own, but do have properties inherited from any superclasses.

Objects in this class inherit:

- IDLitContainer
- IDLitData

IDLitDataContainer::Add

The IDLitDataContainer::Add procedure method adds items to the data container object, and sends out an OnDataChange and OnDataComplete messages to all observers of the data container.

Syntax

Obj->[IDLitDataContainer::]Add, *Data* [, /NO_NOTIFY]

Arguments

Data

An object reference (or array of object references) to the IDLitData object or objects to be added to the container. Objects that are not of class IDLitData are quietly ignored.

Keywords

NO_NOTIFY

Normally, when an item is added, an ADDITEMS notification message is broadcast to all iTool components registered as monitoring this container. If this keyword is set, no ADDITEMS message is sent.

Note

Regardless of the setting of NO_NOTIFY, the OnDataChange and OnDataComplete messages are always sent.

Version History

6.1	Introduced

IDLitDataContainer::Cleanup

The IDLitDataContainer::Cleanup procedure method performs all cleanup operations on the object, and should be called by the Cleanup method of any subclass of this class. This method destroys all data objects stored in this container.

Note ───

Cleanup methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation and destruction. This means that in most cases, you cannot call the Cleanup method directly. There is one exception to this rule: if you write your own subclass of this class, you can call the Cleanup method from within the Init or Cleanup method of the subclass.

──

Syntax

OBJ_DESTROY, *Obj*

or

Obj->[IDLitDataContainer::]Cleanup   *(In a lifecycle method only.)*

Arguments

None

Keywords

None

Version History

6.0	Introduced

IDLitDataContainer::GetData

The IDLitDataContainer::GetData function method retrieves the data value contained in the data object specified by the *Identifier* argument.

Syntax

Result = Obj->[IDLitDataContainer::]GetData(*Data* [, *Identifier*] [, /NO_COPY])

Return Value

Returns a 1 if the operation succeeds, and 0 if it fails.

Arguments

Data

A named variable that will contain the data value of the specified data object.

Identifier

A string containing the relative object identifier path to the target data object for this method. See "iTool Object Identifiers" (Chapter 2, *iTool Developer's Guide*) for a discussion of object identifier strings.

If *Identifier* is not set. or is set to a null string, the data contained in the data container itself is returned.

Keywords

NO_COPY

Set this keyword to move the data from the data container object to the variable specified by the *Data* argument, leaving the data value of the data object undefined.

Version History

6.0	Introduced

IDLitDataContainer::GetIdentifiers

The IDLitDataContainer::GetIdentifiers function method retrieves the object identifiers for all data and data container objects contained in the data container object.

Syntax

Result = Obj->[IDLitDataContainer::]GetIdentifiers([*Pattern*] [, /LEAF])

Return Value

Returns an array of strings containing the object identifiers for all data and data container objects contained by the data container object. If the container is empty, or if the *Pattern* argument is supplied and no object identifiers are matched, the function returns a scalar null string.

Arguments

Pattern

A string specifying a search pattern to be used for filtering the returned object identifiers. Only object identifiers that match *Pattern* are returned. See STRMATCH for a description of the rules used when matching patterns.

Keywords

LEAF

Set this keyword to return only object identifiers whose final node is *not* a container object.

Version History

6.0	Introduced

IDLitDataContainer::GetProperty

The IDLitDataContainer::GetProperty procedure method retrieves the value of an IDLitDataContainer property, and should be called by the GetProperty method of any subclass of this class.

Syntax

Obj->[IDLitDataContainer::]GetProperty[, *PROPERTY=variable*]

Arguments

None

Keywords

Any property listed under "IDLitDataContainer Properties" on page 3752 that contains the word "Yes" in the "Get" column of the properties table can be retrieved using this method. To retrieve the value of a property, specify the property name as a keyword set equal to a named variable that will contain the value of the property.

Version History

6.0	Introduced

IDLitDataContainer::Init

The IDLitDataContainer::Init function method initializes the IDLitDataContainer object.

Note

Init methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation. This means that in most cases, you cannot call the Init method directly. There is one exception to this rule: if you write your own subclass of this class, you can call the Init method from within the Init method of the subclass.

Syntax

Obj = OBJ_NEW('IDLitDataContainer'[, *Data*] [, *PROPERTY=value*])

or

Result = *Obj*->[IDLitDataContainer::]Init([*Data*] [, *PROPERTY=value*])   *(In a lifecycle method only.)*

Return Value

When this method is called indirectly, as part of the call to the OBJ_NEW function, the return value is an object reference to the newly-created object.

When called directly within a subclass Init method, the return value is 1 if initialization was successful, or zero otherwise.

Arguments

Data

An IDL variable of any type or shape that is stored into the object at initialization.

Keywords

Any property listed under "IDLitDataContainer Properties" on page 3752 that contains the word "Yes" in the "Init" column of the properties table can be initialized during object creation using this method. To initialize the value of a property, specify the property name as a keyword set equal to the appropriate property value.

Version History

6.0	Introduced

IDLitDataContainer::SetData

The IDLitDataContainer::SetData function method stores data in the IDLitData object specified by *Identifier*. This method acts in exactly the same way as the IDLitData::SetData method.

Syntax

Result = Obj->[IDLitDataContainer::]SetData(*Data*, *Identifier*[, /NO_COPY] [, /NULL])

Return Value

Returns a 1 if the operation succeeds, or 0 if it fails.

Arguments

Data

An IDL variable of any type that is copied into the specified data object.

Identifier

A scalar string containing the object identifier of the IDLitData object in which the data specified by *Data* should be stored. This path must specify a valid IDLitData object, or the function fails. See "iTool Object Identifiers" (Chapter 2, *iTool Developer's Guide*) for a discussion of object identifier strings.

Keywords

NO_COPY

Set this keyword to move the data into the specified IDLitData object without creating an additional copy. This leaves the original IDL variable named by the *Data* argument undefined.

NULL

Set this keyword to remove any data stored in the IDLitData object, leaving it empty. If this keyword is set, the *Data* argument is ignored, but must still be present.

Version History

6.0	Introduced

IDLitDataContainer::SetProperty

The IDLitDataContainer::SetProperty procedure method sets the value of an IDLitDataContainer property, and should be called by the SetProperty method of any subclass of this class.

Syntax

Obj->[IDLitDataContainer::]SetProperty[, *PROPERTY=value*]

Arguments

None

Keywords

Any property listed under "IDLitDataContainer Properties" on page 3752 that contains the word "Yes" in the "Set" column of the properties table can be set using this method. To set the value of a property, specify the property name as a keyword set equal to the appropriate property value.

Version History

6.0	Introduced

IDLitDataOperation

The IDLitDataOperation class is a subclass of IDLitOperation that automates data access and automatically records information for the undo-redo system. By automating this functionality, the IDLitDataOperation class eliminates much of the work required to implement a standard subclass of the IDLitOperation class. See IDLitOperation for additional information on iTool operations.

Note ───

The IDLitDataOperation class is designed for use in operations that affect data values. If you are creating an operation that acts on items other than the data that underlies a visualization, you should base your operation class on the IDLitOperation class.

──

While the implementation of a standard subclass of an IDLitOperation class requires the developer to provide implementations of the DoAction, UndoOperation, and RedoOperation methods, the IDLitDataOperation class provides these methods automatically. The only method the developer of an IDLitDataOperation class is *required* to implement is the Execute method, which contains the logic for the specific operation being performed. Depending on the operation being performed, the developer of an IDLitDataOperation may also implement methods to undo the operation, display a user interface before performing the operation, get and set properties specific to the operation, and initialize the IDLitDataOperation object.

When an IDLitDataOperation is requested by a user, the following things occur:

1. As with any operation, execution commences when the DoAction method is called on this object. When called, the IDLitDataOperation retrieves the currently-selected items. If nothing is selected, the operation returns.

2. For each selected item, the data objects of the parameters registered as "operation targets" are retrieved.

3. The data objects are queried for iTool data types that match the types supported by the IDLitDataOperation.

For each data object that includes data of an iTool data type supported by the IDLitDataOperation, the following things occur:

1. The data from the data object is retrieved.

2. If the IDLitDataOperation does not have the REVERSIBLE_OPERATION property set, a copy of the data is created and placed into the undo-redo command set.

3. The Execute method is called, with the retrieved data as its argument.

4. If the Execute method succeeds and the IDLitDataOperation has the EXPENSIVE_COMPUTATION property set, a copy of the results is placed into the undo-redo command set.

5. The result of the IDLitDataOperation is placed in the data object. This action will cause all visualization items that use the data object to update when the operation is completed.

Once all selected data items have been processed, the undo-redo command set is placed into the system undo-redo buffer for later use.

For a detailed discussion of both the IDLitOperation and IDLitDataOperation classes, see Chapter 7, "Creating an Operation" (*iTool Developer's Guide*).

This class is written in the IDL language. Its source code can be found in the file idlitdataoperation__define.pro in the lib/itools/framework subdirectory of the IDL distribution.

Superclasses

IDLitOperation

Note ———

See the "iTools Object Model Diagram" (Chapter 2, *iTool Developer's Guide*) for a visual representation of the iTools object model hierarchy.

———

Creation

See "IDLitDataOperation::Init" on page 3773.

Properties

Objects of this class have the following properties. See "IDLitDataOperation Properties" for details on individual properties.

• WITHIN_UI

Methods

This class has the following methods:

• IDLitDataOperation::Cleanup

- IDLitDataOperation::DoExecuteUI
- IDLitDataOperation::Execute
- IDLitDataOperation::GetProperty
- IDLitDataOperation::Init
- IDLitDataOperation::SetProperty
- IDLitDataOperation::UndoExecute

In addition, this class inherits the methods of its superclasses (if any).

Examples

See "Creating a New Data-Centric Operation" (Chapter 7, *iTool Developer's Guide*) for examples using this class and its methods.

Version History

6.0	Introduced
6.2	Added WITHIN_UI property

See Also

IDLitOperation

IDLitDataOperation Properties

IDLitDataOperation objects have the following properties in addition to properties inherited from any superclasses. Properties with the word "Yes" in the "Get" column of the property table can be retrieved via IDLitDataOperation::GetProperty. Properties with the word "Yes" in the "Init" column of the property table can be set via IDLitDataOperation::Init. Properties with the word "Yes" in the "Set" column in the property table can be set via IDLitDataOperation::SetProperty.

Note ────────────────────────────────────

For a discussion of the property description tables shown below, see "About Object Property Descriptions" on page 3135.

──

Objects of this class have the following properties.

• WITHIN_UI

In addition, objects of this class inherit properties from the following superclass:

• IDLitOperation

WITHIN_UI

A Boolean value that indicates whether the operation is currently within the IDLitDataOperation::DoExecuteUI method (i.e., it is currently displaying a dialog). This property is automatically set to one (True) just before the method is called, and is reset to zero (False) after the method returns.

Property Type	Boolean		
Name String	*not displayed*		
Get: Yes	**Set:** No	**Init:** No	**Registered:** No

IDLitDataOperation::Cleanup

The IDLitDataOperation::Cleanup procedure method performs all cleanup on the object.

Note

An operation based on the IDLitDataOperation class need not implement this method if the operation does not allocate any pointers or object references of its own.

Note

Cleanup methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation and destruction. This means that in most cases, you cannot call the Cleanup method directly. There is one exception to this rule: if you write your own subclass of this class, you can call the Cleanup method from within the Init or Cleanup method of the subclass.

Syntax

OBJ_DESTROY, *Obj*

or

Obj->[IDLitDataOperation::]Cleanup   *(In a lifecycle method only.)*

Arguments

None

Keywords

None

Version History

6.0	Introduced

IDLitDataOperation::DoExecuteUI

The IDLitDataOperation::DoExecuteUI function method provides a way for the iTool developer to request user input before performing an operation. If the SHOW_EXECUTION_UI property is set, this method will be called before the operation's Execute method is called.

Note

Every operation based directly on the IDLitDataOperation class that requires user interaction before execution must implement its own DoExecuteUI method. See Chapter 7, "Creating an Operation" (*iTool Developer's Guide*) for details.

The DoExecuteUI method itself can present any interface. In practice, most iTool DoExecuteUI methods use the IDLitTool::DoUIService method to display a user interface requesting user input. User interfaces and UI Services are discussed in Chapter 11, "iTool User Interface Architecture" (*iTool Developer's Guide*).

Warning

If the DoExecuteUI method does not return success, the Execute method will not be called.

Syntax

Result = Obj->[IDLitDataOperation::]DoExecuteUI()

Return Value

Returns a 1 if the displayed user interface code executed successfully, and the operation should be executed. If user interface code does not execute successfully, or if the user cancels the operation, this function returns a 0.

Arguments

None

Keywords

None

Example

The following is an example of a DoExecuteUI method, taken from the iTools "Scale Factor" operation:

```
FUNCTION IDLitopScalefactor::DoExecuteUI

oTool = self->GetTool()
IF (oTool EQ OBJ_NEW()) THEN RETURN, 0

RETURN, oTool->DoUIService('ScaleFactor', self)

END
```

This implementation of the DoExecuteUI method does the following:

1. Retrieves an object reference to the current iTool using the GetTool method.

2. Checks to make sure the returned object reference is not a null object (which would be the case if the GetTool method failed).

3. Calls the `ScaleFactor` UI Service.

Version History

6.0	Introduced

IDLitDataOperation::Execute

The IDLitDataOperation::Execute function method contains the execution logic for the operation. This method is called automatically when the iTool user requests an operation based on the IDLitDataOperation class.

Note ───

Every operation based directly on the IDLitDataOperation class must implement its own Execute method. See Chapter 7, "Creating an Operation" (*iTool Developer's Guide*) for details.

──

When the iTool system executes an IDLitDataOperation, it passes the *raw data* (of the appropriate iTools data type) from the selected objects to the Execute method. This means that the Execute method itself does not need to "unpack" a data object before performing the operations, allowing rapid and simple operation execution. For example, if the operation expects data of the iTools data type IDLARRAY2D, the iTool system will include the selected two-dimensional array as the *Data* argument.

Syntax

Result = Obj->[IDLitDataOperation::]Execute(*Data*)

Return Value

The return value is 1 if the operation executed successfully, or 0 otherwise.

Arguments

Data

A single data item on which the operation should be performed. Note that *Data* is *not* an IDLitData object, but actual data.

Keywords

None

Version History

6.0	Introduced

See Also

IDLitDataOperation::UndoExecute

IDLitDataOperation::GetProperty

The IDLitDataOperation::GetProperty procedure method retrieves the value of a property or group of properties of an operation object.

Note ——

An operation based on the IDLitDataOperation class *must* implement this method if the operation defines one or more properties not inherited from the superclass. See Chapter 7, "Creating an Operation" (*iTool Developer's Guide*) for details.

——

Syntax

Obj->[IDLitDataOperation::]GetProperty[, *PROPERTY=variable*]

Arguments

None

Keywords

Any property listed under "IDLitDataOperation Properties" on page 3766 that contains the word "Yes" in the "Get" column of the properties table can be retrieved using this method. To retrieve the value of a property, specify the property name as a keyword set equal to a named variable that will contain the value of the property.

Example

To retrieve the value of the REVERSIBLE_OPERATION property:

```
Obj->IDLitDataOperation::GetProperty, REVERSIBLE_OPERATION = rev
```

Version History

6.0	Introduced

IDLitDataOperation::Init

The IDLitDataOperation::Init function method initializes the IDLitDataOperation object and sets properties that define the behavior the operation provides.

Note ——————————————————————————

An operation based on the IDLitDataOperation class *must* implement this method. See Chapter 7, "Creating an Operation" (*iTool Developer's Guide*) for details.

Note ——————————————————————————

Init methods are special life cycle methods, and as such cannot be called outside the context of object creation. This means that in most cases, you cannot call the Init method directly. There is one exception to this rule: if you write your own subclass of this class, you can call the Init method from within the Init method of the subclass.

Syntax

Obj = OBJ_NEW('IDLitDataOperation' [, *PROPERTY=variable*])

or

Result = Obj->[IDLitDataOperation::]Init([, *PROPERTY=variable*]) *(In a lifecycle method only.)*

Return Value

When this method is called indirectly, as part of the call to the OBJ_NEW function, the return value is an object reference to the newly-created object.

When called directly within a subclass Init method, the return value is 1 if initialization was successful, or zero otherwise.

Arguments

None

Keywords

Any property listed under "IDLitDataOperation Properties" on page 3766 that contains the word "Yes" in the "Init" column of the properties table can be initialized

during object creation using this method. To initialize the value of a property, specify the property name as a keyword set equal the appropriate property value.

Version History

6.0	Introduced

IDLitDataOperation::SetProperty

The IDLitDataOperation::SetProperty procedure method sets the value of a property or group of properties for the operation.

Note ────────────────────────────

An operation based on the IDLitDataOperation class *must* implement this method if the operation defines one or more properties not inherited from the superclass. See Chapter 7, "Creating an Operation" (*iTool Developer's Guide*) for details.
────────────────────────────────

Syntax

Obj->[IDLitDataOperation::]SetProperty[, *PROPERTY=value*]

Arguments

None

Keywords

Any property listed under "IDLitDataOperation Properties" on page 3766 that contains the word "Yes" in the "Set" column of the properties table can be set using this method. To set the value of a property, specify the property name as a keyword set equal to the appropriate property value.

Version History

6.0	Introduced

IDLitDataOperation::UndoExecute

The IDLitDataOperation::UndoExecute function method is called when a user selects the Undo operation after executing an IDLitDataOperation that sets the value of the REVERSIBLE_OPERATION property to 1. (If the IDLitDataOperation does not set this property, the UndoExecute method is not called.) If implemented, this method generally applies the inverse of the operation performed by the Execute method.

Note
An operation based on the IDLitDataOperation class *must* implement this method if the operation sets the REVERSIBLE_OPERATION property. See Chapter 7, "Creating an Operation" (*iTool Developer's Guide*) for details.

When the iTool system undoes an IDLitDataOperation, it passes the *raw data* (of the appropriate iTools data type) from the selected objects to the UndoExecute method. This means that the UndoExecute method itself does not need to "unpack" a data object before performing the operations, allowing rapid and simple operation execution. For example, if the operation expects data of the iTools data type IDLARRAY2D, the iTool system will include the selected two-dimensional array as the *Data* argument.

Syntax

Result = Obj->[IDLitDataOperation::]UndoExecute(*Data*)

Return Value

The return value is 1 if the operation was undone successfully, or 0 otherwise.

Arguments

Data

A single data item on which the operation should be performed. Note that *Data* is *not* an IDLitData object, but actual data.

Keywords

None

Version History

6.0	Introduced

See Also

IDLitDataOperation::Execute

IDLitDirectWindow

An IDLitDirectWindow object is a representation of an on-screen area on a display device that serves as a graphics destination. In contrast to IDLgrWindow and IDLitWindow, the IDLitDirectWindow uses Direct Graphics.

Important! You must note the following:

- The IDLitDirectWindow is designed for use only with the Export Bridge. The event notification methods will be called automatically by the Export Bridge, but will not be called when the IDLitDirectWindow class is used in other contexts. For more information, see "Exporting Drawable Objects" (Chapter 11, *IDL Connectivity Bridges*).

- Objects or subclasses of this type can not be saved or restored.

- If you are using a multi-monitor setup on X (under UNIX), you cannot have the window on the second monitor. For more information, see "UNIX Multi-Monitor Configurations" (Chapter 5, *Using IDL*).

Superclasses

IDLitComponent

Creation

See IDLitDirectWindow::Init.

Properties

Objects of this class have the following properties. See "IDLitDirectWindow Properties" on page 3780 for details on individual properties.

- WINDOW_INDEX

In addition, objects of this class inherit the properties of all superclasses of this class.

Methods

This class has the following methods:

- IDLitDirectWindow::Cleanup

- IDLitDirectWindow::GetProperty

Version History

6.3	Introduced
6.4	Added OnWheel method

IDLitDirectWindow Properties

IDLitDirectWindow objects have the following properties in addition to properties inherited from any superclasses. Properties with the word "Yes" in the "Get" column of the property table can be retrieved via IDLitDirectWindow::GetProperty. Properties with the word "Yes" in the "Init" column of the property table can be set via IDLitDirectWindow::Init. Properties with the word "Yes" in the "Set" column in the property table can be set via IDLitDirectWindow::SetProperty.

Note ───

For a discussion of the property description tables shown below, see "About Object Property Descriptions" on page 3135.

───

Objects of this class have the following properties.

- WINDOW_INDEX

In addition, objects of this class inherit:

- IDLitComponent

WINDOW_INDEX

An integer containing the window index associated with the window.

Property Type	Integer		
Name String	*not displayed*		
Get: Yes	Set: No	Init: No	Registered: No

IDLitDirectWindow::Cleanup

The IDLitDirectWindow::Cleanup procedure method performs all cleanup on the object.

Note ──

Cleanup methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation and destruction. This means that in most cases, you cannot call the Cleanup method directly. There is one exception to this rule: if you write your own subclass of this class, you can call the Cleanup method from within the Init or Cleanup method of the subclass.

──

Syntax

OBJ_DESTROY, *Obj*

or

Obj->[IDLitDirectWindow::]Cleanup *(In a lifecycle method only)*

Arguments

None

Keywords

None

Version History

6.3	Introduced

IDLitDirectWindow::GetProperty

The IDLitDirectWindow::GetProperty procedure method retrieves the value of an IDLitDirectWindow property, and should be called by a subclass's GetProperty method. This method also retrieves properties defined in the superclass.

Syntax

Obj->[IDLitDirectWindow::]GetProperty[, *PROPERTY=variable*]

Arguments

None

Keywords

Any property listed under IDLitDirectWindow Properties that contains the word "Yes" in the "Get" column of the properties table can be retrieved using this method. To retrieve the value of a property, specify the property name as a keyword set equal to a named variable that will contain the value of the property.

Version History

6.3	Introduced

IDLitDirectWindow::Init

The IDLitDirectWindow::Init function method initializes the window object.

This function method initializes the IDLitDirectWindow object, and should be called by the subclass's Init method. This method also calls the superclass's Init method.

Note

Init methods are special lifecycle methods, and as such cannot be called outside the context of object creation. This means that in most cases, you cannot call the Init method directly. There is one exception to this rule: if you write your own subclass of this class, you can call the Init method from within the Init method of the subclass.

Syntax

Obj = OBJ_NEW('IDLitDirectWindow'[, *PROPERTY=value*])

or

Result = Obj->[IDLitDirectWindow::]Init([, *PROPERTY=value*]) *(In a lifecycle method only)*

Arguments

None

Keywords

Any property listed under IDLitDirectWindow Properties that contains the word "Yes" in the "Init" column of the properties table can be initialized during object creation using this method. To initialize the value of a property, specify the property name as a keyword set equal to the appropriate property value.

Version History

6.3	Introduced

IDLitDirectWindow::MakeCurrent

The IDLitDirectWindow::MakeCurrent procedure method sets the current graphics device to the window device and sets the current output window to the IDLitDirectWindow's window.

The IDLitDirectWindow::MakeCurrent method should be called before sending any Direct Graphics commands, to ensure that the graphics appears in the appropriate window.

Syntax

Obj->[IDLitDirectWindow::]MakeCurrent

Arguments

None

Keywords

None

Version History

6.3	Introduced

IDLitDirectWindow::OnEnter

The IDLitDirectWindow::OnEnter procedure method handles notification from the window that a mouse enter event has occurred.

Note
This method is only useful in conjunction with the Export Bridge. The method is only a stub and provides no functionality. In your subclass of IDLitDirectWindow, you should override this method to provide your own functionality. Your method will be automatically called by the Export Bridge. For more information, see "Exporting Drawable Objects" (Chapter 11, *IDL Connectivity Bridges*).

Syntax

Obj->[IDLitDirectWindow::]OnEnter

Arguments

None

Keywords

None

Version History

6.3	Introduced

IDLitDirectWindow::OnExit

The IDLitDirectWindow::OnExit procedure method handles notification from the window that a mouse exit event has occurred.

Note ——————————————————————————————

This method is only useful in conjunction with the Export Bridge. The method is only a stub and provides no functionality. In your subclass of IDLitDirectWindow, you should override this method to provide your own functionality. Your method will be automatically called by the Export Bridge. For more information, see "Exporting Drawable Objects" (Chapter 11, *IDL Connectivity Bridges*).

Syntax

Obj->[IDLitDirectWindow::]OnExit

Arguments

None

Keywords

None

Version History

6.3	Introduced

IDLitDirectWindow::OnExpose

The IDLitDirectWindow::OnExpose procedure method handles notification from the window that an expose event has occurred.

Note

This method is only useful in conjunction with the Export Bridge. By default, the OnExpose method will automatically redraw the window. If you are using a subclass of IDLitDirectWindow and require additional functionality, you should override this method. Your method will be automatically called by the Export Bridge. For more information, see "Exporting Drawable Objects" (Chapter 11, *IDL Connectivity Bridges*).

Syntax

Obj->[IDLitDirectWindow::]OnExpose, *X*, *Y*, *Width*, *Height*

Arguments

X

A floating-point value representing the *x*-coordinate of the lower left corner of the newly exposed portion of the canvas (in device coordinates).

Y

A floating-point value representing the *y*-coordinate of the lower left corner of the newly exposed portion of the canvas (in device coordinates).

Width

A floating-point value representing the width of the newly exposed portion of the canvas (in device coordinates).

Height

A floating-point value representing the height of the newly exposed portion of the canvas (in device coordinates).

Keywords

None

Version History

6.3	Introduced

IDLitDirectWindow::OnKeyboard

The IDLitDirectWindow::OnKeyboard procedure method handles notification from the window that a keyboard event has occurred.

Note

This method is only useful in conjunction with the Export Bridge. The method is only a stub and provides no functionality. In your subclass of IDLitDirectWindow, you should override this method to provide your own functionality. Your method will be automatically called by the Export Bridge. For more information, see "Exporting Drawable Objects" (Chapter 11, *IDL Connectivity Bridges*).

Syntax

Obj->[IDLitDirectWindow::]OnKeyboard, *IsASCII*, *Character*, *KeySymbol*, *X*, *Y*, *Press*, *Release*, *Modifiers*

Arguments

IsASCII

A scalar byte value that indicates whether the keyboard event corresponds to a character in the ASCII character set. If *IsASCII* is non-zero, the *Character* argument will be set to a byte value corresponding to the character of the pressed key. If *IsASCII* is zero, the *KeySymbol* argument will be set to a numeric value indicating the key that was pressed.

Character

If *IsASCII* is non-zero, this argument is set to a byte value corresponding to the ASCII character of the key that was pressed. Otherwise, this argument is set to zero.

KeySymbol

If *IsASCII* is zero, this argument is set to a long integer that indicates the key that was pressed. Otherwise, this argument is set to zero. Valid values for key symbols include:

1	Shift
2	Control

3	Caps Lock
4	Alt
5	Left
6	Right
7	Up
8	Down
9	Page Up
10	Page Down
11	Home
12	End

X,Y

Long integers containing the *x*-coordinate and *y*-coordinate of the mouse cursor (in device coordinates) at the time of the event.

Press

A long integer indicating whether this event represents a key press. This argument is non-zero if the event is the result of pressing the key.

Release

A long integer indicating whether this event represents a key release. This argument is non-zero if the event is the result of releasing the key.

Modifiers

A long integer containing a bitwise mask indicating which modifier keys are active at the time of the keyboard event. If a bit is zero, the key is up; if the bit is set, the key is pressed. The following table describes the bits in this bit mask:

Bit	Value	Modifier Key
0	1	Shift
1	2	Control
2	4	Caps Lock
3	8	Alt

Table 31-1: Modifier Values

Keywords

Version History

6.3	Introduced

IDLitDirectWindow::OnMouseDown

The IDLitDirectWindow::OnMouseDown procedure method handles notification from the window that a mouse down event has occurred.

Note

This method is only useful in conjunction with the Export Bridge. The method is only a stub and provides no functionality. In your subclass of IDLitDirectWindow, you should override this method to provide your own functionality. Your method will be automatically called by the Export Bridge. For more information, see "Exporting Drawable Objects" (Chapter 11, *IDL Connectivity Bridges*).

Syntax

Obj->[IDLitDirectWindow::]OnMouseDown, *X*, *Y*, *ButtonMask*, *Modifiers*, *NumClicks*

Arguments

X

A long integer representing the *x*-location (in device coordinates) of the mouse event.

Y

A long integer representing the *y*-location (in device coordinates) of the mouse event.

ButtonMask

An integer containing a bitwise mask indicating which of the left, center, or right mouse button was pressed:

Bitmask	Mouse Button
1	Left
2	Middle
4	Right

Table 31-2: Bitmask for Button Events

Modifiers

A long integer containing a bitwise mask indicating which modifier keys are active at the time the mouse button is pressed. If a bit is zero, the key is up; if the bit is set, the key is pressed. The following table describes the bits in this bitmask:

Bit	Value	Modifier Key
0	1	Shift
1	2	Control
2	4	Caps Lock
3	8	Alt

Table 31-3: Bits of the Modifier Key Mask

NumClicks

An integer indicating the number of times the mouse button was clicked.

Keywords

None

Version History

6.3	Introduced

IDLitDirectWindow::OnMouseMotion

The IDLitDirectWindow::OnMouseMotion procedure method handles notification from the window that a mouse motion event has occurred.

Note

This method is only useful in conjunction with the Export Bridge. The method is only a stub and provides no functionality. In your subclass of IDLitDirectWindow, you should override this method to provide your own functionality. Your method will be automatically called by the Export Bridge. For more information, see "Exporting Drawable Objects" (Chapter 11, *IDL Connectivity Bridges*).

Syntax

Obj->[IDLitDirectWindow::]OnMouseMotion, *X*, *Y*, *Modifiers*

Arguments

X

A long integer representing the *x*-location (in device coordinates) of the mouse event.

Y

A long integer representing the *y*-location (in device coordinates) of the mouse event.

Modifiers

A long integer containing a bitwise mask indicating which modifier keys are active at the time the mouse button is pressed. If a bit is zero, the key is up; if the bit is set, the key is pressed. The following table describes the bits in this bitmask:

Bit	**Value**	**Modifier Key**
0	1	Shift
1	2	Control
2	4	Caps Lock
3	8	Alt

Table 31-4: Bits of the Modifier Key Mask

Keywords

None

Version History

6.3	Introduced

IDLitDirectWindow::OnMouseUp

The IDLitDirectWindow::OnMouseUp procedure method handles notification from the window that a mouse up event has occurred.

Note ───

This method is only useful in conjunction with the Export Bridge. The method is only a stub and provides no functionality. In your subclass of IDLitDirectWindow, you should override this method to provide your own functionality. Your method will be automatically called by the Export Bridge. For more information, see "Exporting Drawable Objects" (Chapter 11, *IDL Connectivity Bridges*).

───

Syntax

Obj->[IDLitDirectWindow::]OnMouseUp, *X*, *Y*, *ButtonMask*

Arguments

X

A long integer representing the *x*-location (in device coordinates) of the mouse event.

Y

A long integer representing the *y*-location (in device coordinates) of the mouse event.

ButtonMask

An integer containing a bitwise mask indicating which of the left, center, or right mouse button was released:

Bitmask	Mouse Button
1	Left
2	Middle
4	Right

Table 31-5: Bitmask for Button Events

Keywords

None

Version History

6.3	Introduced

IDLitDirectWindow::OnResize

The IDLitDirectWindow::OnResize procedure method handles notification from the window that a resize event has occurred.

Note

This method is only useful in conjunction with the Export Bridge. By default, the OnResize method will automatically resize the window. If you are using a subclass of IDLitDirectWindow and require additional functionality, you should override this method. Your method will be automatically called by the Export Bridge. For more information, see "Exporting Drawable Objects" (Chapter 11, *IDL Connectivity Bridges*).

Syntax

Obj->[IDLitDirectWindow::]OnResize, *Width*, *Height*

Arguments

Width

A floating-point value representing the new width of the canvas (in device coordinates).

Height

A floating-point value representing the new height of the canvas (in device coordinates).

Keywords

None

Version History

6.3	Introduced

IDLitDirectWindow::OnWheel

The IDLitDirectWindow::OnWheel procedure method handles notification (from the native window device) that a mouse wheel event has occurred.

Note ───

This method is only useful in conjunction with the Export Bridge. The method is only a stub and provides no functionality. In your subclass of IDLitDirectWindow, you should override this method to provide your own functionality. Your method will be automatically called by the Export Bridge. For more information, see "Exporting Drawable Objects" (Chapter 11, *IDL Connectivity Bridges*).

───

Syntax

Obj->[IDLitDirectWindow::]OnWheel, *X*, *Y*, *Delta*, *Modifiers*

Arguments

X

A long integer representing the *x*-location (in device coordinates) of the mouse event.

Y

A long integer representing the *y*-location (in device coordinates) of the mouse event.

Delta

A long integer giving the direction and distance that the wheel was rolled. Pushing the wheel towards the front of the mouse generates positive values, pulling the wheel towards the back of the mouse generates negative values. The magnitude of the value depends on the device setting for the individual mouse.

Modifiers

A long integer containing a bitwise mask indicating which modifier keys are active at the time of the wheel event. If a bit is zero, the key is up; if the bit is set, the key is pressed. The following table describes the bits in this bit mask:

Bit	Value	Modifier Key
0	1	Shift
1	2	Control
2	4	Caps Lock
3	8	Alt

Table 31-6: Modifier Values

Keywords

None

Version History

6.4	Introduced

IDLitDirectWindow::SetProperty

The IDLitDirectWindow::SetProperty procedure method sets the value of an IDLitDirectWindow property, and should be called by a subclass's SetProperty method. This method also calls the superclass's SetProperty method.

Syntax

Obj->[IDLitDirectWindow::]SetProperty[, *PROPERTY=variable*]

Arguments

None

Keywords

Any property listed under IDLitDirectWindow Properties that contains the word "Yes" in the "Set" column of the properties table can be set using this method. To set the value of a property, specify the property name as a keyword set equal to the appropriate property value.

Version History

6.3	Introduced

IDLitIMessaging

The IDLitIMessaging interface class provides a set of methods used to allow an object that implements the interface to send notification messages and to react appropriately when notification messages are received from other iTool component objects. This class also provides methods that allow the iTool developer to notify the iTool user of error conditions via graphical dialogs, to prompt the user for input, and to retrieve a reference to the current iTool object.

IDLitIMessaging objects are not intended to be created as standalone entities; rather, this class should be included as the superclass of another iTool class.

Note —————————————————————————————————

In the iTools system, management of messages is handled by the IDLitVisualization class, of which the IDLitIMessaging class is a superclass. In practice, this means that if you need to override any methods of the IDLitIMessaging class, you will do so in the definition of your visualization class.

———————————————————————————————————————

This class is written in the IDL language. Its source code can be found in the file `idlitimessaging__define.pro` in the `lib/itools/framework` subdirectory of the IDL distribution.

Superclasses

None

Note —————————————————————————————————

See the "iTools Object Model Diagram" (Chapter 2, *iTool Developer's Guide*) for a visual representation of the iTools object model hierarchy.

———————————————————————————————————————

Creation

Objects of this class are not created as standalone objects.

Properties

Objects of this class have no properties of their own.

Methods

This class has the following methods:

- IDLitIMessaging::AddOnNotifyObserver
- IDLitIMessaging::DoOnNotify
- IDLitIMessaging::ErrorMessage
- IDLitIMessaging::GetTool
- IDLitIMessaging::ProbeStatusMessage
- IDLitIMessaging::ProgressBar
- IDLitIMessaging::PromptUserText
- IDLitIMessaging::PromptUserYesNo
- IDLitIMessaging::RemoveOnNotifyObserver
- IDLitIMessaging::SignalError
- IDLitIMessaging::StatusMessage

Version History

6.0	Introduced

IDLitIMessaging Properties

Objects of this class have no properties of their own.

IDLitIMessaging::AddOnNotifyObserver

The IDLitIMessaging::AddOnNotifyObserver procedure method is used to register a specified iTool component object to receive messages generated by the DoOnNotify method of another specified iTool component object.

Syntax

Obj->[IDLitIMessaging::]AddOnNotifyObserver, *IdObserver*, *IdSubject*

Arguments

IdObserver

The object identifier of an iTool component object that is the *observer* expressing interest in the subject specified by *IdSubject*. Often, *IdObserver* is the object identifier of the object on which this method is being called.

The object specified by *IdObserver* must implement the OnNotify callback method, which is called when a notification message is dispatched to *IdObserver* by the DoOnNotify method of another iTool component object (usually the object specified by *IdSubject*). The OnNotify method has the following signature:

```
PRO ::OnNotify, idOriginator, idMessage, message
```

where

- *idOriginator* is the object identifier of the iTool component that is the source of the message
- *idMessage* is a string that identifies the type of message being sent
- *message* is the message itself.

In general, the *idMessage* string is used by the OnNotify method to determine what type of action to take. See "IDLitIMessaging::DoOnNotify" on page 3807 for additional details.

IdSubject

A string value identifying the item that *IdObserver* is interested in. This is normally the object identifier of a particular iTool component object, but it can be any string value. When a message sent via IDLitIMessaging::DoOnNotify specifies *IdSubject* as the originator, the *IdObserver* object's OnNotify method is called.

Keywords

None

Version History

6.0	Introduced

IDLitIMessaging::DoOnNotify

The IDLitIMessaging::DoOnNotifiy procedure method is used to broadcast a notification message to iTool component objects that are observing the source of the message.

See the "IDLitIMessaging::AddOnNotifyObserver" on page 3805, and "IDLitIMessaging::RemoveOnNotifyObserver" on page 3817 methods for more information on notification messages.

See "iTool Messaging System" (Chapter 2, *iTool Developer's Guide*) for a more in-depth discussion of notification.

Syntax

Obj->[IDLitIMessaging::]DoOnNotify, *IdOriginator*, *IdMessage*, *Value*

Arguments

IdOriginator

A string value identifying the item that is the source of the message. Normally, *IdOriginator* is the object identifier of the object that calls this method, but it can be any string value.

IdMessage

A string that will uniquely identify the message being sent. The value of *IdMessage* is determined by the iTool developer; it is used by the OnNotify methods of any observer objects to determine what type of message has been received, and to act accordingly. For example, if a property value has changed, this argument might be set to the string SETPROPERTY.

Value

Any value that is associated with the message being sent. For example, if a SETPROPERTY message was sent, *Value* might contain the name of the property changed. If no value is associated with the message, set this argument to a null string (' ').

Keywords

None

Version History

6.0	Introduced

IDLitIMessaging::ErrorMessage

The IDLitIMessaging::ErrorMessage procedure method is used to display an error message to the user.

The actual method used to display the message to the user depends on the user interface in use. Normally, this method will display a modal dialog.

Syntax

Obj->[IDLitIMessaging::]ErrorMessage, *StrMessage*[, SEVERITY=*integer*]
   [, TITLE=*string*] [, /USE_LAST_ERROR]

Arguments

StrMessage

A scalar string or string array containing a description of the error.

Keywords

SEVERITY

Set this keyword to the severity code to use for this message. The system recognizes the following values:

- 0 = Informational
- 1 = Warning
- 2 = Error

TITLE

Set this keyword to the title that should be displayed as part of the prompt. In most cases, this value is placed in the title bar of the modal dialog.

USE_LAST_ERROR

If this keyword is set, the system will use the information that was part of the last error signaled to the iTool. The last error may have been set either by a previous call to this method or by a call to the IDLitIMessaging::SignalError method.

Version History

6.0	Introduced

IDLitIMessaging::GetTool

The IDLitIMessaging::GetTool function method returns an object reference to the iTool object associated with the object on which it is called.

Syntax

Result = Obj->[IDLitIMessaging::]GetTool()

Return Value

Returns an object reference to the iTool object associated with the object on which the GetTool is called. If the object is not contained by an iTool, this function returns a null object reference.

Arguments

None

Keywords

None

Version History

6.0	Introduced

IDLitIMessaging::ProbeStatusMessage

The IDLitIMessaging::ProbeStatusMessage procedure method is used to display a status message to the user, which is displayed in a data-specific region of the user interface. Unlike other messages that require immediate acknowledgement by the user, a status message is passive and no response is needed.

The actual method used to display the value to the user depends on the user interface in use. In a standard iTool included with IDL, this status message is displayed in the lower right corner of the iTool window.

Syntax

Obj->[IDLitIMessaging::]ProbeStatusMessage, *StrMessage*

Arguments

StrMessage

A scalar string that is displayed in the data-specific status area.

Keywords

None

Version History

6.0	Introduced

IDLitIMessaging::ProgressBar

The IDLitIMessaging::ProgressBar function method is used to display a progress bar to the user and update the displayed values.

On the initial call to this method, a dialog is displayed. The dialog remains active until the method is called with the /SHUTDOWN keyword.

The actual method used to display the message to the user depends on the user interface in use. Normally, the progress bar is displayed as a modal dialog.

Syntax

Result = Obj->[IDLitIMessaging::]ProgressBar(*StrMessage* [, CANCEL=*string*] [, PERCENT=*value*] [, /SHUTDOWN])

Return Value

Returns 1 if the progress bar was displayed successfully, or 0 otherwise.

Arguments

StrMessage

A scalar string or string array containing a description of the action taking place.

Keywords

CANCEL

Set this keyword to a string containing the text for the Cancel button on the Progress Bar. If this keyword is not specified, or is set to a null string, then the string "Cancel" is used.

PERCENT

Set this keyword to a value between 0 and 100 that represents the "percentage complete" value to be shown on the progress bar.

SHUTDOWN

If set, any progress bar that is being displayed is removed from the user interface.

Version History

6.0	Introduced
6.1	Added CANCEL keyword

IDLitIMessaging::PromptUserText

The IDLitIMessaging::PromptUserText function method is used to prompt the iTool user with a question and retrieve a text answer. The text answer is returned to the caller of this method via a supplied IDL variable.

The actual method used to prompt the user depends on the user interface in use. Normally, the prompt is displayed as a modal dialog.

Syntax

Result = Obj->[IDLitIMessaging::]PromptUserText(*StrPrompt*, *Answer*
    [, TITLE=*string*])

Return Value

Returns 1 if the prompt was displayed and the user clicked the **OK** button. If the user clicks the **Cancel** button or dismisses the dialog, the return value is 0.

Arguments

StrPrompt

A scalar string or string array containing a prompt for the user to respond to.

Answer

A named variable that will contain the string value entered by the user.

Keywords

TITLE

Set this keyword to a string representing the title of the prompt. This value is placed in the title bar of the modal dialog.

Version History

6.0	Introduced

IDLitIMessaging::PromptUserYesNo

The IDLitIMessaging::PromptUserYesNo function method is used to prompt the user with a yes or no question and return an answer.

The actual method used to prompt the user depends on the user interface in use. Normally, the prompt is displayed as a modal dialog.

Syntax

Result = Obj->[IDLitIMessaging::]PromptUserYesNo(*StrPrompt*, *Answer*
   [, TITLE=*string*])

Return Value

Returns 1 if the dialog executed properly and returned a value in the variable specified. You must check the value stored in the variable specified as the *Answer* argument to determine which button the user pressed.

Arguments

StrPrompt

A scalar string or string array containing a prompt for the user to respond to.

Answer

A named variable that will contain 1 if the user answered Yes to the prompt and 0 if the user answered No.

Keywords

TITLE

Set this keyword to the title that should be displayed as part of the prompt. In most cases, this value is placed in the title bar of the modal dialog.

Version History

6.0	Introduced

IDLitIMessaging::RemoveOnNotifyObserver

The IDLitIMessaging::RemoveOnNotifyObserver procedure method is used to un-register a specified iTool component object as wishing to receive messages generated by the DoOnNotify method of another specified iTool component object. This method reverses the action of calling the IDLitIMessaging::AddOnNotifyObserver method.

Syntax

Obj->[IDLitIMessaging::]RemoveOnNotifyObserver, *IdObserver*, *IdSubject*

Arguments

IdObserver

The object identifier of an iTool component object that is currently registered as an observer of the component specified by *IdSubject*. Often, this is the object identifier of the object on which method is being called.

IdSubject

The object identifier of the iTool component object that *IdObserver* is currently registered as observing. This is normally the object identifier of a particular iTool component object, but it can be any scalar string.

Keywords

None

Version History

6.0	Introduced

IDLitIMessaging::SignalError

The IDLitIMessaging::SignalError procedure method is used to signal an error in the system. No user interface is displayed to the user, but the error is registered with the system, made the current error, and recorded by the iTool log service (if enabled).

Note ——

If this method is used to signal an error, the IDLitIMessaging::ErrorMessage method can be called with the /USE_LAST_ERROR keyword to use the information set by this method.

——

Syntax

Obj->[IDLitIMessaging::]SignalError, *StrMessage* [, CODE=*integer*]
   [, SEVERITY=*integer*]

Arguments

StrMessage

A scalar string or string array containing a description of the error.

Keywords

CODE

Set this keyword to an integer that represents an error code that can be associated with the error. Error codes can be any integer value specified by the iTool developer.

SEVERITY

Set this keyword to the severity code to use for this message. The system recognizes the following values:

- 0 = Informational
- 1 = Warning
- 2 = Error

Version History

6.0	Introduced

IDLitIMessaging::StatusMessage

The IDLitIMessaging::StatusMessage procedure method is used to display a status message to the user. Unlike other messages that require immediate acknowledgement by the user, a status message is passive and no response is needed.

The actual method used to display the value to the user depends on the user interface in use. In a standard iTool included with IDL, this status message is displayed in the lower left corner of the iTool window.

Syntax

Obj->[IDLitIMessaging::]StatusMessage, *StrMessage*
    [, SEGMENT_IDENTIFIER=*string*]

Arguments

StrMessage

A scalar string that is displayed as a status message to the user.

Keywords

SEGMENT_IDENTIFIER

Set this keyword to a string containing the relative identifier of the status bar segment in which the message is to be displayed. By default, iTools have two status bar segments, a described in "Status Messages" (Chapter 12, *iTool Developer's Guide*). By default, the StatusMessage method changes the value of the Status segment; that segment's identifier is 'MESSAGE'.

To change the value of the Probe Status segment, use the segment identifier 'PROBE'. Alternately, you can use the IDLitIMessaging::ProbeStatusMessage method.

Version History

6.0	Introduced
6.1	Added SEGMENT_IDENTIFIER keyword

IDLitManipulator

The IDLitManipulator class provides the base functionality of the iTools manipulator system. Most automation and functional capabilities of the manipulator system are provided by this class. Tasks performed by this class include:

- Selection operations and associated selection state management.
- Automated mouse cursor management (changing the cursor as the mouse traverses different items in the current visualization).
- System event settings management.
- Coordination between the manipulator and manipulator visualization system.

This class is written in the IDL language. Its source code can be found in the file `idlitmanipulator__define.pro` in the `lib/itools/framework` subdirectory of the IDL distribution.

Note
See Chapter 8, "Creating a Manipulator" (*iTool Developer's Guide*) for information on creating a custom manipulator.

Superclasses

IDLitComponent

IDLitIMessaging

Note
See the "iTools Object Model Diagram" (Chapter 2, *iTool Developer's Guide*) for a visual representation of the iTools object model hierarchy.

Creation

See "IDLitManipulator::Init" on page 3836.

Properties

Objects of this class have the following properties. See "IDLitManipulator Properties" on page 3824 for details on individual properties.

- BUTTON_EVENTS

- DEFAULT_CURSOR
- DESCRIPTION
- DISABLE
- KEYBOARD_EVENTS
- MOTION_EVENTS
- OPERATION_IDENTIFIER
- PARAMETER_IDENTIFIER
- TRANSIENT_DEFAULT
- TRANSIENT_MOTION
- TYPES
- VIEWS_ONLY
- VISUAL_TYPE

In addition, objects of this class inherit the properties of the superclass of this class.

Methods

This class has the following methods:

- IDLitManipulator::Cleanup
- IDLitManipulator::CommitUndoValues
- IDLitManipulator::GetCursorType
- IDLitManipulator::GetProperty
- IDLitManipulator::Init
- IDLitManipulator::OnKeyboard
- IDLitManipulator::OnLoseCurrentManipulator
- IDLitManipulator::OnMouseDown
- IDLitManipulator::OnMouseMotion
- IDLitManipulator::OnMouseUp
- IDLitManipulator::OnWheel
- IDLitManipulator::RecordUndoValues
- IDLitManipulator::RegisterCursor

- • IDLitManipulator::SetCurrentManipulator
- • IDLitManipulator::SetProperty

In addition, this class inherits the methods of its superclass.

Examples

See Chapter 8, "Creating a Manipulator" (*iTool Developer's Guide*) for examples.

Version History

6.0	Introduced
6.4	Added OnWheel method

IDLitManipulator Properties

IDLitManipulator objects have the following properties in addition to properties inherited from any superclasses. Properties with the word "Yes" in the "Get" column of the property table can be retrieved via IDLitManipulator::GetProperty. Properties with the word "Yes" in the "Init" column of the property table can be set via IDLitManipulator::Init. Properties with the word "Yes" in the "Set" column in the property table can be set via IDLitManipulator::SetProperty.

Note ———
For a discussion of the property description tables shown below, see "About Object Property Descriptions" on page 3135.
———

Objects of this class have the following properties.

- BUTTON_EVENTS
- DEFAULT_CURSOR
- DESCRIPTION
- DISABLE
- KEYBOARD_EVENTS
- MOTION_EVENTS
- OPERATION_IDENTIFIER
- PARAMETER_IDENTIFIER
- TRANSIENT_DEFAULT
- TRANSIENT_MOTION
- TYPES
- VIEWS_ONLY
- VISUAL_TYPE

In addition, objects of this class inherit:

- IDLitComponent
- IDLitIMessaging

BUTTON_EVENTS

A boolean value controlling whether mouse button events are generated. If set, mouse button up and button down events will be dispatched to this manipulator. These events are enabled by default.

Property Type	Boolean		
Name String	*not displayed*		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** No

DEFAULT_CURSOR

A string containing the name of the default cursor for the manipulator. This is the name of the cursor that is displayed if no items are hit during mouse cursor motion. The default manipulator cursor is set to 'ARROW'. Allowable values are:

- ARROW
- CROSSHAIR
- ICON
- IBEAM
- MOVE
- ORIGINAL
- SIZE_NE
- SIZE_NW
- SIZE_SE
- SIZE_SW
- SIZE_NS
- SIZE_EW
- UP_ARROW

Property Type	String		
Name String	*not displayed*		
Get: No	**Set:** Yes	**Init:** Yes	**Registered:** No

Note ──

Set a pre-defined default cursor using the Init or SetProperty method. Set a custom cursor as the default cursor using the IDLitManipulator::RegisterCursor method's DEFAULT keyword.

──

DESCRIPTION

A string representing the full name or description of this object.

Property Type	STRING		
Name String	Description		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** Yes

DISABLE

A boolean value indicating that the manipulator should be disabled. Disabling a manipulator prevents it from being chosen by a user or by the iTool system. The default value is 0b (false).

Property Type	Boolean		
Name String	*not displayed*		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** No

KEYBOARD_EVENTS

A boolean value controlling whether keyboard events are generated. If set, keyboard events will be dispatched to the manipulator. These events are enabled by default.

Property Type	Boolean		
Name String	*not displayed*		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** No

MOTION_EVENTS

A boolean value controlling whether motion events are generated. If set, motion events will be dispatched to this manipulator. These events are enabled by default.

Property Type	Boolean		
Name String	*not displayed*		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** No

OPERATION_IDENTIFIER

A string identifier for the operation that is associated with the manipulator. This identifier specifies the operation that is used by the undo-redo system to transact the actions performed by this manipulator. If not specified, the manipulator actions are not recorded by the undo-redo system.

Property Type	String		
Name String	*not displayed*		
Get: Yes	Set: Yes	Init: Yes	Registered: No

Note
See "Manipulators and the Undo/Redo System" (Chapter 8, *iTool Developer's Guide*) for information on configuring a custom manipulator to support undo/redo operations.

PARAMETER_IDENTIFIER

A string identifier specifying which parameter the operation should query when transacting the manipulator. If specified, this identifier is used in conjunction with the operation specified by the OPERATION_IDENTIFIER property to transact the operations performed by a manipulator. The parameter is primarily used to specify the property identifier for manipulators that change the values of properties.

Property Type	String		
Name String	*not displayed*		
Get: Yes	Set: Yes	Init: Yes	Registered: No

Note
See "Retrieving Property Information" (Appendix A, *iTool Developer's Guide*) for more information about property identifiers and names. See "Manipulators and the Undo/Redo System" (Chapter 8, *iTool Developer's Guide*) for information on configuring a custom manipulator to support undo/redo operations.

TRANSIENT_DEFAULT

An integer value used to indicate that the manipulator is *transient*, which causes the system to automatically switch to the default manipulator when this manipulator's

mouse actions are complete (that is, when the OnMouseUp method has been called) or when an end-of-keyboard-entry character (carriage return or escape key) is detected. The default value is 0.

This property can be set to any of the following values:

- 0 = No transient behavior

- 1 = Mouse transient behavior is enabled. When a mouse button up is detected, the manipulation system will switch to the default manipulator for the system

- 2 = Keyboard transient behavior is enabled. When a carriage return or escape key is pressed, the system will switch to the default manipulator for the system

- 3 = Both keyboard and mouse transient behavior are enabled

Property Type	Enumerated List		
Name String	*not displayed*		
Get: Yes	Set: Yes	Init: Yes	Registered: No

TRANSIENT_MOTION

A boolean value controlling whether transient motion events are generated. If set, the manipulator will generate motion events beginning when the OnMouseDown method is called and ending when the OnMouseUp method is called. The default value is 0b (false).

Property Type	Boolean		
Name String	*not displayed*		
Get: Yes	Set: Yes	Init: Yes	Registered: No

TYPES

A string array specifying the visualization types that this manipulator can operate on. If not specified, the manipulator will support all registered visualization types.

Allowable TYPES values are those returned by the IDLitVisualization::GetTypes method.

Property Type	Vector		
Name String	*not displayed*		
Get: Yes	Set: No	Init: Yes	Registered: No

VIEWS_ONLY

A boolean value controlling the content of the manipulator hierarchy. If set, the manipulator will only operate on views in the manipulator hierarchy. The default value is 0b (false).

Property Type	Boolean		
Name String	*not displayed*		
Get: No	Set: No	Init: Yes	Registered: No

VISUAL_TYPE

A string representing the type of selection visual to use with this manipulator. The VISUAL_TYPE property should match the corresponding property of an IDLitManipulatorVisual object. This high-level abstraction allows similar selection visuals to be assigned across multiple manipulators. The default value is an empty string.

Property Type	String		
Name String	*not displayed*		
Get: Yes	Set: Yes	Init: Yes	Registered: No

IDLitManipulator::Cleanup

The IDLitManipulator::Cleanup procedure method performs all cleanup on the object.

Note ───

Cleanup methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation and destruction. This means that in most cases, you cannot call the Cleanup method directly. There is one exception to this rule: if you write your own subclass of this class, you can call the Cleanup method from within the Init or Cleanup method of the subclass.

───

Syntax

OBJ_DESTROY, *Obj*

or

Obj->[IDLitManipulator::]Cleanup()   *(In a lifecycle method only.)*

Arguments

None

Keywords

None

Version History

6.0	Introduced

IDLitManipulator::CommitUndoValues

The IDLitManipulator::CommitUndoValues function method is used to complete a transaction that is occurring as a result of the manipulator interaction. This method works in conjunction with the RecordUndoValues method.

When a manipulator interaction is complete, the manipulator should call this method, which in turn calls the RecordFinalValues method of the operation associated with the manipulator. The RecordFinalValues method records any information needed to undo the operation and places the information in the iTool's undo-redo transaction buffer.

For interactive manipulators, the CommitUndoValues method should be called by the OnMouseUp method.

Note

This method must be called on the current manipulator before being called on a superclass to ensure that the current selection state maintained by the manipulator is valid.

Syntax

Result = Obj->[IDLitManipulator::]CommitUndoValues([/UNCOMMIT])

Return Value

Returns 1 if the commit was successful, or 0 otherwise.

Arguments

None

Keywords

UNCOMMIT

Set this keyword to discard any pending information from a previous call to RecordUndoValues. The interaction is not recorded in the iTool's undo-redo transaction buffer.

Version History

6.0	Introduced

IDLitManipulator::GetCursorType

The IDLitManipulator::GetCursorType function method retrieves the name of the cursor to display for the manipulator. The name of the cursor can be used with the SetCurrentCursor method of the IDLitWindow component.

The system will use this method to automatically change the cursor when the mouse traverses the contents of a visualization window. As the mouse transverses the window, the name for the hit item that is part of the current selection group is retrieved and passed to this routine. This action gives the manipulator the ability to change cursors depending on the area of the visualization the cursor is over.

Syntax

Result = Obj->[IDLitManipulator::]GetCursorType(*TypeIn, KeyMods*)

Return Value

Returns a string containing the name of the cursor. If nothing is matched, an empty string is returned.

Note

This name is defined during cursor registration using the IDLitManipulator::RegisterCursor method.

Arguments

TypeIn

A string variable containing the name of the portion of the selection visual for which the cursor is being requested.

KeyMods

An integer representing the keyboard modifiers for the button. These can have one of the following values

1 = SHIFT Key

2 = CTRL Key

4 = CAPS LOCK key

8 = ALT key

Keywords

None

Version History

6.0	Introduced

IDLitManipulator::GetProperty

The IDLitManipulator::GetProperty procedure method retrieves the value of an IDLitManipulator property, and should be called by the subclass's GetProperty method. This method also retrieves properties defined in the superclass.

Syntax

Obj->[IDLitManipulator::]GetProperty[, *PROPERTY=variable*]

Arguments

None

Keywords

Any property listed under "IDLitManipulator Properties" on page 3824 that contains the word "Yes" in the "Get" column of the properties table can be retrieved using this method. To retrieve the value of a property, specify the property name as a keyword set equal to a named variable that will contain the value of the property.

Version History

6.0	Introduced

IDLitManipulator::Init

The IDLitManipulator::Init function method initializes the IDLitManipulator object, and should be called by the subclass's Init method. This method also calls the superclass's Init method.

Note ───

Init methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation. This means that in most cases, you cannot call the Init method directly. There is one exception to this rule: if you write your own subclass of this class, you can call the Init method from within the Init method of the subclass.

───

Syntax

Obj = OBJ_NEW('IDLitManipulator'[, *PROPERTY=value*])

or

Result = Obj->[IDLitManipulator::]Init([, *PROPERTY=value*])   *(In a lifecycle method only.)*

Return Value

When this method is called indirectly, as part of the call to the OBJ_NEW function, the return value is an object reference to the newly-created object.

When called directly within a subclass Init method, the return value is 1 if initialization was successful, or zero otherwise.

Arguments

None

Keywords

Any property listed under "IDLitManipulator Properties" on page 3824 that contains the word "Yes" in the "Init" column of the properties table can be initialized during object creation using this method. To initialize the value of a property, specify the property name as a keyword set equal to the appropriate property value.

Version History

6.0	Introduced

IDLitManipulator::OnKeyboard

The IDLitManipulator::OnKeyboard procedure method is used when a keyboard event occurs on the target IDLitWindow.

Syntax

Obj->[IDLitManipulator::]OnKeyboard, *Win*, *IsASCII*, *Character*, *KeyValue*, *X*, *Y*, *Press*, *Release*, *KeyMods*

Arguments

Win

An object reference for the IDLitWindow from which the event came.

IsASCII

A Boolean value to determine if the character is in the ASCII character set. This value is True if the character is in the ASCII character set.

KeyValue

The numeric value representing the key pressed if the key is non-ASCII. The possible numeric values are:

- 1 = Shift
- 2 = Control
- 3 = Caps Lock
- 4 = Alt
- 5 = Left
- 6 = Right
- 7 = Up
- 8 = Down
- 9 = Page Up
- 10 = Page Down
- 11 = Home
- 12 = End

Character

A string containing the ASCII character of the key pressed.

X

A floating-point value representing the *x*-coordinate in the window's coordinates.

Y

A floating-point value representing the *y*-coordinate in the window's coordinates.

Press

A Boolean value to determine if the current event is a key press. This value is True if the event is pressing the key

Release

A Boolean value to determine if the current event is a key release. This value is True if event is releasing the key

KeyMods

An integer representing the keyboard modifiers for the button. These can have one of the following values:

- 1 = SHIFT key
- 2 = CTRL key
- 4 = CAPS LOCK key
- 8 = ALT key

Keywords

None

Version History

6.0	Introduced

IDLitManipulator::OnLoseCurrentManipulator

The IDLitManipulator::OnLoseCurrentManipulator procedure method is used when this manipulator is no longer the current manipulator in the system.

Note ───

This method is designed to be implemented by a subclass of IDLitManipulator, to perform any cleanup work necessary when a new manipulator is selected.

───

Syntax

Obj->[IDLitManipulator::]OnLoseCurrentManipulator

Arguments

None

Keywords

None

Version History

6.0	Introduced

IDLitManipulator::OnMouseDown

The IDLitManipulator::OnMouseDown procedure method is used when a mouse down event occurs on the target IDLitWindow. When applied, this method will perform a select operation on the current contents of the target IDLitWindow.

When overriding this method in a sub-class, this method is normally the first task performed so that the instance data of the object is properly setup.

If the manipulator is in the middle of a mouse-down, mouse-up transaction, the following instance data will be valid:

- ButtonPress — Set to the mouse buttons pressed.
- nSelectionList — The number of items selected.
- pSelectionList — A pointer to the objects current selected in the iTool.

These values can be helpful in performing actions in the manipulator and are automatically managed. See "Using Manipulator Public Instance Data" (Chapter 8, *iTool Developer's Guide*) for more information.

Syntax

Obj->[IDLitManipulator::]OnMouseDown, *Win*, *X*, *Y*, *IButton*, *KeyMods*, *NClicks*

Arguments

Win

An object reference for the IDLitWindow from which the event came.

X

A floating-point value representing the *x*-coordinate in the window's coordinates.

Y

A floating-point value representing the *y*-coordinate in the window's coordinates.

IButton

An integer value representing the mask for the button pressed:

- 1 = Left
- 2 = Middle
- 4 = Right

KeyMods

An integer representing the keyboard modifiers for the button. These can have one of the following values:

- 1 = SHIFT key

- 2 = CTRL key

- 4 = CAPS LOCK key

- 8 = ALT key

NClicks

An integer value representing number of clicks

Keywords

None

Version History

6.0	Introduced

IDLitManipulator::OnMouseMotion

The IDLitManipulator::OnMouseMotion procedure method implements the OnMouseMotion method. If no mouse button is down, this method manages the setting of the cursor on the IDLitWindow object.

If the manipulator is in the middle of a mouse-down, mouse-up transaction, the following instance data will be valid:

- ButtonPress — Set to the mouse buttons pressed.

- nSelectionList — The number of items selected.

- pSelectionList — A pointer to the objects current selected in the iTool.

These values can be helpful in performing actions in the manipulator and are automatically managed. See "Using Manipulator Public Instance Data" (Chapter 8, *iTool Developer's Guide*) for more information.

Syntax

Obj->[IDLitManipulator::]OnMouseMotion, *Win*, *X*, *Y*, *KeyMods*

Arguments

Win

An object reference for the IDLitWindow object from which the event came.

X

A floating-point value representing the *x*-coordinate in the window's coordinates.

Y

A floating-point value representing the *y*-coordinate in the window's coordinates.

KeyMods

An integer representing the keyboard modifiers for the button. These can have one of the following values:

- 1 = SHIFT key
- 2 = CTRL key
- 4 = CAPS LOCK key
- 8 = ALT key

Keywords

None

Version History

6.0	Introduced

IDLitManipulator::OnMouseUp

The IDLitManipulator::OnMouseUp procedure method is used when a mouse up event occurs on the target IDLitWindow object.

When overriding this method in a sub-class, this method is normally the last task performed so that the instance data of the object is properly setup.

Syntax

Obj->[IDLitManipulator::]OnMouseUp, *Win*, *X*, *Y*, *IButton*

Arguments

Win

An object reference for the IDLitWindow object from which the event came.

X

A floating-point value representing the *x*-coordinate in the window's coordinates.

Y

A floating-point value representing the *y*-coordinate in the window's coordinates.

IButton

An integer value representing the mask for the button pressed:

- 1 = Left
- 2 = Middle
- 4 = Right

Keywords

None

Version History

6.0	Introduced

IDLitManipulator::OnWheel

The IDLitManipulator::OnWheel procedure method handles notification (from the native window device) that a mouse wheel event has occurred.

Note ──

This method is only useful in conjunction with the Export Bridge. The method is only a stub and provides no functionality. In your subclass of IDLitManipulator, you should override this method to provide your own functionality. Your method will be automatically called by the Export Bridge. For more information, see "Exporting Drawable Objects" (Chapter 11, *IDL Connectivity Bridges*).

───

Syntax

Obj->[IDLitManipulator::]OnWheel, *Win*, *X*, *Y*, *Delta*, *Modifiers*

Arguments

Win

An object reference for the IDLitWindow object from which the event came.

X

A long integer representing the *x*-location (in device coordinates) of the mouse event.

Y

A long integer representing the *y*-location (in device coordinates) of the mouse event.

Delta

A long integer giving the direction and distance that the wheel was rolled. Pushing the wheel towards the front of the mouse generates positive values, pulling the wheel towards the back of the mouse generates negative values. The magnitude of the value depends on the device setting for the individual mouse.

Modifiers

A long integer containing a bitwise mask indicating which modifier keys are active at the time of the wheel event. If a bit is zero, the key is up; if the bit is set, the key is pressed. The following table describes the bits in this bit mask:

Bit	Value	Modifier Key
0	1	Shift
1	2	Control
2	4	Caps Lock
3	8	Alt

Table 31-7: Modifier Values

Keywords

None

Version History

6.4	Introduced

IDLitManipulator::RecordUndoValues

The IDLitManipulator::RecordUndoValues function method is used to begin recording the transaction that is occurring as a result of the manipulator interaction. This method works in conjunction with the CommitUndoValues method.

To capture information for the undo-redo system of the tools framework, the initial and final values for the items that the manipulator will adjust must be recorded. This recording process is accomplished with the RecordUndoValues and CommitUndoValues methods.

These two methods make use of the operation that is associated with this manipulator (specified by the OPERATION_IDENTIFIER keyword to the Init method) to capture the needed information. When the RecordUndoValues method is called, the manipulator will retrieve the operation associated with this manipulator and call the RecordInitialValues method on this operation. The RecordInitialValues method is called with a command set, the list of currently selected items (which the manipulator is operating on) and the value that was provided by the PARAMETER_IDENTIFIER keyword to this manipulator. This method will record any information needed to undo the operation and place the values in the provided command set. See IDLitOperation for more information on operations.

For interactive manipulators, the RecordUndoValues method is called as part of the OnMouseDown method.

Syntax

Result = Obj->[IDLitManipulator::]RecordUndoValues()

Return Value

Returns a 1 if recording was successful, or 0 otherwise.

Arguments

None

Keywords

None

Version History

6.0	Introduced

IDLitManipulator::RegisterCursor

The IDLitManipulator::RegisterCursor procedure method defines the appearance and name of a cursor associated with the manipulator.

Syntax

Obj->[IDLitManipulator::]RegisterCursor, *ArrCursor*, *Name* [, /DEFAULT]

Return Value

None

Arguments

ArrCursor

This must be a 16 element string array of 16 characters each that represents a window cursor. The array can consist of the "#" character, space and non-space characters, and optionally, a "$" character as follows:

- The "#" characters define the black outline of the cursor.
- Any non-space characters define the shape of the white mask. Adding a mask ensures the cursor's visibility in light and dark areas of a visualization.
- The "$" defines a hot spot.

See CREATE_CURSOR for more information on the structure of the cursor array.

Name

A string value identifying the cursor.

Note
This name should be returned by the IDLitManipulator::GetCursorType function method for your manipulator.

Keywords

DEFAULT

Set this keyword to specify this cursor as the default cursor for the manipulator. If no cursor is specified as the default cursor, then the standard arrow is used.

Note

This will be the cursor used if the GetCursorType method returns a null string.

Example

The RegisterCursor method is typically called within the scope of a manipulator's
initialization so that the cursor appears when the manipulator (`my_manip`) is
activated. The following code defines the appearance of the manipulator cursor and
sets it as the default.

```
; Define the default cursor for this manipulation.
strArray = [ $
    '                ', $
    '                ', $
    '                ', $
    '                ', $
    '                ', $
    '   .#.      .#.  ', $
    '  .#.........#.  ', $
    '.#############.', $
    '###....$.....###', $
    '.#############.', $
    '  .#.........#.  ', $
    '   .#.      .#.  ', $
    '                ', $
    '                ', $
    '                ', $
    '                ']

; Register the new cursor with the manipulator.
my_manip->RegisterCursor, strArray, 'SCROLL', /DEFAULT
```

Version History

6.1	Introduced

IDLitManipulator::SetCurrentManipulator

The IDLitManipulator::SetCurrentManipulator procedure method sets the manipulator as the current manipulator in the system.

Syntax

Obj->[IDLitManipulator::]SetCurrentManipulator [, *Item*]

Arguments

Item

If this method is being called on a manipulator container object, *Item* can optionally be set to a string containing the relative object ID of the manipulator that should be set as the current manipulator. If *Item* is not supplied, the manipulator on which the method is called is set as the current manipulator.

Keyword

None

Version History

6.0	Introduced

IDLitManipulator::SetProperty

The IDLitManipulator::SetProperty procedure method sets the value of an
IDLitManipulator property, and should be called by the subclass's SetProperty
method. This method also calls the superclass's SetProperty method.

Syntax

Obj->[IDLitManipulator::]SetProperty[, *PROPERTY=value*]

Arguments

None

Keywords

Any property listed under "IDLitManipulator Properties" on page 3824 that contains
the word "Yes" in the "Set" column of the properties table can be set using this
method. To set the value of a property, specify the property name as a keyword set
equal to the appropriate property value.

Version History

6.0	Introduced

IDLitManipulatorContainer

The IDLitManipulatorContainer class allows for the construction of manipulator hierarchies. Building on the functionality provided by the IDLitManipulator class, the manipulator container implements the concept of a *current manipulator* for the items it contains.

This class is written in the IDL language. Its source code can be found in the file `idlitmanipulatorcontainer__define.pro` in the `lib/itools/framework` subdirectory of the IDL distribution.

Superclasses

IDLitContainer

Note ───
See the "iTools Object Model Diagram" (Chapter 2, *iTool Developer's Guide*) for a visual representation of the iTools object model hierarchy.
───

Creation

See "IDLitManipulatorContainer::Init" on page 3861.

Properties

Objects of this class have the following properties. See "IDLitManipulatorContainer Properties" on page 3856 for details on individual properties.

- AUTO_SWITCH

In addition, objects of this class inherit the properties of all superclasses of this class.

Methods

This class has the following methods:

- IDLitManipulatorContainer::Add
- IDLitManipulatorContainer::GetCurrent
- IDLitManipulatorContainer::GetCurrentManipulator
- IDLitManipulatorContainer::GetProperty

- IDLitManipulatorContainer::Init
- IDLitManipulatorContainer::OnKeyboard
- IDLitManipulatorContainer::OnMouseDown
- IDLitManipulatorContainer::OnMouseMotion
- IDLitManipulatorContainer::OnMouseUp
- IDLitManipulatorContainer::OnWheel
- IDLitManipulatorContainer::SetCurrent
- IDLitManipulatorContainer::SetCurrentManipulator
- IDLitManipulatorContainer::SetProperty

In addition, this class inherits the methods of its superclasses.

Version History

6.0	Introduced
6.4	Added OnWheel method

IDLitManipulatorContainer Properties

IDLitManipulatorContainer objects have the following properties in addition to properties inherited from any superclasses. Properties with the word "Yes" in the "Get" column of the table are retrieved via IDLitManipulatorContainer::GetProperty. Properties with the word "Yes" in the "Init" column of the property table are set via IDLitManipulatorContainer::Init. Properties with the word "Yes" in the "Set" column in the property table are set via IDLitManipulatorContainer::SetProperty.

Note
For a discussion of the property description tables shown below, see "About Object Property Descriptions" on page 3135.

Objects of this class have the following properties.

- AUTO_SWITCH

In addition, objects of this class inherit:

- IDLitContainer

AUTO_SWITCH

A boolean that, if set, causes the manipulator container to automatically change the value of its current child manipulator depending on the portion of the selection visual hit during a mouse down operation. This is performed by matching the name of the portion of the selection visual hit during the mouse down operation and the name of the sub-manipulators of this container.

Property Type	Boolean		
Name String	*not displayed*		
Get: No	**Set:** No	**Init:** Yes	**Registered:** No

IDLitManipulatorContainer::Add

The IDLitManipulatorContainer::Add procedure method is used to add a new manipulator to the container.

Syntax

Obj->[IDLitManipulatorContainer::]Add, *Manipulator*

Arguments

Manipulator

The new manipulator to add to this manipulator container. When completed, this manipulator is also set to the current manipulator for this manipulator container.

Keywords

All keywords are passed to the IDLitContainer superclass during the add operation.

Version History

6.0	Introduced

IDLitManipulatorContainer::GetCurrent

The IDLitManipulatorContainer::GetCurrent function method is used to get the object reference of the current manipulator of the container.

Syntax

Result = Obj->[IDLitManipulatorContainer::]GetCurrent()

Return Value

Returns an object reference to the current manipulator for this container or a null object reference if no manipulators are contained by the container.

Arguments

None

Keywords

None

Version History

6.0	Introduced

IDLitManipulatorContainer::GetCurrentManipulator

The IDLitManipulatorContainer::GetCurrentManipulator function method is used to get the current manipulator of the system. When applied, this function method causes a traversal of the manipulator hierarchy, returning the current leaf manipulator of the system.

Syntax

Result =
   Obj->[IDLitManipulatorContainer::]GetCurrentManipulator([, /IDENTIFIER])

Return Value

Returns an object reference to the current manipulator in the system. If the IDENTIFIER keyword is set, the routine will return the identifier for the current manipulator.

Arguments

None

Keywords

IDENTIFIER

If set, the identifier of the current manipulator is returned. If not set, the current manipulator itself is returned.

Version History

6.0	Introduced

IDLitManipulatorContainer::GetProperty

The IDLitManipulatorContainer::GetProperty procedure method retrieves the value of an IDLitManipulatorContainer property, and should be called by the subclass's GetProperty method. This method also retrieves properties defined in the superclass.

Syntax

Obj->[IDLitManipulatorContainer::]GetProperty[, *PROPERTY=variable*]

Arguments

None

Keywords

Any property listed under "IDLitManipulatorContainer Properties" on page 3856 that contains the word "Yes" in the "Get" column of the properties table can be retrieved using this method. To retrieve the value of a property, specify the property name as a keyword set equal to a named variable that will contain the value of the property.

Version History

6.0	Introduced

IDLitManipulatorContainer::Init

The IDLitManipulatorContainer::Init function method initializes the IDLitManipulatorContainer object, and should be called by the subclass's Init method. This method also calls the superclass's Init method.

Note ───────────────────────────────────────

Init methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation. This means that in most cases, you cannot call the Init method directly. There is one exception to this rule: if you write your own subclass of this class, you can call the Init method from within the Init method of the subclass.

───

Syntax

Obj = OBJ_NEW('IDLitManipulatorContainer'[, *PROPERTY=value*])

or

Result = Obj->[IDLitManipulatorContainer::]Init([, *PROPERTY=value*])   *(In a lifecycle method only.)*

Return Value

When this method is called indirectly, as part of the call to the OBJ_NEW function, the return value is an object reference to the newly-created object.

When called directly within a subclass Init method, the return value is 1 if initialization was successful, or zero otherwise.

Arguments

None

Keywords

Any property listed under "IDLitManipulatorContainer Properties" on page 3856 that contains the word "Yes" in the "Init" column of the properties table can be initialized during object creation using this method. To initialize the value of a property, specify the property name as a keyword set equal to the appropriate property value.

Version History

6.0	Introduced

IDLitManipulatorContainer::OnKeyboard

The IDLitManipulatorContainer::OnKeyboard procedure method is used when a keyboard event occurs on the target IDLitWindow object. If the current child manipulator supports keyboard events, the OnKeyboard method for that manipulator is called.

Syntax

Obj->[IDLitManipulatorContainer::]OnKeyboard, *Win*, *IsASCII*, *Character*, *Key Value, X*, Y, *Press*, *Release*, *KeyMods*

Arguments

Win

An object reference for the IDLitWindow object from which the event came.

IsASCII

A Boolean value to determine if the character is in the ASCII character set. This value is True if the character is in the ASCII character set.

KeyValue

The numeric value representing a non-ASCII key pressed. The possible values are:

- 1 = Shift
- 2 = Control
- 3 = Caps Lock
- 4 = Alt
- 5 = Left
- 6 = Right
- 7 = Up
- 8 = Down
- 9 = Page Up
- 10 = Page Down
- 11 = Home
- 12 = End

Character

A string containing the ASCII character of the key pressed

X

A floating-point value representing the *x*-coordinate in the window's coordinates.

Y

A floating-point value representing the *y*-coordinate in the window's coordinates.

Press

A Boolean value to determine if the current event is a key press. This value is True if the event is pressing the key

Release

A Boolean value to determine if the current event is a key release. This value is True if event is releasing the key

KeyMods

An integer representing the keyboard modifiers for the button. These can have one of the following values:

- 1 = SHIFT key
- 2 = CTRL key
- 4 = CAPS LOCK key
- 8 = ALT key

Keywords

None

Version History

6.0	Introduced

IDLitManipulatorContainer::OnMouseDown

The IDLitManipulatorContainer::OnMouseDown procedure method is used when a mouse down event occurs on the target IDLitWindow object. When applied and auto-switch mode is enabled in the container, the current child manipulator will be determined by matching the type of the visualization hit with the identifier of the sub-manipulators contained in this container. If no match is made, the default child manipulator is selected. Once complete, normal processing continues.

If the current sub-manipulator supports mouse button events, its OnMouseDown method is called.

Syntax

Obj->[IDLitManipulatorContainer::]OnMouseDown, *Win*, *X*, *Y*, *IButton*, *KeyMods*, *NClicks*

Arguments

Win

An object reference for the IDLitWindow object from which the event came.

X

A floating-point value representing the *x*-coordinate in the window's coordinates.

Y

A floating-point value representing the *y*-coordinate in the window's coordinates.

IButton

An integer value representing the mask for the button pressed:

- 1 = Left
- 2 = Middle
- 4 = Right

KeyMods

An integer representing the keyboard modifiers for the button. These can have one of the following values:

- 1 = SHIFT key
- 2 = CTRL key
- 4 = CAPS LOCK key
- 8 = ALT key

NClicks

An integer value representing number of clicks

Keywords

None

Version History

6.0	Introduced

IDLitManipulatorContainer::OnMouseMotion

The IDLitManipulatorContainer::OnMouseMotion procedure method implements the OnMouseMotion method. If no mouse button is down and auto-switch mode is enabled, this method manages the setting of the cursor on the IDLitWindow object. Otherwise if the current sub-manipulator supports motion events, its OnMouseMotion method is called.

Syntax

Obj->[IDLitManipulatorContainer::]OnMouseMotion, *Win*, *X*, *Y*, *KeyMods*

Arguments

Win

An object reference for the IDLitWindow object from which the event came.

X

A floating-point value representing the *x*-coordinate in the window's coordinates.

Y

A floating-point value representing the *y*-coordinate in the window's coordinates.

KeyMods

An integer representing the keyboard modifiers for the button. These can have one of the following values:

- 1 = SHIFT key
- 2 = CTRL key
- 4 = CAPS LOCK key
- 8 = ALT key

Keywords

None

Version History

6.0	Introduced

IDLitManipulatorContainer::OnMouseUp

The IDLitManipulatorContainer::OnMouseUp procedure method is used when a mouse up event occurs on the target IDLitWindow object. When applied, the container will call the OnMouseUp method of the current child manipulator if that manipulator supports button events.

Syntax

Obj->[IDLitManipulatorContainer::]OnMouseUp, *Win*, *X*, *Y*, *IButton*

Arguments

Win

An object reference for the IDLitWindow object from which the event came.

X

A floating-point value representing the *x*-coordinate in the window's coordinates.

Y

A floating-point value representing the *y*-coordinate in the window's coordinates.

IButton

An integer value representing the mask for the button pressed:

- 1 = Left
- 2 = Middle
- 4 = Right

Keywords

None

Version History

6.0	Introduced

IDLitManipulatorContainer::OnWheel

The IDLitManipulatorContainer::OnWheel procedure method handles notification (from the native window device) that a mouse wheel event has occurred.

Note ——————————————————————————————

This method is only useful in conjunction with the Export Bridge. The method is only a stub and provides no functionality. In your subclass of IDLitManipulatorContainer, you should override this method to provide your own functionality. Your method will be automatically called by the Export Bridge. For more information, see "Exporting Drawable Objects" (Chapter 11, *IDL Connectivity Bridges*).

Syntax

Obj->[IDLitManipulatorContainer::]OnWheel, *Win*, *X*, *Y*, *Delta*, *Modifiers*

Arguments

Win

An object reference for the IDLitWindow object from which the event came.

X

A long integer representing the *x*-location (in device coordinates) of the mouse event.

Y

A long integer representing the *y*-location (in device coordinates) of the mouse event.

Delta

A long integer giving the direction and distance that the wheel was rolled. Pushing the wheel towards the front of the mouse generates positive values, pulling the wheel towards the back of the mouse generates negative values. The magnitude of the value depends on the device setting for the individual mouse.

Modifiers

A long integer containing a bitwise mask indicating which modifier keys are active at the time of the wheel event. If a bit is zero, the key is up; if the bit is set, the key is pressed. The following table describes the bits in this bit mask:

Bit	Value	Modifier Key
0	1	Shift
1	2	Control
2	4	Caps Lock
3	8	Alt

Table 31-8: Modifier Values

IDLitManipulatorContainer::SetCurrent

The IDLitManipulatorContainer::SetCurrent procedure method is used to set a manipulator within the container to be the current manipulator.

Syntax

Obj->[IDLitManipulatorContainer::]SetCurrent, *Manipulator*

Arguments

Manipulator

The object reference of the manipulator to be set as current in the manipulator container. This manipulator must be contained in the container or an error is thrown.

Keywords

None

Version History

6.0	Introduced

IDLitManipulatorContainer::SetCurrentManipulator

The IDLitManipulatorContainer::SetCurrentManipulator procedure method is used to set the current child manipulator in a manipulator hierarchy. When applied, the manipulator will use the provided identifier to call the SetCurrentManipulator on the target child manipulator. If the provided identifier is null, the default manipulator is set as current.

Syntax

Obj->[IDLitManipulatorContainer::]SetCurrentManipulator, *Identifier*

Arguments

Identifier

Either the identifier for the manipulator that is to be made current in the system or its object reference.

Keywords

None

Version History

6.0	Introduced

IDLitManipulatorContainer::SetProperty

The IDLitManipulatorContainer::SetProperty procedure method sets the value of an IDLitManipulatorContainer property, and should be called by the subclass's SetProperty method. This method also calls the superclass's SetProperty method.

Syntax

Obj->[IDLitManipulatorContainer::]SetProperty[, *PROPERTY=value*]

Arguments

None

Keywords

Any property listed under "IDLitManipulatorContainer Properties" on page 3856 that contains the word "Yes" in the "Set" column of the properties table can be set using this method. To set the value of a property, specify the property name as a keyword set equal to the appropriate property value.

Version History

6.0	Introduced

IDLitManipulatorManager

The IDLitManipulatorManager class is a specialization of a IDLitManipulatorContainer class that acts as the root of a manipulator hierarchy. In addition, this class provides the functionality that allows it to interface with external elements in the iTool system.

This class is written in the IDL language. Its source code can be found in the file `idlitmanipulatormanager__define.pro` in the `lib/itools/framework` subdirectory of the IDL distribution.

Superclasses

IDLitManipulatorContainer

Note ——

See the "iTools Object Model Diagram" (Chapter 2, *iTool Developer's Guide*) for a visual representation of the iTools object model hierarchy.

Creation

See "IDLitManipulatorManager::Init" on page 3881.

Properties

Objects of this class have no properties of their own, but do have properties inherited from any superclasses.

Methods

This class has the following methods:

- IDLitManipulatorManager::Add
- IDLitManipulatorManager::AddManipulatorObserver
- IDLitManipulatorManager::GetDefaultManipulator
- IDLitManipulatorManager::Init
- IDLitManipulatorManager::RemoveManipulatorObserver

In addition, this class inherits the methods of its superclass.

Version History

6.0	Introduced

IDLitManipulatorManager Properties

Objects of this class have no properties of their own, but do have properties inherited from its superclass.

Objects in this class inherit:

- IDLitManipulatorContainer

IDLitManipulatorManager::Add

The IDLitManipulatorManager::Add procedure method is used to add manipulators to the manipulator manager. This method uses the add functionality of its superclass to add the given manipulator to the hierarchy and checks the default keyword to determine if the given manipulator should be treated as the default for the system.

Syntax

Obj->[IDLitManipulatorManager::]Add, *Manipulator* [, /DEFAULT]

Arguments

Manipulator

A manipulator to add to the manipulator manager

Keywords

DEFAULT

If set, the added manipulator is made default for the system. This is primarily used with manipulators that implement transient behavior (mouse or keyboard). When these manipulators complete interaction, the current manipulator of the system is set to the default manipulator.

Version History

6.0	Introduced

IDLitManipulatorManager::AddManipulatorObserver

The IDLitManipulatorManager::AddManipulatorObserver procedure method is used to add an observer to the manipulator system. An observer object is notified when the current manipulator of the manipulator hierarchy changes.

To perform this action, the observer object must implement the method OnManipulatorChange. This method has the following signature:

```
PRO ObjectClass::OnManipulatorChange, Subject
```

Where *Subject* is this class, the manipulator manager.

Syntax

Obj->[IDLitManipulatorManager::]AddManipulatorObserver, *Observer*

Arguments

Observer

A scalar or array of objects that implement the manipulator observer interface.

Keywords

None

Version History

6.0	Introduced

IDLitManipulatorManager::GetDefaultManipulator

The IDLitManipulatorManager::GetDefaultManipulator function method returns a reference to the manipulator that was most recently added as the default manipulator. The return value is a reference to an IDLitManipulator object, or the NULL object reference if no manipulators have been added as a default.

Syntax

Result = Obj->[IDLitManipulatorManager::]GetDefaultManipulator()

Keywords

None

Arguments

None

Version History

6.1	Introduced

IDLitManipulatorManager::Init

The IDLitManipulatorManager::Init function method initializes the IDLitManipulatorManager object, and should be called by the subclass's Init method. This method also calls the superclass's Init method.

Note _____

Init methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation. This means that in most cases, you cannot call the Init method directly. There is one exception to this rule: if you write your own subclass of this class, you can call the Init method from within the Init method of the subclass.

_____

Syntax

Obj = OBJ_NEW('IDLitManipulatorManager' [, *PROPERTY=value*])

or

Result = Obj->[IDLitManipulatorManager::]Init([*PROPERTY=value*])   *(In a lifecycle method only.)*

Return Value

When this method is called indirectly, as part of the call to the OBJ_NEW function, the return value is an object reference to the newly-created object.

When called directly within a subclass Init method, the return value is 1 if initialization was successful, or zero otherwise.

Arguments

None

Keywords

Any property listed under "IDLitManipulatorManager Properties" on page 3877 that contains the word "Yes" in the "Init" column of the properties table can be initialized during object creation using this method. To initialize the value of a property, specify the property name as a keyword set equal to the appropriate property value.

Version History

6.0	Introduced

IDLitManipulatorManager::RemoveManipulatorObserver

The IDLitManipulatorManager::RemoveManipulatorObserver procedure method is used to remove a manipulator observer from the manipulator object. If the value for the *Observer* argument is not a valid manipulator observer, this method does nothing and no error is reported.

Syntax

Obj->[IDLitManipulatorManager::]RemoveManipulatorObserver, *Observer*

Arguments

Observer

A scalar or array of objects that are to be removed from this container

Keywords

None

Version History

6.0	Introduced

IDLitManipulatorVisual

The IDLitManipulatorVisual class implements methods that allow the iTool developer to create visual elements that are associated with an interactive manipulator. IDLitManipulatorVisual objects are not intended to be created as standalone entities; rather, this class should be included as the superclass of another iTool class.

Superclasses

IDLgrModel

IDLitIMessaging

Note ———————————————————————————————————————
See the "iTools Object Model Diagram" (Chapter 2, *iTool Developer's Guide*) for a visual representation of the iTools object model hierarchy.
——

Creation

See "IDLitManipulatorVisual::Init" on page 3890.

Properties

Objects of this class have the following properties. See "IDLitManipulatorVisual Properties" on page 3886 for details on individual properties.

- UNIFORM_SCALE
- VISUAL_TYPE

Methods

This class has the following methods:

- IDLitManipulatorVisual::Cleanup
- IDLitManipulatorVisual::GetProperty
- IDLitManipulatorVisual::Init
- IDLitManipulatorVisual::SetProperty

Version History

6.0	Introduced

IDLitManipulatorVisual Properties

IDLitManipulatorVisual objects have the following properties. Properties with the word "Yes" in the "Get" column of the property table can be retrieved via IDLitManipulatorVisual::GetProperty. Properties with the word "Yes" in the "Init" column of the property table can be set via IDLitManipulatorVisual::Init. Properties with the word "Yes" in the "Set" column in the property table can be set via IDLitManipulatorVisual::SetProperty.

Note ───
For a discussion of the property description tables shown below, see "About Object Property Descriptions" on page 3135.
───

Objects of this class have the following properties.

- UNIFORM_SCALE
- VISUAL_TYPE

In addition, objects of this class inherit:

- IDLgrModel
- IDLitIMessaging

UNIFORM_SCALE

Set this property to create a manipulator visual which should be scaled equally in all three dimensions when fitting the manipulator visual to the size of its associated visualization. If this property is not set, then the manipulator visual will use a different scale factor in the *x*, *y*, and *z* dimensions, in order to match its associated visualization.

Property Type	Boolean		
Name String	*not applicable*		
Get: Yes	Set: Yes	Init: Yes	Registered: No

VISUAL_TYPE

Set this keyword to a string representing the manipulator visual type. The VISUAL_TYPE property should match the corresponding string in its associated IDLitManipulator object. When a new manipulator is selected in an iTool, the

VISUAL_TYPE property on the manipulator object is used to search for a corresponding manipulator visual.

Property Type	String		
Name String	*not applicable*		
Get: Yes	Set: Yes	Init: Yes	Registered: No

IDLitManipulatorVisual::Cleanup

The IDLitManipulatorVisual::Cleanup procedure method performs all cleanup on the object, and should be called by the Cleanup method of a subclass.

Note ──

Cleanup methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation and destruction. This means that in most cases, you cannot call the Cleanup method directly. There is one exception to this rule: if you write your own subclass of this class, you can call the Cleanup method from within the Init or Cleanup method of the subclass.

──

Syntax

OBJ_DESTROY, *Obj*

or

Obj->[IDLitManipulatorVisual::]Cleanup   *(In a lifecycle method only.)*

Arguments

None

Keywords

None

Version History

6.0	Introduced

IDLitManipulatorVisual::GetProperty

The IDLitManipulatorVisual::GetProperty procedure method retrieves the value of an IDLitManipulatorVisual property.

Syntax

Obj->[IDLitManipulatorVisual::]GetProperty

Arguments

None

Keywords

Any property listed under "IDLitManipulatorVisual Properties" on page 3886 that contains the word "Yes" in the "Get" column of the properties table can be retrieved using this method. To retrieve the value of a property, specify the property name as a keyword set equal to a named variable that will contain the value of the property.

Version History

6.0	Introduced

IDLitManipulatorVisual::Init

The IDLitManipulatorVisual::Init function method initializes the IDLitManipulatorVisual object, and should be called by the Init method of a subclass.

Note

Init methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation. This means that in most cases, you cannot call the Init method directly. There is one exception to this rule: if you write your own subclass of this class, you can call the Init method from within the Init method of the subclass.

Syntax

Obj = OBJ_NEW('IDLitManipulatorVisual'[, *PROPERTY=value*])

or

Result = Obj->[IDLitManipulatorVisual::]Init([, *PROPERTY=value*])   *(In a lifecycle method only.)*

Return Value

When this method is called indirectly, as part of the call to the OBJ_NEW function, the return value is an object reference to the newly-created object.

When called directly within a subclass Init method, the return value is 1 if initialization was successful, or zero otherwise.

Arguments

None

Keywords

Any property listed under "IDLitManipulatorVisual Properties" on page 3886 that contains the word "Yes" in the "Init" column of the properties table can be initialized during object creation using this method. To initialize the value of a property, specify the property name as a keyword set equal to the appropriate property value.

Version History

6.0	Introduced

IDLitManipulatorVisual::SetProperty

The IDLitManipulatorVisual::SetProperty procedure method sets the value of an IDLitManipulatorVisual property.

Syntax

Obj->[IDLitManipulatorVisual::]SetProperty[, *PROPERTY=value*]

Arguments

None

Keywords

Any property listed under "IDLitManipulatorVisual Properties" on page 3886 that contains the word "Yes" in the "Set" column of the properties table can be set using this method. To set the value of a property, specify the property name as a keyword set equal to the appropriate property value.

Version History

6.0	Introduced

IDLitOperation

The IDLitOperation class is the basis for all iTool operations. It defines how an operation is executed and how information about the operation is recorded for the command transaction (undo-redo) system.

An operation encapsulates a specific set of tasks that perform some atomic action on a target. Between executions of the operation, no state values other than properties of the operation itself are maintained by this object. Two major areas of functionality are provided: automated operation execution and undo-redo capabilities.

Once defined, the operation object exposes a set of properties whose values can affect how the operation executes. The properties that an operation exposes are valid across multiple executions; properties can be set interactively via the Operation browser or programmatically using the operation object's GetProperty and SetProperty methods.

Note
For operations that act directly on data items that underlie a visualization, consider basing your operation class on the IDLitDataOperation class. IDLitDataOperation is a subclass of IDLitOperation that automates many of the target-selection and undo-redo mechanisms that must be provided by operation classes based directly on this class.

For a detailed discussion of both the IDLitOperation and IDLitDataOperation classes, see Chapter 7, "Creating an Operation" (*iTool Developer's Guide*).

This class is written in the IDL language. Its source code can be found in the file idlitoperation__define.pro in the lib/itools/framework subdirectory of the IDL distribution.

Superclasses

IDLitComponent

IDLitIMessaging

Note
See the "iTools Object Model Diagram" (Chapter 2, *iTool Developer's Guide*) for a visual representation of the iTools object model hierarchy.

Creation

See "IDLitOperation::Init" on page 3902.

Properties

Objects of this class have the following properties. See "IDLitOperation Properties" on page 3896 for details on individual properties.

- EXPENSIVE_COMPUTATION
- REVERSIBLE_OPERATION
- SHOW_EXECUTION_UI
- TYPES

In addition, objects of this class inherit the properties of all superclasses of this class.

Note

By default, for IDLitOperation and its subclasses, the NAME property is hidden and the DESCRIPTION property is desensitized. This prevents a user from changing the name of an operation via the property sheet, which could change the name of a menu item. If you wish to expose these properties for your own subclass of IDLitOperation, you will need to unhide and sensitize the NAME and DESCRIPTION properties in your Init method.

Methods

This class has the following methods:

- IDLitOperation::Cleanup
- IDLitOperation::DoAction
- IDLitOperation::GetProperty
- IDLitOperation::Init
- IDLitOperation::QueryAvailability
- IDLitOperation::RecordFinalValues
- IDLitOperation::RecordInitialValues
- IDLitOperation::RedoOperation
- IDLitOperation::SetProperty

- IDLitOperation::UndoOperation

In addition, this class inherits the methods of its superclasses.

Examples

See Chapter 7, "Creating an Operation" (*iTool Developer's Guide*) for examples using this class and its methods.

Version History

6.0	Introduced
6.2	Added QueryAvailability method

See Also

IDLitDataOperation

IDLitOperation Properties

IDLitOperation objects have the following properties in addition to properties inherited from any superclasses. Properties with the word "Yes" in the "Get" column of the properties table can be retrieved via IDLitOperation::GetProperty. Properties with the word "Yes" in the "Init" column of the properties table can be initialized via IDLitOperation::Init. Properties with the word "Yes" in the "Set" column of the properties table can be set via IDLitOperation::SetProperty.

Note
For a discussion of the property description tables shown below, see "About Object Property Descriptions" on page 3135.

Objects of this class have the following properties.

- EXPENSIVE_COMPUTATION
- REVERSIBLE_OPERATION
- SHOW_EXECUTION_UI
- TYPES

In addition, objects of this class inherit:

- IDLitComponent
- IDLitIMessaging

EXPENSIVE_COMPUTATION

Set this property to 1 to indicate that a computation of the operation is *expensive*. Expensive computations are those that require significant memory or processing time to execute. Individual operations should use the value of this property to determine whether the results of the operation should be cached to avoid re-execution when undoing or redoing.

Property Type	Boolean		
Name String	*not displayed*		
Get: Yes	**Set:** No	**Init:** Yes	**Registered:** No

REVERSIBLE_OPERATION

Set this property to 1 to indicate that the operation is *reversible*. When an operation is reversible, it can be undone by applying an operation rather than restoring a stored value. Rotation by a specified angle is an example of an operation that is reversible, since applying another rotation by the complementary angle returns the visualization to its original state. Individual operations should use the value of this property to determine how the operation should be undone.

Property Type	Boolean		
Name String	*not displayed*		
Get: Yes	**Set:** No	**Init:** Yes	**Registered:** No

SHOW_EXECUTION_UI

Set this property to 1 to indicate that the operation should display a user interface element such as a dialog when the operation is executed. The flag is ignored by the IDLitOperation itself, but can be used by subclasses (notably IDLitDataOperation) to determine when to display user interface elements. This property is registered, but it is hidden by default.

Property Type	Boolean		
Name String	Show Dialog		
Get: Yes	**Set:** No	**Init:** Yes	**Registered:** Yes

TYPES

Set this property to a string or an array of strings indicating the data or visualization types to which the operation can be applied. iTools data types are described in Chapter 3, "Data Management" (*iTool Developer's Guide*); iTools visualization types are described in Chapter 6, "Creating a Visualization" (*iTool Developer's Guide*). Set this property to a null string (' ') to specify that the operation can be applied to data and visualizations of all types.

Property Type	User Defined		
Name String	*not displayed*		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** No

IDLitOperation::Cleanup

The IDLitOperation::Cleanup procedure method performs all cleanup on the object.

Note ———

An operation based on the IDLitOperation class need not implement this method if the operation does not allocate any pointers or object references of its own.

Note ———

Cleanup methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation and destruction. This means that in most cases, you cannot call the Cleanup method directly. There is one exception to this rule: if you write your own subclass of this class, you can call the Cleanup method from within the Init or Cleanup method of the subclass.

Syntax

OBJ_DESTROY, *Obj*

or

Obj->[IDLitOperation::]Cleanup   *(In a lifecycle method only.)*

Arguments

None

Keywords

None

Version History

6.0	Introduced

IDLitOperation::DoAction

The IDLitOperation::DoAction function method is called when an operation is requested by the iTools system, either as the result of a user action such as selection of a menu item or toolbar button, or by another operation.

Note ———————————————————————

Every operation based directly on the IDLitOperation class must implement its own DoAction method. See Chapter 7, "Creating an Operation" (*iTool Developer's Guide*) for details.

———————————————————————————————

A specific operation class' implementation of this method must create an initialized IDLitCommandSet object, execute the operation, and return the command set object to the caller. DoAction can also call the IDLitOperation::RecordInitialValues and IDLitOperation::RecordFinalValues methods to ensure that the appropriate values are committed to the undo-redo transaction buffer.

If your operation changes the values of its own registered properties (as the result of user interaction with a dialog or other interface element called by DoUIService, for example), be sure to call the RecordInitialValues and RecordFinalValues methods. This ensures that changes made through the dialog are placed in the undo-redo transaction buffer.

Note ———————————————————————

If you are creating an operation that acts directly on the data that underlies a visualization, consider using the IDLitDataOperation class rather than the IDLitOperation class. IDLitDataOperation provides additional automation of the Undo/Redo mechanism.

———————————————————————————————

Syntax

Result = Obj->[IDLitOperation::]DoAction(*Tool*)

Return Value

If successful, this method returns an IDLitCommandSet object or array of IDLitCommandSet objects that will be placed in the iTool's command buffer. The command set object will be passed to the UndoOperation and RedoOperation methods as necessary. If not successful, this method returns a null object reference.

Note ———————————————————————————————————

The OPERATION_IDENTIFIER property of the command set object returned by the IDLitOperation::DoAction method is set equal to the full identifier of the operation itself. This implies that UndoOperation and RedoOperation methods exist for the operation, and that they implement the necessary undo and redo mechanisms. If you are overriding this method, you must either ensure that the appropriate UndoOperation and RedoOperation methods exist, or manually create an IDLitCommandSet object with the OPERATION_IDENTIFIER set to another operation that is capable of undoing or redoing the changes made by your method.

Arguments

Tool

An object reference to the iTool object on which the operation executes.

Keywords

None

Version History

6.0	Introduced

IDLitOperation::GetProperty

The IDLitOperation::GetProperty procedure method retrieves the value of a property or group of properties of an operation object.

Note ────────────────────────────────

An operation based on the IDLitOperation class *must* implement this method if the operation defines one or more properties not inherited from the superclass. See Chapter 7, "Creating an Operation" (*iTool Developer's Guide*) for details.

──

Syntax

Obj->[IDLitOperation::]GetProperty [, *PROPERTY=variable*]

Arguments

None

Keywords

Any property listed under "IDLitOperation Properties" on page 3896 that contains the word "Yes" in the "Get" column of the properties table can be retrieved using this method. To retrieve the value of a property, specify the property name as a keyword set equal to a named variable that will contain the value of the property.

Example

To retrieve the value of the REVERSIBLE_OPERATION property:

```
Obj->IDLitOperation::GetProperty, REVERSIBLE_OPERATION = rev
```

Version History

6.0	Introduced

IDLitOperation::Init

The IDLitOperation::Init function method initializes the IDLitOperation object and sets properties that define the behavior the operation provides.

Note ───────────────────────────────────────

An operation based on the IDLitOperation class *must* implement this method. See Chapter 7, "Creating an Operation" (*iTool Developer's Guide*) for details.

───

Note ───────────────────────────────────────

Init methods are special life cycle methods, and as such cannot be called outside the context of object creation. This means that in most cases, you cannot call the Init method directly. There is one exception to this rule: if you write your own subclass of this class, you can call the Init method from within the Init method of the subclass.

───

Syntax

Obj = OBJ_NEW('IDLitOperation' [, *PROPERTY=variable*])

or

Result = Obj->[IDLitOperation::]Init([, *PROPERTY=variable*])   *(In a lifecycle method only.*)

Return Value

When this method is called indirectly, as part of the call to the OBJ_NEW function, the return value is an object reference to the newly-created object.

When called directly within a subclass Init method, the return value is 1 if initialization was successful, or zero otherwise.

Arguments

None

Keywords

Any property listed under "IDLitOperation Properties" on page 3896 that contains the word "Yes" in the "Init" column of the properties table can be initialized during

object creation using this method. To initialize the value of a property, specify the property name as a keyword set equal to the appropriate property value.

Version History

6.0	Introduced

IDLitOperation::QueryAvailability

The IDLitOperation::QueryAvailability function method is automatically called by the iTool to determine whether this operation is applicable for the selected data and/or visualization. By default, whenever selection changes in the tool, the operation is queried to determine if its type matches the type of the visualization or the data within the visualization. The menu item or toolbar button associated with the operation is then enabled or disabled automatically.

If you are writing a subclass of IDLitOperation and you do not want to use the standard type matching, you might want to override this method in your own subclass.

Syntax

Result = Obj->[IDLitOperation::]QueryAvailability(*Tool*, *SelTypes*)

Return Value

This method returns a 1 if the object is applicable for the selected items, or 0 (zero) otherwise.

Arguments

Tool

An object reference to the iTool object on which the operation executes.

SelTypes

A string array containing the types of the currently selected visualizations. For an explanation of iTool types, see "Predefined iTool Visualization Classes" (Chapter 6, *iTool Developer's Guide*).

Keywords

None

Version History

6.2	Introduced

IDLitOperation::RecordFinalValues

The IDLitOperation::RecordFinalValues function method records the information needed to redo an operation. Information about individual operations is recorded in IDLitCommand objects, which are in turn stored in an IDLitCommandSet object that is passed to the IDLitOperation::UndoOperation and IDLitOperation::RedoOperation methods.

Note

If you are creating an operation that acts directly on the data that underlies a visualization, consider using the IDLitDataOperation class rather than the IDLitOperation class. IDLitDataOperation provides additional automation of the Undo and Redo mechanisms.

If this method is implemented for an operation, it should do the following:

- Retrieve the appropriate IDLitCommand object from the IDLitCommandSet object specified as the first parameter,

- Record any information necessary to redo the operation in the IDLitCommand object,

- Return 1 for success.

Syntax

Result = Obj->[IDLitOperation::]RecordFinalValues(*CommandSet*, *Targets* [*, IdProperty*])

Return Value

The return value is 1 if the final values were recorded successfully, or zero otherwise.

Arguments

CommandSet

An IDLitCommandSet object that encapsulates all information recorded for this execution of the operation. The command set object is generally created by the IDLitOperation::DoAction method, which then calls the RecordInitialValues method to store the initial state of the target object.

Targets

An array of objects that are the targets of this operation. In most cases, the target objects are the currently selected objects, as returned by the IDLitTool::GetSelectedItems method.

IdProperty

A property identifier string specifying the target property or parameter of the operation.

Keywords

None

Version History

6.0	Introduced

IDLitOperation::RecordInitialValues

The IDLitOperation::RecordInitialValues function method records the information needed to undo an operation. Information about individual operations is recorded in IDLitCommand objects, which are in turn stored in an IDLitCommandSet object that is passed to the IDLitOperation::UndoOperation and IDLitOperation::RedoOperation methods.

Note ──

If you are creating an operation that acts directly on the data that underlies a visualization, consider using the IDLitDataOperation class rather than the IDLitOperation class. IDLitDataOperation provides additional automation of the Undo and Redo mechanisms.

──

If this method is implemented for an operation, it should do the following:

- Create an IDLitCommand object, setting its TARGET_IDENTIFIER property to the identifier of the target object

- Record any information necessary to redo the operation in the IDLitCommand object

- Add the IDLitCommand object to the IDLitCommandSet object specified as the first parameter

- Return 1 for success

Syntax

Result = Obj->[IDLitOperation::]RecordInitialValues(*CommandSet*, *Targets* [, *IdProperty*])

Return Value

The return value is 1 if the initial values were recorded successfully, or zero otherwise.

Arguments

CommandSet

An IDLitCommandSet object that encapsulates all information recorded for this execution of the operation. The command set object is generally created by the

IDLitOperation::DoAction method, which then calls the RecordInitialValues method to store the initial state of the target object.

Targets

An array of objects that are the targets of this operation. In most cases, the target objects are the currently selected objects, as returned by the IDLitTool::GetSelectedItems method.

IdProperty

A property identifier string specifying the target property or parameter of the operation.

Keywords

None

Version History

6.0	Introduced

IDLitOperation::RedoOperation

The IDLitOperation::RedoOperation function method is called by the iTool system when the user requests the re-execution of an operation (usually by selecting Redo from the iTool Edit menu or toolbar).

Note ───

An operation based on the IDLitOperation class *must* implement this method. See Chapter 7, "Creating an Operation" (*iTool Developer's Guide*) for details.

───

Note ───

If you are creating an operation that acts directly on the data that underlies a visualization, consider using the IDLitDataOperation class rather than the IDLitOperation class. IDLitDataOperation provides additional automation of the Undo and Redo mechanisms.

───

If this method is implemented for an operation, it should do the following:

- • Retrieve the IDLitCommand objects from the IDLitCommandSet object passed as the first argument,

- • For each IDLitCommand object, retrieve the target of the operation, using the TARGET_IDENTIFIER property,

- • Retrieve the stored information and use it to redo the operation,

- • Return 1 for success.

Syntax

Result = Obj->[IDLitOperation::]RedoOperation(*CommandSet*)

Return Value

The return value is 1 if the operation was redone successfully, or zero otherwise.

Arguments

CommandSet

An IDLitCommandSet object that contains all the IDLitCommand objects that were stored during the original execution of the operation.

Keywords

None

Version History

6.0	Introduced

See Also

IDLitOperation::RecordFinalValues, IDLitOperation::RecordInitialValues,
IDLitOperation::UndoOperation

IDLitOperation::SetProperty

The IDLitOperation::SetProperty procedure method sets the value of a property or group of properties for the operation.

Note ———

An operation based on the IDLitOperation class *must* implement this method if the operation defines one or more properties not inherited from the superclass. See Chapter 7, "Creating an Operation" (*iTool Developer's Guide*) for details.

——

Syntax

Obj->[IDLitOperation::]SetProperty [, *PROPERTY=value*]

Arguments

None

Keywords

Any property listed under "IDLitOperation Properties" on page 3896 that contains the word "Yes" in the "Set" column of the properties table can be set using this method. To set the value of a property, specify the property name as a keyword set equal to the appropriate property value.

Version History

6.0	Introduced

IDLitOperation::UndoOperation

The IDLitOperation::UndoOperation function method is called by the iTool system when the user requests the un-execution of an operation (usually by selecting Undo from the iTool Edit menu or toolbar).

Note ————————————————————————————————

An operation based on the IDLitOperation class *must* implement this method. See Chapter 7, "Creating an Operation" (*iTool Developer's Guide*) for details.

Note ————————————————————————————————

If you are creating an operation that acts directly on the data that underlies a visualization, consider using the IDLitDataOperation class rather than the IDLitOperation class. IDLitDataOperation provides additional automation of the Undo and Redo mechanisms.

If this method is implemented for an operation, it should do the following:

- Retrieve the IDLitCommand objects from the IDLitCommandSet object passed as the first argument,

- For each IDLitCommand object, retrieve the target of the operation, using the TARGET_IDENTIFIER property,

- Retrieve the stored information and use it to undo the operation,

- Return 1 for success.

Syntax

Result = Obj->[IDLitOperation::]UndoOperation(*CommandSet*)

Return Value

The return value is 1 if the operation was undone successfully, or zero otherwise.

Arguments

CommandSet

An IDLitCommandSet object that contains all the IDLitCommand objects that were stored during the original execution of the operation.

Keywords

None

Version History

6.0	Introduced

IDLitOperation::RecordFinalValues, IDLitOperation::RecordInitialValues, IDLitOperation::RedoOperation

IDLitParameter

The IDLitParameter class implements parameter management methods that allow parameter names to be associated with IDLitData objects. IDLitParameter objects are not intended to be created as standalone entities; rather, this class should be included as the superclass of another iTool class.

Note ───

In the iTools system, management of data parameters is handled by the IDLitVisualization class, of which the IDLitParameter class is a superclass. In practice, this means that if you need to override any methods of the IDLitParameter class, you will do so in the definition of your visualization class. In most cases, the only method you will need to implement is the OnDataChangeUpdate method.

───

When an object that inherits from the IDLitParameter class is created, the following are created as part of the new object's instance data:

- An IDL_Container object, which will contain parameter names for all parameters registered with the object. Parameter names are discussed in "Parameters" (Chapter 3, *iTool Developer's Guide*),

- A pointer to a string array containing the parameter names for all parameters registered with the object,

- An IDLitParameterSet object, which will contain the actual IDLitData objects associated with the object's parameters. Parameter sets are discussed in "Parameter Sets" (Chapter 3, *iTool Developer's Guide*), and in "IDLitParameterSet" on page 3938.

This class is written in the IDL language. Its source code can be found in the file idlitparameter__define.pro in the lib/itools/framework subdirectory of the IDL distribution.

Superclasses

None

Note ───

See the "iTools Object Model Diagram" (Chapter 2, *iTool Developer's Guide*) for a visual representation of the iTools object model hierarchy.

───

Creation

The objects of this class are not created as standalone objects.

Properties

Objects of this class have no properties of their own.

Methods

This class has the following methods:

- IDLitParameter::Cleanup
- IDLitParameter::GetParameter
- IDLitParameter::GetParameterAttribute
- IDLitParameter::GetParameterSet
- IDLitParameter::Init
- IDLitParameter::OnDataChangeUpdate
- IDLitParameter::OnDataDisconnect
- IDLitParameter::QueryParameter
- IDLitParameter::RegisterParameter
- IDLitParameter::SetData
- IDLitParameter::SetParameterAttribute
- IDLitParameter::SetParameterSet

Version History

6.0	Introduced

IDLitParameter Properties

Objects of this class have no properties of their own.

IDLitParameter::Cleanup

The IDLitParameter::Cleanup procedure method removes the *data observer* from each data object in the visualization object's parameter set, and cleans up the objects and pointers defined to hold parameter data when the visualization object was created.

Note ————————————————————————————————————

Cleanup methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation and destruction. This means that in most cases, you cannot call the Cleanup method directly. There is one exception to this rule: If you write your own subclass of this class, you can call the Cleanup method from within the Init or Cleanup method of the subclass.

Syntax

OBJ_DESTROY, *Obj*

or

Obj->[IDLitParameter::]Cleanup()   *(In a lifecycle method only.)*

Arguments

None

Keywords

None

Version History

6.0	Introduced

IDLitParameter::GetParameter

The IDLitParameter::GetParameter function method retrieves the IDLitData object associated with a registered parameter.

Syntax

Result = Obj->[IDLitParameter::]GetParameter(*Name* [, /ALL]
[, COUNT=*variable*])

Return Value

Returns an object reference to the IDLitData object associated with the specified parameter name, or a null object reference if no data objects are associated with the specified parameter name.

Arguments

Name

A scalar string containing the parameter name associated with the IDLitData object to be retrieved.

Keywords

ALL

Set this keyword to retrieve all of the IDLitData objects contained in the visualization object's IDLitParameterSet object.

COUNT

Set this keyword equal to a named variable that will contain the number of items returned by this function.

Version History

6.0	Introduced

IDLitParameter::GetParameterAttribute

The IDLitParameter::GetParameterAttribute procedure method retrieves one or more parameter attributes for a registered parameter.

Syntax

Obj->[IDLitParameter::]GetParameterAttribute(*ParamName*
   [, BY_VALUE=*variable*] [, DESCRIPTION=*variable*] [, INPUT=*variable*]
   [, OPTARGET=*variable*] [, OPTIONAL=*variable*] [, OUTPUT=*variable*]
   [, TYPES=*variable*])

Arguments

ParamName

A scalar string or string array containing names of registered parameters.

Keywords

BY_VALUE

Set this keyword equal to a named variable that will contain a 1 (one) if *ParamName* is marked as being a by-value parameter, or a 0 (zero) if *ParamName* is marked as being a by-reference parameter.

DESCRIPTION

Set this keyword equal to a named variable that will contain the full name or description of this object.

INPUT

Set this keyword equal to a named variable that will contain a 1 (one) if *ParamName* is an input parameter, or a 0 (zero) otherwise.

OPTARGET

Set this keyword equal to a named variable that will contain a 1 (one) if *ParamName* may be the target of any operations, or a 0 (zero) otherwise.

OPTIONAL

Set this keyword equal to a named variable that will contain a 1 (one) if *ParamName* is an optional parameter, or a 0 (zero) otherwise.

OUTPUT

Set this keyword equal to a named variable that will contain a 1 (one) if *ParamName* is an output parameter, or a 0 (zero) otherwise.

TYPES

Set this keyword equal to a named variable that will contain a scalar string or string array giving the data types that correspond to this parameter. See "iTool Data Types" (Chapter 3, *iTool Developer's Guide*) for more on parameter data types.

Example

This example creates an iPlot tool and retrieves the description attribute of the registered parameter named "vertices":

```
IPLOT, RANDOMU(seed, 15)
idTool = ITGETCURRENT(TOOL=otool)
idPlot = oTool->FindIdentifiers('*plot*', /VISUALIZATIONS)
oPlot = oTool->GetByIdentifier(idPlot)
oPlot->GetParameterAttribute, 'vertices', DESCRIPTION=desc
PRINT, desc
```

IDL prints:

```
Vertex Data
```

Version History

6.1	Introduced

See Also

IDLitParameter::QueryParameter, IDLitParameter::RegisterParameter, IDLitParameter::SetParameterAttribute

IDLitParameter::GetParameterSet

The IDLitParameter::GetParameterSet function method returns a reference to the IDLitParameterSet object associated with the visualization object.

Syntax

Result = Obj->[IDLitParameter::]GetParameterSet([/DEEP_COPY])

Return Value

Returns an IDLitParameterSet object that contains the IDLitData objects and associated parameter names for the visualization object.

Arguments

None

Keywords

DEEP_COPY

Set this keyword to cause GetParameterSet to return a parameter set that contains *copies* of the IDLitData objects used by the visualization object's registered parameters. If this keyword is not set, the parameter set returned by this function will contain *references* to the IDLitData objects that are being used by the visualization object's registered parameters.

Version History

6.0	Introduced

IDLitParameter::Init

The IDLitParameter::Init function method initializes object instance fields that contain parameter data. Since the IDLitParameter class is always used as a superclass of another class (IDLitVisualization, in the context of the iTool system), initializing this class simply initializes the objects and pointers used to store parameter information in the IDLitVisualization object.

Note

Init methods are special lifecycle methods, and as such cannot be called outside the context of object creation. This means that in most cases, you cannot call the Init method directly. There is one exception to this rule: if you write your own subclass of this class, you can call the Init method from within the Init method of the subclass.

Syntax

Result = Obj->[IDLitParameter::]Init()   *(In a lifecycle method only.)*

Return Value

When called directly within a subclass Init method, the return value is 1 if initialization was successful, or zero otherwise.

Arguments

None

Keywords

None

Version History

6.0	Introduced

IDLitParameter::OnDataChangeUpdate

The IDLitParameter::OnDataChangeUpdate method is called when a data value has been updated or a new data object has been associated with the visualization object.

Note

A visualization class based on the IDLitVisualization class *must* implement this method in order for changes or additions to the data parameters to be updated automatically in the resulting visualizations.

Syntax

Obj->[IDLitParameter::]OnDataChangeUpdate, *Data*, *ParameterName*

Arguments

Data

An object reference to the IDLitData object or the IDLitParameterSet object containing the changed parameter data. If *Data* is an IDLitParameterSet object, the *ParameterName* argument must be set to the string `'<PARAMETER SET>'`.

ParameterName

An upper-case scalar string containing the name of the parameter that has changed. The parameter specified via this argument must be registered with the visualization object. If *oData* is an IDLitParameterSet object, this argument must be set to the string `'<PARAMETER SET>'`.

Keywords

None

Example

Normally, an implementation of this method will contain a CASE statement that switches based on the value of the *ParameterName* argument. For example, the following code handles a parameter named `z`:

```
PRO MyVis::OnDataChangeUpdate, oData, ParameterName

CASE ParameterName OF
   'Z': BEGIN
      ;; do something with the z data
   END
   '<PARAMETER SET>': BEGIN
      oZ = oData->GetByName('Z')
      ;; do something with the z data.
   END
ENDCASE

END
```

Note

The Z parameter is handled twice — once if supplied as an individual IDLitData object and once if supplied via the IDLitParameterSet object.

See "Creating an OnDataChangeUpdate Method" in the section "Creating a New Visualization Type" (Chapter 6, *iTool Developer's Guide*) for more discussion of the OnDataChangeUpdate method.

Version History

6.0	Introduced

IDLitParameter::OnDataDisconnect

The IDLitParameter::OnDataDisconnect procedure method is called when a data value has been disconnected from a parameter. The general idea is that when a data item is disassociated from a visualization parameter, one or more properties of the visualization may need to be reset to reasonable default values.

Note ──

A visualization class based on the IDLitVisualization class *must* implement this method in order for changes or additions to the data parameters to be updated automatically in the resulting visualizations.

──

Syntax

Obj->[IDLitParameter::]OnDataDisconnect, *ParameterName*

Arguments

ParameterName

An upper-case string containing the name of the parameter that was disconnected. The parameter must have been previously registered with the visualization.

Keywords

None

Example

Normally, an implementation of this method will contain a CASE statement that switches based on the value of the *ParameterName* argument. For example, the following sample code performs some action when the parameter name is TEXTURE:

```
PRO MyVis::OnDataDisconnect, ParameterName

CASE ParameterName OF
   'TEXTURE': BEGIN
   ;; do something to remove the ref. of the texture
   END
ENDCASE

END
```

Version History

6.0	Introduced

IDLitParameter::QueryParameter

The IDLitParameter::QueryParameter function method checks whether a parameter is registered, or retrieves a list of the names of all registered parameters.

Syntax

Result = Obj->[IDLitParameter::]QueryParameter([*ParamName*]
    [, COUNT=*variable*])

Return Value

If *ParamName* is a scalar string, this function returns a 1 if *ParamName* corresponds to a valid registered parameter, or a 0 otherwise. If *ParamName* is an array, the result is an array of 1s and 0s. If *ParamName* is not specified, *Result* is a string array containing the names of all registered parameters.

Arguments

ParamName

A scalar string or string array containing parameter names. If *ParamName* is not supplied, this function returns a list of all registered parameters.

Keywords

COUNT

Set this keyword equal to a named variable that will contain the number of parameters in *Result*. If *ParamName* is not supplied, then COUNT contains the number of registered parameters. If *ParamName* is supplied then COUNT contains the total number of matched parameters.

Example

This example creates an iPlot tool and tests whether a the plot visualization has a registered parameter named "vertices":

```
IPLOT, RANDOMU(seed, 15)
idTool = ITGETCURRENT(TOOL=otool)
idPlot = oTool->FindIdentifiers('*plot*', /VISUALIZATIONS)
oPlot = oTool->GetByIdentifier(idPlot)
PRINT, oPlot->QueryParameter('vertices')
```

IDL prints:

```
1
```

Continuing the same example, we now query for the names of all parameters of the plot visualization:

```
Params = oPlot->QueryParameter(COUNT=count)
FOR i=0,count-1 DO PRINT, Params[i]
```

IDL prints:

```
Y
X
VERTICES
Y ERROR
X ERROR
PALETTE
VERTEX_COLORS
```

Version History

6.1	Introduced

See Also

IDLitParameter::GetParameter, IDLitParameter::GetParameterAttribute, IDLitParameter::RegisterParameter, IDLitParameter::SetParameterAttribute

IDLitParameter::RegisterParameter

The IDLitParameter::RegisterParameter procedure method registers a parameter with the visualization object. Registered parameters are displayed in the iTool parameter editor dialog, allowing users to interactively assign data values to individual visualization parameters.

Syntax

Obj->[IDLitParameter::]RegisterParameter, *Name* [, /BY_VALUE]
    [, DESCRIPTION=*string*] [, /INPUT] [, /OPTARGET] [, /OPTIONAL]
    [, /OUTPUT] [, TYPES=*string*]

Arguments

Name

Set this argument to a string specifying the name of the parameter.

Keywords

BY_VALUE

Set this keyword to indicate that this parameter is a by-value parameter. If a parameter is marked as by value, when data is associated with it a copy of the data is made and managed by this class.

DESCRIPTION

Set this keyword to a string giving the full name or description of this object.

INPUT

Set this keyword to indicate that this is an input parameter.

OPTARGET

Set this keyword to indicate that this parameter may be the target of any operations.

OPTIONAL

If this keyword is set, then this parameter is an optional parameter, and it is not required to be set. The default is OPTIONAL=0, indicating that it is required to be set.

OUTPUT

Set this keyword to indicate that this is an output parameter.

TYPES

Set this keyword to a scalar string or string array giving the data types that correspond to this parameter. See "iTool Data Types" (Chapter 3, *iTool Developer's Guide*) for more on parameter data types.

Version History

6.0	Introduced

IDLitParameter::SetData

The IDLitParameter::SetData function method is used to set data in this interface, associating a data object with a given parameter. This method can automatically perform type matching to determine which parameter to associate with a particular parameter or the user can specify a parameter name.

If a parameter name is provided by the user via the PARAMETER_NAME keyword, this method will query the given data object for a data item that is of one of the types supported by this parameter and associate the found data item with the parameter. This could be the data object provided or if the data object contains other data objects, one of its children. If a type match doesn't occur, the method will return 0.

If no parameter name is provided, this method will start with the first available parameter (non-associated parameters, starting with op-targets first) and attempt to perform a data type match. When a data type match between the parameter and the provided data item (or one of its contained items) the association between the two are made.

When a data match has been made, this object is made an observer of the data object and if the NO_UPDATE keyword is not set, the OnDataChangeUpdate() method is called on this object.

If a type match is found, but the given parameter already has a data object associated with it, the type match will continue.

If a match cannot be found, a value of 0 is returned.

Syntax

Result = Obj->[IDLitParameter::]SetData(*Data* [, /BY_VALUE] [, /NO_UPDATE] [, PARAMETER_NAME=*string*])

Return Value

Returns 1 if the IDLitData object was successfully matched with a parameter registered with the visualization object, or 0 otherwise.

Arguments

Data

An IDLitData object to be matched with a parameter registered with the visualization object.

Keywords

BY_VALUE

Set this keyword to cause *Data* to be copied and managed by the visualization's parameter interface. If this keyword is not set, the data object is managed by the iTool system, and can be altered by other iTools.

NO_UPDATE

Set this keyword to prevent the OnDataChangeUpdate method from being called when *Data* is associated with one of the visualization object's registered parameters. If this keyword is not set, the OnDataChangeUpdate method is called, providing the opportunity for subclasses of the visualization object to be notified that data associated with the parameter interface has changed.

PARAMETER_NAME

Set this keyword to a scalar string containing the name of the registered parameter with which *Data* should be associated. If the iTool data type of the data contained in *Data* does not match one of the data types supported by the specified registered parameter, *Data* will not be associated with the registered parameter and this function will return zero.

Version History

6.0	Introduced

IDLitParameter::SetParameterAttribute

The IDLitParameter::SetParameterAttribute procedure method sets one or more parameter attributes for a registered parameter.

Syntax

Obj->IDLitParameter::SetParameterAttribute(*ParamName*
    [, /BY_VALUE=*variable*] [, /DESCRIPTION=*variable*] [, /INPUT=*variable*]
    [, /OPTARGET=*variable*] [, /OPTIONAL=*variable*] [, /OUTPUT=*variable*]
    [, /TYPES=*variable*])

Arguments

ParamName

A scalar string or string array containing names of registered parameters. If *ParamName* is an array, the specified attribute values are set on all parameters in the array.

Keywords

BY_VALUE

Set this keyword equal to a named variable that will contain a 1 (one) if *ParamName* is marked as being a by-value parameter, or a 0 (zero) if *ParamName* is marked as being a by-reference parameter.

DESCRIPTION

Set this keyword equal to a named variable that will contain the full name or description of this object.

INPUT

Set this keyword equal to a named variable that will contain a 1 (one) if *ParamName* is an input parameter, or a 0 (zero) otherwise.

OPTARGET

Set this keyword equal to a named variable that will contain a 1 (one) if *ParamName* may be the target of any operations, or a 0 (zero) otherwise.

OPTIONAL

Set this keyword equal to a named variable that will contain a 1 (one) if *ParamName* is an optional parameter, or a 0 (zero) otherwise.

OUTPUT

Set this keyword equal to a named variable that will contain a 1 (one) if *ParamName* is an output parameter, or a 0 (zero) otherwise.

TYPES

Set this keyword equal to a named variable that will contain a scalar string or string array giving the data types that correspond to this parameter. See "iTool Data Types" (Chapter 3, *iTool Developer's Guide*) for more on parameter data types.

Example

This example creates an iPlot tool sets the description attribute of the registered parameter named "vertices":

```
IPLOT, RANDOMU(seed, 15)
idTool = ITGETCURRENT(TOOL=otool)
idPlot = oTool->FindIdentifiers('*plot*', /VISUALIZATIONS)
oPlot = oTool->GetByIdentifier(idPlot)
oPlot->SetParameterAttribute, 'vertices', $
   DESCRIPTION='My Vertex Data'
oPlot->GetParameterAttribute, 'vertices', DESCRIPTION=desc
PRINT, desc
```

IDL prints:

```
My Vertex Data
```

Version History

6.1	Introduced

See Also

IDLitParameter::GetParameterAttribute, IDLitParameter::QueryParameter, IDLitParameter::RegisterParameter

IDLitParameter::SetParameterSet

The IDLitParameter::SetParameterSet function method is used to associate an IDLitParameterSet object with the visualization object's parameter interface. IDLitData objects contained in the parameter set object will be associated with the registered parameters of the visualization object, either based on the parameter names included in the parameter set object or on the iTool data types of the data objects. When the association of the parameter set's data objects with the visualization object's registered parameters is complete, the OnDataChangeUpdate method is called with the IDLitParameterSet object and the string '<PARAMETER SET>' as the arguments.

Note
When this method is called, the IDLitParameterSet object created when the visualization object was initialized will be disassociated from the object's parameter interface. This means that any individual data objects or parameter names previously added to the initial parameter set object will also be disassociated from the visualization object's parameter interface.

This method will not destroy or delete the information contained in the specified IDLitParameterSet object.

Syntax

Result = Obj->[IDLitParameter::]SetParameterSet(*ParamSet*)

Return Value

Returns 1 if the IDLitParameterSet object was successfully associated with the visualization object's parameter interface, or 0 otherwise.

Arguments

ParamSet

An IDLitParameterSet object to be associated with the visualization object's parameter interface.

Keywords

None

Version History

6.0	Introduced

IDLitParameterSet

The IDLitParameterSet class is a specialized subclass of the IDLitDataContainer class that provides the ability to associate names with the contained IDLitData objects. This association allows the iTool developer to package a set of data parameters in a single container, which is then provided to the iTools system for processing a display.

In addition to providing a mechanism for associating IDLitData objects with parameter names, the IDLitParameterSet class allows you to incorporate an IDLitData object for which no parameter name is provided. These *auxiliary data* items are treated as parameters for which the parameter name is a null string (`''`). The auxiliary data mechanism allows you to associate any amount of data with a parameter set without the need to define parameter names.

This class is written in the IDL language. Its source code can be found in the file `idlitparameterset__define.pro` in the `lib/itools/framework` subdirectory of the IDL distribution.

Superclasses

IDLitDataContainer

Note ───

See the "iTools Object Model Diagram" (Chapter 2, *iTool Developer's Guide*) for a visual representation of the iTools object model hierarchy.

───

Creation

See "IDLitParameterSet::Init" on page 3951.

Properties

Objects of this class have no properties of their own, but do have properties inherited from the superclass.

Methods

This class has the following methods:

- IDLitParameterSet::Add

- IDLitParameterSet::Cleanup
- IDLitParameterSet::Copy
- IDLitParameterSet::Get
- IDLitParameterSet::GetByName
- IDLitParameterSet::GetParameterName
- IDLitParameterSet::Init
- IDLitParameterSet::Remove

In addition, this class inherits the methods of its superclass.

Examples

See Chapter 3, "Data Management" (*iTool Developer's Guide*) for examples using this class and its methods.

Version History

6.0	Introduced

IDLitParameterSet Properties

Objects of this class have no properties of their own, but do have properties inherited from the superclass.

Objects in this class inherit:

- IDLitDataContainer

IDLitParameterSet::Add

The IDLitParameterSet::Add procedure method is used to add a data object to the parameter set.

Syntax

Obj->[IDLitParameterSet::]Add, *Data* [, PARAMETER_NAME=*string*]
   [, /PRESERVE_LOCATION]

Arguments

Data

An object reference or array of object references to IDLitData objects to be added to the parameter set.

Note ————————————————————————————————————

The objects to be added must be of class type IDLitData or a subclass of IDLitData. You cannot add the same Parameter Set object to itself.

————————————————————————————————————

Keywords

PARAMETER_NAME

Set this keyword to a string or array of strings containing the names of parameters to be associated with the data objects. If this value is not provided, a null string (' ') is associated with the data object. If the value of this keyword is an array with fewer elements than the array specified as the *Data* argument, null strings are associated with data objects for which no parameter name is specified.

PRESERVE_LOCATION

Set this keyword to leave the PARENT property of all data items specified by the *Data* argument unchanged. Normally, when an item is added to a parameter set (or any data container), the item's PARENT property is changed to be the parameter set or data container object. This, in turn, changes the data item's identifier string, since the item's location in the iTools hierarchy has changed. (See "iTool Object Identifiers" (Chapter 2, *iTool Developer's Guide*) for details.) In many cases, it is desirable to leave the PARENT property unchanged when adding items to a parameter set.

Version History

6.0	Introduced

See Also

IDLitParameterSet::Remove

IDLitParameterSet::Cleanup

The IDLitParameterSet::Cleanup procedure method performs all cleanup on the parameter set object.

Note ───

Cleanup methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation and destruction. This means that in most cases, you cannot call the Cleanup method directly. There is one exception to this rule: If you write your own subclass of this class, you can call the Cleanup method from within the Init or Cleanup method of the subclass.

───

Syntax

OBJ_DESTROY, *Obj*

or

Obj->[IDLitParameterSet::]Cleanup()   *(In a lifecycle method only.)*

Arguments

None

Keywords

None

Version History

6.0	Introduced

IDLitParameterSet::Copy

The IDLitParameterSet::Copy function method will return a copy of the parameter set and its contents. All items contained in the parameter set (and their data) are copied and added to the new parameter set.

For individual data objects contained in the parameter set, the following values are *not* copied:

- Values of unregistered properties.

- Values of properties registered after the data object is created.

- Property attribute values.

Note ──

If the data within the contained data object consists of object references, only the object references are copied.

──

Note ──

When a parameter set is copied, a new copy of each item in the parameter set is created with a new, unique, iTool identifier, even if the data item was originally added with the PRESERVE_LOCATION keyword set.

──

Syntax

Result = Obj->[IDLitParameterSet::]Copy()

Return Value

Returns an IDLitParameterSet object that is a copy of the parameter set object on which the method was called.

Arguments

None

Keywords

None

Version History

6.0	Introduced

IDLitParameterSet::Get

The IDLitParameterSet::Get function method is used to retrieve one or more
IDLitData objects from the parameter set.

Syntax

Result = *Obj*->[IDLitParameterSet::]Get([, /ALL] [, COUNT=*variable*]
   [, NAME=*variable*] [, POSITION=*integer*])

Return Values

Returns an object reference or array of object references to the IDLitData objects
specified, or returns -1 if the method fails.

Arguments

None

Keywords

ALL

Set this keyword to return an array containing object references to all IDLitData
items in the parameter set.

COUNT

Set this keyword equal to a named variable that will contain the number of items
returned by this function.

NAME

Set this keyword equal to a named variable that will contain a string or string array of
the parameter names associated with the returned IDLitData objects. If a returned
data object has no parameter name, a null string (' ') is returned.

POSITION

Set this keyword equal to a scalar or array containing the zero-based indices of the
positions of the desired IDLitData objects within the parameter set.

Version History

6.0	Introduced

IDLitParameterSet::GetByName

The IDLitParameterSet::GetByName function method returns the IDLitData object associated with a specified named parameter.

Syntax

Result = *Obj*->[IDLitParameterSet::]GetByName(*Names* [, COUNT=*variable*]
    [, NAME=*variable*])

Return Value

An object reference or array of object references to the IDLitData objects specified by the *Names* argument. If no matching parameter names are found, a null object is returned.

Note

If multiple parameter names are specified, the IDLitData objects are returned in the order in which they are stored in the IDLitParameterSet object, which is not necessarily the same as the order specified in the *Names* argument. Use the value returned by the NAME keyword to associate the parameter names with IDLitData objects in the returned array.

Arguments

Names

A scalar string or string array that contains the parameter names of the IDLitData objects to be retrieved from the parameter set.

Note

Parameter names can be supplied in any case; the search is case insensitive.

Keywords

COUNT

Set this keyword equal to a named variable that will contain the number of items returned by this function.

NAME

Set this keyword equal to a named variable that will contain a scalar string or string array of the parameter names of the IDLitData objects returned by this method. When multiple parameter names are specified via the *Names* argument, the array returned in the NAME variable can be used to sort through the returned IDLitData objects by matching the indices of the two returned arrays.

Version History

6.0	Introduced

IDLitParameterSet::GetParameterName

The IDLitParameterSet::GetParameterName function method retrieves the name of a specified parameter using a provided data object.

Syntax

Result = Obj->[IDLitParameterSet::]GetParameterName(*Data*, *Name)*

Return Value

Returns an integer 1 if a parameter name was found for the specified IDLitData object, or 0 if no parameter name was found.

Arguments

Data

An IDLitData object for which the parameter name is being requested.

Name

A named variable that will contain the parameter name associated with the object specified by the *oData* argument. If no parameter name is associated with the object specified by the *oData* argument, a null string (' ') is returned.

Keywords

None

Version History

6.0	Introduced

IDLitParameterSet::Init

The IDLitParameterSet::Init function method initializes the IDLitParameter object.

Note ——————————————————————————————————

Init methods are special life cycle methods, and as such cannot be called outside the context of object creation. This means that in most cases, you cannot call the Init method directly. There is one exception to this rule: if you write your own subclass of this class, you can call the Init method from within the Init method of the subclass.

——

Syntax

Obj = OBJ_NEW('IDLitParameterSet')

or

Result = Obj->[IDLitParameterSet::]Init()   *(In a lifecycle method only.)*

Return Value

When this method is called indirectly, as part of the call to the OBJ_NEW function, the return value is an object reference to the newly-created object.

When called directly within a subclass Init method, the return value is 1 if initialization was successful, or 0 otherwise.

Arguments

None

Keywords

The IDLitParameterSet object has no properties of its own, but inherits the properties of its superclass, IDLitDataContainer. Any property listed under "IDLitDataContainer Properties" on page 3752 that contains the word "Yes" in the "Init" column of the properties table can be initialized during object creation using this method. To initialize the value of a property, specify the property name as a keyword set equal to the appropriate property value.

Version History

6.0	Introduced

IDLitParameterSet::Remove

The IDLitParameterSet::Remove procedure method is used to remove a data item from the parameter set.

Syntax

Obj->[IDLitParameterSet::]Remove [, *Items*] [, /ALL] [, POSITION=*integer*]

Arguments

Items

An object reference or array of object references to IDLitData objects to be removed from the parameter set.

Keywords

ALL

Set this keyword to remove all items from the parameter set. If this keyword is set, the *Items* parameter is not required.

POSITION

Set this keyword equal to a scalar or array containing the zero-based indices within the parameter set of the specified IDLitData objects to be removed. If this keyword is set, the *Items* parameter is not required

Version History

6.0	Introduced

See Also

IDLitParameterSet::Add

IDLitReader

The IDLitReader class defines the interface used to construct file readers for the iTools framework. Objects of this class are not intended to be created as standalone entities; rather, this class should be included as the superclass of an iTool file reader class.

This class is written in the IDL language. Its source code can be found in the file `idlitreader__define.pro` in the `lib/itools/framework` subdirectory of the IDL distribution.

Superclasses

IDLitComponent

IDLitIMessaging

Note ───

See the "iTools Object Model Diagram" (Chapter 2, *iTool Developer's Guide*) for a visual representation of the iTools object model hierarchy.

──

Creation

See "IDLitReader::Init" on page 3962.

Properties

Objects of this class do not have any properties of their own, but do have properties inherited from any superclasses.

Methods

This class has the following methods:

- IDLitReader::Cleanup
- IDLitReader::GetData
- IDLitReader::GetFileExtensions
- IDLitReader::GetFilename
- IDLitReader::GetProperty

- IDLitReader::Init
- IDLitReader::IsA
- IDLitReader::SetFilename
- IDLitReader::SetProperty

In addition, this class inherits the methods of its superclasses.

Examples

See Chapter 9, "Creating a File Reader" (*iTool Developer's Guide*) for examples using this class and its methods.

Version History

6.0	Introduced

IDLitReader Properties

Objects of this class do not have any properties of their own, but do have properties inherited from any superclasses.

Objects in this class inherit:

- IDLitComponent
- IDLitIMessaging

IDLitReader::Cleanup

The IDLitReader::Cleanup procedure method performs all cleanup on the object, and should be called by the subclass' Cleanup method.

Note ————————————————————————————————————

Cleanup methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation and destruction. This means that in most cases, you cannot call the Cleanup method directly. There is one exception to this rule: if you write your own subclass of this class, you can call the Cleanup method from within the Init or Cleanup method of the subclass.

Syntax

OBJ_DESTROY, *Obj*

or

Obj->[IDLitReader::]Cleanup   *(In a lifecycle method only.)*

Arguments

None

Keywords

None

Version History

6.0	Introduced

IDLitReader::GetData

The IDLitReader::GetData function method is called by the system to retrieve the data from the current file. When called, the reader should access the current filename and read the desired data. Once the information is loaded, the reader should place the obtained data in a data object, which is then passed back to the system.

This method will contain a majority of the implementation for a new reader class.

Syntax

Result = Obj->[IDLitReader::]GetData(*Data*)

Return Value

Returns a 1 if successful, or a 0 if the initialization failed.

Arguments

Data

A data object that contains the read information. The reader determines the exact type and format of this data object, which keys off the type of information being read and what the format supports.

Keywords

None

Version History

6.0	Introduced

IDLitReader::GetFileExtensions

The IDLitReader::GetFileExtensions function method is called by the system to retrieve the file extensions supported by this particular reader.

Syntax

Result = Obj->[IDLitReader::]GetFileExtensions([, COUNT=*variable*])

Return Value

Returns a scalar or string array that contains the file extensions associated with this reader.

Arguments

None

Keywords

COUNT

Set this keyword equal to a named variable that will contain the number of items returned by this function.

Version History

6.0	Introduced

IDLitReader::GetFilename

The IDLitReader::GetFilename function method is called by the system to retrieve the current filename associated with this reader. Due to the automated nature of the file reader system, filenames can be associated with a file reader and then read at a later time. This method allows direct access to the file currently associated with the reader.

In addition, this methodology is helpful when multiple reads are performed from a given file.

Syntax

Result = Obj->[IDLitReader::]GetFilename()

Return Value

Returns a string containing the current file name associated with this reader, or an empty string if no filename has been associated.

Arguments

None

Keywords

None

Version History

6.0	Introduced

IDLitReader::GetProperty

The IDLitReader::GetProperty procedure method retrieves the value of an IDLitReader property, and should be called by the subclass' GetProperty method. This method also retrieves properties defined in the superclasses.

Syntax

Obj->[IDLitReader::]GetProperty[, *PROPERTY=variable*]

Arguments

None

Keywords

Any property listed under "IDLitReader Properties" on page 3956 that contains the word "Yes" in the "Get" column of the properties table can be retrieved using this method. To retrieve the value of a property, specify the property name as a keyword set equal to a named variable that will contain the value of the property.

Version History

6.0	Introduced

IDLitReader::Init

The IDLitReader::Init function method initializes the IDLitReader object, and should be called by the subclass' Init method. This method also calls the superclass' Init method.

Note ―――――――――――――――――――――――――――――――――――――

Init methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation. This means that in most cases, you cannot call the Init method directly. There is one exception to this rule: if you write your own subclass of this class, you can call the Init method from within the Init method of the subclass.

―――

Syntax

Obj = OBJ_NEW('IDLitReader' [, *Extensions*] [, *PROPERTY=value*])

or

Result = Obj->[IDLitReader::]Init([, *Extensions*] [, *PROPERTY=value*])   *(In a lifecycle method only.)*

Return Value

When this method is called indirectly, as part of the call to the OBJ_NEW function, the return value is an object reference to the newly-created object.

When called directly within a subclass Init method, the return value is 1 if initialization was successful, or zero otherwise.

Arguments

Extensions

A optional argument containing a scalar or string array with the file extensions that are common for this file type. These values should not include the period that is often associated with file extensions (i.e., a correct value is 'jpeg' and not '.jpeg'). If this argument is not set, or if a null string is provided, IDL does not include this file reader in the list of filters in a file-selection dialog, but still uses it when attempting to match a file to a reader.

Keywords

Any property listed under "IDLitReader Properties" on page 3956 that contains the word "Yes" in the "Init" column of the properties table can be initialized during object creation using this method. To initialize the value of a property, specify the property name as a keyword set equal to the appropriate property value.

Version History

6.0	Introduced

IDLitReader::IsA

The IDLitReader::IsA function method is called by the system to determine if the given file is of the type supported by this file reader. Often this is used to determine what file reader to use when opening a new file.

The default behavior provided by this method is to check the file extension on the provided file name with the extensions provided to this object during initialization.

When a new reader is implemented, the default behavior can be used, or the developer can provide further logic to determine if the provided file is the correct type.

Syntax

Result = Obj->[IDLitReader::]IsA(*Filename*)

Return Value

Returns a 1 if the reader supports this type of file, or a 0 if the reader does not support this type of file.

Arguments

Filename

A string representing of the filename, which is used to check and determine if the reader supports its format.

Keywords

None

Version History

6.0	Introduced

IDLitReader::SetFilename

The IDLitReader::SetFilename procedure method is called by the system to set the current filename associated with this reader. Due to the automated nature of the file reader system, filenames can be associated with a file reader and then the read at a later time.

Syntax

Obj->[IDLitReader::]SetFilename, *Filename*

Arguments

Filename

A string that contains the filename associated with this reader.

Keywords

None

Version History

6.0	Introduced

IDLitReader::SetProperty

The IDLitReader::SetProperty procedure method sets the value of an IDLitReader property, and should be called by the subclass' SetProperty method. This method also calls the superclass' SetProperty method.

Syntax

Obj->[IDLitReader::]SetProperty[, *PROPERTY=value*]

Arguments

None

Keywords

Any property listed under "IDLitReader Properties" on page 3956 that contains the word "Yes" in the "Set" column of the properties table can be set using this method. To set the value of a property, specify the property name as a keyword set equal to the appropriate property value.

Version History

6.0	Introduced

IDLitTool

The IDLitTool class represents all the functionality provided by a particular instance of an IDL Intelligent Tool. It provides the management systems for the underlying iTool functionality and implements the desired interfaces for external parties to interact with this functionality in a known manner.

This class is written in the IDL language. Its source code can be found in the file idlittool__define.pro in the lib/itools/framework subdirectory of the IDL distribution.

Note on the IDLitToolbase Class

All iTools included with the IDL release are based on a subclass of the IDLitTool class named IDLitToolbase. If your aim is to create a new iTool that shares the common features of the iTools included with IDL, you should base your new iTool on the IDLitToolbase class. Since IDLitToolbase is a subclass of IDLitTool, it inherits all of IDLitTool's methods and properties. Additional features included in the IDLitToolbase class are described in "Subclassing from the IDLitToolbase Class" (Chapter 5, *iTool Developer's Guide*).

Superclasses

IDLitContainer

IDLitIMessaging

Note
See the "iTools Object Model Diagram" (Chapter 2, *iTool Developer's Guide*) for a visual representation of the iTools object model hierarchy.

Creation

See "IDLitTool::Init" on page 4000.

Properties

Objects of this class have the following properties. See "IDLitTool Properties" on page 3971 for details on individual properties.

- DESCRIPTION

- ICON
- NAME
- TYPE
- UPDATE_BYTYPE
- VERBOSE
- VERSION

In addition, objects of this class inherit the properties of all superclasses of this class.

Methods

This class has the following methods:

- IDLitTool::ActivateManipulator
- IDLitTool::Add
- IDLitTool::AddService
- IDLitTool::Cleanup
- IDLitTool::CommitActions
- IDLitTool::DisableUpdates
- IDLitTool::DoAction
- IDLitTool::DoSetProperty
- IDLitTool::DoUIService
- IDLitTool::EnableUpdates
- IDLitTool::FindIdentifiers
- IDLitTool::GetCurrentManipulator
- IDLitTool::GetFileReader
- IDLitTool::GetFileWriter
- IDLitTool::GetManipulators
- IDLitTool::GetOperations
- IDLitTool::GetProperty
- IDLitTool::GetSelectedItems
- IDLitTool::GetService

- IDLitTool::GetVisualization
- IDLitTool::Init
- IDLitTool::RefreshCurrentWindow
- IDLitTool::Register
- IDLitTool::RegisterCustomization
- IDLitTool::RegisterFileReader
- IDLitTool::RegisterFileWriter
- IDLitTool::RegisterManipulator
- IDLitTool::RegisterOperation
- IDLitTool::RegisterStatusBarSegment
- IDLitTool::RegisterVisualization
- IDLitTool::SetProperty
- IDLitTool::UnRegister
- IDLitTool::UnRegisterCustomization
- IDLitTool::UnRegisterFileReader
- IDLitTool::UnRegisterFileWriter
- IDLitTool::UnRegisterManipulator
- IDLitTool::UnRegisterOperation
- IDLitTool::UnRegisterStatusBarSegment
- IDLitTool::UnRegisterVisualization

In addition, this class inherits the methods of its superclasses.

Examples

See "Example: Simple iTool" (Chapter 5, *iTool Developer's Guide*).

Version History

6.0	Introduced

See Also

Chapter 5, "Creating an iTool" (*iTool Developer's Guide*)

IDLitTool Properties

IDLitTool objects have the following properties in addition to properties inherited from any superclasses. Properties with the word "Yes" in the "Get" column of the property table can be retrieved via IDLitTool::GetProperty. Properties with the word "Yes" in the "Init" column of the property table can be set via IDLitTool::Init. Properties with the word "Yes" in the "Set" column in the property table can be set via IDLitTool::SetProperty.

Note

For a discussion of the property description tables shown below, see "About Object Property Descriptions" on page 3135.

Objects of this class have the following properties.

- DESCRIPTION
- ICON
- NAME
- TYPE
- UPDATE_BYTYPE
- VERBOSE
- VERSION

In addition, objects of this class inherit:

- IDLitContainer
- IDLitIMessaging

DESCRIPTION

This property contains a string representing the full name or description of this object.

Property Type	STRING		
Name String	Description		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** Yes

ICON

A string identifying the icon that should be used when displaying the iTool object.
See "System Resources" (Chapter 2, *iTool Developer's Guide*) for additional details.

Property Type	String		
Name String	*not displayed*		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** No

NAME

A string representing the name of this object.

Property Type	STRING		
Name String	Name		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** Yes

TYPE

A string or vector of strings that identify the type(s) that this iTool represents.

Property Type	String		
Name String	*not displayed*		
Get: No	**Set:** Yes	**Init:** Yes	**Registered:** No

UPDATE_BYTYPE

A Boolean value controlling whether the given iTool will add new functionality to it
as new visualization types are added. By default, when a new visualization is added
to the iTool, any functionality associated with that visualization type is added to the
iTool. If this property is set to zero (False), this updating is disabled.

Property Type	Boolean		
Name String	*not displayed*		
Get: No	**Set:** Yes	**Init:** Yes	**Registered:** No

VERBOSE

A named variable that will control the verbose logging of the iTool. If set to a non-zero value, the iTool will log more information than normal. If this keyword is set to 0, minimal logging (error conditions only) will be sent to the logging system.

Property Type	Boolean		
Name String	*not displayed*		
Get: Yes	Set: Yes	Init: Yes	Registered: No

VERSION

A named variable that will be set to the version of the iTool system.

Property Type	String		
Name String	*not displayed*		
Get: Yes	Set: No	Init: Yes	Registered: No

IDLitTool::ActivateManipulator

Version History

The IDLitTool::ActivateManipulator procedure method activates a manipulator that has been registered with this tool.

Syntax

Obj->[IDLitTool::]ActivateManipulator, *Identifier* [, /DEFAULT]

Arguments

Identifier

A string representing the identifier of the manipulator to activate.

Keywords

DEFAULT

Set this keyword to a non-zero value to indicate that the default manipulator registered with this tool should be activated. If this keyword is set, the Identifier argument is ignored.

Version History

6.1	Introduced

IDLitTool::Add

The IDLitTool::Add procedure method adds any item to the iTool. If called with a Visualization, that visualization is added to the current IDLitWindow object. If called with a data object, that data object is placed in the systems data manager. All other items are added to the iTool container.

Syntax

Obj->[IDLitTool::]Add, *Item*

Arguments

Item

The item to add to the iTool.

Keywords

This method passes keywords to the Add method of the appropriate object. If the target destination is a data object, no keywords are passed. If the target destination is a visualization object, the keywords are passed to the IDLitWindow::Add method; otherwise, the keywords are passed to the IDLitContainer::Add method.

Version History

6.0	Introduced

IDLitTool::AddService

The IDLitTool::AddService procedure method adds a service to the iTool. Unlike the *register* methods, which register the definition of an object class to be instantiated later, this method takes an existing object instance and adds it to the service repository in the iTool.

The relative identifier for the service added will be SERVICES/*identifier*, where *identifier* is the value of the IDENTIFIER property of the service object.

Syntax

Obj->[IDLitTool::]AddService, *oService*

Arguments

oService

An object reference to the service to be added to the service repository.

Note

The service object reference can be retrieved later by providing the service's object identifier to the IDLitTool::GetService method.

Keywords

None

Version History

6.0	Introduced

IDLitTool::Cleanup

The IDLitTool::Cleanup procedure method performs all cleanup on the object, and should be called by the Cleanup method of a subclass.

Note ───

Cleanup methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation and destruction. This means that in most cases, you cannot call the Cleanup method directly. There is one exception to this rule: if you write your own subclass of this class, you can call the Cleanup method from within the Init or Cleanup method of the subclass.

──

Syntax

OBJ_DESTROY, *Obj*

or

Obj->[IDLitTool::]Cleanup   *(In a lifecycle method only.)*

Arguments

None

Keywords

None

Version History

6.0	Introduced

IDLitTool::CommitActions

The IDLitTool::CommitActions procedure method commits all pending transactions to the undo-redo buffer and causes a refresh of the current window.

This method is designed to be used in conjunction with the IDLitTool::DoSetProperty method.

Syntax

Obj->[IDLitTool::]CommitActions

Arguments

None

Keywords

None

Version History

6.0	Introduced

See Also

IDLitTool::DoSetProperty

IDLitTool::DisableUpdates

The IDLitTool::DisableUpdates procedure method disables all drawing updates to the current window and UI updates (menu sensitivity) being passed to the user interface. After this method is called, updates are re-enabled by calling the EnableUpdates method.

Syntax

Obj->[IDLitTool::]DisableUpdates ([, PREVIOUSLY_DISABLED=*variable*])

Arguments

None

Keywords

PREVIOUSLY_DISABLED

Set this keyword to a named variable that upon return will be 1 if the tool had previously been disabled, or 0 otherwise.

Version History

6.0	Introduced
6.1	Added PREVIOUSLY_DISABLED keyword

IDLitTool::DoAction

The IDLitTool::DoAction function method initiates an operation or action in the iTool object. The identifier that is passed in as the argument to this method specifies the action that executes.

Syntax

Result = Obj->[IDLitTool::]DoAction(*Identifier*)

Return Value

Returns 1 if the action succeeds, or 0 if the action fails.

Arguments

Identifier

This argument is set to a string identifier that specifies the object in the iTool that performs the operation that it implements.

Keywords

All keywords are passed to the DoAction function of the object in the iTool that performs the operation.

Version History

6.0	Introduced

IDLitTool::DoSetProperty

The IDLitTool::DoSetProperty function method sets the value of a registered property on a target component object, and places the change in the undo/redo transaction buffer.

Note

In order to commit the change to the undo/redo transaction buffer, you must call the IDLitTool::CommitActions method. The property change is not actually undoable until it has been committed.

The separation of addition of the change to the buffer and commit of the change allows you to "package" several property changes into a single undo/redo transaction. The call to the CommitActions method will commit any changes that have been performed but not committed. For example, the following statements change two properties on an iTool component (`oTarget`) and commit them together:

```
targetID = oTarget->GetFullIdentifier()
status = oTool->DoSetProperty(targetID, 'Property1', 'Value 1')
status = oTool->DoSetProperty(targetID, 'Property2', 'Value 2')
oTool->CommitActions
```

If the user later undoes the action, both property value changes will be reversed in one step.

Syntax

Result = Obj->[IDLitTool::]DoSetProperty(*TargetIdentifier*, *PropertyIdentifier*, *Value*)

Return Value

Returns 1 if the SetProperty was successful, or 0 otherwise.

Note

If successful, you are responsible for calling IDLitTool::CommitActions to complete the transaction.

Arguments

TargetIdentifier

A scalar string or a string array containing the full object identifiers of the objects on which the property is being set.

PropertyIdentifier

A scalar string containing the identifier of the property whose value is being changed. *PropertyIdentifier* must be a registered property of the target objects.

Value

The new property value.

Keywords

None

Version History

6.0	Introduced

See Also

IDLitTool::CommitActions

IDLitTool::DoUIService

The IDLitTool::DoUIService function method initiates a request for a UI service to execute. This method allows underlying iTool functionality to perform user-interface interactions without having a direct connection to the user interface portion of the iTool.

An example of an iTool UI service would be the **File → Open** command, which will prompt the user to select a file using the standard file open dialog. This command is identified by setting the *ServiceIdentifier* argument to FileOpen. See Chapter 13, "Creating a User Interface Service" (*iTool Developer's Guide*) for more information about UI services.

Syntax

Result = Obj->[IDLitTool::]DoUIService(*ServiceIdentifier*, *Requestor*)

Return Value

Returns 1 if the action succeeds, or 0 if the action fails.

Arguments

ServiceIdentifier

A string identifier that specifies the UI service being requested. This identifier is passed to the tools user interface for control dispatching purposes.

Requestor

An object reference to the object that is requesting the UI service. The UI service uses this object to obtain any information particular to the interaction taking place.

Keywords

None

Version History

6.0	Introduced

IDLitTool::EnableUpdates

The IDLitTool::EnableUpdates procedure method re-enables all drawing updates to the current window and UI updates (menu sensitivity) being passed to the user interface. After this method is called, updates can be disabled by calling the DisableUpdates method.

Syntax

Obj->[IDLitTool::]EnableUpdates

Arguments

None

Keywords

None

Version History

6.0	Introduced

IDLitTool::FindIdentifiers

The IDLitTool::FindIdentifiers function method allows you to retrieve the full identifiers for items within the tool container.

Warning ──

The FindIdentifiers method recurses through the entire object hierarchy of the specified object, which may be slow for large container hierarchies. If you find it necessary to call FindIdentifiers multiple times, it may be more efficient to use a single call with one or more wildcards ("*") to return all relevant identifiers, and then perform the necessary searches using the returned list.

──

Syntax

Result = *Obj*->[IDLitTool::]FindIdentifiers([*Pattern*] [, /ANNOTATIONS]
   [, COUNT=*variable*] [, /DATA_MANAGER] [, /FILE_READERS]
   [, /FILE_WRITERS] [, /LEAF_NODES] [, /MANIPULATORS]
   [, /OPERATIONS] [, /VISUALIZATIONS])

Return Value

Returns a scalar string or string array containing the full object identifiers for all items matching the *Pattern*. If no object identifiers are matched, the function returns a scalar null string.

Arguments

Pattern

A string specifying a search pattern to be used for filtering the returned object identifiers. Only object identifiers that match *Pattern* are returned. Matching is case insensitive. If *Pattern* is not supplied, identifiers for all objects within the object on which this method is called are returned. See STRMATCH for a description of the rules used when matching patterns. See "Retrieving Component Identifiers" (Appendix A, *iTool Developer's Guide*) for additional information and examples.

Note ──

Objects for which the PRIVATE property contains a True value are not included in the *Result*. Only objects that subclass from IDLitComponent can be marked as private.

──

Keywords

ANNOTATIONS

Set this keyword to only return identifiers for items within the annotation layer of all views within the graphics window.

COUNT

Set this keyword equal to a named variable that will contain the number of identifiers in *Result*.

DATA_MANAGER

Set this keyword to only return identifiers for items within the Data Manager container.

FILE_READERS

Set this keyword to only return identifiers for items within the File Readers container.

FILE_WRITERS

Set this keyword to only return identifiers for items within the File Writers container.

LEAF_NODES

Set this keyword to return only leaf nodes. Leaf nodes are objects which are either not a container, or are an empty container.

Note
If all of the objects within a container are marked as PRIVATE, then that container is considered a leaf node. Only objects that subclass from IDLitComponent can be marked as private.

MANIPULATORS

Set this keyword to only return identifiers for items within the Manipulators container.

OPERATIONS

Set this keyword to only return identifiers for items within the Operations container.

VISUALIZATIONS

Set this keyword to only return identifiers for items within the Visualization layer of all views within the graphics window.

Example

This example finds the plot visualization and changes the color:

```
IPLOT, RANDOMU(s,100)
void = ITGETCURRENT(TOOL=oTool)

; Find the Plot visualization and change the color.
id = oTool->FindIdentifiers('*plot*', /VISUALIZATIONS)

void = oTool->DoSetProperty(id, 'COLOR', [255,0,0])
```

This example finds the file open operation and loads in an image:

```
IIMAGE
void = ITGETCURRENT(TOOL=oTool)

; Find the File Open operation and open a file.
id = oTool->FindIdentifiers('*File/Open*', /OPERATIONS)

oOp = oTool->GetByIdentifier(id)
oOp->SetProperty, SHOW_EXECUTION_UI=0, $
   FILENAMES=FILEPATH('rose.jpg', SUBDIR=['examples','data'])
void = oTool->DoAction(id)
oOp->SetProperty, SHOW_EXECUTION_UI=1
```

Version History

6.1	Introduced

See Also

"Retrieving Component Identifiers" (Appendix A, *iTool Developer's Guide*)

IDLitTool::GetCurrentManipulator

The IDLitTool::GetCurrentManipulator function method returns the current manipulator in the system.

Syntax

Result = Obj->[IDLitTool::]GetCurrentManipulator()

Return Value

Returns an object reference to the current manipulator.

Arguments

None

Keywords

None

Version History

6.0	Introduced

IDLitTool::GetFileReader

The IDLitTool::GetFileReader function method retrieves a file reader registered with the iTool object. If the requested item does not exist in the given iTool, the system will be queried to see if it supports an object of the given identifier.

Syntax

Result = Obj->[IDLitTool::]GetFileReaders(*Identifier* [, /ALL]
   [, COUNT=*variable*])

Return Value

Returns the object descriptors constructed for the registered file reader.

If the ALL keyword is set, the *Identifier* argument is ignored and the resulting list of object descriptors will be both those registered with the specific iTool and those file readers registered with the system.

Arguments

Identifier

A string representing the single level identifier of the item that is being requested. This identifier is the value provided during object registration and is either supplied using the IDENTIFIER keyword during registration, or constructed automatically by the name that is provided during the registration call.

Keywords

ALL

Set this keyword to return all file readers registered with the iTool and the system.

COUNT

Set this keyword to a named variable that will contain the number of object descriptors returned by this method.

Version History

6.0	Introduced

IDLitTool::GetFileWriter

The IDLitTool::GetFileWriter function method retrieves a file writer registered with the iTool object. If the requested item does not exist in the given iTool, the system will be queried to see if it supports an object of the given identifier.

Syntax

Result = Obj->[IDLitTool::]GetFileWriters(*Identifier* [, /ALL]
    [, COUNT=*variable*])

Return Value

Returns the object descriptors constructed for the registered file writer.

If the ALL keyword is set, the *Identifier* argument is ignored and the resulting list of object descriptors will be both those registered with the specific iTool and those file writers registered with the system.

Arguments

Identifier

A string representing the identifier of the item that is being requested. This identifier is the value provided during object registration and is either supplied using the IDENTIFIER keyword during registration, or constructed automatically by the name that is provided during the registration call.

Keywords

ALL

Set this keyword to return all file writers registered with the iTool and the system.

COUNT

Set this keyword to a named variable that will contain the number of object descriptors returned by this method.

Version History

6.0	Introduced

IDLitTool::GetManipulators

The IDLitTool::GetManipulators function method retrieves the manipulators registered with the iTool object. Unlike other items in the iTool and due to the active nature of the subsystem, manipulators are instantiated when registered.

Syntax

Result = Obj->[IDLitTool::]GetManipulators([, COUNT=*variable*])

Return Value

Returns the object references to the manipulators that were instantiated when items were registered with the iTool.

Arguments

None

Keywords

COUNT

Set this keyword to a named variable that will contain the number of object descriptors returned by this method.

Version History

6.0	Introduced

IDLitTool::GetOperations

The IDLitTool::GetOperations function method retrieves the operations registered with the iTool object.

Note

This routine returns a set of object descriptor classes that reference the items registered with the iTool. In addition, if the operation folder in the registry contains sub-folders, the returned list will contain IDLitContainer classes, each containing sub-operations.

Syntax

Result = Obj->[IDLitTool::]GetOperations([, COUNT=*variable*]
   [, IDENTIFIER=*string*])

Return Value

Returns the object descriptors constructed for the registered operations.

Arguments

None

Keywords

COUNT

Set this keyword to a named variable that will contain the number of object descriptors returned by this method.

IDENTIFIER

Set this keyword to an optional identifier that identifies the location in the operation hierarchy to retrieve the operation object descriptors from.

Version History

6.0	Introduced

IDLitTool::GetProperty

The IDLitTool::GetProperty procedure method retrieves the value of an IDLitTool property, and should be called by the subclass' GetProperty method. This method also retrieves properties defined in the superclasses.

Syntax

Obj->[IDLitTool::]GetProperty, [*PROPERTY=variable]*

Arguments

None

Keywords

Any property listed under "IDLitTool Properties" on page 3971 that contains the word "Yes" in the "Get" column of the properties table can be retrieved using this method. To retrieve the value of a property, specify the property name as a keyword set equal to a named variable that will contain the value of the property.

Version History

6.0	Introduced

IDLitTool::GetSelectedItems

The IDLitTool::GetSelectedItems function method returns a vector of references to the objects currently selected within the current window in the iTool. If no objects are currently selected, this function returns -1.

Syntax

Result = Obj->[IDLitTool::]GetSelectedItems([, COUNT=*variable*])

Return Value

Returns a vector of references to the currently selected objects. If no objects are currently selected, this function returns -1.

Arguments

None

Keywords

COUNT

Set this keyword to a named variable that will contain the number of valid items returned by this function.

Version History

6.0	Introduced

IDLitTool::GetService

The IDLitTool::GetService method retrieves a service that has been registered with the iTool.

Syntax

Result = Obj->[IDLitTool::]GetService(*IdService*)

Return Value

Returns an object reference for the service.

Arguments

IdService

The relative identifier of the desired service.

Note
IdService should specify only the relative identifier, not the fully-qualified identifier. See "iTool Object Identifiers" (Chapter 2, *iTool Developer's Guide*) for details.

Keywords

None

Version History

6.0	Introduced

IDLitTool::GetVisualization

The IDLitTool::GetVisualization function method retrieves a visualization registered with the iTool object. If the requested item does not exist in the given iTool, the system will be queried to see if it supports an object of the given identifier.

Syntax

Result = Obj->[IDLitTool::]GetVisualization(*Identifier* [, /ALL]
   [, COUNT=*variable*])

Return Value

Returns the object descriptors constructed for the registered visualizations. (See "iTool Object Identifiers" (Chapter 2, *iTool Developer's Guide*) for a discussion of object descriptors.)

If the ALL keyword is set, the *Identifier* argument is ignored and the resulting list of object descriptors will be both those registered with the specific iTool as well as those visualizations registered with the system.

Arguments

Identifier

A string containing the relative identifier of the item that is being requested. This identifier is the value provided during object registration and is either supplied using the IDENTIFIER keyword during registration, or constructed automatically by the name that is provided during the registration call. (See "iTool Object Identifiers" (Chapter 2, *iTool Developer's Guide*) for a discussion of relative vs. fully-qualified identifiers.)

Keywords

ALL

Set this keyword to return all visualizations registered with the iTool and the system.

COUNT

Set this keyword to a variable that will contain the number of object descriptors returned by this method. (See "iTool Object Identifiers" (Chapter 2, *iTool Developer's Guide*) for a discussion of object descriptors.)

Version History

6.0	Introduced

IDLitTool::Init

The IDLitTool::Init function method initializes the IDLitTool object, and should be called by the Init method of a subclass.

Note ———

Init methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation. This means that in most cases, you cannot call the Init method directly. There is one exception to this rule: if you write your own subclass of this class, you can call the Init method from within the Init method of the subclass.

———

Syntax

Obj = OBJ_NEW('IDLitTool'[, *PROPERTY=value*])

or

Result = Obj->[IDLitTool::]Init([, *PROPERTY=value*])   *(In a lifecycle method only.)*

Return Value

When this method is called indirectly, as part of the call to the OBJ_NEW function, the return value is an object reference to the newly-created object.

When called directly within a subclass Init method, the return value is 1 if initialization was successful, or zero otherwise.

Arguments

None

Keywords

Any property listed under "IDLitTool Properties" on page 3971 that contains the word "Yes" in the "Init" column of the properties table can be initialized during object creation using this method. To initialize the value of a property, specify the property name as a keyword set equal to the appropriate property value.

Version History

6.0	Introduced

IDLitTool::RefreshCurrentWindow

The IDLitTool::RefreshCurrentWindow procedure method redraws the current window of the iTool. The redraw will occur only if updates are enabled in the iTool.

Syntax

Obj->[IDLitTool::]RefreshCurrentWindow

Arguments

None

Keywords

None

Version History

6.0	Introduced

IDLitTool::Register

The IDLitTool::Register procedure method registers a generic object subclassed from the IDLitComponent class with the iTool. Once registered, the iTool has the ability to instantiate this type of component when needed. Unlike the other provided methods to register components, this method is generic.

This method allows items to be registered in the standard registry folders of the IDLitTool object, and can be used as well for the creation of new folders. If the provided identifier specifies a folder that does not currently exist in the iTool, it is created.

Note

For information on registering functionality with the iTool system, making the registered functionality available to all iTools, see ITREGISTER.

This method performs none of the validation performed by the specific registration functions. As such, it can cause issues with iTool operation, if used incorrectly. You should use the following related methods for registering certain, specific components to insure validation:

- File readers — "IDLitTool::RegisterFileReader" on page 4007
- File writers — "IDLitTool::RegisterFileWriter" on page 4010
- Manipulators — "IDLitTool::RegisterManipulator" on page 4013
- Operations — "IDLitTool::RegisterOperation" on page 4015
- Visualizations — "IDLitTool::RegisterVisualization" on page 4020

Syntax

Obj->[IDLitTool::]Register, *Name*, *ClassName* [, /DEFAULT]
   [, DESCRIPTION=*string*] [, ICON=*string*] [, IDENTIFIER=*string*]
   [, PROXY=*string*]

Arguments

Name

A string containing the human readable name of the component type being registered with the iTool.

Note ───
If the IDENTIFIER keyword is not supplied, the *Name* argument will be used as the basis for the component's identifier.
──

ClassName

A string containing the class name of the component being registered. This class name is used by the iTool object to instantiate a component of this type when requested by the system.

Keywords

Note ───
Any keywords provided to this routine but not listed here are treated as property defaults for the registered item and applied to the registered object when it is created.
──

DEFAULT

Set this keyword to specify that the item being registered should be the *default item* of its type. Making an item the default places the item first in the list of items of its type. When the iTool system chooses an item, it will use the first item in the list that matches the data type of the selected data. When items are displayed in a list for the user to select from, the default item will appear at the top of the list.

For example, if you register a visualization type with the DEFAULT keyword set, your visualization type will be used by the iTool (assuming the selected data is of the proper type) unless you specifically choose a different visualization type.

Note ───
If you register more than one item with the DEFAULT keyword set, the *last* item registered will appear *first* in the list of items of that type.
──

DESCRIPTION

Set this keyword to a string that provides a brief description of the component being registered.

ICON

Set this keyword to the icon that should be used when displaying the iTool object. See "System Resources" (Chapter 2, *iTool Developer's Guide*) for additional details.

IDENTIFIER

Set this keyword to the identifier that should be used by the system for this component type. If not provided, an identifier is constructed from the provided *Name* value.

To use one of the iTool-provided registration locations, the value of this keyword should contain the destination for the new component that is being registered. Valid destinations in the iTool are:

- Visualizations
- Operations
- Manipulators
- File Writers
- File Readers

Note
If an item with the specified identifier has already been registered with the iTool system, the existing item will be *replaced* by the new item.

PROXY

Set this keyword to the identifier of the object that this registered item should utilize instead of providing a new object descriptor. If a proxy is registered, all requests and actions performed to this item are routed to the item specified by the identifier provide to this keyword. (See "iTool Object Identifiers" (Chapter 2, *iTool Developer's Guide*) for a discussion of object descriptors.)

Version History

6.0	Introduced
6.1	Added DEFAULT keyword

IDLitTool::RegisterCustomization

The IDLitTool::RegisterCustomization procedure method registers an operation class that represents the graphics customization operation to be associated with this tool.

Syntax

Obj->[IDLitTool::]RegisterCustomization, *Name*, *ClassName*

Arguments

Name

A string representing the name of the customization operation.

ClassName

A string representing the classname of the operation being registered.

Keywords

Note
Any keywords provided to this routine are treated as property defaults for the registered operation and applied to the registered object when it is created.

Version History

6.1	Introduced

IDLitTool::RegisterFileReader

The IDLitTool::RegisterFileReader procedure method registers a file reader component with the iTool. Once registered, the iTool has the ability to instantiate this type of component when needed.

When a reader class is registered with the iTool, an object descriptor for this operation class is placed in the iTool's file reader folder. To retrieve this descriptor at a later time, the iTool relative identifier would be FILE READERS/identifier, where identifier is the identifier provided to this method.

Syntax

Obj->[IDLitTool::]RegisterFileReader, *Name*, *ClassName* [, /DEFAULT]
   [, DESCRIPTION=*string*] [, ICON=*string*] [, IDENTIFIER=*string*]
   [, PROXY=*string*]

Arguments

Name

The human readable name of the component type being registered with the iTool.

Note ———

If the IDENTIFIER keyword is not supplied, the *Name* argument will be used as the basis for the component's identifier.

——

ClassName

A string containing the class name of the component being registered. This class name is used by the iTool object to instantiate a component of this type when requested by the system.

Keywords

Note ———

Any keywords provided to this routine but not listed here are treated as property defaults for the registered item and applied to the registered object when it is created.

——

DEFAULT

Set this keyword to specify that the file reader being registered should be the *default* file reader. When the iTool system picks a reader for a file of the specified type, it will attempt to use the specified file reader first. The file reader will also be displayed at the top of the list of file readers displayed for the user to select from.

Note

If you register more than one file reader with the DEFAULT keyword set, the *last* file reader registered will appear *first* in the list of items of file readers.

DESCRIPTION

Set this keyword to a string that provides a brief description of the component being registered.

ICON

Set this keyword to the icon that should be used when displaying the file reader in an iTool browser. See "System Resources" (Chapter 2, *iTool Developer's Guide*) for additional details.

IDENTIFIER

Set this keyword to the identifier that should be used by the system for this visualization type. If not provided, an identifier is constructed from the provided *Name* value.

While some items registered with an iTool can contain sub-folders that are specified by identifiers, the file reader registration cannot. As such, any nested identifiers that are registered are not visible to the iTool system.

Note

If an item with the specified identifier has already been registered with the iTool system, the existing item will be *replaced* by the new item.

PROXY

Set this keyword to the identifier of the object that this registered item should utilize instead of providing a new object descriptor. If a proxy is registered, all requests and actions performed on this item are routed to the item specified by the identifier provided for this keyword. (See "iTool Object Identifiers" (Chapter 2, *iTool Developer's Guide*) for a discussion of object descriptors.)

Version History

6.0	Introduced
6.1	Added DEFAULT keyword

ITREGISTER

IDLitTool::RegisterFileWriter

The IDLitTool::RegisterFileWriter procedure method registers a file writer component with the iTool. Once registered, the iTool has the ability to instantiate this type of component when needed.

When a writer class is registered with the system, an object descriptor for this operation class is placed in the iTool's file writer folder. To retrieve this descriptor at a later time, the iTool relative identifier would be FILE WRITERS/identifier, where identifier is the identifier provided to this method.

Syntax

Obj->[IDLitTool::]RegisterFileWriter, *Name*, *ClassName* [, /DEFAULT]
   [, DESCRIPTION=*string*] [, ICON=*string*] [, IDENTIFIER=*string*]
   [, PROXY=*string*]

Arguments

Name

A string containing the human readable name of the component type being registered with the iTool.

Note
If the IDENTIFIER keyword is not supplied, the *Name* argument will be used as the basis for the component's identifier.

ClassName

A string containing the class name of the component being registered. The iTool object uses this class name to instantiate a component of this type when requested by the system.

Keywords

Note
Any keywords provided to this routine but not listed here are treated as property defaults for the registered item and applied to the registered object when it is created.

DEFAULT

Set this keyword to specify that the file writer being registered should be the *default* file writer. When the iTool system picks a writer for a file of the specified type, it will attempt to use the specified file writer first. The file writer will also be displayed at the top of the list of file writers displayed for the user to select from.

Note ───────────────────────────

If you register more than one file writer with the DEFAULT keyword set, the *last* file writer registered will appear *first* in the list of file writers.

─────────────────────────────────

DESCRIPTION

Set this keyword to a string that provides a brief description of the component being registered.

ICON

Set this keyword to the icon that should be used when displaying the file writer in an iTool browser. See "System Resources" (Chapter 2, *iTool Developer's Guide*) for additional details.

IDENTIFIER

Set this keyword to the identifier that should be used by the system for this visualization type. If not provided, an identifier is constructed from the provided *Name* value.

While some items registered with an iTool can contain sub-folders that are specified by identifiers, the file writer registration cannot. As such, any nested identifiers that are registered are not visible to the iTool system.

Note ───────────────────────────

If an item with the specified identifier has already been registered with the iTool system, the existing item will be *replaced* by the new item.

─────────────────────────────────

PROXY

Set this keyword to the identifier of the object that this registered item should utilize instead of providing a new object descriptor. If a proxy is registered, all requests and actions performed on this item are routed to the item specified by the identifier provided for this keyword. (See "iTool Object Identifiers" (Chapter 2, *iTool Developer's Guide*) for a discussion of object descriptors.)

ITREGISTER

IDLitTool::RegisterManipulator

The IDLitTool::RegisterManipulator procedure method registers a manipulator component with the iTool. Once registered, the iTool has the ability to instantiate this type of component when needed.

When a manipulator class is registered with the system, an object of the given class is created and added to the tools manipulator manager (an instance of IDLitManipulatorManager). To reference the new manipulator, the identifier that is provided should be prepended with the MANIPULATORS identifier level.

Syntax

Obj->[IDLitTool::]RegisterManipulator, *Name*, *ClassName* [, /DEFAULT]
   [, DESCRIPTION=*string*] [, ICON=*string*] [, IDENTIFIER=*string*]

Arguments

Name

A string containing the human readable name of the component type being registered with the iTool.

Note ───
If the IDENTIFIER keyword is not supplied, the *Name* argument will be used as the basis for the component's identifier.
───

ClassName

A string containing the class name of the component being registered. This class name is used by the iTool object to instantiate a component of this type when requested by the system.

Keywords

Note ───
Any keywords provided to this routine but not listed here are treated as property defaults for the registered item and applied to the registered object when it is created.
───

DEFAULT

If set, this registered item will be treated as the default manipulator for this iTool. Only one default manipulator can exist at anytime.

DESCRIPTION

Set this keyword to a string that provides a brief description of the component being registered.

ICON

Set this keyword to the icon that should be used when displaying the manipulator in an iTool menubar. See "System Resources" (Chapter 2, *iTool Developer's Guide*) for additional details.

IDENTIFIER

Set this keyword to the identifier that should be used by the system for this visualization type. If not provided, an identifier is constructed from the provided name value.

Note ──

If an item with the specified identifier has already been registered with the iTool system, the existing item will be *replaced* by the new item.

───

Version History

6.0	Introduced

IDLitTool::RegisterOperation

The IDLitTool::RegisterOperation procedure method registers an operation component with the iTool. Once registered, the iTool has the ability to instantiate this type of operation when needed.

When an operation class is registered with the system, an object descriptor for this operation class is placed in the tools operations folder. To retrieve this descriptor at a later time, the iTool relative identifier would be OPERATIONS/identifier, where identifier is the identifier provided to this method.

Syntax

Obj->[IDLitTool::]RegisterOperation, *Name*, *ClassName*
    [, ACCELERATOR=string] [, /CHECKED] [, DESCRIPTION=*string*]
    [, /DROPLIST_EDIT] [, DROPLIST_INDEX=*value*]
    [, DROPLIST_ITEMS=*string array*] [, ICON=*string*] [, IDENTIFIER=*string*]
    [, PROXY=*string*] [, /SEPARATOR]

Arguments

Name

A string containing the human readable name of the operation type being registered with the iTool.

Note ——————————————————————————————————————

If the IDENTIFIER keyword is not supplied, the *Name* argument will be used as the basis for the component's identifier.

——

ClassName

A string containing the class name of the operation component being registered. This class name is used by the iTool object to instantiate an operation component of this type when requested.

Keywords

Note
Any keywords provided to this routine but not listed here are treated as property
defaults for the registered item and applied to the registered object when it is
created.

ACCELERATOR

Set this keyword to a string giving the keyboard accelerator to be used for the menu
item associated with this operation. For valid values see the ACCELERATOR
keyword to WIDGET_BUTTON.

Note
This keyword is only a hint to the Tool, and may be ignored if a non-standard user
interface is being used.

CHECKED

Set this keyword to indicate that a "checked" menu item should be used for this
operation.

Note
This keyword is only a hint to the Tool, and may be ignored if a non-standard user
interface is being used.

DESCRIPTION

Set this keyword to a string that provides a brief description of the component being
registered.

DROPLIST_EDIT

Set this keyword to indicate that a droplist associated with this operation should be
editable (that is, the droplist should be a combobox widget). The default is to create a
non-editable droplist widget. The DROPLIST_ITEMS keyword must be set for this
keyword to have any effect.

Note
This keyword is only a hint to the iTool, and may be ignored if a non-standard user
interface is being used.

DROPLIST_INDEX

Set this keyword equal to the starting index of the droplist associated with this operation. The default is 0 (zero). The DROPLIST_ITEMS keyword must be set for this keyword to have any effect.

Note

This keyword is only a hint to the iTool, and may be ignored if a non-standard user interface is being used.

DROPLIST_ITEMS

Set this keyword equal to a scalar string or string array containing values to be used for the droplist. If this keyword is set, the DoAction method for the associated operation must accept a keyword called OPTION. When an item from the droplist is selected, the DoAction method will be called with the OPTION keyword set equal to the selected string value.

Note

This keyword is only a hint to the iTool, and may be ignored if a non-standard user interface is being used.

ICON

Set this keyword to the icon that should be used when displaying the operation in an iTool browser. See "System Resources" (Chapter 2, *iTool Developer's Guide*) for additional details.

IDENTIFIER

Set this keyword to the identifier for the iTool for this component type. If not provided, an identifier is constructed from the *Name*.

Operations are placed in the operation folder of the iTool component hierarchy. If a multiple level identifier is provided (indicated by the presence of one or more "/" characters), the item is placed in the corresponding subfolder of the tool's operation folder. If the specified subfolder is not present, it is created. This functionality allows operations to be classified in logical groupings and results in sub-menu items in the menus of the iTool interface.

See "iTool Object Hierarchy" (Chapter 2, *iTool Developer's Guide*) for a discussion of object identifiers and the iTool component hierarchy.

Note ———

If an item with the specified identifier has already been registered with the iTool
system, the existing item will be *replaced* by the new item.

———

PROXY

Set this keyword to the identifier of the object that this registered item should utilize
instead of providing a new object descriptor. If a proxy is registered, all requests and
actions performed on this item are routed to the item specified by the identifier
provided for this keyword. (See "iTool Object Identifiers" (Chapter 2, *iTool
Developer's Guide*) for a discussion of object descriptors.)

SEPARATOR

Set this keyword to indicate that a menu separator should be placed before this
operation, if this operation appears in a menu.

Note ———

This keyword is only a hint to the Tool, and may be ignored if a non-standard user
interface is being used.

———

Version History

6.0	Introduced
6.1	Added ACCELERATOR, CHECKED, DISABLE, DROPLIST_EDIT, DROPLIST_INDEX, DROPLIST_ITEMS, SEPARATOR keywords
6.2	Deprecated DISABLE keyword

For information on obsolete keywords, see Appendix I, "Obsolete Features".

IDLitTool::RegisterStatusBarSegment

The IDLitTool::RegisterStatusBarSegment procedure method registers a status message bar segment with the tool.

Syntax

Obj->[IDLitTool::]RegisterStatusBarSegment, *Name* [, IDENTIFIER=*string*]
   [, NORMALIZED_WIDTH=*scalar*]

Arguments

Name

A scalar string containing the name of the status bar segment.

Keywords

IDENTIFIER

Set this keyword to a string containing the relative identifier for the status bar segment being registered. If this keyword is not specified, the *Name* argument is used as the identifier. See "iTool Object Identifiers" (Chapter 2, *iTool Developer's Guide*) for a discussion of iTool identifiers.

NORMALIZED_WIDTH

Set this keyword to a floating-point integer between 0 and 1.0 indicating the normalized width (relative to the overall width of the status bar) that this segment should occupy.

Version History

6.1	Introduced

See Also

IDLitTool::UnRegisterStatusBarSegment

IDLitTool::RegisterVisualization

The IDLitTool::RegisterVisualization procedure method registers a visualization component with the iTool. Once registered, the iTool has the ability to instantiate this type of visualization when needed.

When a visualization class is registered with the system, an object descriptor for this visualization class is placed in the iTool's visualization folder. To retrieve this descriptor at a later time, the iTool relative identifier would be: VISUALIZATIONS/identifier where identifier is the identifier provided to this method.

Syntax

Obj->[IDLitTool::]RegisterVisualization, *Name*, *ClassName* [, /DEFAULT]
    [, DESCRIPTION=*string*] [, ICON=*string*] [, IDENTIFIER=*string*]
    [, PROXY=*string*]

Arguments

Name

A string containing the human readable name of the visualization type being registered with the iTool.

Note
If the IDENTIFIER keyword is not supplied, the *Name* argument will be used as the basis for the component's identifier.

ClassName

A string containing the class name of the visualization component being registered. The iTool object uses this class name to instantiate a visualization component of this type when requested.

Keywords

Note
Any keywords provided to this routine but not listed here are treated as property defaults for the registered item and applied to the registered object when it is created.

DEFAULT

If set, this registered item will be treated as the default visualization for this iTool. Only one default visualization can exist at a time.

DESCRIPTION

Set this keyword to a string that provides a brief description of the component being registered.

ICON

Set this keyword to the icon that should be used when displaying the visualization in an iTool browser. See "System Resources" (Chapter 2, *iTool Developer's Guide*) for additional details.

IDENTIFIER

Set this keyword to the identifier that should be used by the system for this visualization type. If not provided, an identifier is constructed from the provided name value.

While some items registered with an iTool can contain sub-folders that are specified by identifiers, the visualization registration cannot. As such, any nested identifiers that are registered are not visible to the iTool system.

Note
If an item with the specified identifier has already been registered with the iTool system, the existing item will be *replaced* by the new item.

PROXY

Set this keyword to the identifier of the object that this registered item should utilize instead of providing a new object descriptor. If a proxy is registered, all requests and actions performed on this item are routed to the item specified by the identifier provided for this keyword.

Version History

6.0	Introduced

ITREGISTER

IDLitTool::SetProperty

The IDLitTool::SetProperty procedure method sets the value of an IDLitTool property, and should be called by the subclass' SetProperty method. This method also calls the superclass' SetProperty method.

Syntax

Obj->[IDLitTool::]SetProperty[, *PROPERTY=value]*

Arguments

None

Keywords

Any property listed under "IDLitTool Properties" on page 3971 that contains the word "Yes" in the "Set" column of the properties table can be set using this method. To set the value of a property, specify the property name as a keyword set equal to the appropriate property value.

Version History

6.0	Introduced

See Also

IDLitTool::DoSetProperty

IDLitTool::UnRegister

The IDLitTool::UnRegister procedure method unregisters a component with the iTool. When a component is unregistered, it is no longer available to perform whatever function it performs, and it is removed from iTool menus and toolbars.

Syntax

Obj->[IDLitTool::]UnRegister, *Identifier*

Arguments

Identifier

Set this to the relative identifier of the component to be removed from the iTool. To remove a component from the standard folders in the iTool's content registry, this identifier should contain the location of the component as well as the component identifier itself. See "iTool Object Identifiers" (Chapter 2, *iTool Developer's Guide*) for a discussion of iTool identifiers.

Valid destinations in the iTool are:

- Visualizations
- Operations
- Manipulators
- File Writers
- File Readers

Keywords

None

Syntax

Obj->[IDLitTool::]UnRegisterVisualization, *Identifier*

Arguments

Identifier

Set this to the relative identifier of the visualization to remove from the iTool. See "iTool Object Identifiers" (Chapter 2, *iTool Developer's Guide*) for a discussion of iTool identifiers.

Keywords

None

Version History

6.0	Introduced

IDLitToolbase

The IDLitToolbase class is a subclass of the IDLitTool class that *registers* all of the features (menu items, operations, manipulators, *etc*.) of a standard iTool. If your aim is to create a new iTool that shares the common features of the iTools included with IDL, you should base your new iTool on the IDLitToolbase class. Since IDLitToolbase is a subclass of IDLitTool, it inherits all of IDLitTool's methods and properties. Additional features included in the IDLitToolbase class are described in "Subclassing from the IDLitToolbase Class" (Chapter 5, *iTool Developer's Guide*).

Warning ───

The list of items registered by the IDLitToolbase class may change from release to release. If your aim is to have your tool present the same features as the standard iTools provided in an IDL release, subclass your tool from IDLitToolbase. If your aim is to create your own interface that stays static between releases of IDL, use IDLitToolbase as a template for your own tool, but do not subclass it directly.

───

This class is written in the IDL language. Its source code can be found in the file `idlittoolbase__define.pro` in the `lib/itools/framework` subdirectory of the IDL distribution.

Superclasses

IDLitTool

Note ──

See the "iTools Object Model Diagram" (Chapter 2, *iTool Developer's Guide*) for a visual representation of the iTools object model hierarchy.

───

Creation

See "IDLitTool::Init" on page 4000.

Properties

Objects of this class have no properties of their own, but do have properties inherited from any superclasses.

Methods

Objects of this class have no methods of their own, but do have methods inherited from any superclasses.

Examples

See "Example: Simple iTool" (Chapter 5, *iTool Developer's Guide*).

Chapter 5, "Creating an iTool" (*iTool Developer's Guide*)

IDLitUI

The IDLitUI class serves as the link between the underlying functionality of an iTool and the IDL Widget interface that is displayed to the user. The user interface object provides the following functionality:

- Access to and communication with the underlying iTool object.
- Registration of various user interface elements that are part of the iTool.
- Registration and management of dialog sub-elements that are used by the iTool to perform specific tasks.

For additional information on the IDLitUI class, and user interface issues in general, see Chapter 11, "iTool User Interface Architecture" (*iTool Developer's Guide*).

This class is written in the IDL language. Its source code can be found in the file idlitui__define.pro in the lib/itools/ui_widgets subdirectory of the IDL distribution.

Superclasses

IDLitContainer

Note
See the "iTools Object Model Diagram" (Chapter 2, *iTool Developer's Guide*) for a visual representation of the iTools object model hierarchy.

Creation

See "IDLitUI::Init" on page 4045.

Properties

Objects of this class have the following properties. See "IDLitUI Properties" on page 4036 for details on individual properties.

- GROUP_LEADER

Methods

This class has the following methods:

- IDLitUI::AddOnNotifyObserver

- IDLitUI::Cleanup
- IDLitUI::DoAction
- IDLitUI::GetProperty
- IDLitUI::GetTool
- IDLitUI::GetWidgetByName
- IDLitUI::Init
- IDLitUI::RegisterUIService
- IDLitUI::RegisterWidget
- IDLitUI::RemoveOnNotifyObserver
- IDLitUI::SetProperty
- IDLitUI::UnRegisterUIService
- IDLitUI::UnRegisterWidget

In addition, this class inherits the methods of its superclasses (if any).

Examples

See "Example: A Simple UI Panel" (Chapter 14, *iTool Developer's Guide*).

Version History

IDLitUI Properties

IDLitUI objects have the following properties in addition to properties inherited from any superclasses. Properties with the word "Yes" in the "Get" column of the property table can be retrieved via IDLitUI::GetProperty. Properties with the word "Yes" in the "Init" column of the property table can be set via IDLitUI::Init. Properties with the word "Yes" in the "Set" column in the property table can be set via IDLitUI::SetProperty.

Note ───

For a discussion of the property description tables shown below, see "About Object Property Descriptions" on page 3135.

───

Objects of this class have the following properties.

- GROUP_LEADER

In addition, objects of this class inherit:

- IDLitContainer

GROUP_LEADER

A long integer containing the IDL Widget ID of the group leader widget for the user interface.

Property Type	Long Integer (Widget ID)		
Name String	*not displayed*		
Get: Yes	**Set:** No	**Init:** No	**Registered:** No

IDLitUI::AddOnNotifyObserver

The IDLitUI::AddOnNotifyObserver procedure method is used to register a specified iTool component object as wishing to receive messages generated by the DoOnNotify method of another specified iTool component object.

Syntax

Obj->[IDLitUI::]AddOnNotifyObserver, *IdObserver*, *IdSubject*

Arguments

IdObserver

The object identifier of an iTool component object that is the *observer* expressing interest in the subject specified by *IdSubject*. Often, *IdObserver* is the object identifier of the object on which this method is being called.

The object specified by *IdObserver* must implement the OnNotify callback method, which is called when a notification message is dispatched to *IdObserver* by the DoOnNotify method of another iTool component object (usually the object specified by *IdSubject*). The OnNotify method has the following signature:

```
PRO ::OnNotify, idObject, idMessage, message
```

where

- *idObject* is the object identifier of the iTool component that is the source of the message.

- *idMessage* is a string that identifies the type of message being sent.

- *message* is the message data itself.

In general, the *idMessage* string is used by the OnNotify method to determine what type of action to take. See "IDLitIMessaging::DoOnNotify" on page 3807 for additional details.

IdSubject

A string identifying the item that *IdObserver* is interested in. This is normally the object identifier of a particular iTool component object, but it can be any string value. When a message sent via IDLitIMessaging::DoOnNotify specifies *IdSubject* as the originator, the *IdObserver* object's OnNotify method is called.

Keywords

None

Version History

6.0	Introduced

IDLitUI::Cleanup

The IDLitUI::Cleanup procedure method performs all cleanup on the object, and should be called by the Cleanup method of a subclass.

Note ───

Cleanup methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation and destruction. This means that in most cases, you cannot call the Cleanup method directly. There is one exception to this rule: if you write your own subclass of this class, you can call the Cleanup method from within the Init or Cleanup method of the subclass.

───

Syntax

OBJ_DESTROY, *Obj*

or

Obj->[IDLitUI::]Cleanup   *(In a lifecycle method only.)*

Arguments

None

Keywords

None

Version History

6.0	Introduced

IDLitUI::DoAction

The IDLitUI::DoAction function method initiates an operation or action in the iTool object associated with this user interface. The identifier that is passed in as the argument to this method specifies the action that executes.

Syntax

Result = Obj->[IDLitUI::]doAction(*Identifier*)

Return Value

Returns 1 if the action succeeds, or 0 if the action fails.

Arguments

Identifier

This argument is set to a string identifier that specifies the object in the iTool that performs the operation or action that it implements.

Keywords

None.

Version History

6.0	Introduced

IDLitUI::GetProperty

The IDLitUI::GetProperty procedure method retrieves the value of an IDLitUI property, and should be called by the subclass' GetProperty method. This method also retrieves properties defined in the superclass.

Syntax

Obj->[IDLitUI::]GetProperty, [*PROPERTY=variable*]

Arguments

None

Keywords

Any property listed under "IDLitUI Properties" on page 4036 that contains the word "Yes" in the "Get" column of the properties table can be retrieved using this method. To retrieve the value of a property, specify the property name as a keyword set equal to a named variable that will contain the value of the property.

Version History

6.0	Introduced

IDLitUI::GetTool

The IDLitUI::GetTool function method returns an object reference to the iTool with which the user interface is associated.

Syntax

Result = *Obj*->[IDLitUI::]GetTool()

Return Value

Returns an object reference to the iTool associated with the current user interface, or a null object if there is no associated iTool.

Arguments

None

Keywords

None

Version History

6.0	Introduced

IDLitUI::GetWidgetByName

The IDLitUI::GetWidgetByName function method returns the IDL Widget ID of a widget that has been registered with the user interface object via a call to the IDLitUI::RegisterWidget method.

Syntax

Result = Obj->[IDLitUI::]GetWidgetByName(*Name*)

Return Value

Returns the widget identifier (a long integer) of the widget specified by the Name argument, or 0 if the widget was not registered with the iTool system.

Arguments

Name

Set this argument to the name that the desired widget was registered with.

Keywords

None

Example

This method can be used to determine whether a given widget already exists and act accordingly. For example, the following code checks to determine whether a widget registered as myWidget exists; if it does, that widget is mapped and un-iconified:

```
wID = oUI->GetWidgetByName(myWidget)
IF(wID NE 0) THEN BEGIN
   WIDGET_CONTROL, wID, /MAP, ICONIFY=0 ;; show the widget
   RETURN
ENDIF
```

Similar code is used in many of the widget interface elements used by the standard iTools included with IDL.

Version History

6.0	Introduced

IDLitUI::Init

The IDLitUI::Init function method initializes the IDLitUI object, and should be called by the Init method of a subclass.

Note ────────────────────────────────

Init methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation. This means that in most cases, you cannot call the Init method directly. There is one exception to this rule: if you write your own subclass of this class, you can call the Init method from within the Init method of the subclass.

──

Syntax

Obj = OBJ_NEW('IDLitUI', *oTool*)

or

Result = Obj->[IDLitUI::]Init(*oTool*)   *(In a lifecycle method only.)*

Return Value

When this method is called indirectly, as part of the call to the OBJ_NEW function, the return value is an object reference to the newly-created object.

When called directly within a subclass Init method, the return value is 1 if initialization was successful, or zero otherwise.

Arguments

oTool

An object reference to the IDLitTool object with which the user interface object is associated.

Keywords

None

Version History

6.0	Introduced

IDLitUI::RegisterUIService

The IDLitUI::RegisterUIService function method registers a *user interface service* with the user interface. Once the user interface service has been registered, the iTool with which the user interface is associated can call the UI service to display dialogs or other UI elements.

Note

Every UI service must implement a callback function that displays the requested user interface. See Chapter 13, "Creating a User Interface Service" (*iTool Developer's Guide*) for details.

Syntax

Restult = Obj->[IDLitUI::]RegisterUIService(*Name, Callback*)

Return Value

Returns an iTool object identifier for the UI service specified by *Name*.

Arguments

Name

A string containing the human readable name of the user interface being registered.

Callback

A string containing the name of the callback function for this UI service. The callback function is called when execution of the UI service is requested. The callback should have the following calling signature:

```
FUNCTION NAME, oUI, oTarget
```

where:

- *NAME* is the name of the callback function,
- *oUI* is an object reference to the user interface object of which the UI service is a part
- *oTarget* is an object reference to the object that is the target of the operation or action with which the UI service is associated.

Keywords

None

Version History

6.0	Introduced

IDLitUI::RegisterWidget

The IDLitUI::RegisterWidget function method registers an IDL widget hierarchy with the user interface object. Once a widget has been registered with the UI object, the UI can route messages to that widget and manage visibility if the widget is registered with the FLOATING property set.

Syntax

Result = Obj->[IDLitUI::]RegisterWidget(*wID*, *Name*, *Callback*[, /FLOATING])

Return Value

The iTool object identifier of the user interface adaptor that links the widget specified by *wID* with the iTool.

Arguments

wID

A long integer containing the widget ID of the widget being registered. This value is provided to the routine specified by the *Callback* argument when it is called.

Name

A string containing the human readable name for the widget being registered.

Callback

A string containing the name of a *callback procedure* for the widget. Any notification messages sent by the iTool to this widget are sent to this callback procedure. The callback procedure should have the following calling signature:

```
PRO NAME, wID, strID, message, messageData
```

where:

- *NAME* is the name of the callback procedure,
- *wID* is the widget ID provided to the IDLitUI:;RegisterWidget method,
- *strID* is a string containing the object identifier of the iTool object that triggered the message,
- *message* is the message being sent to the callback procedure,
- *messageData* is any data associated with the message.

Note ——
   If this argument is set to an empty string, no callbacks will be made to this widget.
———

Keywords

FLOATING

Set this keyword to treat the widget as a floating element of the specified iTool user
interface, to be managed by the user interface object. If this keyword is set, the
widget will only be visible if the associated iTool is "current," and the widget will be
destroyed when the iTool is destroyed.

Version History

6.0	Introduced

IDLitUI::RemoveOnNotifyObserver

The IDLitUI::RemoveOnNotifyObserver procedure method is used to un-register a specified iTool component object as wishing to receive messages generated by the DoOnNotify method of another specified iTool component object. This method reverses the action of calling the IDLitUI::AddOnNotifyObserver method.

Syntax

Obj->[IDLitUI::]RemoveOnNotifyObserver, *IdObserver*, *IdSubject*

Arguments

IdObserver

The object identifier of an iTool component object that is currently registered as an observer of the component specified by *IdSubject*. Often, this is the object identifier of the object on which method is being called.

IdSubject

The object identifier of the iTool component object that *IdObserver* is currently registered as observing. This is normally the object identifier of a particular iTool component object, but it can also be a string that references a global system service.

Keywords

None

Version History

6.0	Introduced

IDLitUI::SetProperty

The IDLitUI::SetProperty procedure method sets the value of an IDLitUI property, and should be called by the subclass' SetProperty method. This method also calls the superclass' SetProperty method.

Syntax

Obj->[IDLitUI::]SetProperty[, *PROPERTY=value*]

Arguments

None

Keywords

None

Version History

6.0	Introduced

IDLitUI::UnRegisterUIService

The IDLitUI::UnRegisterUIService procedure method unregisters a user interface service with the user interface object.

Syntax

Obj->[IDLitUI::]UnRegisterUIService, *Name*

Arguments

Name

A string containing the name of the UI service to be unregistered.

Keywords

None

Version History

6.0	Introduced

IDLitUI::UnRegisterWidget

The IDLitUI::UnRegisterWidget procedure method unregisters a widget with the user interface object.

Syntax

Obj->[IDLitUI::]UnRegisterWidget, *Name*

Arguments

Name

A string containing the name of the widget to be unregistered.

Keywords

None

Version History

6.0	Introduced

IDLitVisualization

The IDLitVisualization class represents the base visualization component, from which all iTool visualization classes should subclass. IDLitVisualization acts as a container and provides methods for adding, removing, and grouping visualization components.

This class is written in the IDL language. Its source code can be found in the file idlitvisualization__define.pro in the lib/itools/framework subdirectory of the IDL distribution.

Superclasses

IDLgrModel

IDLitIMessaging

IDLitParameter

Note

See the "iTools Object Model Diagram" (Chapter 2, *iTool Developer's Guide*) for a visual representation of the iTools object model hierarchy.

Creation

See "IDLitVisualization::Init" on page 4084.

Properties

Objects of this class have the following properties. See "IDLitVisualization Properties" on page 4059 for details on individual properties.

- CENTER_OF_ROTATION
- IMPACTS_RANGE
- ISOTROPIC
- MANIPULATOR_TARGET
- PROPERTY_INTERSECTION
- SELECT_TARGET
- TYPE

In addition, objects of this class inherit the properties of all superclasses of this class.

Methods

This class has all the methods associated with the superclasses, plus the following methods:

- IDLitVisualization::Add
- IDLitVisualization::Aggregate
- IDLitVisualization::BeginManipulation
- IDLitVisualization::Cleanup
- IDLitVisualization::EndManipulation
- IDLitVisualization::Get
- IDLitVisualization::GetCenterRotation
- IDLitVisualization::GetCurrentSelectionVisual
- IDLitVisualization::GetDataSpace
- IDLitVisualization::GetDataString
- IDLitVisualization::GetDefaultSelectionVisual
- IDLitVisualization::GetManipulatorTarget
- IDLitVisualization::GetProperty
- IDLitVisualization::GetRequestedAxesStyle
- IDLitVisualization::GetSelectionVisual
- IDLitVisualization::GetTypes
- IDLitVisualization::GetXYZRange
- IDLitVisualization::Init
- IDLitVisualization::Is3D
- IDLitVisualization::IsIsotropic
- IDLitVisualization::IsManipulatorTarget
- IDLitVisualization::IsSelected
- IDLitVisualization::Move
- IDLitVisualization::On2DRotate

- IDLitVisualization::OnAxesRequestChange
- IDLitVisualization::OnAxesStyleRequestChange
- IDLitVisualization::OnDataChange
- IDLitVisualization::OnDataComplete
- IDLitVisualization::OnDataRangeChange
- IDLitVisualization::OnDimensionChange
- IDLitVisualization::OnWorldDimensionChange
- IDLitVisualization::Remove
- IDLitVisualization::RequestsAxes
- IDLitVisualization::Restore
- IDLitVisualization::Rotate
- IDLitVisualization::Scale
- IDLitVisualization::Select
- IDLitVisualization::Set3D
- IDLitVisualization::SetAxesRequest
- IDLitVisualization::SetAxesStyleRequest
- IDLitVisualization::SetCurrentSelectionVisual
- IDLitVisualization::SetData
- IDLitVisualization::SetDefaultSelectionVisual
- IDLitVisualization::SetParameterSet
- IDLitVisualization::SetProperty
- IDLitVisualization::UpdateSelectionVisual
- IDLitVisualization::VisToWindow
- IDLitVisualization::WindowToVis

In addition, this class inherits the methods of its superclasses.

Examples

See Chapter 6, "Creating a Visualization" (*iTool Developer's Guide*) for examples using this class and its methods.

Version History

6.0	Introduced
6.1	Deprecated GROUP_PARENT property

For more information on deprecated features, see Appendix I, "Obsolete Features".

IDLitVisualization Properties

IDLitVisualization objects have the following properties in addition to properties inherited from any superclasses. Properties with the word "Yes" in the "Get" column of the property table can be retrieved via IDLitVisualization::GetProperty. Properties with the word "Yes" in the "Init" column of the property table can be initialized via IDLitVisualization::Init. Properties with the word "Yes" in the "Set" column of the property table can be set via IDLitVisualization::SetProperty.

Note ———
For a discussion of the property description tables shown below, see "About Object Property Descriptions" on page 3135.
——

Objects of this class have the following properties.

- CENTER_OF_ROTATION
- IMPACTS_RANGE
- ISOTROPIC
- MANIPULATOR_TARGET
- PROPERTY_INTERSECTION
- SELECT_TARGET
- TYPE

In addition, objects of this class inherit:

- IDLgrModel
- IDLitIMessaging
- IDLitParameter

CENTER_OF_ROTATION

A two- or three-element vector, [*x*, *y*] or [*x*, *y*, *z*] indicating the center (in data coordinates) of rotation for this visualization. If a two-element vector is supplied, the

z value remains unchanged. When retrieving the value of this property, the center of rotation is always returned as a three-element vector.

Property Type	Vector		
Name String	*not displayed*		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** No

IMPACTS_RANGE

A boolean that, when set to 0, indicates that the *x*, *y*, and *z* range of the contents of this visualization should not impact the *x*, *y*, and *z* range of any visualization that contains it. By default, IMPACTS_RANGE is 1.

Property Type	Boolean		
Name String	*not displayed*		
Get: Yes	**Set:** Yes	Init: Yes	**Registered:** No

ISOTROPIC

A boolean that, when set to a non-zero value, indicates that this object should have isotropic scaling applied to it. By default, ISOTROPIC is 0 (isotropic scaling is not enforced).

Setting isotropic scaling to True implies that the dimensions of the visualization can be related to physical dimensions and that the ratio of the dimensions must be preserved. An example is an image, where the pixels are usually square and should remain square.

Setting isotropic scaling to False implies that the visualization dimensions do not relate to physical dimensions and that the ratio of the dimensions is arbitrary. An example is a plot, where the aspect ratio of the X and Y coordinates is arbitrary and can be changed for appearance's sake.

Property Type	Boolean		
Name String	*not displayed*		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** No

MANIPULATOR_TARGET

A boolean that, when set to a non-zero value, indicates that this object should be treated as a target for manipulations. By default, MANIPULATOR_TARGET is 0 (this object is not a target for manipulations). Whenever selection changes in a tool, each manipulator is checked against the selected visualization, to verify that the manipulator is allowable for that visualization. The MANIPULATOR_TARGET setting is only used when the manipulator does not have its TYPES property set. If the manipulator has its TYPES set, then the type must match the selected visualization (or a parent of the visualization).

Property Type	Boolean		
Name String	*not displayed*		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** No

PROPERTY_INTERSECTION

A boolean value that indicates whether the visualization should display the intersection or the union of the properties of any aggregated objects. Visualizations that display the union of their aggregated objects' properties appear in iTool browsers as a single visualization with one set of properties. Visualizations that display the intersection of their aggregated objects' properties appear in iTool browsers as a container for the aggregated objects, allowing access to the contained objects' properties as well as to those of the container. See "Working with Aggregated Properties" (Chapter 4, *iTool Developer's Guide*) for additional discussion of aggregated properties.

Property Type	Boolean		
Name String	*no default value*		
Get: Yes	**Set:** No	**Init:** Yes	**Registered:** No

SELECT_TARGET

A Boolean value that tags the visualization object as the target object to be returned when any object contained by the visualization is selected via the IDLitVisualization::Select method.

- 0 = Do not tag the visualization object as the target object.
- 1 = Tag the visualization object as the target object (default).

This property is registered as a Boolean property, but it is hidden by default.

Property Type	Boolean		
Name String	Select target		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** Yes

TYPE

A string or vector of strings that identify the type(s) that this visualization represents. See "Predefined iTool Visualization Classes" (Chapter 6, *iTool Developer's Guide*) for a list of predefined types.

Property Type	String		
Name String	*not displayed*		
Get: No	**Set:** Yes	**Init:** Yes	**Registered:** No

IDLitVisualization::Add

The IDLitVisualization::Add procedure method adds objects to the visualization container.

This method overrides the superclass IDLgrModel::Add method. This specialized implementation performs the following actions:

- Stores visualizations in the correct order based on type so that they are correctly displayed

- Adds the objects to appropriate positions

- Handles property aggregation (if the AGGREGATE keyword is set)

- Updates this visualization's state flags (indicating whether this visualization is 3-D, isotropic, etc.) as appropriate

- Sends notification that the scene needs to be redrawn (unless the NO_UPDATE keyword is set)

Syntax

Obj->[IDLitVisualization::]Add, *Objects* [, /AGGREGATE] [, /NO_UPDATE] [, POSITION=*index*]

Arguments

Objects

An object reference (or array of object references), each referring to an atomic graphic object, an IDLgrModel, or another IDLitVisualization object to be added to the visualization container.

Keywords

AGGREGATE

Set this keyword to indicate that the object(s) being added should become part of this visualization's property aggregate. The properties of all aggregated objects are exposed as properties of this visualization (accessible via the GetProperty and SetProperty methods). See "Property Aggregation" (Chapter 4, *iTool Developer's Guide*) for additional details.

NO_UPDATE

Set this keyword to indicate that the overall scene should not be updated after the addition of the object(s). By default, the overall scene is updated.

POSITION

Set this keyword equal to a scalar or vector of zero-based index values. The number of elements specified must be equal to the number of object references specified by the *Objects* argument. Each index value specifies the position within this visualization container at which the corresponding object should be placed. The default is to add new objects at the end of the list of contained items.

Version History

6.0	Introduced
6.1	Deprecated GROUP keyword

For more information on deprecated features, see Appendix I, "Obsolete Features".

IDLitVisualization::Aggregate

The IDLitVisualization::Aggregate procedure method adds the given object(s) to this visualization's property aggregate. The properties of all aggregated objects are exposed as properties of this visualization (via ::GetProperty and ::SetProperty).

See "Property Aggregation" (Chapter 4, *iTool Developer's Guide*) for additional details.

Syntax

Obj->[IDLitVisualization::]Aggregate, *Objects*

Arguments

Objects

An object reference (or array of object references), each of which refers to an atomic graphic object, an IDLgrModel, or another IDLitVisualization object to be aggregated within this visualization container.

Keywords

None.

Version History

6.0	Introduced

IDLitVisualization::BeginManipulation

The IDLitVisualization::BeginManipulation procedure method handles notifications that an IDLitManipulator object is about to manipulate this visualization.

Note ———————————————————————————————————

Calling this method on this visualization object simply returns without action. This method is designed to be implemented by a sub-class (such as those listed in "Predefined iTool Visualization Classes" (Chapter 6, *iTool Developer's Guide*)).

Syntax

Obj->[IDLitVisualization::]BeginManipulation, *Manipulator*

Arguments

Manipulator

An object reference to the manipulator object sending notification.

Keywords

None

Version History

6.1	Introduced

IDLitVisualization::Cleanup

The IDLitVisualization::Cleanup procedure method performs all cleanup on the object, and should be called by the subclass' Cleanup method.

Note ─────────────────────────────────

Cleanup methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation and destruction. This means that in most cases, you cannot call the Cleanup method directly. There is one exception to this rule: if you write your own subclass of this class, you can call the Cleanup method from within the Init or Cleanup method of the subclass.

───

Syntax

OBJ_DESTROY, *Obj*

or

Obj->[IDLitVisualization::]Cleanup   *(In a lifecycle method only.)*

Arguments

None

Keywords

None

Version History

6.0	Introduced

IDLitVisualization::EndManipulation

The IDLitVisualization::EndManipulation procedure method handles notifications that an IDLitManipulator object has finished manipulating this visualization.

Note ───────────────────────────────────

Calling this method on this visualization object simply returns without action. This method is designed to be implemented by a sub-class (such as those listed in "Predefined iTool Visualization Classes" (Chapter 6, *iTool Developer's Guide*)).

───

Syntax

Obj->[IDLitVisualization::]EndManipulation, *Manipulator*

Arguments

Manipulator

An object reference to the manipulator object sending notification.

Keywords

None

Version History

6.1	Introduced

IDLitVisualization::Get

The IDLitVisualization::Get function method retrieves object(s) from the visualization.

Syntax

Result = Obj->[IDLitVisualization::]Get([, /ALL] [, COUNT=*variable*]
   [, ISA=*string* or *array of strings*] [, POSITION=*index* or *array of indices*]
   [, /SKIP_PRIVATE])

Return Value

Returns the reference of the object retrieved from the visualization. If the object is not contained by this visualization, a NULL object reference is returned.

Arguments

None

Keywords

ALL

Set this keyword to return an array of object references to all of the objects in the container.

COUNT

Set this keyword equal to a named variable that will contain the number of objects selected by the function.

ISA

Set this keyword equal to a class name or vector of class names. This keyword is used in conjunction with the ALL keyword. The ISA keyword filters the array returned by the ALL keyword, returning only the objects that inherit from the class or classes specified by the ISA keyword.

Note
  This keyword is ignored if the ALL keyword is not provided.

POSITION

Set this keyword equal to a scalar or array containing the zero-based indices of the positions of the objects to return.

SKIP_PRIVATE

Set this keyword to indicate that this method should return only those objects that do not have the PRIVATE property set.

Version History

6.0	Introduced

IDLitVisualization::GetCenterRotation

The IDLitVisualization::GetCenterRotation function method returns the center of rotation for this visualization.

Syntax

Result = Obj->[IDLitVisualization::]GetCenterRotation([, /NO_TRANSFORM]
   [, XRANGE=[*xmin*, *xmax*]] [, YRANGE=[*ymin*, *ymax*]] [, ZRANGE=[*zmin*,
   zmax]])

Return Value

Returns a two- or three-element vector, [*x*, *y*] or [*x*, *y*, *z*] indicating the center (in data coordinates) of the bounding box for this visualization if the center of rotation was not explicitly specified with the CENTER_OF_ROTATION property of this visualization. See the CENTER_OF_ROTATION property for more details.

Arguments

None

Keywords

NO_TRANSFORM

Set this keyword to indicate that this visualization's transform should not be applied when computing the *x*, *y*, and *z* ranges. By default, the transform is applied.

XRANGE

Set this keyword to a named variable that will contain a 2-element vector, [*xmin*, *xmax*], representing the *x* range of the bounding box for this visualization.

YRANGE

Set this keyword to a named variable that will contain a 2-element vector, [*ymin*, *ymax*], representing the *y* range of the bounding box for this visualization.

ZRANGE

Set this keyword to a named variable that will contain a 2-element vector, [*zmin*, *zmax*], representing the *z* range of the bounding box for this visualization.

Version History

6.0	Introduced
6.1	Deprecated DATA keyword

For more information on deprecated features, see Appendix I, "Obsolete Features".

IDLitVisualization::GetCurrentSelectionVisual

The IDLitVisualization::GetCurrentSelectionVisual function method returns the currently active selection visual object for this visualization.

Syntax

Result = Obj->[IDLitVisualization::]GetCurrentSelectionVisual()

Return Value

Returns a reference to an IDLitManipulatorVisual object. If no selection visual is currently active, the NULL object reference is returned.

Arguments

None

Keywords

None

Version History

6.0	Introduced

IDLitVisualization::GetDataSpace

The IDLitVisualization::GetDataSpace function method returns a reference to the parent data space object within the graphics hierarchy that contains the visualization.

Syntax

Result = *Obj*->[IDLitVisualization::]GetDataSpace([, /UNNORMALIZED])

Return Value

Returns a reference to the nearest data space object in the graphics hierarchy. If no data space objects are found by walking up the hierarchy, then a null object reference is returned.

Arguments

None

Keywords

UNNORMALIZED

Set this keyword to indicate that the returned data space should be the parent data space that subclasses from the IDLitVisDataSpace class (which is not normalized) rather than the IDLitVisNormDataSpace class (which is normalized).

Version History

6.0	Introduced

IDLitVisualization::GetDataString

The IDLitVisualization::GetDataString function method retrieves a description of this visualization's data at the given *x*, *y*, and *z* location.

Note

This method is designed to be implemented as needed by subclasses. The IDLitVisualization::GetDataString method simply always returns an empty string

Syntax

Result = Obj->[IDLitVisualization::]GetDataString(*XYZLocation*)

Return Value

Returns a string describing the visualization's data at the given location.

Arguments

XYZLocation

A three-element vector representing the *x*, *y*, and *z* location of the data for which a string description is to be returned.

Keywords

None

Version History

6.0	Introduced

IDLitVisualization::GetDefaultSelectionVisual

The IDLitVisualization::GetDefaultSelectionVisual function method returns an object that serves as the default selection visual for this visualization.

Note ──

If the visualization on which this method is called is not a manipulator target (see "MANIPULATOR_TARGET" on page 4061), the default selection visual returned by this method will be used as the current selection visual whenever the visualization is selected.

───

Syntax

Result = Obj->[IDLitVisualization::]GetDefaultSelectionVisual()

Return Value

Returns a reference to an IDLitManipulatorVisual object.

Arguments

None

Keywords

None

Version History

6.0	Introduced

IDLitVisualization::GetManipulatorTarget

The IDLitVisualization::GetManipulatorTarget function method retrieves the manipulator target associated with this visualization. The manipulator target may be this visualization itself.

Syntax

Result = Obj->[IDLitVisualization::]GetManipulatorTarget()

Return Value

Returns an object reference to the manipulator target, or a NULL object reference if none is found.

Arguments

None

Keywords

None

Version History

6.0	Introduced

IDLitVisualization::GetProperty

The IDLitVisualization::GetProperty procedure method retrieves the value of a property or group of properties for the object.

Syntax

Obj->[IDLitVisualization::]GetProperty[, *PROPERTY=variable*]

Arguments

None

Keywords

Any property listed under "IDLitVisualization Properties" on page 4059 that contains the word "Yes" in the "Get" column of the properties table can be retrieved using this method. To retrieve the value of a property, specify the property name as a keyword set equal to a named variable that will contain the value of the property.

Version History

6.0	Introduced

IDLitVisualization::GetRequestedAxesStyle

The IDLitVisualization::GetRequestedAxesStyle function method returns a scalar value indicating the axes style requested by this visualization. This method returns the axes style request made by the first visualization within the hierarchy (beginning with the root visualization) to make a request. If none of the visualizations in the hierarchy requests an axes style then -1 is returned.

Syntax

Result = Obj->[IDLitVisualization::]GetRequestedAxesStyle( )

Return Value

Returns a scalar value indicating the requested axes style. Possible return values are:

Value	Requested Axes Style
0	None.
1	At Dataspace Minimum.
2	Box Axes.
3	Crosshairs.
-1	No visualization in the hierarchy requested axes.

Table 31-9: Axes Style Values

Arguments

None

Keywords

None

Version History

6.1	Introduced

IDLitVisualization::GetSelectionVisual

The IDLitVisualization::GetSelectionVisual function method retrieves the selection visual for this visualization that corresponds to the given manipulator.

Syntax

Result = Obj->[IDLitVisualization::]GetSelectionVisual(*Manipulator*)

Return Value

Returns a reference to an IDLitManipulatorVisual object that corresponds to the given manipulator. If this visualization already has a selection visual for the given manipulator, a reference to that selection visual is returned. Otherwise, a default selection visual will be requested from the manipulator, added to the visualization, and returned.

Arguments

Manipulator

Set this argument to a reference to an IDLitManipulator object that identifies the manipulator for which a selection visual is to be retrieved.

Keywords

None

Version History

6.0	Introduced

IDLitVisualization::GetTypes

The IDLitVisualization::GetTypes function method identifies the types that this visualization represents, including base types and any specializations.

Note ──

This method is designed to be implemented as needed by subclasses of the IDLitVisualization class. Calling this method on the IDLitVisualization class itself returns the following string array: [`'VISUALIZATION'`, `'_VISUALIZATION'`, *AnySpecifiedTypes*] where *AnySpecifiedTypes* are provided by any value set for the TYPE property of the IDLitVisualization class.

───

Syntax

Result = *Obj*->[IDLitVisualization::]GetTypes()

Return Value

Returns a vector of strings identifying the types that this visualization represents. See "Predefined iTool Visualization Classes" (Chapter 6, *iTool Developer's Guide*) for a list of predefined types

Arguments

None

Keywords

None

Version History

6.0	Introduced

IDLitVisualization::GetXYZRange

The IDLitVisualization::GetXYZRange function method computes the *x*, *y*, and *z* ranges of the overall contents of the visualization, taking into account the IMPACTS_RANGE property setting for itself and its contents.

Syntax

Result = Obj->[IDLitVisualization::]GetXYZRange(*XRange*,*YRange*, *ZRange*
    [, /DATA] [, /NO_TRANSFORM])

Return Value

Returns a 1 if the *x*, *y*, and *z* ranges were successfully computed, or 0 otherwise.

Arguments

XRange

A named variable that, upon return, will contain a two-element vector, [*xmin*, *xmax*], representing the *x*-range of the contents of this visualization that impact ranges.

YRange

A named variable that, upon return, will contain a two-element vector, [*ymin*, *ymax*], representing the *y*-range of the contents of this visualization that impact ranges.

ZRange

A named variable that, upon return, will contain a two-element vector, [*zmin*, *zmax*], representing the *z*-range of the contents of this visualization that impact ranges.

Keywords

DATA

Set this keyword to indicate that the ranges should be computed for the full data sets of the contents of this visualization. By default, if the keyword is not set, the ranges are computed for the displayed portions of the data sets.

NO_TRANSFORM

Set this keyword to indicate that this visualization's transform matrix should not be applied when computing the *x*, *y*, and *z* ranges. By default, the transform matrix is applied.

Version History

6.0	Introduced

IDLitVisualization::Init

The IDLitVisualization::Init function method initializes the visualization object.

Note

Init methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation. This means that in most cases, you cannot call the Init method directly. There is one exception to this rule: if you write your own subclass of this class, you can call the Init method from within the Init method of the subclass.

Syntax

Obj = OBJ_NEW('IDLitVisualization' [, *PROPERTY=value*])

or

Result = Obj->[IDLitVisualization::]Init([, *PROPERTY=value*])   *(In a lifecycle method only.)*

Return Value

When this method is called indirectly, as part of the call to the OBJ_NEW function, the return value is an object reference to the newly-created object.

When called directly within a subclass Init method, the return value is 1 if initialization was successful, or zero otherwise.

Arguments

None

Keywords

Any property listed under "IDLitVisualization Properties" on page 4059 that contains the word "Yes" in the "Init" column of the properties table can be initialized during object creation using this method. To initialize the value of a property, specify the property name as a keyword set equal to the appropriate property value.

Version History

6.0	Introduced

IDLitVisualization::Is3D

The IDLitVisualization::Is3D function method determines whether or not this visualization is marked as being three-dimensional.

Syntax

Result = Obj->[IDLitVisualization::]Is3D()

Return Value

Returns 1 if this visualization is marked as being three-dimensional, or 0 if it is not three-dimensional.

Arguments

None

Keywords

None

Version History

6.0	Introduced

IDLitVisualization::IsIsotropic

The IDLitVisualization::IsIsotropic function method indicates whether or not this visualization (or any of its contents) is marked as being isotropic. See the ISOTROPIC property for more information.

Syntax

Result = Obj->[IDLitVisualization::]IsIsotropic()

Return Value

Returns 1 if the visualization or any of the items it contains has the ISOTROPIC property set, or 0 otherwise.

Arguments

None

Keywords

None

Version History

6.0	Introduced

IDLitVisualization::IsManipulatorTarget

The IDLitVisualization::IsManipulatorTarget function method determines whether or not this visualization is a manipulator target.

Syntax

Result = Obj->[IDLitVisualization::]IsManipulatorTarget()

Return Value

Returns 1 if this visualization is a manipulator target, or 0 if it is not.

Arguments

None

Keywords

None

Version History

6.0	Introduced

IDLitVisualization::IsSelected

The IDLitVisualization::IsSelected function method determines if this visualization is currently selected or not.

Syntax

Result = Obj->[IDLitVisualization::]IsSelected()

Return Value

Returns 1 if this visualization is currently selected, or 0 if it is not selected.

Arguments

None

Keywords

None

Version History

6.0	Introduced

IDLitVisualization::Move

The IDLitVisualization::Move procedure method moves an object from one position in the visualization container to a new position. Use the IDLitVisualization::Get method to return the objects within the visualization.

The positions of the objects within a container controls how they are rendered. The object whose location has the lowest index value is rendered first. If several objects are located at the same point in three-dimensional space, the object rendered first will occlude objects rendered later.

Note

This method overrides the IDL_Container::Move method, which IDLitVisualization inherits since IDL_Container is a superclass of IDLgrModel. This specialized implementation of the Move method ensures visualizations are stored in the correct order based on type when they are moved. Those items that must appear on top of other objects are stored as the last items in the list of objects contained by this visualization.

Syntax

Obj->[IDLitVisualization::]Move, *Source, Destination*

Arguments

Source

The zero-based index of the current location of the object to be moved.

Destination

The zero-based index of the new location where the object will reside after being moved.

Keywords

None

Version History

6.1	Introduced

IDLitVisualization::On2DRotate

The IDLitVisualization::On2DRotate procedure method notifies objects that use the visualization's data when the rotation of the parent dataspace changes.

Syntax

Obj->[IDLitVisualization::]On2DRotate, *Notifier, IsRotated*

Arguments

Notifier

An object reference to the parent object that is sending notification when the dataspace rotation changes.

IsRotated

A scalar value that is non-zero if the dataspace is now rotated, or zero otherwise.

Keywords

None

Version History

6.1	Introduced

IDLitVisualization::OnAxesRequestChange

The IDLitVisualization::OnAxesRequestChange procedure method notifies objects that use the visualization's data when the axes of a contained object change.

Syntax

Obj->[IDLitVisualization::]OnAxesRequestChange, *Notifier, AxesRequest*

Arguments

Notifier

An object reference to the object that is sending notification when axes change.

AxesRequest

A scalar value representing the new axes request. Allowable values are:

Value	Requested Axes
0	No axes requested.
1	Axes requested.
2	Axes should be automatically computed.

Table 31-10: Allowable AxesRequest Values

Keywords

None

Version History

6.1	Introduced

IDLitVisualization::OnAxesStyleRequestChange

The IDLitVisualization::OnAxesStyleRequestChange procedure method notifies objects that use the visualization's data when the axes style of a contained object changes.

Syntax

Obj->[IDLitVisualization::]OnAxesStyleRequestChange, *Notifier, StyleRequest*

Arguments

Notifier

An object reference to the object that is sending notification when the axes style changes.

StyleRequest

A scalar value representing the new axes style request. Allowable values are:

Value	Requested Axes Style
0	None.
1	At Dataspace Minimum.
2	Box Axes.
3	Crosshairs.
-1	No visualization in the hierarchy requested axes.

Table 31-11: Axes Style Values

Keywords

None

Version History

6.1	Introduced

IDLitVisualization::OnDataChange

The IDLitVisualization::OnDataChange procedure method notifies objects that use the visualization's data when the visualization's data changes.

Note

 This method is generally not called explicitly.

Syntax

Obj->[IDLitVisualization::]OnDataChange, *Notifier*

Arguments

Notifier

A reference to the object that is sending notification when the data changes.

Keywords

None

Version History

6.0	Introduced

IDLitVisualization::OnDataComplete

The IDLitVisualization::OnDataComplete procedure method notifies objects that use the visualization's data when changes to the visualization's data are complete.

Note
This method is generally not called explicitly.

Syntax

Obj->[IDLitVisualization::]OnDataComplete, *Notifier*

Arguments

Notifier

A reference to the object that is sending notification when the data changes are complete.

Keywords

None

Version History

6.0	Introduced

IDLitVisualization::OnDataRangeChange

The IDLitVisualization::OnDataRangeChange procedure method notifies objects that use the visualization's data when the range of the visualization's data changes.

Note ───

This method is generally not called explicitly.

───

Syntax

Obj->[IDLitVisualization::]OnDataRangeChange, *Notifier*, *XRange*, *YRange*, *Zrange*

Arguments

Notifier

A reference to the object that is sending notification when the data range changes.

XRange

A two-element vector, [*xmin*, *xmax*], representing the new *x*-range.

YRange

A two-element vector, [*ymin*, *ymax*], representing the new *y*-range.

ZRange

A two-element vector, [*zmin*, *zmax*], representing the new *z*-range.

Keywords

None

Version History

6.0	Introduced

IDLitVisualization::OnDimensionChange

The IDLitVisualization::OnDimensionChange procedure method notifies objects that use the visualization's data when the dimensionality of the visualization's data changes.

Syntax

Obj->[IDLitVisualization::]OnDimensionChange, *Notifier, Is3D*

Arguments

Notifier

An object reference to the object that is sending notification when the dimensionality changes.

Is3D

A scalar value that is non-zero if the object is now three-dimensional, or zero otherwise.

Keywords

None

Version History

6.1	Introduced

IDLitVisualization::OnWorldDimensionChange

The IDLitVisualization::OnWorldDimensionChange procedure method notifies objects that use the visualization's data when the dimensionality of the visualization's parent dataspace changes.

Syntax

Obj->[IDLitVisualization::]OnWorldDimensionChange, *Notifier, Is3D*

Arguments

Notifier

An object reference to the parent object that is sending notification when the dimensionality changes.

Is3D

A scalar value that is non-zero if the object is now three-dimensional, or zero otherwise.

Keywords

None

Version History

6.1	Introduced

IDLitVisualization::Remove

The IDLitVisualization::Remove procedure method removes the given object(s) from the visualization.

This method overrides the IDL_Container::Remove method, which IDLitVisualization inherits since IDL_Container is a superclass of IDLgrModel. This specialized implementation of the Remove method performs the following actions:

- Handles property aggregation

- Updates this visualization's state flags (indicating whether this visualization is 3-D, isotropic, etc.) as appropriate

- Sends notification that the scene needs to be redrawn (unless the NO_UPDATE keyword is set)

Syntax

Obj->[IDLitVisualization::]Remove, *Object* [, /NO_UPDATE]

Arguments

Object

A reference (or vector of references) to the object(s) to be removed from this visualization.

Keywords

NO_UPDATE

Set this keyword to indicate the scene should not be updated after objects are removed. By default, the overall scene is updated.

Version History

6.0	Introduced
6.1	Added NO_UPDATE keyword

IDLitVisualization::RequestsAxes

The IDLitVisualization::RequestsAxes function method indicates whether or not the visualization requests axes. Most visualization classes do request axes. However, axes, images, ROIs, map grids, profile lines, and backgrounds do not request axes.

Syntax

Result = Obj->[IDLitVisualization::]RequestsAxes( )

Return Value

Returns a 1 if the visualization does request axes, or 0 if does not request axes.

Arguments

None

Keywords

None

Version History

6.1	Introduced

IDLitVisualization::Restore

The IDLitVisualization::Restore procedure method performs any transitional work required after an object of this class has been restored from a SAVE file, to ensure that its state is appropriate for the current version.

Note ————————————————————————————————

This method overrides the implementation in the IDLitComponent class. This specialized implementation ensures that all axes requests and axis style requests are set properly.

——

Syntax

Obj->[IDLitVisualization::]Restore

Arguments

None

Keywords

None

Version History

6.1	Introduced

See Also

IDL_Savefile, SAVE, RESTORE

IDLitVisualization::Rotate

The IDLitVisualization::Rotate procedure method rotates this visualization about the given axis by the given angle.

This method overrides the superclass's IDLgrModel::Rotate method. This specialized implementation rotates about a center of rotation rather than about the origin, [0,0,0].

Syntax

Obj->[IDLitVisualization::]Rotate, *Axis*, *Angle* [, CENTER_OF_ROTATION=[*x*, *y*, *z*]] [, /PREMULTIPLY]

Arguments

Axis

A three-element vector of the form [*x*, *y*, *z*] describing the axis about which the visualization is to be rotated.

Angle

A scalar value indicating the angle of rotation (measured in degrees).

Keywords

CENTER_OF_ROTATION

Set this keyword to a three-element vector, [x, y, *z*], representing the center of the rotation. By default, the visualization's own center of rotation (accessible through "IDLitVisualization::GetCenterRotation" on page 4071) will be used.

PREMULTIPLY

Set this keyword to cause the rotation matrix specified by *Axis* and *Angle* to be pre-multiplied to this visualization's current transformation matrix. By default, the rotation matrix is post-multiplied.

Note
In pre-multiplication, the current visualization's transform and scaling are applied before the specified rotation. In post-multiplication, the specified rotation is applied before the visualization's transformation and scaling.

Version History

6.1	Introduced

IDLitVisualization::Scale

The IDLitVisualization::Scale procedure method scales the visualization by the given scale factors.

Syntax

Obj->[IDLitVisualization::]Scale, *SX*, *SY*, *SZ* [, CENTER_OF_ROTATION=[*x*, *y*] | [*x*, *y*, *z*]] [, /PREMULTIPLY]

Arguments

SX

The factor in the *x*-dimension by which the visualization is to be scaled.

SY

The factor in the *y*-dimension by which the visualization is to be scaled.

SZ

The factor in the *z*-dimension by which the visualization is to be scaled.

Keywords

CENTER_OF_ROTATION

Set this keyword to a 2- or 3-element vector, [*x*, *y*] or [*x*,*y*,*z*], representing the center of rotation (in data coordinates) to be used as the center for scaling. By default, if PREMULTIPLY is set, then this visualization's own center of rotation will be used as the center for scaling; if PREMULTIPLY is not set, the result of transforming this visualization's center of rotation by its own transformation matrix will be used as the center for scaling.

PREMULTIPLY

Set this keyword to cause the scaling matrix specified by *Sx*, *Sy*, and *Sz* to be pre-multiplied to this visualization's transformation matrix. By default, the scaling matrix is post-multiplied.

Version History

6.0	Introduced

IDLitVisualization::Select

The IDLitVisualization::Select procedure method handles notification of mechanisms that key off the current selection (such as the visualization browser) when this visualization has been selected.

Syntax

Obj->[IDLitVisualization::]Select[, *Mode*]
  [, /ADDITIVE | /SELECT | /TOGGLE | /UNSELECT] [, /NO_NOTIFY]

Arguments

Mode

A scalar that indicates the selection mode. Valid values include:

- 0 - Unselect (deselect this visualization).

- 1 - Select (set this visualization as the current selection). This mode is the default.

- 2 - Toggle (toggle the selection of this visualization). Use the **CRTL** key to toggle.

- 3 - Additive (add this visualization to the current selection list). Use the **SHIFT** key to add.

Keywords

ADDITIVE

Set this keyword to indicate that the selection mode is additive. This is equivalent to setting *Mode* to 3.

NO_NOTIFY

Set this keyword to indicate that this visualization's parent should not be notified of this selection. By default, the parent is notified.

SELECT

Set this keyword to indicate that the selection mode is select. This is equivalent to setting *Mode* to 1.

TOGGLE

Set this keyword to indicate that the selection mode is toggle. This is equivalent to setting *Mode* to 2.

UNSELECT

Set this keyword to indicate that the selection mode is unselect. This is equivalent to setting *Mode* to 0.

Version History

6.0	Introduced

IDLitVisualization::Set3D

The IDLitVisualization::Set3D procedure method sets a flag indicating this visualization is three-dimensional.

Syntax

Obj->[IDLitVisualization::]Set3D, *Is3D* [, /ALWAYS] [, /AUTO_COMPUTE]

Arguments

Is3D

A non-zero value indicates that the visualization is three-dimensional; 0 indicates that it is two-dimensional.

Keywords

ALWAYS

Set this keyword to indicate that the given 3-D setting always applies.

AUTO_COMPUTE

Set this keyword to indicate that the 3-D setting for this visualization should be auto-computed based upon the dimensionality of its contents. This keyword is mutually exclusive of the ALWAYS keyword, and the *Is3D* argument is ignored if AUTO_COMPUTE is set.

Version History

6.0	Introduced

IDLitVisualization::SetAxesRequest

The IDLitVisualization::SetAxesRequest procedure method sets the current axes request for this visualization.

Syntax

Obj->[IDLitVisualization::]SetAxesRequest [, *AxesRequest*]
   [, /ALWAYS | /AUTO_COMPUTE] [, /NO_NOTIFY]

Arguments

AxesRequest

A scalar value indicating whether this visualization requests axes:

- •   0 – Axes are not requested by the visualization
- •   1 – Axes are requested by the visualization.

Note ———————————————————————————————

If this argument is not present, the visualization is marked as requesting axes.

———————————————————————————————————————

Keywords

ALWAYS

Set this keyword to always request or not request axes as specified by the *AxesRequest* argument. This setting will override the requests made by children of the visualization.

AUTO_COMPUTE

Set this keyword to compute the axes for this visualization based on the axes requested by objects contained in the visualization.

Note ———————————————————————————————

This keyword is mutually exclusive of the ALWAYS keyword. If this keyword is set, the *AxesRequest* argument is ignored.

———————————————————————————————————————

NO_NOTIFY

Set this keyword to indicate that this visualization's parent should not be notified of a change in axes request. By default, the parent is notified.

Version History

6.1	Introduced

IDLitVisualization::SetAxesStyleRequest

The IDLitVisualization::SetAxesStyleRequest procedure method sets the current axes style request for this visualization. The axes container is automatically created whenever a data space is instantiated, but the default axes style property is 0 (None) until visualizations are added.

Whenever a visualization is added to the visualization container, it is queried for axes requirements. Most visualization classes do request axes (with the exception of axes, images, ROIs, map grids, profile lines, and backgrounds). When visualizations are added, and the current axes style value is 0 (None), then the axes style will be changed as follows:

- The axes style is set according to the request of the first visualization in the hierarchy to request a *particular* axes style. By default, most visualizations do not request a particular style. The exceptions are plots, which request style 2 (Box Axes) if non-polar, or style 3 (Crosshairs) if polar.

- The default style 1 (At Dataspace Minimum) is used if none of the visualizations in the hierarchy request a particular axes style.

Syntax

Obj->[IDLitVisualization::]SetAxesStyleRequest, *StyleRequest* [, /NO_NOTIFY]

Arguments

StyleRequest

A scalar value representing the requested axes style. The value should correspond to one of the values listed in the following table:

Value	Requested Axes Style
0	None.
1	At Dataspace Minimum.
2	Box Axes.
3	Crosshairs.
-1	No visualization in the hierarchy requested a particular axes style.

Table 31-12: Axes Style Values

Keywords

NO_NOTIFY

Set this keyword to indicate that this visualization's parent should not be notified of a change in the axes style request. By default, the parent is notified.

Version History

6.1	Introduced

IDLitVisualization::SetCurrentSelectionVisual

The IDLitVisualization::SetCurrentSelectionVisual procedure method sets the current selection visual for the given manipulator.

Syntax

Obj->[IDLitVisualization::]SetCurrentSelectionVisual, *Manipulator*

Arguments

Manipulator

An object reference (that subclasses from IDLitManipulator) identifying the manipulator that corresponds to the selection visual to be set as current.

Keywords

None

Version History

6.0	Introduced

IDLitVisualization::SetData

The IDLitVisualization::SetData function method sets the data parameter of the visualization.

Note
If the SetData method returns successfully, notification of a data change is issued to all observers of the data object.

Syntax

Result = Obj->[IDLitVisualization::]SetData(*Data*)

Return Value

Returns a 1 if successful, or 0 if it fails.

Arguments

Data

A reference to the data object to be associated with the visualization parameter.

Keywords

This method accepts all keywords accepted by the IDLitParameter::SetData method.

Version History

6.0	Introduced

IDLitVisualization::SetDefaultSelectionVisual

The IDLitVisualization::SetDefaultSelectionVisual procedure method sets the default selection visual to be associated with this visualization.

Note

If the visualization on which this method is called is not a manipulator target (see "MANIPULATOR_TARGET" on page 4061) the default selection visual set by this method will be used as the current selection visual whenever the visualization is selected.

Syntax

Obj->[IDLitVisualization::]SetDefaultSelectionVisual, *SelectionVisual*
    [, POSITION=*value*]

Arguments

SelectionVisual

A reference to the IDLitManipulatorVisual object that is added to the visualization object and serves as the default selection visual for this visualization.

Keywords

POSITION

Set this keyword equal to the zero-based position at which the selection visual should be inserted within the container. The default is to add the object to the end of the container (the visualization object).

Version History

6.0	Introduced

IDLitVisualization::SetParameterSet

The IDLitVisualization::SetParameterSet function method associates a parameter set with this visualization.

Note ──

If the SetParameterSet method returns successfully, notification of a data change is issued to all observers of the visualization's data.

──

Syntax

Result = Obj->[IDLitVisualization::]SetParameterSet(*ParameterSet*)

Return Value

Returns a 1 if successful, or a 0 otherwise.

Arguments

ParameterSet

A reference to the IDLitParameterSet object to be associated with the visualization.

Keywords

None

Version History

6.0	Introduced

IDLitVisualization::SetProperty

The IDLitVisualization::SetProperty procedure method sets the value of a property or group of properties for the object.

Syntax

Obj->[IDLitVisualization::]SetProperty[, *PROPERTY=value*]

Arguments

None

Keywords

Any property listed under "IDLitVisualization Properties" on page 4059 that contains the word "Yes" in the "Set" column of the properties table can be set using this method. To set the value of a property, specify the property name as a keyword set equal to the appropriate property value.

Version History

6.0	Introduced

IDLitVisualization::UpdateSelectionVisual

The IDLitVisualization::UpdateSelectionVisual procedure method transforms this visualization's selection visual to match the visualization's geometry.

Syntax

Obj->[IDLitVisualization::]UpdateSelectionVisual

Arguments

None

Keywords

None

Version History

6.0	Introduced

IDLitVisualization::VisToWindow

The IDLitVisualization::VisToWindow procedure method transforms given points from visualization data space to window device coordinates.

Syntax

Obj->[IDLitVisualization::]VisToWindow, *InX*, *InY*, *InZ*, *OutX*, *OutY*, *OutZ*
   [, /NO_TRANSFORM]

or

Obj->[IDLitVisualization::]VisToWindow, *InX*, *InY*, *OutX*, *OutY*
   [, /NO_TRANSFORM]

or

Obj->[IDLitVisualization::]VisToWindow, *InVerts*, *OutVerts* [, /NO_TRANSFORM]

Arguments

InX

A vector of input X values (in visualization data space).

InY

A vector of input Y values (in visualization data space). The number of elements of this vector must match the number of elements in *InX*.

InZ

A vector of input Z values (in visualization data space). The number of elements of this vector must match the number of elements in *InX*.

InVerts

A [2, *n*] or [3, *n*] array of input vertices (in visualization data space).

OutX

A named variable that will contain a vector of output X values (in window device coordinates).

OutY

A named variable that will contain a vector of output Y values (in window device coordinates).

OutZ

A named variable that will contain a vector of output Z values (in window device coordinates).

OutVerts

A named variable that will contain a vector of output vertices (in window device coordinates).

Keywords

NO_TRANSFORM

If this keyword is set, the current transformation matrix is not included in the computation. Setting this keyword is useful when computing selection visual scaling.

Version History

6.0	Introduced

IDLitVisualization::WindowToVis

The IDLitVisualization::WindowToVis procedure method transforms given points from window device coordinates to visualization data space.

Syntax

Obj->[IDLitVisualization::]WindowToVis, *InX*, *InY*, *InZ*, *OutX*, *OutY*, *OutZ*

or

Obj->[IDLitVisualization::]WindowToVis, *InX*, *InY*, *OutX*, *OutY*

or

Obj->[IDLitVisualization::]WindowToVis, *InVerts*, *OutVerts*

Arguments

InX

A vector representing the input x values (in window device coordinates).

InY

A vector representing the input y values (in window device coordinates). The number of elements of this vector must match the number of elements in *InX*.

InZ

A vector representing the input z values (in window device coordinates). The number of elements of this vector must match the number of elements in *InX*.

InVerts

A [2, *n*] or [3, *n*] array representing the input vertices (in window device coordinates).

OutX

A named variable that upon return will contain a vector representing the output x values (in visualization data space).

OutY

A named variable that upon return will contain a vector representing the output y values (in visualization data space).

OutZ

A named variable that upon return will contain a vector representing the output z values (in visualization data space).

OutVerts

A named variable that upon return will contain a vector representing the output vertices (in visualization data space).

Keywords

None

6.0	Introduced

IDLitWindow

The IDLitWindow class serves as the base class for all windows within the iTools framework.

Superclasses

IDLgrWindow

Note

See the "iTools Object Model Diagram" (Chapter 2, *iTool Developer's Guide*) for a visual representation of the iTools object model hierarchy.

Creation

See "IDLitWindow::Init" on page 4139.

Properties

Objects of this class inherit properties from the IDLgrWindow superclass. See "IDLgrWindow Properties" on page 4963 for descriptions of these properties.

Methods

This class has the following methods:

- IDLitWindow::Add
- IDLitWindow::AddWindowEventObserver
- IDLitWindow::Cleanup
- IDLitWindow::ClearSelections
- IDLitWindow::DoHitTest
- IDLitWindow::GetEventMask
- IDLitWindow::GetProperty
- IDLitWindow::GetSelectedItems
- IDLitWindow::Init
- IDLitWindow::OnEnter

- IDLitWindow::OnExit
- IDLitWindow::OnExpose
- IDLitWindow::OnKeyboard
- IDLitWindow::OnMouseDown
- IDLitWindow::OnMouseMotion
- IDLitWindow::OnMouseUp
- IDLitWindow::OnResize
- IDLitWindow::OnScroll
- IDLitWindow::OnTimer
- IDLitWindow::OnWheel
- IDLitWindow::Remove
- IDLitWindow::RemoveWindowEventObserver
- IDLitWindow::SetCurrentZoom
- IDLitWindow::SetEventMask
- IDLitWindow::SetManipulatorManager
- IDLitWindow::SetProperty
- IDLitWindow::SetTimerInterval
- IDLitWindow::ZoomIn
- IDLitWindow::ZoomOut

In addition, this class inherits the methods of its superclass.

Version History

6.0	Introduced
6.2	Added OnTimer and SetTimerInterval methods
6.3	Added OnEnter, OnExit, OnExpose, and OnResize methods
6.4	Added OnWheel method

IDLitWindow Properties

IDLitWindow objects inherit properties from the IDLgrWindow superclass. See "IDLgrWindow Properties" on page 4963 for descriptions of these properties.

Properties with the word "Yes" in the "Get" column of the table can be retrieved via IDLitWindow::GetProperty. Properties with the word "Yes" in the "Init" column of the property table can be set via IDLitWindow::Init. Properties with the word "Yes" in the "Set" column in the property table can be set via IDLitWindow::SetProperty.

IDLitWindow::Add

The IDLitWindow::Add procedure method adds the given object(s) to the window.

Syntax

Obj->[IDLitWindow::]Add, *Objects* [, POSITION=*value*]

Arguments

Objects

A reference (or array of references) to the object(s) to be added to the window. Any of the objects that inherit from IDLgrViewGroup are added directly to the window's scene, which represents a container for all of the views (and their corresponding visualization hierarchies) that appear within a window. The remaining objects are added to the current view within the window's scene.

Keywords

POSITION

Set this keyword equal to a scalar or array containing the zero-based indices of the position within the container at which the new object should be placed.

Version History

6.0	Introduced

IDLitWindow::AddWindowEventObserver

The IDLitWindow::AddWindowEventObserver procedure method adds the given object(s) to the list of observers that are to be notified of events that occur within the window. Each observer must implement one or more methods corresponding to bits in the IDLitWindow object's event mask, as set by the IDLitWindow::SetEventMask method:

Bit	Value	Event Type	Required Methods
0	1	Button Events	OnMouseDown OnMouseUp
1	2	Motion Events	OnMouseMotion
2	4	Keyboard Events	OnKeyboard
3	8	Tracking Events	*n/a*
4	16	Timer Events	OnTimer
5	32	Wheel Events	OnWheel

Table 31-13: Event Mask values and their corresponding methods

Note
See "Designing a Behavior Object" (Chapter 10, *Object Programming*) for examples that implement the OnTimer event in an animation display.

When an event occurs within this window, the corresponding method (from the list above) will be called for each observer in the window's list.

See the IDLitWindow methods of the same name for information on creating window observer methods.

Syntax

Obj->[IDLitWindow::]AddWindowEventObserver, *Objects*

Arguments

Objects

A reference (or vector of references) to the object(s) to be added as window event observers.

Keywords

None

Version History

6.0	Introduced

See Also

IDLitWindow::OnKeyboard, IDLitWindow::OnMouseDown, IDLitWindow::OnMouseMotion, IDLitWindow::OnMouseUp, IDLitWindow::OnTimer, IDLitWindow::OnWheel, IDLitWindow::SetEventMask

IDLitWindow::Cleanup

The IDLitWindow::Cleanup procedure method performs all cleanup on the object.

Note ———————————————————————————————————

Cleanup methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation and destruction. This means that in most cases, you cannot call the Cleanup method directly. There is one exception to this rule: if you write your own subclass of this class, you can call the Cleanup method from within the Init or Cleanup method of the subclass.

Syntax

OBJ_DESTROY, *Obj*

or

Obj->[IDLitWindow::]Cleanup   *(In a lifecycle method only.)*

Arguments

None

Keywords

None

Version History

6.0	Introduced

IDLitWindow::ClearSelections

The IDLitWindow::ClearSelections procedure method clears the window's list of currently selected items (within its current view). The items within the current view that had been selected are deselected.

Syntax

Obj->[IDLitWindow::]ClearSelections

Arguments

None

Keywords

None

Version History

6.0	Introduced

IDLitWindow::DoHitTest

The IDLitWindow::DoHitTest function method performs a hit test to determine which visualizations within the destination are displayed at a given pixel location.

Note ──

The objects returned in *Result* are the "top-level" objects (usually IDLgrModel or IDLitVisualization objects). Objects *contained* by the returned objects can be returned using the SUB_HIT keyword.

───

Syntax

Result = Obj->[IDLitWindow::]DoHitTest(*X*, *Y* [, DIMENSIONS=[*width*, *height*]]
    [, /ORDER] [, SUB_HIT=*variable*] [, UNITS={0 | 1 | 2 | 3}])

Return Value

Returns a vector of references to the objects (usually IDLgrModel or IDLitVisualization objects) that appear at the given location. If no visualizations are displayed at that location, a null reference is returned.

Arguments

X

A floating-point value representing the *x*-location at which the hit test is to be performed

Y

A floating-point value representing the *y*-location at which the hit test is to be performed.

Keywords

DIMENSIONS

Set this keyword to a two-element integer vector, [*w*, *h*], to specify the dimensions (width and height) of the hit test box. The hit test box is centered at the location specified by the *X* and *Y* arguments. Any object that falls within this hit test box will be included in the return vector. By default, the hit test box is 3 pixels by 3 pixels.

ORDER

Set this keyword to control the ordering of objects in the returned hit test list when the objects are at the same distance from the viewer. Set ORDER=0 (the default) to return the objects in the order in which they were drawn. Set ORDER=1 to return objects in the reversed order from which they were drawn.

Note ───

If the visualization objects use DEPTH_TEST_FUNCTION=4 (less than or equal), then it is recommended that the ORDER keyword be set to 1 to ensure that objects at the same depth are returned in the same order in which they appear visually.

───

SUB_HIT

Set this keyword to a named variable that will contain references to all *contained* visualization objects that satisfy all of the following conditions:

- The objects are contained by the nearest hit visualization (the first object in the return value)

- The objects are SELECT_TARGETs (see "IDLgrModel" on page 4469)

- The objects are actively displayed at the given *X* and *Y* coordinates

The results of SUB_HIT are returned in the order in which the sub-hit visualizations appear in the graphics hierarchy. Sub-hits are only returned for the first visualization.

UNITS

Set this keyword to a scalar value to indicate the units of measure for the *X*, *Y* arguments and the DIMENSIONS keyword. Valid values include:

- 0 = Device (default)

- 1 = Inches

- 2 = Centimeters

- 3 = Normalized: relative to the dimensions of the primary monitor/screen, as stored in the SCREEN_DIMENSIONS property

Version History

6.0	Introduced
6.1	Added ORDER keyword

IDLitWindow::GetEventMask

The IDLitWindow::GetEventMask function method returns a bitwise mask representing the events that are enabled for this window.

Syntax

Result = Obj->[IDLitWindow::]GetEventMask([, BUTTON_EVENTS=*variable*]
   [, KEYBOARD_EVENTS=*variable*] [, MOTION_EVENTS=*variable*]
   [, TIMER_EVENTS=*variable*] [, TRACKING_EVENTS=*variable*]
   [, WHEEL_EVENTS=*variable*])

Return Value

Returns the bitwise mask as an unsigned long integer. The bits in the mask are as follows:

Bit	Value	Event
0	1	Button Events
1	2	Motion Events
2	4	Keyboard Events
3	8	Tracking Events
4	16	Timer Events
5	32	Wheel Events

Table 31-14: Bits of the Event Mask

Arguments

None

Keywords

BUTTON_EVENTS

Set this keyword equal to a named variable that will contain a 1 if mouse button events are currently enabled for this window, or a 0 otherwise.

KEYBOARD_EVENTS

Set this keyword equal to a named variable that will contain a 1 if keyboard events are currently enabled for this window, or a 0 otherwise.

MOTION_EVENTS

Set this keyword equal to a named variable that will contain a 1 if mouse motion events are currently enabled for this window, or a 0 otherwise.

TIMER_EVENTS

Set this keyword equal to a named variable that will contain a 1 if timer events are currently enabled for this window, or a 0 otherwise.

TRACKING_EVENTS

Set this keyword equal to a named variable that will contain a 1 if tracking events are currently enabled for this window, or a 0 otherwise.

WHEEL_EVENTS

Set this keyword equal to a named variable that will contain a 1 if wheel events are currently enabled for this window, or a 0 otherwise.

Version History

6.0	Introduced
6.2	Added TIMER_EVENTS keyword
6.4	Added WHEEL_EVENTS keyword

IDLitWindow::GetProperty

The IDLitWindow::GetProperty procedure method retrieves the value of an IDLitWindow property, and should be called by the subclass' GetProperty method. This method also retrieves properties defined in the superclass.

Syntax

Obj->[IDLitWindow::]GetProperty[, *PROPERTY=variable*]

Arguments

None

Keywords

Any property listed under "IDLitWindow Properties" on page 4126 that contains the word "Yes" in the "Get" column of the properties table can be retrieved using this method. To retrieve the value of a property, specify the property name as a keyword set equal to a named variable that will contain the value of the property.

Version History

6.0	Introduced

IDLitWindow::GetSelectedItems

The IDLitWindow::GetSelectedItems function method returns the objects (visualizations only, by default) currently selected within this window's scene.

Syntax

Result = Obj->[IDLitWindow::]GetSelectedItems([, /ALL] [, COUNT=*named variable*])

Return Value

Returns a vector of references to the objects currently selected within this window's scene. If no objects are currently selected, this function returns a –1.

Arguments

None

Keywords

ALL

Set this keyword to return all classes of selected items. By default, only visualizations are returned.

COUNT

Set this keyword to a named variable that will contain the number of items returned by this method.

Version History

6.0	Introduced
6.1	Added ALL keyword

IDLitWindow::Init

The IDLitWindow::Init function method initializes the window object.

This function method initializes the IDLitWindow object, and should be called by the subclass's Init method. This method also calls the superclass's Init method.

Note

Init methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation. This means that in most cases, you cannot call the Init method directly. There is one exception to this rule: if you write your own subclass of this class, you can call the Init method from within the Init method of the subclass.

Syntax

Obj = OBJ_NEW('IDLitWindow'[, *PROPERTY=value*])

or

Result = Obj->[IDLitWindow::]Init([, *PROPERTY=value*])   *(In a lifecycle method only.)*

Return Value

When this method is called indirectly, as part of the call to the OBJ_NEW function, the return value is an object reference to the newly-created object.

When called directly within a subclass Init method, the return value is 1 if initialization was successful, or 0 otherwise.

Arguments

None

Keywords

Any property listed under "IDLitWindow Properties" on page 4126 that contains the word "Yes" in the "Init" column of the properties table can be initialized during object creation using this method. To initialize the value of a property, specify the property name as a keyword set equal to the appropriate property value.

Version History

6.0	Introduced

IDLitWindow::OnEnter

Syntax | Arguments | Keywords | Version History

The IDLitWindow::OnEnter procedure method handles notification from the window that a mouse enter event has occurred.

Note

This method is only a stub and provides no functionality. In your subclass of IDLitWindow, you should override this method to provide your own functionality. Your method will be automatically called when a mouse enter event occurs.

Syntax

Obj->[IDLitWindow::]OnEnter

Arguments

None

Keywords

None

Version History

6.3	Introduced

IDLitWindow::OnExit

The IDLitWindow::OnExit procedure method handles notification from the window that a mouse exit event has occurred.

Note ————————————————————————————

This method is only a stub and provides no functionality. In your subclass of IDLitWindow, you should override this method to provide your own functionality. Your method will be automatically called when a mouse exit event occurs.

Syntax

Obj->[IDLitWindow::]OnExit

Arguments

None

Keywords

None

Version History

6.3	Introduced

IDLitWindow::OnExpose

Syntax | Arguments | Keywords | Version History

The IDLitWindow::OnExpose procedure method handles notification from the window that an expose event has occurred.

Note

By default, the OnExpose method will automatically redraw the graphics hierarchy. If you are using a subclass of IDLitWindow and require additional functionality, you should override this method. Your method will be automatically called when an expose event occurs.

Syntax

Obj->[IDLitWindow::]OnExpose, *X*, *Y*, *Width*, *Height*

Arguments

X

A floating-point value representing the *x*-coordinate of the lower left corner of the newly exposed portion of the canvas (in device coordinates).

Y

A floating-point value representing the *y*-coordinate of the lower left corner of the newly exposed portion of the canvas (in device coordinates).

Width

A floating-point value representing the width of the newly exposed portion of the canvas (in device coordinates).

Height

A floating-point value representing the height of the newly exposed portion of the canvas (in device coordinates).

Keywords

None

Version History

6.3	Introduced

IDLitWindow::OnKeyboard

The IDLitWindow::OnKeyboard procedure method handles notification (from the native window device) that a keyboard event has occurred, and passes along that notification to all observers in the list of window event observers (as specified by calls to the IDLitWindow::AddWindowEventObserver method). You can also *simulate* a keyboard event by calling this method directly.

Note

Window event observers that handle keyboard events *must* implement the OnKeyboard method, as described in "Implementing the OnKeyboard Interface" on page 4147. In addition, window event observers must implement the OnMouseDown, OnMouseMotion, and OnMouseUp methods. See IDLitWindow::AddWindowEventObserver for details.

Syntax

Obj->[IDLitWindow::]OnKeyboard, *IsASCII*, *Character*, *KeySymbol*, *X*, *Y*, *Press*, *Release*, *Modifiers*

Arguments

IsASCII

A scalar byte value that indicates whether the keyboard event corresponds to a character in the ASCII character set. If *IsASCII* is non-zero, the *Character* argument will be set to that ASCII character. If *IsASCII* is zero, the *KeySymbol* argument will be set to a numeric value indicating the key that was pressed.

Character

If *IsASCII* is non-zero, this argument is set to a byte value containing the ASCII character that corresponds to the key that was pressed. Otherwise, this argument is set to zero.

KeySymbol

If *IsASCII* is zero, this argument is set to a long integer that indicates the key that was pressed. Otherwise, this argument is set to zero. Valid values for key symbols include:

1	Shift
2	Control
3	Caps Lock
4	Alt
5	Left
6	Right
7	Up
8	Down
9	Page Up
10	Page Down
11	Home
12	End

X,Y

Long integers containing the *x*-coordinate and *y*-coordinate of the mouse cursor (in device coordinates) at the time of the event.

Press

A long integer indicating whether this event represents a key press. This argument is non-zero if the event is the result of pressing the key.

Release

A long integer indicating whether this event represents a key release. This argument is non-zero if the event is the result of releasing the key.

Modifiers

A long integer containing a bitwise mask indicating which modifier keys are active at the time of the keyboard event. If a bit is zero, the key is up; if the bit is set, the key is pressed. The following table describes the bits in this bit mask:

Bit	Value	Modifier Key
0	1	Shift
1	2	Control
2	4	Caps Lock
3	8	Alt

Table 31-15: Modifier Values

Keywords

None

Implementing the OnKeyboard Interface

When defining a window event observer that handles keyboard events, you must implement an OnKeyboard procedure method with the following signature:

```
PRO OnKeyboard, Window, IsASCII, Character, KeySymbol, X, Y, $
    Press, Release, Modifiers
```

where the *Window* argument is an object reference to the IDLitWindow object in which the event was generated, and all of the other arguments are described above.

In addition, you must implement OnMouseDown, OnMouseMotion, and OnMouseUp procedure methods, as discussed in "IDLitWindow::AddWindowEventObserver" on page 4128.

Version History

6.0	Introduced
6.1	Corrected syntax to read *IsASCII* instead of *IsAlphaNumeric*
	Corrected *KeySymbol* values
	Added *X*, *Y*, *Press*, *Release*, *Modifiers* arguments

See Also

IDLitWindow::AddWindowEventObserver, IDLitWindow::OnMouseDown, IDLitWindow::OnMouseMotion, IDLitWindow::OnMouseUp

IDLitWindow::OnMouseDown

The IDLitWindow::OnMouseDown procedure method handles notification (from the native window device) that a mouse down event has occurred, and passes along that notification to all observers in the list of window event observers (as specified by calls to the IDLitWindow::AddWindowEventObserver method). You can also *simulate* a mouse down event by calling this method directly.

Note ──

Window event observers that handle mouse down events *must* implement the OnMouseDown method, as described in "Implementing the OnMouseDown Interface" on page 4150. In addition, window event observers must implement the OnKeyboard, OnMouseMotion, and OnMouseUp methods. See IDLitWindow::AddWindowEventObserver for details.

──

Syntax

Obj->[IDLitWindow::]OnMouseDown, *X*, *Y*, *ButtonMask*, *Modifiers*, *NumClicks*

Arguments

X

A long integer representing the *x*-location (in device coordinates) of the mouse event.

Y

A long integer representing the *y*-location (in device coordinates) of the mouse event.

ButtonMask

An integer containing a bitwise mask indicating which of the left, center, or right mouse button was pressed:

Bitmask	Mouse Button
1	Left
2	Middle
4	Right

Table 31-16: Bitmask for Button Events

Modifiers

A long integer containing a bitwise mask indicating which modifier keys are active at the time the mouse button is pressed. If a bit is zero, the key is up; if the bit is set, the key is pressed. The following table describes the bits in this bitmask:

Bit	Value	Modifier Key
0	1	Shift
1	2	Control
2	4	Caps Lock
3	8	Alt

Table 31-17: Bits of the Modifier Key Mask

NumClicks

An integer indicating the number of times the mouse button was clicked.

Keywords

None

Implementing the OnMouseDown Interface

When defining a window event observer that handles mouse down events, you must implement an OnMouseDown procedure method with the following signature:

```
PRO OnMouseDown, Window, X, Y, ButtonMask, Modifiers, NumClicks
```

where the *Window* argument is an object reference to the IDLitWindow object in which the event was generated, and all of the other arguments are described above.

In addition, you must implement OnKeyboard, OnMouseMotion, and OnMouseUp procedure methods, as discussed in "IDLitWindow::AddWindowEventObserver" on page 4128.

Version History

6.0	Introduced

See Also

IDLitWindow::AddWindowEventObserver, IDLitWindow::OnKeyboard,
IDLitWindow::OnMouseMotion, IDLitWindow::OnMouseUp

IDLitWindow::OnMouseMotion

The IDLitWindow::OnMouseMotion procedure method handles notification (from the native window device) that a mouse motion event has occurred, and passes along that notification to all observers in the list of window event observers (as specified by calls to the IDLitWindow::AddWindowEventObserver method). You can also *simulate* a mouse motion event by calling this method directly.

Note —————————————————————————————————————

Window event observers that handle mouse motion events *must* implement the OnMouseMotion method, as described in "Implementing the OnMouseMotion Interface" on page 4153. In addition, window event observers must implement the OnKeyboard, OnMouseDown, and OnMouseUp methods. See IDLitWindow::AddWindowEventObserver for details.

Syntax

Obj->[IDLitWindow::]OnMouseMotion, *X*, *Y*, *Modifiers*

Arguments

X

A long integer representing the *x*-location (in device coordinates) of the mouse event.

Y

A long integer representing the *y*-location (in device coordinates) of the mouse event.

Modifiers

A long integer containing a bitwise mask indicating which modifier keys are active at the time the mouse button is pressed. If a bit is zero, the key is up; if the bit is set, the key is pressed. The following table describes the bits in this bitmask:

Bit	Value	Modifier Key
0	1	Shift
1	2	Control

Table 31-18: Bits of the Modifier Key Mask

Bit	Value	Modifier Key
2	4	Caps Lock
3	8	Alt

Table 31-18: Bits of the Modifier Key Mask

Keywords

None

Implementing the OnMouseMotion Interface

When defining a window event observer that handles mouse motion events, you must implement an OnMouseMotion procedure method with the following signature:

```
PRO OnMouseMotion, Window, X, Y, Modifiers
```

where the *Window* argument is an object reference to the IDLitWindow object in which the event was generated, and all of the other arguments are described above.

In addition, you must implement OnKeyboard, OnMouseDown, and OnMouseUp procedure methods, as discussed in "IDLitWindow::AddWindowEventObserver" on page 4128.

Version History

6.0	Introduced

See Also

IDLitWindow::AddWindowEventObserver, IDLitWindow::OnKeyboard, IDLitWindow::OnMouseDown, IDLitWindow::OnMouseUp

IDLitWindow::OnMouseUp

The IDLitWindow::OnMouseUp procedure method handles notification (from the native window device) that a mouse up event has occurred, and passes along that notification to all observers in the list of window event observers (as specified by calls to the IDLitWindow::AddWindowEventObserver method). You can also *simulate* a mouse up event by calling this method directly.

Note
Window event observers that handle mouse up events *must* implement the OnMouseUp method, as described in "Implementing the OnMouseUp Interface" on page 4155. In addition, window event observers must implement the OnKeyboard, OnMouseDown, and OnMouseMotion methods. See IDLitWindow::AddWindowEventObserver for details.

Syntax

Obj->[IDLitWindow::]OnMouseUp, *X*, *Y*, *ButtonMask*

Arguments

X

A long integer representing the *x*-location (in device coordinates) of the mouse event.

Y

A long integer representing the *y*-location (in device coordinates) of the mouse event.

ButtonMask

An integer containing a bitwise mask indicating which of the left, center, or right mouse button was released:

Bitmask	Mouse Button
1	Left
2	Middle
4	Right

Table 31-19: Bitmask for Button Events

Keywords

None

Implementing the OnMouseUp Interface

When defining a window event observer that handles mouse up events, you must implement an OnMouseUp procedure method with the following signature:

```
PRO OnMouseUp, Window, X, Y, ButtonMask
```

where the *Window* argument is an object reference to the IDLitWindow object in which the event was generated, and all of the other arguments are described above.

In addition, you must implement OnKeyboard, OnMouseMotion, and OnMouseMotion procedure methods, as discussed in "IDLitWindow::AddWindowEventObserver" on page 4128.

Version History

6.0	Introduced

See Also

IDLitWindow::AddWindowEventObserver, IDLitWindow::OnKeyboard, IDLitWindow::OnMouseDown, IDLitWindow::OnMouseMotion

IDLitWindow::OnResize

The IDLitWindow::OnResize procedure method handles notification from the window that a resize event has occurred.

Note

By default, the OnResize method will automatically resize the window and then call the OnResize method for the contained scene. If you are using a subclass of IDLitWindow and require additional functionality, you should override this method. Your method will be automatically called when a resize event occurs.

Syntax

Obj->[IDLitWindow::]OnResize, *Width*, *Height*

Arguments

Width

A floating-point value representing the new width of the canvas (in device coordinates).

Height

A floating-point value representing the new height of the canvas (in device coordinates).

Keywords

None

Version History

6.3	Introduced

IDLitWindow::OnScroll

The IDLitWindow::OnScroll procedure method handles notification (from the native window device) that a scrolling event has occurred. This notification is passed on to the window's scene, which handles the cropping of each of its contained views. A scene represents a container for all of the views (and their corresponding visualization hierarchies) that appear within a window.

Syntax

Obj->[IDLitWindow::]OnScroll, *X*, *Y*

Arguments

X

A long integer representing the *x*-coordinate of the lower left corner of the visible portion of the canvas (in device coordinates) after the scroll.

Y

A long integer representing the *y*-coordinate of the lower left corner of the visible portion of the canvas (in device coordinates) after the scroll.

Keywords

None

Version History

6.0	Introduced

IDLitWindow::OnTimer

The IDLitWindow::OnTimer procedure method handles notification (from the native window device) that a timer event has occurred, and passes that notification to all observers in the list of window event observers (as specified by calls to the IDLitWindow::AddWindowEventObserver method). You can also *simulate* a timer event by calling this method directly.

Note ——
Window event observers that handle timer events *must* implement the OnTimer method, as described in "Implementing the OnTimer Interface" on page 4158. See IDLitWindow::AddWindowEventObserver for details.

——

Note ——
See "Designing a Behavior Object" (Chapter 10, *Object Programming*) for examples that implement the OnTimer method in an animation display.

——

Syntax

Obj->[IDLitWindow::]OnTimer

Arguments

None

Keywords

None

Implementing the OnTimer Interface

When defining a window event observer that handles timer events, you must implement an OnTimer procedure method with the following signature:

```
PRO OnTimer, Window
```

where the *Window* argument is an object reference to the IDLitWindow object in which the event was generated.

Version History

6.2	Introduced

See Also

IDLitWindow::AddWindowEventObserver

IDLitWindow::OnWheel

The IDLitWindow::OnWheel procedure method handles notification (from the native window device) that a mouse wheel event has occurred, and passes along that notification to all observers in the list of window event observers (as specified by calls to the IDLitWindow::AddWindowEventObserver method). You can also simulate a mouse wheel event by calling this method directly.

Note ————————————————————————————————

Window event observers that handle mouse wheel events must implement the OnWheel method, as described in "Implementing the OnWheel Interface" on page 4161.

———

Syntax

Obj->[IDLitWindow::]OnWheel, *X*, *Y*, *Delta*, *Modifiers*

Arguments

X

A long integer representing the *x*-location (in device coordinates) of the mouse event.

Y

A long integer representing the *y*-location (in device coordinates) of the mouse event.

Delta

A long integer giving the direction and distance that the wheel was rolled. Pushing the wheel generates positive values, pulling the wheel generates negative values. The magnitude of the value depends on the device setting for the individual mouse, but is usually limited to small integer values such as +1, -1, +2, -2, etc.

Modifiers

A long integer containing a bitwise mask indicating which modifier keys are active at the time of the wheel event. If a bit is zero, the key is up; if the bit is set, the key is pressed. The following table describes the bits in this bit mask:

Bit	Value	Modifier Key
0	1	Shift
1	2	Control
2	4	Caps Lock
3	8	Alt

Table 31-20: Modifier Values

Keywords

None

Implementing the OnWheel Interface

When defining a window event observer that handles mouse wheel events, you must implement an OnWheel procedure method with the following signature:

```
PRO MyObject::OnWheel, Window, X, Y, Delta, Modifiers
```

where the *Window* argument is an object reference to the IDLitWindow object in which the event was generated, and all of the other arguments are described above.

Version History

6.4	Introduced

See Also

IDLitWindow::AddWindowEventObserver

IDLitWindow::Remove

The IDLitWindow::Remove procedure method removes the given object(s) from the window.

Syntax

Obj->[IDLitWindow::]Remove, *Object* [, /ALL] [, POSITION=index]

Arguments

Object

A reference (or vector of references) to the object(s) to be removed from this window.

Keywords

ALL

Set this keyword to remove all objects from the container. If this keyword is set, the *Object* argument is not required.

POSITION

Set this keyword equal to the zero-based index of the object to be removed. If the *Object* argument is supplied, this keyword is ignored.

Version History

6.0	Introduced

IDLitWindow::RemoveWindowEventObserver

The IDLitWindow::RemoveWindowEventObserver procedure method removes the given object(s) from the list of observers that are notified of events that occur within this window.

Syntax

Obj->[IDLitWindow::]RemoveWindowEventObserver, *Objects*

Arguments

Objects

A reference (or vector of references) to the object(s) to be removed from the list of window event observers.

Keywords

None

Version History

6.0	Introduced

IDLitWindow::Resize

The IDLitWindow::RemoveWindowEventObserver procedure method removes the given object(s) from the list of observers that are notified of events that occur within this window.

Syntax

Obj->[IDLitWindow::]Resize, *Objects*

Arguments

Objects

A reference (or vector of references) to the object(s) to be removed from the list of window event observers.

Keywords

None

Version History

6.3	Introduced

IDLitWindow::SetCurrentZoom

The IDLitWindow::SetCurrentZoom procedure method sets the current zoom factor for this window by changing its virtual dimensions. Setting the zoom factor on this window overrides any zoom factor inherited from the IDLgrWindow. The contents of the window are updated to reflect the new zoom factor.

Syntax

Obj->[IDLitWindow::]SetCurrentZoom, *ZoomFactor* [, /RESET]

Arguments

ZoomFactor

A positive floating point value indicating the zoom factor to be applied to the window. Values less than 1.0 result in a zooming out; values greater than 1.0 result in a zooming in on the contents of the window.

Keywords

RESET

Set this keyword to indicate that the zoom factor should be reset to 1.0. If this keyword is present, the *ZoomFactor* argument is ignored.

Version History

6.0	Introduced

IDLitWindow::SetEventMask

The IDLitWindow::SetEventMask procedure method enables the given events within this window.

When an event occurs within this window, if the corresponding event type is enabled, then the list of its window event observers will be notified of the event. See "IDLitWindow::AddWindowEventObserver" on page 4128 for more details.

Syntax

Obj->[IDLitWindow::]SetEventMask, [*EventMask*] [, /BUTTON_EVENTS]
   [, /KEYBOARD_EVENTS] [, /MOTION_EVENTS] [, /TIMER_EVENTS]
   [, /TRACKING_EVENTS] [, /WHEEL_EVENTS]

Arguments

EventMask

An unsigned long integer representing the bitwise mask for the events that are to be enabled for this window. The bits in the mask are as follows:

Bit	Value	Event
0	1	Button Events
1	2	Motion Events
2	4	Keyboard Events
3	8	Tracking Events
4	16	Timer Events
5	32	Wheel Events

Table 31-21: Bits of the Event Mask

This argument is optional; the keywords described below may be used instead.

Keywords

BUTTON_EVENTS

Set this keyword to indicate that mouse button events are to be enabled for this window.

KEYBOARD_EVENTS

Set this keyword to indicate the keyboard events are to be enabled for this window.

MOTION_EVENTS

Set this keyword to indicate that mouse motion events are to be enabled for this window.

TIMER_EVENTS

Set this keyword to indicate that timer events are to be enabled for this window.

TRACKING_EVENTS

Set this keyword to indicate that tracking events are to be enabled for this window.

Warning ————————————————————————————————

In order to receive tracking events, you *must* implement the IDLitWindow::OnEnter and IDLitWindow::OnExit methods in your own subclass of the IDLitWindow class.

——

WHEEL_EVENTS

Set this keyword to indicate that mouse wheel events are to be enabled for this window.

Version History

6.0	Introduced
6.2	Added TIMER_EVENTS keyword
6.4	Added WHEEL_EVENTS keyword

IDLitWindow::SetManipulatorManager

The IDLitWindow::SetManipulatorManager procedure method sets the given IDLitManipulatorManager object as the current manager of this window's manipulators.

Syntax

Obj->[IDLitWindow::]SetManipulatorManager, *Manager*

Arguments

Manager

A reference to the IDLitManipulatorManager object that is to serve as the manager for this window's manipulators.

Keywords

None

Version History

6.0	Introduced

IDLitWindow::SetProperty

The IDLitWindow::SetProperty procedure method sets the value of an IDLitWindow property, and should be called by the subclass's SetProperty method. This method also calls the superclass's SetProperty method.

Syntax

Obj->[IDLitWindow::]SetProperty[, *PROPERTY=value*]

Arguments

None

Keywords

Any property listed under "IDLitWindow Properties" on page 4126 that contains the word "Yes" in the "Set" column of the properties table can be set using this method. To set the value of a property, specify the property name as a keyword set equal to the appropriate property value.

Version History

6.0	Introduced

IDLitWindow::SetTimerInterval

The IDLitWindow::SetTimerInterval procedure method specifies the floating-point number of seconds between timer events. When a timer event occurs, the window calls the OnTimer method of all window event observers. The generation of timer events is controlled by the window event mask.

See "Controlling the Animation Rate" (Chapter 10, *Object Programming*) for examples of using this method in an animation display.

Syntax

Obj->[IDLitWindow::]SetTimerInterval, *Interval*

Arguments

Interval

The default interval value is 0, which indicates that the timer event interval is the smallest amount of time allowed by the system.

Keywords

None

Version History

6.2	Introduced

IDLitWindow::ZoomIn

The IDLitWindow::ZoomIn procedure method causes the current zoom factor for this window to be increased (that is, multiplied by the factor given by the inherited IDLgrWindow ZOOM_BASE property). The contents of the window are updated to reflect the new zoom factor. See "IDLitWindow::SetCurrentZoom" on page 4165 for additional details.

Syntax

Obj->[IDLitWindow::]ZoomIn

Arguments

None

Keywords

None

Version History

6.0	Introduced

IDLitWindow::ZoomOut

The IDLitWindow::ZoomOut procedure method causes the current zoom factor for this window to be decreased (that is, divided by the factor given by the inherited IDLgrWindow ZOOM_BASE property). The current contents of the window are updated to reflect the new zoom factor. See "IDLitWindow::SetCurrentZoom" on page 4165 for additional details.

Syntax

Obj->[IDLitWindow::]ZoomOut

Arguments

None

Keywords

None

Version History

6.0	Introduced

IDLitWriter

The IDLitWriter class defines the interface used to construct file writers for the iTools framework. Objects of this class are not intended to be created as standalone entities; rather, this class should be included as the superclass of an iTool file writer class.

This class is written in the IDL language. Its source code can be found in the file idlitwriter__define.pro in the lib/itools/framework subdirectory of the IDL distribution.

Superclasses

IDLitComponent

IDLitIMessaging

Note ———————————————————————————————

See the "iTools Object Model Diagram" (Chapter 2, *iTool Developer's Guide*) for a visual representation of the iTools object model hierarchy.

―――

Creation

See "IDLitWriter::Init" on page 4180.

Properties

Objects of this class have the following properties. See "IDLitWriter Properties" on page 4175 for details on individual properties.

- TYPES

Methods

This class has the following methods:

- IDLitWriter::Cleanup
- IDLitWriter::GetFileExtensions
- IDLitWriter::GetFilename
- IDLitWriter::GetProperty

- IDLitWriter::Init
- IDLitWriter::IsA
- IDLitWriter::SetData
- IDLitWriter::SetFilename
- IDLitWriter::SetProperty

In addition, this class inherits the methods of its superclasses.

Examples

See Chapter 10, "Creating a File Writer" (*iTool Developer's Guide*) for examples using this class and its methods.

Version History

6.0	Introduced

IDLitWriter Properties

IDLitWriter objects have the following properties in addition to properties inherited from any superclasses. Properties with the word "Yes" in the "Get" column of the properties table can be retrieved via IDLitWriter::GetProperty. Properties with the word "Yes" in the "Init" column of the properties table can be initialized via IDLitWriter::Init. Properties with the word "Yes" in the "Set" column of the properties table can be set via IDLitWriter::SetProperty.

Note ————————————————————————————————

For a discussion of the property description tables shown below, see "About Object Property Descriptions" on page 3135.

————————————————————————————————————

Objects of this class have the following properties.

- TYPES

In addition, objects of this class inherit:

- IDLitComponent
- IDLitIMessaging

TYPES

Set this property to a string or an array of strings indicating the types of data that this file writer accepts. iTools data types are described in Chapter 3, "Data Management" (*iTool Developer's Guide*). Set this property to a null string (`' '`) to specify that the file reader can accept all types of data.

Property Type	User Defined		
Name String	*not displayed*		
Get: Yes	**Set:** No	**Init:** Yes	**Registered:** No

IDLitWriter::Cleanup

The IDLitWriter::Cleanup procedure method performs all cleanup on the object, and should be called by the subclass' Cleanup method.

Note ───

Cleanup methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation and destruction. This means that in most cases, you cannot call the Cleanup method directly. There is one exception to this rule: if you write your own subclass of this class, you can call the Cleanup method from within the Init or Cleanup method of the subclass.

───

Syntax

OBJ_DESTROY, *Obj*

or

Obj->[IDLitWriter::]Cleanup   *(In a lifecycle method only.)*

Arguments

None

Keywords

None

Version History

6.0	Introduced

IDLitWriter::GetFileExtensions

The IDLitWriter::GetFileExtensions method is called by the system to retrieve the file extensions supported by this particular writer.

Syntax

Result = Obj->[IDLitWriter::]GetFileExtensions([, COUNT=*count*])

Return Value

Returns a scalar or string array that contains the file extensions associated with this writer.

Arguments

None

Keywords

COUNT

Set this keyword to a named variable that will contain the number of file extensions returned by this method.

Version History

6.0	Introduced

IDLitWriter::GetFilename

The IDLitWriter::GetFilename function method is called by the system to retrieve the current filename associated with this writer. Due to the automated nature of the file writer system, filenames can be associated with a file writer and then the file can be written at a later time. This method allows direct access to the file currently associated with the writer.

In addition, this methodology is helpful when multiple writes are performed from a given file.

Syntax

Result = Obj->[IDLitWriter::]GetFilename()

Return Value

Returns a string containing the current file name associated with this writer, or an empty string if no filename has been associated.

Arguments

None

Keywords

None

Version History

6.0	Introduced

IDLitWriter::GetProperty

The IDLitWriter::GetProperty procedure method retrieves the value of an IDLitWriter property, and should be called by the subclass' GetProperty method. This method also retrieves properties defined in the superclasses.

Syntax

Obj->[IDLitWriter::]GetProperty[, *PROPERTY=variable*]

Arguments

None

Keywords

Any property listed under "IDLitWriter Properties" on page 4175 that contains the word "Yes" in the "Get" column of the properties table can be retrieved using this method. To retrieve the value of a property, specify the property name as a keyword set equal to a named variable that will contain the value of the property.

Version History

6.0	Introduced

IDLitWriter::Init

The IDLitWriter::Init function method initializes the IDLitWriter object, and should be called by the subclass' Init method. This method also calls the superclass' Init method.

Note ───

Init methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation. This means that in most cases, you cannot call the Init method directly. There is one exception to this rule: if you write your own subclass of this class, you can call the Init method from within the Init method of the subclass.

───

Syntax

Obj = OBJ_NEW('IDLitWriter' [, *Extensions*] [, *PROPERTY=value*])

or

Result = Obj->[IDLitWriter::]Init([, *Extensions*] [, *PROPERTY=value*])   *(In a lifecycle method only.)*

Return Value

When this method is called indirectly, as part of the call to the OBJ_NEW function, the return value is an object reference to the newly-created object.

When called directly within a subclass Init method, the return value is 1 if initialization was successful, or 0 otherwise.

Arguments

Extensions

A optional argument containing a scalar or string array with the file extensions that are common for this file type. These values should not include the period that is often associated with file extensions (i.e., a correct value is 'jpeg' and not '.jpeg'). If this argument is not set, or if a null string is provided, IDL does not include this file writer in the list of filters in a file-selection dialog, but still uses it when attempting to match a file to a writer.

Keywords

Any property listed under "IDLitWriter Properties" on page 4175 that contains the word "Yes" in the "Init" column of the properties table can be initialized during object creation using this method. To initialize the value of a property, specify the property name as a keyword set equal to the appropriate property value.

Version History

6.0	Introduced

IDLitWriter::IsA

The IDLitWriter::IsA function method is called by the system to determine if the given file is of the type supported by this file writer. Often this is used to determine what file writer to use when opening a new file.

The default behavior provided by this method is to check the file extension on the provided file name with the extensions provided to this object during initialization.

When a new writer is implemented, the default behavior can be used, or the developer can provide further logic to determine if the provided file is the correct type.

Syntax

Result = Obj->[IDLitWriter::]IsA(*Filename*)

Return Value

Returns a 1 if the writer supports this type of file, or a 0 if the writer does not support this type of file.

Arguments

Filename

A string scalar representing of the filename, which is used to check and determine if the writer supports its format.

Keywords

None

Version History

6.0	Introduced

IDLitWriter::SetData

The IDLitWriter::SetData function method is called by the system to set the data for the current file. When called, the writer should access the current filename and write the desired data.

This method will contain a majority of the implementation for a new writer class.

Syntax

Result = Obj->[IDLitWriter::]SetData(*Data*)

Return Value

Returns a 1 if successful, or a 0 if the initialization failed.

Arguments

Data

A data object that contains the information to be written.

Keywords

None

Version History

6.0	Introduced

IDLitWriter::SetFilename

The IDLitWriter::SetFilename procedure method is called by the system to set the current filename associated with this writer. Due to the automated nature of the file writer system, filenames can be associated with a file writer and then the file can be written at a later time.

Syntax

Obj->[IDLitWriter::]SetFilename, *Filename*

Arguments

Filename

A string that contains the filename associated with this writer.

Keywords

None

Version History

6.0	Introduced

IDLitWriter::SetProperty

The IDLitWriter::SetProperty procedure method sets the value of an IDLitWriter property, and should be called by the subclass' SetProperty method. This method also calls the superclass' SetProperty method.

Syntax

Obj->[IDLitWriter::]SetProperty[, *PROPERTY=value*]

Arguments

None

Keywords

Any property listed under "IDLitWriter Properties" on page 4175 that contains the word "Yes" in the "Set" column of the properties table can be set using this method. To set the value of a property, specify the property name as a keyword set equal to the appropriate property value.

Version History

6.0	Introduced

Chapter 32
Graphics Object Classes

This chapter describes IDL's built-in graphics class library.

IDLgrAxis

An axis object represents a single vector that may include a set of tick marks, tick labels, and a title.

An IDLgrAxis object is an *atomic graphic object*; it is one of the basic drawable elements of the IDL Object Graphics system, and it is not a container for other objects.

Superclasses

IDLitComponent

Creation

See "IDLgrAxis::Init" on page 4222.

Properties

Objects of this class have the following properties. See "IDLgrAxis Properties" on page 4192 for details on individual properties.

- ALL
- AM_PM
- COLOR
- DAYS_OF_WEEK
- DEPTH_TEST_FUNCTION
- DIRECTION
- EXTEND
- HIDE
- LOG
- MINOR
- NOTEXT
- PARENT
- REGISTER_PROPERTIES

- ALPHA_CHANNEL
- CLIP_PLANES
- CRANGE
- DEPTH_TEST_DISABLE
- DEPTH_WRITE_DISABLE
- EXACT
- GRIDSTYLE
- LOCATION
- MAJOR
- MONTHS
- PALETTE
- RANGE
- SHADER

- SUBTICKLEN
- TEXTBASELINE
- TEXTUPDIR
- TICKDIR
- TICKFRMTDATA
- TICKLAYOUT
- TICKTEXT
- TICKVALUES
- USE_TEXT_COLOR
- XRANGE
- YRANGE
- ZRANGE

- TEXTALIGNMENTS
- TEXTPOS
- THICK
- TICKFORMAT
- TICKINTERVAL
- TICKLEN
- TICKUNITS
- TITLE
- XCOORD_CONV
- YCOORD_CONV
- ZCOORD_CONV

In addition, objects of this class inherit the properties of all superclasses of this class.

Methods

This class has the following methods:

- IDLgrAxis::Cleanup
- IDLgrAxis::GetCTM
- IDLgrAxis::GetProperty
- IDLgrAxis::Init
- IDLgrAxis::SetProperty

In addition, this class inherits the methods of its superclasses (if any).

Version History

5.0	Introduced
5.6	Added CLIP_PLANES property

6.1	Added ALPHA_CHANNEL property
6.4	Added SHADER property

IDLgrAxis Properties

IDLgrAxis objects have the following properties in addition to properties inherited from any superclasses. Properties with the word "Yes" in the "Get" column of the property table can be retrieved via IDLgrAxis::GetProperty. Properties with the word "Yes" in the "Init" column of the property table can be set via IDLgrAxis::Init. Properties with the word "Yes" in the "Set" column in the property table can be set via IDLgrAxis::SetProperty.

Note ───

For a discussion of the property description tables shown below, see "About Object Property Descriptions" on page 3135.

───

Objects of this class have the following properties.

- ALL
- AM_PM
- COLOR
- DAYS_OF_WEEK
- DEPTH_TEST_FUNCTION
- DIRECTION
- EXTEND
- HIDE
- LOG
- MINOR
- NOTEXT
- PARENT
- REGISTER_PROPERTIES
- SUBTICKLEN
- TEXTBASELINE
- TEXTUPDIR
- TICKDIR
- TICKFRMTDATA

- ALPHA_CHANNEL
- CLIP_PLANES
- CRANGE
- DEPTH_TEST_DISABLE
- DEPTH_WRITE_DISABLE
- EXACT
- GRIDSTYLE
- LOCATION
- MAJOR
- MONTHS
- PALETTE
- RANGE
- SHADER
- TEXTALIGNMENTS
- TEXTPOS
- THICK
- TICKFORMAT
- TICKINTERVAL

- TICKTEXT
- TICKVALUES
- USE_TEXT_COLOR
- XRANGE
- YRANGE
- ZRANGE

- TICKLEN
- TICKUNITS
- TITLE
- XCOORD_CONV
- YCOORD_CONV
- ZCOORD_CONV

In addition, objects of this class inherit:

- IDLitComponent

ALL

An anonymous structure containing the values of all of the properties associated with the *state* of this object. State information about the object includes things like color, range, tick direction, etc., but not image, vertex, or connectivity data, or user values.

Note ────────────────────────────────────

The fields of this structure may change in subsequent releases of IDL.

──

Property Type	Structure		
Name String	*not displayed*		
Get: Yes	**Set:** No	**Init:** No	**Registered:** No

ALPHA_CHANNEL

A floating-point value in the range [0.0, 1.0] to specify the opacity of the entire axis, including tick text and title text. The default value of 1.0 causes IDL to draw the axis completely opaque. If the value of this property is less than 1.0, then the pixels of the axis are blended with the pixels already on the screen, where the color of the axis is multiplied by the alpha value and the pixels already on the screen are multiplied by 1.0-alpha. Because an object can only be blended with objects already drawn on the screen, the drawing order of the objects must be considered carefully in order to obtain the desired results. This property has no effect on devices using indexed color mode. When the USE_TEXT_COLOR property is set to a non-zero value, the tick and title text is drawn using the value of the ALPHA_CHANNEL property from the

tick and/or title text objects. In other words, USE_TEXT_COLOR also implies using the text objects' alpha as well as its color.

Note ───

For more detailed information on alpha channel support for IDL Object Graphics, see "Controlling Object Transparency" (Chapter 2, *Object Programming*).

──

Property Type	Float-point value		
Name String	*Transparency*		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

AM_PM

A string array of 2 names to be used for the names of the AM and PM string when processing explicitly formatted dates (CAPA, CApA, and CapA format codes) with the TICKFORMAT property.

Property Type	String array		
Name String	*not displayed*		
Get: Yes	Set: Yes	Init: Yes	Registered: No

CLIP_PLANES

A 4 by *n* floating-point array that specifies the coefficients of the clipping planes to be applied to this object. The four coefficients for each clipping plane are of the form [A, B, C, D], where $Ax + By + Cz + D = 0$. Portions of this object that fall in the half space $Ax + By + Cz + D > 0$ will be clipped. By default, the value of this property is a scalar (-1) indicating that no clipping planes are to be applied.

Note ───

The clipping planes specified via this property are applied in addition to the near and far clipping planes associated with the IDLgrView in which this object appears.

──

Note ───

Clipping planes are applied in the data space of this object (prior to the application of any *x*, *y*, or *z* coordinate conversion).

──

Note

To determine the maximum number of clipping planes supported by the device, use the MAX_NUM_CLIP_PLANES property of the GetDeviceInfo method for the IDLgrBuffer, IDLgrClipboard, IDLgrWindow, and IDLgrVRML objects.

Property Type	Floating-point array		
Name String	*not displayed*		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** No

COLOR

The color to be used as the foreground color for this axis. The color may be specified as a color lookup table index or as a three-element vector [*red*, *green*, *blue*]. The default is [0, 0, 0].

Property Type	Color		
Name String	Color		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** Yes

CRANGE

A double-precision floating-point vector of the form [*minval*, *maxval*] that will contain the actual full range of the axis. This computed range may not exactly match the requested range provided via the RANGE property due to tick mark rounding and effects of the EXTEND property.

Property Type	Floating-point vector		
Name String	*not displayed*		
Get: Yes	**Set:** No	**Init:** No	**Registered:** No

DAYS_OF_WEEK

A string array of 7 names to be used for the names of the days of the week when processing explicitly formatted dates (CDWA, CDwA, and CdwA format codes) with the TICKFORMAT property.

Property Type	String array		
Name String	*not displayed*		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** No

DEPTH_TEST_DISABLE

An integer value that determines whether depth testing is disabled.

0	Inherit the value set by the parent model or view (the default). The parent view always enables depth testing. A model may also enable or disable depth testing.
1	Explicitly disable depth buffer testing while drawing this object.
2	Explicitly enable depth testing for this object

Disabling depth testing allows an object to draw itself "on top" of other objects already on the screen, even if the object is located behind them.

Note

Disabling depth testing also disables depth buffer writing. When disabling depth testing, the DEPTH_TEST_FUNCTION and DEPTH_WRITE_DISABLE properties are effectively ignored.

This property is registered as an enumerated list, but it is hidden by default.

Property Type	ENUMLIST		
Name String	*not displayed*		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** No

DEPTH_TEST_FUNCTION

An integer value that determines the depth test function. Set this property to 0 (the default) to inherit the value set by the parent model or view. The parent view always

sets a depth test function of LESS. A model may also set a depth test function value. The graphics device compares the object's depth at a particular pixel location with the depth stored in the depth buffer at that same pixel location. If the comparison test passes, the object's pixel is drawn at that location on the screen and the depth buffer is updated (if depth writing is enabled).

Set this property to any of the following values to use the desired function while rendering this object.

0	INHERIT	Use value from parent model or view
1	NEVER	Never passes
2	LESS	Passes if the object's depth is less than the depth buffer's value
3	EQUAL	Passes if the object's depth is equal to the depth buffer's value
4	LESS OR EQUAL	Passes if the object's depth is less than or equal to the depth buffer's value
5	GREATER	Passes if the object's depth is greater than or equal to the depth buffer's value
6	NOT EQUAL	Passes if the object's depth is not equal to the depth buffer's value
7	GREATER OR EQUAL	Passes if the object's depth is greater than or equal to the depth buffer's value
8	ALWAYS	Always passes

Less means closer to the viewer.

This property is registered as an enumerated list, but it is hidden by default.

Property Type	ENUMLIST		
Name String	*not displayed*		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** No

DEPTH_WRITE_DISABLE

An integer value that determines whether depth writing is disabled:

0	Inherit the value set by the parent model or view (the default). The parent view always enables depth writing. A model may also enable or disable depth writing.
1	Explicitly disable depth buffer writing while rendering this object.
2	Explicitly enable depth writing for this object.

Disabling depth writing allows an object to be overdrawn by other objects, even if the object is located in front of them.

Note

If depth testing (see DEPTH_TEST_DISABLE property) is disabled, depth writing is also automatically disabled.

This property is registered as an enumerated list, but it is hidden by default.

Property Type	ENUMLIST		
Name String	*not displayed*		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** No

DIRECTION

An integer value that specifies which axis is being created:

0	Create X axis
1	Create Y axis
2	Create Z axis

Specifying this property is the same as specifying the optional *Direction* argument to the IDLgrAxis::Init method.

This property is registered as an enumerated list, but it is hidden by default.

Property Type	ENUMLIST		
Name String	Direction		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** Yes

EXACT

A Boolean value that determines whether to force the axis range to be exactly as specified. If this property is not set, the range may be lengthened or shortened slightly to allow for evenly spaced tick marks.

Property Type	Boolean		
Name String	Use exact axis range		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** Yes

EXTEND

A Boolean value that determines whether to extend the axis slightly beyond the range of data to be plotted, which is a value specified by the RANGE property. This can be useful when you specify the axis range based on the minimum and maximum data values, but do not want the graphic to extend all the way to the end of the axis. The amount by which the axis is extended is determined by the system using a number of factors, including the MAJOR property of the axis.

Property Type	Boolean		
Name String	Extend axis		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** Yes

GRIDSTYLE

An integer or two-element vector that indicates the line style that should be used to draw the axis' tick marks. The value can be either an integer value specifying a pre-defined line style, or a two-element vector specifying a stippling pattern.

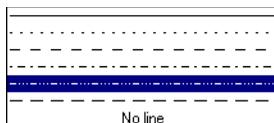
To use a pre-defined line style, set this property equal to one of the following integer values:

0	Solid line (the default)
1	Dotted
2	Dashed
3	Dash dot
4	Dash dot dot dot
5	Long dash
6	No line drawn

To define your own stippling pattern, specify a two-element vector [*repeat*, *bitmask*], where *repeat* indicates the number of times consecutive runs of 1's or 0's in the *bitmask* should be repeated. (That is, if three consecutive 0's appear in the *bitmask* and the value of *repeat* is 2, then the line that is drawn will have six consecutive bits turned off.) The value of *repeat* must be in the range $1 \leq repeat \leq 255$.

The *bitmask* indicates which pixels are drawn and which are not along the length of the line. *Bitmask* is most conveniently specified as a 16-bit hexadecimal value.

For example, GRIDSTYLE = [2, 'F0F0'X] describes a dashed line (8 bits on, 8 bits off, 8 bits on, 8 bits off).

In a property sheet, this property appears as a Linestyle drop-down list, with the following options:


Property Type	Linestyle			
Name String	Line style			
Get: Yes	**Set:** Yes	**Init:** Yes		**Registered:** Yes

HIDE

A Boolean value or enumerated list item indicating whether this object should be drawn. Options:

Value	Property Sheet Value	Description
0	True	Draw graphic (the default)
1	False	Do not draw graphic

Property Type	ENUMLIST		
Name String	Show		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** Yes

LOCATION

A two- or three-element floating-point vector of the form [*x, y*] or [*x, y, z*] to specify the coordinate through which the axis should pass. The default is [0, 0, 0]. IDL converts, maintains, and returns this data as double-precision floating-point.

Property Type	Floating-point vector		
Name String	*not displayed*		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** No

LOG

A Boolean value that indicates whether the axis is logarithmic.

Property Type	Boolean		
Name String	Use logarithmic axis		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** Yes

MAJOR

An integer representing the number of major tick marks. The default is -1, specifying that IDL will compute the number of tickmarks. Setting MAJOR equal to zero suppresses major tickmarks entirely.

Property Type	Integer		
Name String	Number of major ticks		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** Yes

MINOR

An integer representing the number of minor tick marks. The default is -1, specifying that IDL will compute the number of tickmarks. Setting MINOR equal to zero suppresses minor tickmarks entirely.

Property Type	Integer		
Name String	Number of minor ticks		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** Yes

MONTHS

A string array of 12 names to be used for the names of the months when processing explicitly formatted dates (CMOA, CMoA, and CmoA format codes) with the TICKFORMAT property.

Property Type	String array		
Name String	*not displayed*		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** No

NOTEXT

A Boolean value or an enumerated list item indicating whether the tick labels and the axis title should be drawn.

Value	Property Sheet Value	Description
0	True	Draw tick labels and axis title (the default)
1	False	Do not draw tick labels and axis title

Property Type	ENUMLIST		
Name String	Text show		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** Yes

PALETTE

The object reference of a palette object (an instance of the IDLgrPalette object class) that defines the color palette of this object. This property is only used if the destination device is using the RGB color model. If so, and a color value for the object is specified as a color index value, the palette set by this property is used to translate the color to RGB space. If the PALETTE property on this object is not set, the destination object PALETTE property is used (which defaults to a grayscale ramp).

Note ――――――――――――――――――――――――――――――――

Objects specified via this property are not automatically cleaned up when the IDLgrAxis object is destroyed.

――

This property is registered as a user-defined property, but it is hidden by default.

Property Type	USERDEF		
Name String	Color palette		
Get: Yes	**Set:** No	**Init:** No	**Registered:** Yes

PARENT

An object reference to the object that contains this object.

Property Type	Object reference		
Name String	*not displayed*		
Get: Yes	**Set:** No	**Init:** No	**Registered:** No

RANGE

A two-element floating-point vector containing the minimum and maximum data values covered by the axis. The default is [0.0, 1.0]. IDL converts, maintains, and returns this data as double-precision floating-point.

Property Type	Floating-point vector		
Name String	*not displayed*		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** No

REGISTER_PROPERTIES

A Boolean value that determines whether to register properties available for this object. If this property is set, all properties marked in this properties section as "Registered: Yes" will be registered for display in a property sheet. This property is useful mainly when creating iTools. By default, no properties are registered.

Property Type	Boolean		
Name String	*not displayed*		
Get: No	**Set:** No	**Init:** Yes	**Registered:** No

SHADER

An object reference to an IDLgrShader object (or an object containing IDLgrShader as a superclass). When there is suitable graphics card hardware support, the axis is rendered using the GLSL shader program (executed on the graphics card) instead of using fixed OpenGL properties when initially drawn. (If a suitable graphics card is not present, IDL ignores the shader object when the scene is drawn.) A single

IDLgrShader object may be associated with additional axis objects or other graphic objects that have the SHADER property.

Property Type	Object reference		
Name String	*not displayed*		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** No

SUBTICKLEN

A floating-point scale ratio specifying the length of minor tick marks relative to the length of major tick marks. The default is 0.5, specifying that the minor tick mark is one-half the length of the major tick mark.

Property Type	FLOAT		
Name String	Minor tick length		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** Yes

TEXTALIGNMENTS

A two-element floating-point vector, [*horizontal*, *vertical*], specifying the horizontal and vertical alignments for the tick text. Each alignment value should be a value between 0.0 and 1.0. For horizontal alignment, 0.0 left-justifies the text; 1.0 right-justifies the text. For vertical alignment, 0.0 bottom-justifies the text, 1.0 top-justifies the text.

The defaults are as follows:

- *X*-Axis: [0.5, 1.0] (centered horizontally, top-justified vertically)
- Y-Axis: [1.0, 0.5] (right-justified horizontally, centered vertically)
- Z-Axis: [1.0, 0.5] (right-justified horizontally, centered vertically)

Set this property to a scalar value to *restore* the default values after they have been explicitly set.

Property Type	Floating-point scalar or vector		
Name String	*not displayed*		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** No

TEXTBASELINE

A two- or three-element floating-point vector describing the direction in which the baseline of the tick text is to be oriented. Use this property in conjunction with the TEXTUPDIR property to specify the plane on which the tick text lies. The default is [1,0,0].

Property Type	Floating-point vector		
Name String	*not displayed*		
Get: Yes	Set: Yes	Init: Yes	Registered: No

TEXTPOS

An integer that indicates on which side of the axis to draw the tick text labels. The table below describes the placement of the tick text with each setting.

Axis	TEXTPOS = 0	TEXTPOS = 1
X	Tick text will be drawn *below* the X axis, where *below* is defined as being toward the direction of the negative Y axis (this is the default).	Tick text will be drawn *above* the X axis, where *above* is described as being toward the direction of the positive Y axis.
Y	Tick text will be drawn to the *left* of the Y Axis, where *left* is defined as being toward the direction of the negative X axis (this is the default).	Tick text will be drawn to the *right* of the Y axis, where *right* is defined as being toward the direction of the positive X axis.
Z	Tick text will be drawn to the *left* of the Z axis, where *left* is defined as being toward the direction of the negative X axis (this is the default).	Tick text will be drawn to the *right* of the Z axis, where *right* is defined as being toward the direction of the positive X axis.

Table 32-1: Values for the TEXTPOS property

In a property sheet, this property appears as an enumerated list. Options:

• Below/left: Text will be drawn below the axis and to the left.

• Above/right: Text will be drawn above the axis and to the right.

Property Type	ENUMLIST		
Name String	Text position		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

TEXTUPDIR

A two- or three-element floating-point vector describing the direction in which the up-vector of the tick text is to be oriented. Use this property in conjunction with the TEXTBASELINE property to specify the plane on which the tick text lies. TEXTUPDIR should be orthogonal to TEXTBASELINE. The default is as follows:

- *X*-Axis: [0, 1, 0]

- *Y*-Axis: [0, 1, 0]

- *Z*-Axis: [0, 0, 1]

Property Type	Floating-point vector		
Name String	*not displayed*		
Get: Yes	Set: Yes	Init: Yes	Registered: No

THICK

A floating-point value in points between 1.0 and 10.0 that specifies the line thickness used to draw the axis. Out-of-range values are quietly clamped to the allowed range. The default is 1.0 points.

In a property sheet, this property appears as a Thickness drop-down list with the following options:

Property Type	Thickness		
Name String	Line thickness		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** Yes

TICKDIR

An integer value of zero or one to indicate the tick mark direction.

Axis	TICKDIR = 0	TICKDIR = 1
X	Tick marks will be drawn above the X axis, in the direction of the positive Y axis (this is the default).	Tick marks will be drawn below the X axis.
Y	Tick marks will be drawn to the right of the Y axis, in the direction of the positive X axis (this is the default).	Tick marks will be drawn to the left of the Y axis.
Z	Tick marks will be drawn to the right the Z axis, in the direction of the positive X axis (this is the default).	Tick marks will be drawn to the left of the Z axis.

Table 32-2: Tick Mark Direction Values

In a property sheet, this property appears as an enumerated list, with the following options:

- Right/above: Tick marks will be drawn above the axis and to the right.

- Left/below: Tick marks will be drawn below the axis and to the left.

Property Type	ENUMLIST		
Name String	Tick direction		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** Yes

TICKFORMAT

A string, or an array of strings, in which each string represents a format string or the name of a function to be used to format the tick mark labels. If an array is provided, each string corresponds to a level of the axis. (The TICKUNITS property determines the number of levels for an axis.) If the number of strings stored in this property is one, GetProperty returns a scalar string, otherwise GetProperty returns an array of strings.

If the string begins with an open parenthesis, it is treated as a standard format string. (See "Format Codes" (Chapter 18, *Application Programming*).)

If the string does not begin with an open parenthesis, it is interpreted as the name of a callback function to be used to generate tick mark labels. This function is defined with either three or four parameters, depending on whether TICKUNITS is specified.

If TICKUNITS are not specified:

- The callback function is called with three parameters: *Axis*, *Index*, and *Value*, where:

- *Axis* is the axis number: 0 for X axis, 1 for Y axis, 2 for Z axis

- *Index* is the tick mark index (indices start at 0)

- *Value* is the data value at the tick mark (a double-precision floating point value)

If TICKUNITS are specified:

The callback function is called with four parameters: *Axis*, *Index*, *Value*, and *Level*, where:

- *Axis*, *Index*, and *Value* are the same as described above.

- *Level* is the index of the axis level for the current tick value to be labeled. (Level indices start at 0.)

Whether or not TICKUNITS is specified, the callback function can also define a DATA keyword. If the callback function accepts the DATA keyword, it will be set equal to the value (if any) of the TICKFRMTDATA property.

Note ───

For more information, see "[XYZ]TICKFORMAT" on page 5478.

───

Used with the LABEL_DATE function, this property can easily create axes with date/time labels.

Property Type	String or string array		
Name String	*not displayed*		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** No

TICKFRMTDATA

A value of any type that will be passed to the user-supplied formatting callback function (specified via the TICKFORMAT property) as the value of the DATA keyword. By default, this value is undefined, indicating that the value of the DATA keyword will be undefined.

Note ───

TICKFRMTDATA will not be included in the structure returned via the ALL property to the IDLgrAxis::GetProperty method.

───

Property Type	Scalar of any type		
Name String	*not displayed*		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** No

TICKINTERVAL

A floating-point scalar indicating the interval between major tick marks for the first axis level. The default value is computed according to the axis RANGE and the number of major tick marks (MAJOR). This property takes precedence over MAJOR.

For example, if TICKUNITS=['S','H','D'], and TICKINTERVAL=30, then the interval between major ticks for the first axis level will be 30 seconds.

Property Type	FLOAT		
Name String	Tick interval		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

TICKLAYOUT

An integer scalar or enumerated list item that indicates the tick layout style to be used to draw each level of the axis. Valid values include:

Value	Property Sheet Value	Description
0	Axis plus labels	The axis line, major tick marks and tick labels are all included. Minor tick marks only appear on the first level of the axis. This is the default tick layout style.
1	Labels only	Only the labels for the major tick marks are drawn. The axis line, major tick marks, and minor tick marks are omitted.
2	Box style	Each major tick interval is outlined by a box. The tick labels are positioned within that box (left-aligned). For the first axis level only, the major and minor tick marks will also be drawn.

Note

For all tick layout styles, at least one tick label will appear on each level of the axis (even if no major tick marks fall along the axis line). If there are no major tick marks, the single tick label will be centered along the axis.

Property Type	ENUMLIST		
Name String	Tick layout		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

TICKLEN

A floating-point value that specifies the length of each major tick mark, measured in data units. The recommended, and default, tick mark length is 0.2. IDL converts, maintains, and returns this data as double-precision floating-point.

Property Type	FLOAT		
Name String	Major tick length		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** Yes

TICKTEXT

An object reference to a single instance of the IDLgrText object class (with multiple strings) or a vector of instances of the IDLgrText object class (one per major tick) to specify the annotations to be assigned to the tickmarks. By default, with TICKTEXT set equal to a null object, IDL computes the tick labels based on major tick values. The positions of the provided text objects may be overwritten; position is determined according to tick mark location. The tickmark text will have the same color as the IDLgrAxis object, regardless of the color specified by the COLOR property of the IDLgrText object or objects, unless the USE_TEXT_COLOR property is specified.

Note

If IDL computes the tick labels, the text object it creates will be destroyed automatically when the axis object is destroyed, even if you have altered the properties of the text object. If you create your own text object containing tickmark text, however, it will *not* be destroyed automatically.

Property Type	Object reference or string vector		
Name String	*not displayed*		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** No

TICKUNITS

A string (or a vector of strings) indicating the units to be used for axis tick labeling. If the number of levels in the axis is one, GetProperty returns a scalar string, otherwise GetProperty returns an array of strings.

If more than one unit is provided, the axis will be drawn in multiple levels, one level per unit.

The order in which the strings appear in the vector determines the order in which the corresponding unit levels will be drawn. The first string corresponds to the first level (the level nearest to the primary axis line).

Valid unit strings include:

- "Numeric"

- "Years"

- "Months"

- "Days"

- "Hours"

- "Minutes"

- "Seconds"

- "Time" - Use this value to indicate that the tick values are time values; IDL will determine the appropriate time intervals and tick label formats based upon the range of values covered by the axis.

- ""- Use the empty string to indicate that no tick units are being explicitly set. This implies that a single axis level will be drawn using the "Numeric" unit. This is the default setting.

If any of the time units are utilized, then the tick values are interpreted as Julian date/time values. Note that the singular form of each of the time value strings is also acceptable (e.g, TICKUNITS='Day' is equivalent to TICKUNITS='Days').

Note

Julian values must be in the range -1095 to 1827933925, which corresponds to calendar dates 1 Jan 4716 B.C.E. and 31 Dec 5000000 A.D., respectively.

This property is registered as a user-defined property, but it is hidden by default.

Property Type	STRING		
Name String	*not displayed*		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** Yes

TICKVALUES

A floating-point vector of data values representing the values at each tick mark. If TICKVALUES is set to 0, the default, IDL computes the tick values based on the

axis range and the number of major ticks. IDL converts, maintains, and returns this data as double-precision floating-point.

Property Type	Floating-point vector		
Name String	*not displayed*		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** No

TITLE

An object reference to an instance of the IDLgrText object class that specifies the title for the axis. The default is the null object, specifying that no title is drawn. The title will be centered along the axis, even if the text object itself has an associated location. The title will have the same color as the IDLgrAxis object, regardless of the color specified by the COLOR property of the IDLgrText object, unless the USE_TEXT_COLOR property is specified.

Note
Objects specified via this property are not automatically cleaned up when the IDLgrAxis object is destroyed.

The IDLgrText object becomes a child of the IDLgrAxis object; therefore, to use the same IDLgrText object for multiple axes, you must use multiple IDLgrAxis objects.

Property Type	Object reference		
Name String	*not displayed*		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** No

USE_TEXT_COLOR

A Boolean value that indicates whether, for the tick text and/or title of the axis, the color property values set for the given IDLgrText objects are to be used to draw those text items. By default, this value is zero, indicating that the color properties of the IDLgrText objects will be ignored, and that the COLOR property for the axis object will be used for these text items instead.

Property Type	Boolean		
Name String	*not displayed*		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** No

XCOORD_CONV

A floating-point vector, $[s_0, s_1]$, of scaling factors that convert X coordinates from data units to normalized units. The formula for the conversion is as follows:

Normalized$X = s_0 + s_1 *$ Data$X$

Recommended values are:

$[(-X_{min})/(X_{max}-X_{min}), 1/(X_{max}-X_{min})]$

The default is [0.0, 1.0]. IDL converts, maintains, and returns this data as double-precision floating-point.

Property Type	Floating-point vector		
Name String	*not displayed*		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** No

XRANGE

A two-element double-precision floating-point vector of the form [*xmin*, *xmax*] that specifies the range of *x* data coordinates covered by the graphic object.

Property Type	Floating-point vector		
Name String	*not displayed*		
Get: Yes	**Set:** No	**Init:** No	**Registered:** No

YCOORD_CONV

A floating-point vector, $[s_0, s_1]$, of scaling factors that convert Y coordinates from data units to normalized units. The formula for the conversion is as follows:

Normalized$Y = s_0 + s_1 *$ Data$Y$

Recommended values are:

$[(-Y_{min})/(Y_{max}-Y_{min}), 1/(Y_{max}-Y_{min})]$

The default is [0.0, 1.0]. IDL converts, maintains, and returns this data as double-precision floating-point.

Property Type	Floating-point vector		
Name String	*not displayed*		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** No

YRANGE

A two-element double-precision floating-point vector of the form [*ymin*, *ymax*] that specifies the range of *y* data coordinates covered by the graphic object.

Property Type	Floating-point vector		
Name String	*not displayed*		
Get: Yes	**Set:** No	**Init:** No	**Registered:** No

ZCOORD_CONV

A floating-point vector, $[s_0, s_1]$, of scaling factors used to convert Z coordinates from data units to normalized units. The formula for the conversion is as follows:

$$\text{Normalized}Z = s_0 + s_1 * \text{Data}Z$$

Recommended values are:

$$[(-Z_{min})/(Z_{max}-Z_{min}), 1/(Z_{max}-Z_{min})]$$

The default is [0.0, 1.0]. IDL converts, maintains, and returns this data as double-precision floating-point.

Property Type	Floating-point vector		
Name String	*not displayed*		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** No

ZRANGE

A two-element double-precision floating-point vector of the form [*zmin*, *zmax*] that specifies the range of *z* data coordinates covered by the graphic object.

Property Type	Floating-point vector		
Name String	*not displayed*		
Get: Yes	Set: No	Init: No	Registered: No

IDLgrAxis::Cleanup

The IDLgrAxis::Cleanup procedure method performs all cleanup on the object.

Note ———

Cleanup methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation and destruction. This means that in most cases, you cannot call the Cleanup method directly. There is one exception to this rule: if you write your own subclass of this class, you can call the Cleanup method from within the Init or Cleanup method of the subclass.

Syntax

OBJ_DESTROY, *Obj*

or

Obj->[IDLgrAxis::]Cleanup   *(In a lifecycle method only.)*

Arguments

None

Keywords

None

Version History

5.0	Introduced

IDLgrAxis::GetCTM

The IDLgrAxis::GetCTM function method returns the graphics transform matrix from the current object upward through the graphics tree.

Syntax

Result = Obj->[IDLgrAxis::]GetCTM([, DESTINATION=*objref*] [, PATH=*objref(s)*] [, TOP=*objref*])

Return Value

Returns the 4 x 4 double-precision floating-point graphics transform matrix.

Arguments

None

Keywords

DESTINATION

Set this keyword to the object reference of a destination object to specify that the projection matrix for the View object in the current tree be included in the returned transformation matrix. The resulting matrix will transform a point in the data space of the object on which the GetCTM method is called into a normalized coordinate system (-1 to +1 in X, Y, and Z), relative to the View object that contains the axis object.

PATH

Set this keyword to a single object reference or a vector of object references. This keyword specifies the path in the graphics hierarchy to compute the transformation matrix. Each path object reference specified with this keyword must contain an alias. The transformation matrix is computed for the version of the object falling within that path. If this keyword is not set, the PARENT properties determine the path from the current object to the top of the graphics hierarchy and no alias paths are pursued. If IDLgrAxis::GetCTM is called from within a Draw method, with the DESTINATION keyword set and the PATH keyword not set, the alias path used to find the object during the draw is used, rather than the PARENT path.

Note ——
For more information on aliases, refer to the ALIAS keyword in IDLgrModel::Add.
——

TOP

Set this keyword equal to the object reference to an IDLgrModel object to specify
that the returned matrix accumulate from the object on which the GetCTM method is
called up to but not including the specified model object.

Version History

5.0	Introduced

IDLgrAxis::GetProperty

The IDLgrAxis::GetProperty procedure method retrieves the value of a property or group of properties for the axis.

Syntax

Obj->[IDLgrAxis::]GetProperty [, *PROPERTY=variable*]

Arguments

None

Keywords

Any property listed under "IDLgrAxis Properties" on page 4192 that contains the word "Yes" in the "Get" column of the properties table can be retrieved using this method. To retrieve the value of a property, specify the property name as a keyword set equal to a named variable that will contain the value of the property.

Version History

5.0	Introduced

IDLgrAxis::Init

The IDLgrAxis::Init function method initializes an axis object.

Note ――――――――――――――――――――――――――――――――――――――

Init methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation. This means that in most cases, you cannot call the Init method directly. There is one exception to this rule: if you write your own subclass of this class, you can call the Init method from within the Init method of the subclass.

――

Syntax

Obj = OBJ_NEW('IDLgrAxis' [, *Direction*] [, *PROPERTY=value*])

or

Result = Obj->[IDLgrAxis::]Init([*Direction*] [, *PROPERTY=value*])   *(In a lifecycle method only.)*

Return Value

When this method is called indirectly, as part of the call to the OBJ_NEW function, the return value is an object reference to the newly-created object.

When called directly within a subclass Init method, the return value is 1 if initialization was successful, or zero otherwise.

Arguments

Direction

An integer value specifying which axis is being created. Specify 0 (zero) to create an X axis, 1 (one) to create a Y axis, or 2 to create a Z axis.

Note ――――――――――――――――――――――――――――――――――――――

The value specified by the *Direction* argument is used to initialize the value of the DIRECTION property of the IDLgrAxis object.

――

Keywords

Any property listed under "IDLgrAxis Properties" on page 4192 that contains the word "Yes" in the "Init" column of the properties table can be initialized during object creation using this method. To initialize the value of a property, specify the property name as a keyword set equal to the appropriate property value.

Version History

5.0	Introduced

IDLgrAxis::SetProperty

The IDLgrAxis::SetProperty procedure method sets the value of a property or group of properties for the axis.

Syntax

Obj->[IDLgrAxis::]SetProperty[, *PROPERTY=value*]

Arguments

None

Keywords

Any property listed under "IDLgrAxis Properties" on page 4192 that contains the word "Yes" in the "Set" column of the properties table can be set using this method. To set the value of a property, specify the property name as a keyword set equal to the appropriate property value.

Version History

5.0	Introduced

IDLgrBuffer

An IDLgrBuffer object is an in-memory, off-screen destination object. Object trees can be drawn to instances of the IDLgrBuffer object and the resulting image can be retrieved from the buffer using the Read() method. The off-screen representation avoids dithering artifacts by providing a full-resolution buffer for objects using either the RGB or Color Index color models.

Note ——
Objects or subclasses of this type can not be saved or restored.

Superclasses

IDLitComponent

Creation

See "IDLgrBuffer::Init" on page 4247.

Properties

Objects of this class have the following properties. See "IDLgrBuffer Properties" on page 4227 for details on individual properties.

- ALL
- COLOR_MODEL
- DIMENSIONS
- GRAPHICS_TREE
- IMAGE_DATA
- N_COLORS
- PALETTE
- QUALITY
- REGISTER_PROPERTIES
- RESOLUTION
- SCREEN_DIMENSIONS

- UNITS
- ZBUFFER_DATA

In addition, objects of this class inherit the properties of all superclasses of this class.

Methods

This class has the following methods:

- IDLgrBuffer::Cleanup
- IDLgrBuffer::Draw
- IDLgrBuffer::Erase
- IDLgrBuffer::GetContiguousPixels
- IDLgrBuffer::GetDeviceInfo
- IDLgrBuffer::GetFontnames
- IDLgrBuffer::GetProperty
- IDLgrBuffer::GetTextDimensions
- IDLgrBuffer::Init
- IDLgrBuffer::PickData
- IDLgrBuffer::QueryRequiredTiles
- IDLgrBuffer::Read
- IDLgrBuffer::Select
- IDLgrBuffer::SetProperty

In addition, this class inherits the methods of its superclasses (if any).

Version History

5.0	Introduced
6.2	Added QueryRequiredTiles method

IDLgrBuffer Properties

IDLgrBuffer objects have the following properties in addition to properties inherited from any superclasses. Properties with the word "Yes" in the "Get" column of the property table can be retrieved via IDLgrBuffer::GetProperty. Properties with the word "Yes" in the "Init" column of the property table can be set via IDLgrBuffer::Init. Properties with the word "Yes" in the "Set" column in the property table can be set via IDLgrBuffer::SetProperty.

Note ───

For a discussion of the property description tables shown below, see "About Object Property Descriptions" on page 3135.

───

Objects of this class have the following properties.

- ALL
- COLOR_MODEL
- DIMENSIONS
- GRAPHICS_TREE
- IMAGE_DATA
- N_COLORS
- PALETTE
- QUALITY
- REGISTER_PROPERTIES
- RESOLUTION
- SCREEN_DIMENSIONS
- UNITS
- ZBUFFER_DATA

In addition, objects of this class inherit:

- IDLitComponent

ALL

An anonymous structure containing the values of all of the retrievable properties
associated with this object (except IMAGE_DATA and ZBUFFER_DATA).

Property Type	Structure		
Name String	*not displayed*		
Get: Yes	**Set:** No	**Init:** No	**Registered:** No

COLOR_MODEL

A Boolean value or enumerated list item that determines the color model to be used
for the buffer:

Value	Property Sheet Value	Description
0	RGB	RGB (default)
1	Indexed	Color Index

Note
See "Color and Destination Objects" (*Object Programming*) for more information.

Property Type	ENUMLIST		
Name String	Color model		
Get: Yes	**Set:** No	**Init:** Yes	**Registered:** Yes

DIMENSIONS

A two-element integer vector of the form [*width*, *height*] that specifies the
dimensions of the buffer in units specified by the UNITS property. The default is
[640,480].

Property Type	Integer vector		
Name String	*not displayed*		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** No

GRAPHICS_TREE

An object reference of type IDLgrScene, IDLgrViewgroup, or IDLgrView that specifies the graphics tree of this object. If this property is set to a valid object reference, calling the Draw method on the destination object with no arguments will cause the object reference associated with this property to be drawn. If this object is valid and the destination object is destroyed, this object reference will be destroyed as well. By default the GRAPHICS_TREE property is set equal to the null-object.

Property Type	Object reference		
Name String	*not displayed*		
Get: Yes	Set: Yes	Init: Yes	Registered: No

IMAGE_DATA

A byte array representing the image that is currently rendered within the buffer. If the buffer uses an RGB color model, the returned array will have dimensions (3, *xdim*, *ydim*). If the window object uses an indexed color model, the returned array will have dimensions (*xdim*, *ydim*).

Property Type	Byte array		
Name String	*not displayed*		
Get: Yes	Set: No	Init: No	Registered: No

N_COLORS

An integer that determines the number of colors (between 2 and 256) to be used if COLOR_MODEL is set to Color Index.

Property Type	Integer		
Name String	Number of colors		
Get: Yes	Set: No	Init: Yes	Registered: Yes

PALETTE

An object reference to a palette object (an instance of the IDLgrPalette object class) that specifies the red, green, and blue values to be loaded into the buffer's color lookup table.

Note ───

Objects specified via this property are not automatically cleaned up when the IDLgrBuffer object is destroyed.

───

This property is registered as a user-defined property, but it is hidden by default.

Property Type	USERDEF		
Name String	Color palette		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** Yes

QUALITY

An integer value or enumerated list item that indicates the rendering quality with which graphics are to be drawn to the buffer. Valid values are:

Value	Property Sheet Value	Description
0	Low	Low quality
1	Medium	Medium quality
2	High	High quality (the default)

Property Type	ENUMLIST		
Name String	Draw quality		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** Yes

REGISTER_PROPERTIES

A Boolean value that determines whether to register properties available for this object. If this property is set, all properties marked in this properties section as "Registered: Yes" will be registered for display in a property sheet. This property is useful mainly when creating iTools. By default, no properties are registered.

Property Type	Boolean		
Name String	*not displayed*		
Get: No	**Set:** No	**Init:** Yes	**Registered:** No

RESOLUTION

A two-element floating-point vector of the form [*xres*, *yres*] that specifies the device resolution in centimeters per pixel. This value is stored in double precision. The default value is: [0.035277778, 0.035277778] (72 DPI).

This property is registered as a user-defined property, but it is hidden by default.

Property Type	USERDEF		
Name String	Resolution		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** Yes

SCREEN_DIMENSIONS

A two-element integer vector of the form [*width*, *height*] that specifies the maximum allowed dimensions (measured in device units) for the buffer object.

Note ───
  The maximum buffer dimension size is always 4096 by 4096.
───

Property Type	Integer vector		
Name String	*not displayed*		
Get: Yes	**Set:** No	**Init:** No	**Registered:** No

UNITS

An integer value that indicates the units of measure for the DIMENSIONS property. Valid values are:

- 0 = Device (default)
- 1 = Inches
- 2 = Centimeters
- 3 = Normalized: relative to 1600 x 1200

Property Type	Integer		
Name String	*not displayed*		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** No

ZBUFFER_DATA

A floating-point array representing the zbuffer that is currently within the buffer. The returned array will have dimensions (*xdim*, *ydim*).

Property Type	Floating-point array		
Name String	*not displayed*		
Get: Yes	**Set:** No	**Init:** No	**Registered:** No

IDLgrBuffer::Cleanup

The IDLgrBuffer::Cleanup procedure method performs all cleanup on the object.

Note

Cleanup methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation and destruction. This means that in most cases, you cannot call the Cleanup method directly. There is one exception to this rule: if you write your own subclass of this class, you can call the Cleanup method from within the Init or Cleanup method of the subclass.

Syntax

OBJ_DESTROY, *Obj*

or

Obj->[IDLgrBuffer::]Cleanup   *(In a lifecycle method only.)*

Arguments

None

Keywords

None

Version History

5.0	Introduced

IDLgrBuffer::Draw

The IDLgrBuffer::Draw procedure method draws the given picture to this graphics destination.

Note ──

Objects are drawn to the destination device in the order that they are added to the model, view, viewgroup, or scene object that contains them.

───

Syntax

Obj->[IDLgrBuffer::]Draw [, *Picture*] [, CREATE_INSTANCE={1 | 2}]
  [, DRAW_INSTANCE={1 | 2}]

Arguments

Picture

The view (an instance of an IDLgrView object), viewgroup (an instance of an IDLgrViewgroup object) or scene (an instance of an IDLgrScene object) to be drawn.

Keywords

CREATE_INSTANCE

Set this keyword equal to one to specify that this scene or view is the unchanging part of a drawing. Some destinations can make an instance from the current window contents without having to perform a complete redraw. If the view or scene to be drawn is identical to the previously drawn view or scene, this keyword can be set equal to 2 to hint the destination to create the instance from the current window contents if it can.

DRAW_INSTANCE

Set this keyword to specify that the instance, or unchanging part of the drawing, is drawn to the device first. IDL then draws the changing part of the drawing, indicated by the scene, view or viewgroup specified by the Picture argument.

If the value of this keyword is 1, IDL copies both the instance image (color buffer) and the instance depth buffer to the device.

If the value of this keyword is 2, IDL copies only the instance image to the device.

Version History

5.0	Introduced

IDLgrBuffer::Erase

The IDLgrBuffer::Erase procedure method erases this graphics destination.

Syntax

Obj->[IDLgrBuffer::]Erase [, COLOR=*index or RGB vector*]

Arguments

None

Keywords

COLOR

Set this keyword to the color to be used for the erase. The color may be specified as a color lookup table index or as a three-element vector [*red*, *green*, *blue*].

Version History

5.0	Introduced

IDLgrBuffer::GetContiguousPixels

The IDLgrBuffer::GetContiguousPixels function method returns an array of long integers whose length is equal to the number of colors available in the index color mode (that is, the value of the N_COLORS property).

The returned array marks contiguous pixels with the ranking of the range's size. This means that within the array, the elements in the largest available range are set to zero, the elements in the second-largest range are set to one, etc. Use this range to set an appropriate colormap for use with the SHADE_RANGE property of the IDLgrSurface and IDLgrPolygon object classes.

To get the largest contiguous range, you could use the following IDL command:

```
result = obj->GetContiguousPixels()
Range0 = WHERE(result EQ 0)
```

A contiguous region in the colormap can be increasing or decreasing in values. The following would be considered contiguous:

```
[0,1,2,3,4]
[4,3,2,1,0]
```

Syntax

Result = Obj->[IDLgrBuffer::]GetContiguousPixels()

Return Value

Returns an array of long integers whose length is equal to the number of colors available in the index color mode.

Arguments

None

Keywords

None

Version History

5.0	Introduced

IDLgrBuffer::GetDeviceInfo

The IDLgrBuffer::GetDeviceInfo procedure method returns information which allows IDL applications to intelligently make decisions for optimal performance. For example, it allows an application to determine if RENDERER=1 is actually implemented in hardware. It also allows applications to make optimal quality decisions when dynamically building texture maps.

Syntax

Obj->[IDLgrBuffer::]GetDeviceInfo [, ALL=*variable*]
   [, MAX_NUM_CLIP_PLANES=*variable*]
   [, MAX_TEXTURE_DIMENSIONS=*variable*]
   [, MAX_TILE_DIMENSIONS=variable]
   [, MAX_VIEWPORT_DIMENSIONS=*variable*] [, NAME=*variable*]
   [, NUM_CPUS=*variable*] [, VENDOR=*variable*] [, VERSION=*variable*]

Arguments

None

Keywords

ALL

Set this keyword to a named variable which, upon return, contains a structure with the values of all the device information keywords as fields.

MAX_NUM_CLIP_PLANES

Set this keyword to a named variable that upon return will contain an integer that specifies the maximum number of user-defined clipping planes supported by the device.

MAX_TEXTURE_DIMENSIONS

Set this keyword equal to a named variable. Upon return, MAX_TEXTURE_DIMENSIONS contains a two-element integer array that specifies the maximum texture size supported by the device.

MAX_TILE_DIMENSIONS

Set this keyword equal to a named variable. Upon return,
MAX_TILE_DIMENSIONS contains a two element integer array that specifies the
maximum tile size supported by the device.

MAX_VIEWPORT_DIMENSIONS

Set this keyword equal to a named variable. Upon return,
MAX_VIEWPORT_DIMENSIONS contains a two-element integer array that
specifies the maximum size of a graphics display supported by the device.

NAME

Set this keyword equal to a named variable. Upon return, NAME contains the name
of the rendering device as a string.

NUM_CPUS

Set this keyword equal to a named variable. Upon return, NUM_CPUS contains an
integer that specifies the number of CPUs that are known to, and available to IDL.

Note

The NUM_CPUS keyword accurately returns the number of CPUs for the SUN and
Microsoft Windows platforms. For platforms other than these, the number returned
may not reflect the actual number of CPUs available to IDL in the current system.

VENDOR

Set this keyword equal to a named variable. Upon return, VENDOR contains the
name of the rendering device creator as a string.

VERSION

Set this keyword equal to a named variable. Upon return, VERSION contains the
version of the rendering device driver as a string.

Version History

5.0	Introduced
5.6	Added MAX_NUM_CLIP_PLANES keyword
6.2	Added MAX_TILE_DIMENSIONS keyword

IDLgrBuffer::GetFontnames

The IDLgrBuffer::GetFontnames function method returns the list of available fonts that can be used in IDLgrFont objects. This method will only return the names of the available TrueType fonts. Hershey fonts will not be returned. See Appendix H, "Fonts" for more information.

Syntax

Result = Obj->[IDLgrBuffer::]GetFontnames(*FamilyName*[, IDL_FONTS={0 | 1 | 2 }] [, STYLES=*string*])

Return Value

Returns the list of available fonts that can be used in IDLgrFont objects.

Arguments

FamilyName

A string representing the name of the font family to which all of the returned fonts must belong. The string may be a fully specified family name—such as "Helvetica". You can use both "*" and "?" as wildcard characters, matching any number of characters or one character respectively. To return all available family names, use "*".

Keywords

IDL_FONTS

Set this keyword to specify where to search for fonts that IDL may use. Set IDL_FONT to 1 to select only fonts installed by IDL and to 2 to select only fonts detected in the host operating system. The default value is 0, specifying that both IDL and operating system fonts should be returned.

STYLES

Set this keyword to a string specifying the styles that are to be matched by the returned font names. You can set STYLES to a fully specified style string, such as "Bold Italic". If you set STYLES to the null string, ' ', only fontnames without style modifiers will be returned. You can use both "*" and "?" as wildcard characters, matching any number of characters or one character respectively. The default value is

the string, "*", which returns all fontnames containing the *FamilyName* argument, with or without style modifiers.

Version History

5.0	Introduced

IDLgrBuffer::GetProperty

The IDLgrBuffer::GetProperty procedure method retrieves the value of a property or group of properties for the buffer.

Syntax

Obj->[IDLgrBuffer::]GetProperty[, *PROPERTY=variable*]

Keywords

Any property listed under "IDLgrBuffer Properties" on page 4227 that contains the word "Yes" in the "Get" column of the properties table can be retrieved using this method. To retrieve the value of a property, specify the property name as a keyword set equal to a named variable that will contain the value of the property.

Any keyword not recognized is passed to this object's super-class.

Version History

5.0	Introduced

IDLgrBuffer::GetTextDimensions

The IDLgrBuffer::GetTextDimensions function method retrieves the dimensions of a text or axis object that will be rendered in a window. In order to compute the effective text dimensions, the object must be inserted into an object graphics hierarchy prior to using this method. The result is a 3-element double-precision floating-point vector [*xDim*, *yDim*, *zDim*] representing the dimensions of the text or axis object, measured in data units. If the object specified is an axis object, the result encompasses the tick labels and the title of the axis (if any).

Note

The returned results take into account the setting of the IDLgrText RECOMPUTE_DIMENSIONS property.

Syntax

Result = Obj->[IDLgrBuffer::]GetTextDimensions(*TextObj* [, DESCENT=*variable*] [, PATH=*objref(s)*])

Return Value

Returns the dimensions of a text or axis object that will be rendered in a window.

Arguments

TextObj

The object reference to a text or axis object for which text dimensions are requested.

Keywords

DESCENT

Set this keyword equal to a named variable that will contain an array of double-precision floating-point values (one for each string in the IDLgrText object). The values represent the distance to travel (parallel to the UPDIR vector) from the text baseline to reach the bottom of the lowest descender in the string. All values will be negative numbers, or zero. This keyword is valid only if *TextObj* is an IDLgrText object.

PATH

Set this keyword to a single object reference or a vector of object references. This keyword specifies the path in the graphics hierarchy to compute the text dimensions. Each path object reference specified with this keyword must contain an alias. The text dimensions are computed for the version of the object falling within that path. If this keyword is not set, the PARENT properties determine the path from the current object to the top of the graphics hierarchy and no alias paths are pursued. If IDLgrBuffer::GetTextDimensions is called from within a Draw method and the PATH keyword is not set, the alias path used to find the object during the draw is used, rather than the PARENT path.

Note ────────────────────────────────────

For more information on aliases, refer to the ALIAS keyword in IDLgrModel::Add.

───

Version History

5.0	Introduced

IDLgrBuffer::Init

The IDLgrBuffer::Init function method initializes the buffer object.

Note ———————————————————————————————

Init methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation. This means that in most cases, you cannot call the Init method directly. There is one exception to this rule: if you write your own subclass of this class, you can call the Init method from within the Init method of the subclass.

Syntax

Obj = OBJ_NEW('IDLgrBuffer' [, *PROPERTY=value*])

or

Result = Obj->[IDLgrBuffer::]Init([, *PROPERTY=value*])   *(In a lifecycle method only.)*

Return Value

When this method is called indirectly, as part of the call to the OBJ_NEW function, the return value is an object reference to the newly-created object.

When called directly within a subclass Init method, the return value is 1 if initialization was successful, or zero otherwise.

Arguments

None

Keywords

Any property listed under "IDLgrBuffer Properties" on page 4227 that contains the word "Yes" in the "Init" column of the properties table can be initialized during object creation using this method. To initialize the value of a property, specify the property name as a keyword set equal to the appropriate property value.

All other keywords are passed to the superclass of this object.

Version History

5.0	Introduced

IDLgrBuffer::PickData

The IDLgrBuffer::PickData function method maps a point in the two-dimensional device space of the buffer to a point in the three-dimensional data space of an object tree. The resulting 3-D data space coordinates are returned in a user-specified variable. The PickData function returns one if the specified location in the buffer's device space "hits" a graphic object, or zero otherwise.

Warning

If you use the DEPTH_WRITE_DISABLE or DEPTH_TEST_DISABLE property of an object to prevent an object from modifying the depth buffer as it is drawn, this also prevents the object from affecting the result returned by the PickData method (the return value will be 0). The PickData method relies on the contents of the depth buffer at the time it is called to compute and return its results. Be sure that the depth buffer contents are appropriate for getting the expected results from PickData.

Syntax

Result = Obj->[IDLgrBuffer*::*]PickData(*View*, *Object*, *Location*, *XYZLocation*
   [, DIMENSIONS=*[width,height]*][, PATH=*objref(s)*]
   [, PICK_STATUS=*variable*])

Return Value

Returns one if the specified location in the buffer's device space "hits" a graphic object, or zero otherwise.

Arguments

View

The object reference of an IDLgrView object that contains the object being picked.

Object

The object reference of a model or atomic graphic object from which the data space coordinates are being requested.

Note

Even though you can specify any object for this argument, the location that is returned may not lie on this object. If another object is in front of the specified object then the returned location lies on the object in front. However, the coordinate system used is that of the object specified by this argument.

Location

A two-element vector [*x*, *y*] specifying the location in the buffer's device space of the point to pick data from.

XYZLocation

A named variable that will contain the three-dimensional double-precision floating-point data space coordinates of the picked point. Note that the value returned in this variable is a location, not a data value.

Note

If the atomic graphic object specified as the target has been transformed using either the LOCATION or DIMENSIONS properties (this is only possible with IDLgrAxis, IDLgrImage, and IDLgrText objects), these transformations will *not* be included in the data coordinates returned by the PickData function. This means that you may need to re-apply the transformation accomplished by specifying LOCATION or DIMENSIONS once you have retrieved the data coordinates with PickData. This situation does not occur if you transform the axis, text, or image object using the [XYZ]COORD_CONV properties.

Keywords

DIMENSIONS

Set this keyword to a two-element array [*w*, *h*] to specify data picking should occur for all device locations that fall within a *pick box* of these dimensions. The pick box will be centered about the coordinates [*x, y*] specified in the *Location* argument, and will occupy the rectangle defined by:

```
(x-(w/2), y-(h/2)) - (x+(w/2), y+(h/2))
```

By default, the pick box covers a single pixel. The array returned via the *XYZLocation* argument will have dimensions [*3, w, h*].

PATH

Set this keyword to a single object reference or a vector of object references. This keyword specifies the path in the graphics hierarchy to map the device position to a data space coordinate. Each path object reference specified with this keyword must contain an alias. The data space coordinate is computed for the version of the object falling within that path. If this keyword is not set, the PARENT properties determine the path from the current object to the top of the graphics hierarchy and no alias paths are pursued.

Note

For more information on aliases, refer to the ALIAS keyword in IDLgrModel::Add.

PICK_STATUS

Set this keyword to a named variable that will contain "hit" information for each pixel in the pick box. If the DIMENSIONS keyword is not set, the PICK_STATUS will be a scalar value exactly matching the *Result* of the method call. If the DIMENSIONS keyword is set, the PICK_STATUS variable will be an array matching the dimensions of the pick box. Each value in the PICK_STATUS array corresponds to a pixel in the pick box, and will be set to one of the following values:

Value	Description
-1	The pixel falls outside of the window's viewport.
0	No graphic object is "hit" at that pixel location.
1	A graphic object is "hit" at that pixel location.

Table 32-3: PICK_STATUS Keyword Values

Version History

5.0	Introduced
5.6	Added PICK_STATUS keyword

IDLgrBuffer::QueryRequiredTiles

The IDLgrBuffer::QueryRequiredTiles function method is used in conjunction with an IDLgrImage object that supports tiling. Initially, this type of IDLgrImage object contains no data. Call this method to determine what data to load into this destination object based on which tiles are visible in a view. Pass the results to IDLgrImage::SetTileData to load the required portion of the tiled image. When the Draw method is called, the destination object contains the image tiles that are the results of this method's query.

This method returns an array of named structures containing information about the tiles that are required, or a scalar integer with the value 0 if no tiles are required. The application can check that COUNT is greater than 0 before accessing the returned array.

Note

If the device is in Color Index mode (COLOR_MODEL=1) or the image has RENDER_METHOD=1 set, then IDL will generate an error as tiling is not supported under these circumstances.

Syntax

Result = Obj->[IDLgrBuffer::]QueryRequiredTiles(*View*, *Image*
[, ALL_VISIBLE=*value*] [, COUNT=*variable*] [, PATH=*objref(s)*])

Return Value

Returns an array of named structures containing information about the tiles that are required, or a scalar integer with the value 0 if no tiles are required.

Each structure in the array describes one required tile and has the following fields:

Field	Data Type	Description
X	Long	The horizontal position of the left side of the tile measured from the left of the image in pixels.
Y	Long	The vertical position of the bottom of the tile measured from the bottom of the image in pixels.
WIDTH	Long	The width of the tile in pixels.

Table 32-4: IDLIMAGETILE Structure

Field	Data Type	Description
HEIGHT	Long	The height of the tile in pixels.
LEVEL	Long	The data resolution, where 0 is the full resolution image. A value of *n* (*n* > 0) indicates that the resolution is half that of the *n*-1 level.
DEST	OBJREF	The object reference to the destination object that was used to query for the required tiles.

Table 32-4: IDLIMAGETILE Structure (Continued)

The X, Y, WIDTH and HEIGHT elements are all relative to the specified LEVEL. For example, say a large image (level 0) has dimensions of 10000 by 10000 pixels. The tile structure [2048, 2048, 1024, 1024, 0] specifies a 1024 by 1024 pixel area where the lower-left corner of the tile is (2048, 2048) pixels from the lower-left corner of the original, level 0 image. This is shown in the left portion of the following figure.

When you zoom out to 50% of the original resolution, you can load the level 1 image (5000 by 5000 pixels), a subsampled version of the large image. Here, the tile [1024, 1024, 1024, 1024, 1] specifies a 1024 by 1024 pixel area of the image with the lower-left corner being (1024, 1024) from the lower-left corner of the image. Both of these tiles have their lower-left corner at the same physical location of the image, but the second tile covers four times the area as it is a lower resolution version of the data.

Figure 32-1: Interaction Between Image Level and Zoom with Equal Tile Sizes

Note

See "Image Tiling" (Chapter 4, *Object Programming*) for more information on creating an image pyramid and for tiling examples.

Arguments

View

An object reference to the IDLgrView object used to render the image object. This is required so the visible tiles can be determined.

Image

An object reference to the tiled IDLgrImage object that will be tested to determine which of its tiles are required.

Keywords

ALL_VISIBLE

Set this keyword if QueryRequiredTiles should return all tiles that are visible even if they already have tile data loaded at the required level.

COUNT

Set this keyword equal to a named variable that, on return, contains the number of tiles that are required.

PATH

Set this keyword equal to a vector of object references that uniquely defines the path through the graphics hierarchy used to compute which tiles are visible. Each object specified must contain an alias; tile visibility is computed for the version of the image object (specified by *Image*) that lies at the end of the specified path.

Specifying a unique path through the graphics hierarchy may require multiple objects if multiple aliases are used. If multiple objects are required to define the value of PATH, the objects must be specified in the order they appear in the path, beginning with the object that is closest to the root of the hierarchy.

If this keyword is not set, the path from *Image* to the top of the graphics hierarchy is determined by the PARENT properties of the objects in the hierarchy. In this case, no alias paths are followed.

Note ————————————————————————————————

For more information on aliases, refer to the ALIAS keyword in IDLgrModel::Add.

————————————————————————————————

Version History

6.2	Introduced
7.0	Added PATH keyword to QueryRequiredTiles to handle aliases.

IDLgrBuffer::Read

The IDLgrBuffer::Read function method reads an image from a buffer. The returned value is an instance of the IDLgrImage object class.

Syntax

Result = Obj->[IDLgrBuffer::]Read()

Return Value

Returns an instance of the IDLgrImage object class.

Arguments

None

Keywords

None

Version History

5.0	Introduced

IDLgrBuffer::Select

The IDLgrBuffer::Select function method returns a list of objects selected at a specified location. If no objects are selected, the Select function returns -1.

Note
IDL returns a maximum of 512 objects. This maximum may be smaller if any of the objects are contained in deep model hierarchies. Because of this limit, it is possible that not all objects eligible for selection will appear in the list.

Syntax

Result = Obj->[IDLgrBuffer::]Select(*Picture, XY* [, DIMENSIONS=[*width*, *height*]] [, /ORDER] [, SUB_SELECTION=*variable*] [, UNITS={0 | 1 | 2 | 3}])

Return Value

Returns a list of objects selected at a specified location. Returns -1 if no objects are selected.

Arguments

Picture

The view, viewgroup, or scene (an instance of the IDLgrView, IDLgrViewgroup, or IDLgrScene class) whose children are among the candidates for selection.

If the first argument is a scene or viewgroup, then the returned object list will contain one or more views. If the first argument is a view, the list will contain atomic graphic objects (or model objects which have their SELECT_TARGET property set). Objects are returned in order, according to their distance from the viewer. The closer an object is to the viewer, the lower its index in the returned object list. If multiple objects are at the same distance from the viewer (views in a scene or 2-D geometry), the first object drawn will appear at a lower index in the list. (The ORDER keyword can be used to change this behavior.)

XY

A two-element array defining the center of the selection box in device space. By default, the selection box is 3 pixels by 3 pixels.

Keywords

DIMENSIONS

Set this keyword to a two-element array [*w*, *h*] to specify that the selection box will have a width *w* and a height *h*, and will be centered about the coordinates [*x*, *y*] specified in the *XY* argument. The box occupies the rectangle defined by:

```
(x-(w/2), y-(h/2)) - (x+(w/2), y+(h/2))
```

Any object which intersects this box is considered to be selected. By default, the selection box is 3 pixels by 3 pixels.

ORDER

Set this keyword to control how objects that are the same distance from the viewer are ordered in the selection list. If ORDER=0 (the default), the order of objects in the selection list will be the same as the order in which the objects are drawn. If ORDER=1, the order of objects in the selection list will be the reverse of the order in which they are drawn. This keyword has no affect on the ordering of objects that are not at the same distance from the viewer.

Tip
If you are using DEPTH_TEST_FUNCTION=4 ("less than or equal") on your graphics objects, set ORDER=1 to return objects at the same depth in the order in which they appear visually.

SUB_SELECTION

Set this keyword to a named variable that upon return will contain a vector of references to the graphic objects that were sub-selected at the given location. This vector includes all graphic objects that are:

- Graphic objects contained by the nearest selected object (the first object in the return value)

- Select targets (IDLgrModel objects with the SELECT_TARGET property set)

- Graphic objects displayed at the given *XY* location

UNITS

Set this keyword to indicate the units of measure. Valid values are:

0	Device (default)
1	Inches
2	Centimeters
3	Normalized: relative to the dimensions of the graphics destination

Version History

5.0	Introduced
6.1	Added SUB_SELECTION keyword

IDLgrBuffer::SetProperty

The IDLgrBuffer::SetProperty procedure method sets the value of a property or group of properties for the buffer.

Syntax

Obj->[IDLgrBuffer::]SetProperty[, *PROPERTY=value*]

Arguments

None

Keywords

Any property listed under "IDLgrBuffer Properties" on page 4227 that contains the word "Yes" in the "Set" column of the properties table can be set using this method. To set the value of a property, specify the property name as a keyword set equal to the appropriate property value.

Version History

5.0	Introduced

IDLgrClipboard

An IDLgrClipboard object sends Object Graphics output to the operating system native clipboard or to a file in bitmap or vector format. The FILENAME, VECTOR, and POSTSCRIPT keyword values in the IDLgrClipboard::Draw method, and the platform on which the call is issued determine the file type and destination. See IDLgrClipboard::Draw for details.

Note

Objects or subclasses of this type can not be saved or restored.

Superclasses

IDLitComponent

Creation

See "IDLgrClipboard::Init" on page 4288.

Properties

Objects of this class have the following properties. See "IDLgrClipboard Properties" on page 4266 for details on individual properties.

- ALL
- COLOR_MODEL
- DIMENSIONS
- GRAPHICS_TREE
- N_COLORS
- PALETTE
- QUALITY
- REGISTER_PROPERTIES
- RESOLUTION
- SCREEN_DIMENSIONS
- UNITS

In addition, objects of this class inherit the properties of all superclasses of this class.

Methods

This class has the following methods:

- IDLgrClipboard::Cleanup
- IDLgrClipboard::Draw
- IDLgrClipboard::GetContiguousPixels
- IDLgrClipboard::GetDeviceInfo
- IDLgrClipboard::GetFontnames
- IDLgrClipboard::GetProperty
- IDLgrClipboard::GetTextDimensions
- IDLgrClipboard::Init
- IDLgrClipboard::QueryRequiredTiles
- IDLgrClipboard::SetProperty

In addition, this class inherits the methods of its superclasses (if any).

Examples

This example demonstrates the process of copying the contents of an IDL graphics display object (a buffer or a window) to the system clipboard, where it becomes available for pasting into another application. The example also uses the IDLgrClipboard::Draw method to create a platform-dependent file type in the current directory.

```
PRO SendingPlotToClipboard

; Determine the path to the "damp_sn2.dat" file.

IDLgrClipboard Properties

IDLgrClipboard objects have the following properties in addition to properties inherited from any superclasses. Properties with the word "Yes" in the "Get" column of the property table can be retrieved via IDLgrClipboard::GetProperty. Properties with the word "Yes" in the "Init" column of the property table can be set via IDLgrClipboard::Init. Properties with the word "Yes" in the "Set" column in the property table can be set via IDLgrClipboard::SetProperty.

Note
For a discussion of the property description tables shown below, see "About Object Property Descriptions" on page 3135.

Objects of this class have the following properties.

- ALL
- COLOR_MODEL
- DIMENSIONS
- GRAPHICS_TREE
- N_COLORS
- PALETTE
- QUALITY
- REGISTER_PROPERTIES
- RESOLUTION
- SCREEN_DIMENSIONS
- UNITS

In addition, objects of this class inherit:

- IDLitComponent

ALL

An anonymous structure that contains the values of all of the retrievable properties associated with this object.

Property Type	Anonymous structure		
Name String	*not displayed*		
Get: Yes	Set: No	Init: No	Registered: No

COLOR_MODEL

An integer value or enumerated list item that determines whether to use the indexed color model for the clipboard buffer:

Value	Property Sheet Value	Description
0	RGB	RGB (default)
1	Indexed	Color Index

Note

See "Color and Destination Objects" (*Object Programming*) for more information.

Property Type	ENUMLIST		
Name String	Color model		
Get: Yes	Set: No	Init: Yes	Registered: Yes

DIMENSIONS

A two-element integer vector of the form [*width*, *height*] to specify the dimensions of the clipboard buffer in units specified by the UNITS property. The default is [640,480].

Property Type	Integer vector		
Name String	*not displayed*		
Get: Yes	Set: Yes	Init: Yes	Registered: No

GRAPHICS_TREE

An object reference of type IDLgrScene, IDLgrViewgroup, or IDLgrView that specifies the graphic tree of this object. If this property is set to a valid object reference, calling the Draw method on the destination object with no arguments will cause the object reference associated with this property to be drawn. If this object is valid and the destination object is destroyed, this object reference will be destroyed as well. By default the GRAPHICS_TREE property is set equal to the null-object.

Property Type	Object reference		
Name String	*not displayed*		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** No

N_COLORS

An integer value that determines the number of colors (between 2 and 256) to be used if COLOR_MODEL is set to Color Index.

Property Type	Integer		
Name String	Number of colors		
Get: Yes	**Set:** No	**Init:** Yes	**Registered:** Yes

PALETTE

An object reference to a palette object (an instance of the IDLgrPalette object class) that specifies the red, green, and blue values that are to be loaded into the clipboard buffer's color lookup table.

Note
Objects specified via this property are not automatically cleaned up when the IDLgrClipboard object is destroyed.

This property is registered as a user-defined property, but it is hidden by default.

Property Type	USERDEF		
Name String	Color palette		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** Yes

QUALITY

An integer value or enumerated list item indicating the rendering quality at which graphics are to be drawn to the clipboard buffer. Valid values are:

Value	Property Sheet Value	Description
0	Low	Low quality
1	Medium	Medium quality
2	High	High quality (the default)

Property Type	ENUMLIST		
Name String	Draw quality		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** Yes

REGISTER_PROPERTIES

A Boolean value that determines whether to register properties available for this object. If this property is set, all properties marked in this properties section as "Registered: Yes" will be registered for display in a property sheet. This property is useful mainly when creating iTools. By default, no properties are registered.

Property Type	Boolean		
Name String	*not displayed*		
Get: No	**Set:** No	**Init:** Yes	**Registered:** No

RESOLUTION

A two-element floating-point vector of the form [*xres*, *yres*] specifying the device resolution in centimeters per pixel. This value is stored in double precision. The default value is: [0.035277778, 0.035277778] (72 DPI).

Note ───

To match screen rendering on an IDLgrClipboard object, the following properties should be matched between the devices: DIMENSIONS, UNITS, RESOLUTION, COLOR_MODEL and N_COLORS.

───

This property is registered as a user-defined property, but it is hidden by default.

Property Type	USERDEF		
Name String	Resolution		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

SCREEN_DIMENSIONS

A two-element integer vector of the form [*width*, *height*] that specifies the maximum allowed dimensions (measured in device units) for the clipboard object.

Property Type	Integer vector		
Name String	*not displayed*		
Get: Yes	Set: No	Init: No	Registered: No

UNITS

An integer value that indicates the units of measure for the DIMENSIONS property. Valid values are:

- 0 = Device (default)

- 1 = Inches

- 2 = Centimeters

- 3 = Normalized (relative to 1600 x 1200)

Property Type	Integer		
Name String	*not displayed*		
Get: Yes	Set: Yes	Init: Yes	Registered: No

IDLgrClipboard::Cleanup

The IDLgrClipboard::Cleanup procedure method performs all cleanup on the object.

Note ——————————————————————————————

Cleanup methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation and destruction. This means that in most cases, you cannot call the Cleanup method directly. There is one exception to this rule: if you write your own subclass of this class, you can call the Cleanup method from within the Init or Cleanup method of the subclass.

Syntax

OBJ_DESTROY, *Obj*

or

Obj->[IDLgrClipboard::]Cleanup   *(In a lifecycle method only.)*

Arguments

None

Keywords

None

Version History

5.1	Introduced

IDLgrClipboard::Draw

The IDLgrClipboard::Draw procedure method draws the given picture to this graphics destination.

Writing to a File

The file type produced when the IDLgrClipboard::Draw method is passed an IDLgrView, IDLgrViewgroup, or IDLgrScene object varies depending upon keyword settings and the platform on which the call is issued. If the FILENAME keyword is set to a non-empty string, the name of the file IDL creates is specified by the string. If the FILENAME keyword is a non-zero, numeric value, IDL creates a file named idl.*ext* where *ext* is replaced with the appropriate extension shown in parentheses in the following table.

Keyword Settings	Windows File Type	UNIX File Type
VECTOR = 1, POSTSCRIPT = 1	Encapsulated PostScript (EPS)	Encapsulated PostScript (EPS)
VECTOR = 1, POSTSCRIPT = 0	Enhanced MetaFile (EMF)	Encapsulated PostScript (EPS)
VECTOR = 0, POSTSCRIPT = 1	Encapsulated PostScript (EPS)	Encapsulated PostScript (EPS)
VECTOR = 0, POSTSCRIPT = 0	Bitmap (BMP)	Encapsulated PostScript (EPS)

Table 32-5: File Types Produced by IDLgrClipboard Draw Method

Writing to the Clipboard

Objects can be written to the operating system clipboard using IDLgrClipboard::Draw. When the FILENAME keyword equals an empty string (" "), equals 0 (zero), or is not specified, the output is written to the clipboard.

Note

The IDLgrClipboard object empties the Windows clipboard before writing to it.

Note

When VECT_SORTING=0, objects are drawn to the destination device in the order that they are added to the model, view, viewgroup, or scene object that contains them. Otherwise, objects are drawn to the destination device based on their average depth value.

Syntax

Obj->[IDLgrClipboard::]Draw [, *Picture*] [, /CMYK] [, FILENAME=*string*]
   [, /ISOLATIN1] [, POSTSCRIPT=*value*] [, VECT_SHADING={ 0 | 1 }]
   [, VECT_SORTING={ 0 | 1 }]
   [, VECT_TEXT_RENDER_METHOD={ 0 | 1 }] [, VECTOR={ 0 | 1 }]

Arguments

Picture

The view (an instance of an IDLgrView object), viewgroup (an instance of an IDLgrViewgroup object), or scene (an instance of an IDLgrScene object) to be drawn.

Keywords

CMYK

This keyword has an effect only when the output format is Encapsulated PostScript (POSTSCRIPT=1). Set this keyword to create a PostScript file using the CMYK (cyan, magenta, yellow, and black) color model. The default is a PostScript file using the RGB (red, green, blue) color model. This keyword applies to both bitmap and vector graphic PostScript files.

The CMYK format is a subtractive color model that is better suited for color printing. This color model allows some document processing applications and printer control software to easily adjust the overall brightness of an image by manipulating a single channel (K). PostScript files created with the CMYK color model must be processed by an interpreter capable of interpreting PostScript Language Level 2 or higher.

FILENAME

To write to a file, set this keyword as follows:

- Set to a string that represents the name of the file to which the output should be written.

- Set to any non-zero numerical value. IDL generates a filename based upon the values of the POSTSCRIPT and VECTOR keywords, and the platform. See "Writing to a File" in the introductory section for details.

If the value is an empty string (" "), equals 0 (zero), or is not specified, the output is written to the clipboard.

Note
You are strongly encouraged to specify a string for this value. The ability to specify a numerical value is maintained for backward compatibility, but its usage should be deprecated.

ISOLATIN1

Set this keyword to use Adobe ISO Latin 1 font encoding with any font that supports such coding. Use of this keyword allows access to many commonly-used foreign characters. This keyword is ignored if the generated output is not PostScript.

POSTSCRIPT

Set this keyword to a non-zero value to indicate that the generated output should be in Encapsulated PostScript format. By default, the generated output is in Bitmap format on Windows platforms and Encapsulated PostScript on UNIX platforms.

VECT_SHADING

This keyword has an effect only when generating vector output (VECTOR=1) and when the output format is Encapsulated PostScript (POSTSCRIPT=1).

This keyword controls the appearance of smooth (Gouraud) shaded IDLgrPolygon and IDLgrSurface objects. Valid values are:

- 0 = disable smooth shading. This causes all polygons and surfaces to be rendered with flat shading. This may be valuable when using slower PostScript interpreters or when memory and stack space are limited. Smoothly shaded polygons require more resources as well as time.

- 1 = enable smooth shading (default). This renders smooth (Gouraud) shaded polygons and surfaces in the Encapsulated PostScript file.

Note ───
Polygons and surfaces in Enhanced MetaFiles (EMF) files will be rendered using flat shading. Only the output in Encapsulated PostScript (EPS) files is affected by this keyword, and only when the VECTOR keyword has been set. See "Bitmap and Vector Graphic Output" (Chapter 12, *Object Programming*) for details about vector graphic output.
───

VECT_SORTING

This keyword has an effect only when generating vector output (VECTOR=1).

This keyword controls the way object primitives in a picture appear in the destination. Valid values are:

- 0 = disable sorting. The object primitives appear in the vector output file in the same order they are drawn on the display device. This is the order in which they appear in the graphics tree.

- 1 = enable sorting (default). The objects are ordered from back to front based on each primitive object's average depth value.

Note ───
Objects that intersect each other, IDLgrImage objects (which do not update the depth buffer), and objects contained within transparent views might not sort correctly. See "Controlling What is Displayed in Vector Graphics" (Chapter 12, *Object Programming*).
───

VECT_TEXT_RENDER_METHOD

This keyword has an effect only when generating vector output (VECTOR=1).

This keyword controls the way text is rendered in a vector graphic file. Valid values are:

- 0 = render text as text primitives (default). The output device renders the text as text primitives. This allows the text to be edited by object-based graphics programs.

- 1 = render text as triangles. The text is rendered as a series of filled triangles in the vector file. This produces text that closely matches the text on the display device, but the output file size is larger, and the text can not be easily edited.

Note —————————————————————————————————
The results of attempting to edit the text primitives depends upon the sophistication
of the graphics program. An Enhanced MetaFile (EMF) inserted into a Microsoft
Word document can be edited. However, not all versions of Microsoft Word
support advanced 3-D graphic primitives such as those associated with obliquely or
vertically aligned text. Choosing to edit a file with non-horizontally aligned text
may result in the text being flattened into two dimensions. Typically, each letter
becomes its own string and alignment is altered. To edit non-horizontal text and
preserve the original quality, create an Encapsulated PostScript (EPS) file that can
be modified in a more sophisticated object-oriented image editing program.

Note —————————————————————————————————
See "Text Rendering in Vector Graphics" (Chapter 12, *Object Programming*) for
more information.

VECTOR

Set this keyword to indicate the type of graphics primitives generated. Valid values
are:

- 0 = generate bitmap graphics (default). Render the scene to a buffer and then
  copy the buffer to the clipboard or file in bitmap format. The bitmap retains the
  quality of the original image, but the bitmaps cannot be effectively scaled on
  all devices.

- 1 = generate vector graphics. Render the scene using simple vector operations
  that result in a representation of the scene that is scalable. The vector
  representation does not retain all the attributes of the original image, but it can
  be effectively scaled on other devices. On Windows, the representation is the
  Windows Enhanced Metafile (EMF). On UNIX platforms, the representation
  is Encapsulated PostScript (EPS).

Note —————————————————————————————————
Transparent objects in a view are not rendered in vector graphic files. Semi-
transparent objects are rendered fully opaque. See "Bitmap and Vector Graphic
Output" (Chapter 12, *Object Programming*) for a complete discussion of when to
output to bitmap or vector graphics based on picture content.

Version History

5.1	Introduced
6.1	Added CMYK, VECT_SHADING, VECT_SORTING, and VECT_TEXT_RENDER_METHOD keywords
6.4	Added ISOLATIN1 keyword

IDLgrClipboard::GetContiguousPixels

The IDLgrClipboard::GetContiguousPixels function method returns an array of long integers whose length is equal to the number of colors available in the index color mode (that is, the value of the N_COLORS property).

The returned array marks contiguous pixels with the ranking of the range's size. This means that within the array, the elements in the largest available range are set to zero, the elements in the second-largest range are set to one, etc. Use this range to set an appropriate colormap for use with the SHADE_RANGE property of the IDLgrSurface and IDLgrPolygon object classes.

To get the largest contiguous range, you could use the following IDL command:

```
result = obj->GetContiguousPixels()
Range0 = WHERE(result EQ 0)
```

A contiguous region in the colormap can be increasing or decreasing in values. The following would be considered contiguous:

```
[0,1,2,3,4]
[4,3,2,1,0]
```

Syntax

Result = Obj->[IDLgrClipboard::]GetContiguousPixels()

Return Value

Returns an array of long integers whose length is equal to the number of colors available in the index color mode.

Arguments

None

Keywords

None

Version History

5.1	Introduced

IDLgrClipboard::GetDeviceInfo

The IDLgrClipboard::GetDeviceInfo procedure method returns information which allows IDL applications to intelligently make decisions for optimal performance. For example, it allows an application to determine if RENDERER=1 is actually implemented in hardware. It also allows applications to make optimal quality decisions when dynamically building texture maps.

Syntax

Obj->[IDLgrClipboard::]GetDeviceInfo [, ALL=*variable*]
   [, MAX_NUM_CLIP_PLANES=*variable*]
   [, MAX_TEXTURE_DIMENSIONS=*variable*]
   [MAX_TILE_DIMENSIONS=*variable*]
   [, MAX_VIEWPORT_DIMENSIONS=*variable*] [, NAME=*variable*]
   [, NUM_CPUS=*variable*] [, VENDOR=*variable*] [, VERSION=*variable*]

Arguments

None

Keywords

ALL

Set this keyword to a named variable which, upon return, contains a structure with the values of all the device information keywords as fields.

MAX_NUM_CLIP_PLANES

Set this keyword to a named variable that upon return will contain an integer that specifies the maximum number of user-defined clipping planes supported by the device.

MAX_TEXTURE_DIMENSIONS

Set this keyword equal to a named variable. Upon return, MAX_TEXTURE_DIMENSIONS contains a two element integer array that specifies the maximum texture size supported by the device.

MAX_TILE_DIMENSIONS

Set this keyword equal to a named variable. Upon return, MAX_TILE_DIMENSIONS contains a two element integer array that specifies the maximum tile size supported by the device.

MAX_VIEWPORT_DIMENSIONS

Set this keyword equal to a named variable. Upon return, MAX_VIEWPORT_DIMENSIONS contains a two element integer array that specifies the maximum size of a graphics display supported by the device.

NAME

Set this keyword equal to a named variable. Upon return, NAME contains the name of the rendering device as a string.

NUM_CPUS

Set this keyword equal to a named variable. Upon return, NUM_CPUS contains an integer that specifies the number of CPUs that are known to, and available to IDL.

Note

The NUM_CPUS keyword accurately returns the number of CPUs for the SUN and Microsoft Windows platforms. For platforms other than these, the number returned may not reflect the actual number of CPUs available to IDL in the current system.

VENDOR

Set this keyword equal to a named variable. Upon return, VENDOR contains the name of the rendering device creator as a string.

VERSION

Set this keyword equal to a named variable. Upon return, VERSION contains the version of the rendering device driver as a string.

Version History

5.1	Introduced

5.6	Added MAX_NUM_CLIP_PLANES keyword
6.2	Added MAX_TILE_DIMENSIONS keyword

IDLgrClipboard::GetFontnames

The IDLgrClipboard::GetFontnames function method returns the list of available fonts that can be used in IDLgrFont objects. This method will only return the names of the available TrueType fonts. Hershey fonts will not be returned; see Appendix H, "Fonts" for more information.

Syntax

Result = Obj->[IDLgrClipboard::]GetFontnames(*FamilyName* [, IDL_FONTS={0 | 1 | 2}] [, STYLES=*string*])

Return Value

Returns the list of available fonts that can be used in IDLgrFont objects.

Arguments

FamilyName

A string representing the name of the font family to which all of the returned fonts must belong. The string may be a fully specified family name—such as "Helvetica". You can use both "*" and "?" as wildcard characters, matching any number of characters or one character respectively. To return all available family names, use "*".

Keywords

IDL_FONTS

Set this keyword to specify where to search for fonts that IDL may use. Set IDL_FONT to 1 to select only fonts installed by IDL and to 2 to select only fonts detected in the host operating system. The default value is 0, specifying that both IDL and operating system fonts should be returned.

STYLES

Set this keyword to a string specifying the styles that are to be matched by the returned font names. You can set STYLES to a fully specified style string, such as "Bold Italic". If you set STYLES to the null string, ' ', only fontnames without style modifiers will be returned. You can use both "*" and "?" as wildcard characters, matching any number of characters or one character respectively. The default value is

the string, "*", which returns all fontnames containing the *FamilyName* argument, with or without style modifiers.

Version History

5.1	Introduced

IDLgrClipboard::GetProperty

The IDLgrClipboard::GetProperty procedure method retrieves the value of a property or group of properties for the clipboard buffer.

Syntax

Obj->[IDLgrClipboard::]GetProperty[, *PROPERTY=variable*]

Arguments

None

Keywords

Any property listed under "IDLgrClipboard Properties" on page 4266 that contains the word "Yes" in the "Get" column of the properties table can be retrieved using this method. To retrieve the value of a property, specify the property name as a keyword set equal to a named variable that will contain the value of the property.

Any keyword not recognized is passed to this object's superclass.

Version History

5.1	Introduced

IDLgrClipboard::GetTextDimensions

The IDLgrClipboard::GetTextDimensions function method retrieves the dimensions of a text or axis object that will be rendered in the clipboard buffer. In order to compute the effective text dimensions, the object must be inserted into an object graphics hierarchy prior to using this method. The result is a 3-element double-precision floating-point vector [*xDim*, *yDim*, *zDim*] representing the dimensions of the text or axis object, measured in data units. If the object specified is an axis object, the result encompasses the tick labels and the title of the axis (if any).

Note

The returned results take into account the setting of the IDLgrText RECOMPUTE_DIMENSIONS property.

Syntax

Result = Obj->[IDLgrClipboard::]GetTextDimensions(*TextObj*
   [, DESCENT=*variable*] [, PATH=*objref(s)*])

Return Value

Returns the dimensions of a text or axis object that will be rendered in the clipboard buffer.

Arguments

TextObj

The object reference to a text or axis object for which the text dimensions are requested.

Keywords

DESCENT

Set this keyword equal to a named variable that will contain an array of double-precision floating-point values (one for each string in the IDLgrText object). The values represent the distance to travel (parallel to the UPDIR vector) from the text baseline to reach the bottom of the lowest descender in the string. All values will be negative numbers, or zero. This keyword is valid only if *TextObj* is an IDLgrText object.

PATH

Set this keyword to a single object reference or a vector of object references. This keyword specifies the path in the graphics hierarchy to compute the text dimensions. Each path object reference specified with this keyword must contain an alias. The text dimensions are computed for the version of the object falling within that path. If this keyword is not set, the PARENT properties determine the path from the current object to the top of the graphics hierarchy and no alias paths are pursued. If IDLgrClipboard::GetTextDimensions is called from within a Draw method and the PATH keyword is not set, the alias path used to find the object during the draw is used, rather than the PARENT path.

Note ―――――――――――――――――――――――――――――――――

For more information on aliases, refer to the ALIAS keyword in IDLgrModel::Add.
―――

Version History

5.1	Introduced

IDLgrClipboard::Init

The IDLgrClipboard::Init function method initializes the clipboard object.

Note ────────────────────────────────────

Init methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation. This means that in most cases, you cannot call the Init method directly. There is one exception to this rule: if you write your own subclass of this class, you can call the Init method from within the Init method of the subclass.

──

Syntax

Obj = OBJ_NEW('IDLgrClipboard' [, *PROPERTY=value*])

or

Result = Obj->[IDLgrClipboard::]Init([, *PROPERTY=value*])   *(In a lifecycle method only.)*

Return Value

When this method is called indirectly, as part of the call to the OBJ_NEW function, the return value is an object reference to the newly-created object.

When called directly within a subclass Init method, the return value is 1 if initialization was successful, or zero otherwise.

Arguments

None

Keywords

Any property listed under "IDLgrClipboard Properties" on page 4266 that contains the word "Yes" in the "Init" column of the properties table can be initialized during object creation using this method. To initialize the value of a property, specify the property name as a keyword set equal to the appropriate property value.

All other keywords are passed to the superclass of this object.

Version History

5.1	Introduced

IDLgrClipboard::QueryRequiredTiles

The IDLgrCliboard::QueryRequiredTiles function method is used in conjunction with an IDLgrImage object that supports tiling. Initially, this type of IDLgrImage object contains no data. Call this method to determine what data to load into this destination object based on which tiles are visible in a view. Pass the results to IDLgrImage::SetTileData to load the required portion of the tiled image. When the Draw method is called, the destination object contains the image tiles that are the results of this method's query.

Note ──

Clipboard support of tiled images is not available in vector mode (when the IDLgrClipboard::Draw method VECTOR keyword is set to 1).

──

This method returns an array of named structures containing information about the tiles that are required, or a scalar integer with the value 0 if no tiles are required. The application can check that COUNT is greater than 0 before accessing the returned array.

Note ──

Tiled images are not supported when generating vector graphics for the clipboard. Bitmap mode (VECTOR=0) must be used when drawing tiled images to an IDLgrClipboard.

──

Note ──

If the device is in Color Index mode (COLOR_MODEL=1) or the image has RENDER_METHOD=1 set, then IDL will generate an error as tiling is not supported under these circumstances.

──

Syntax

Result = Obj->[IDLgrClipboard::]QueryRequiredTiles(*View*, *Image*
   [, ALL_VISIBLE=*value*] [, COUNT=*variable*] [, PATH=*objref(s)*])

Return Value

Returns an array of named structures containing information about the tiles that are required, or a scalar integer with the value 0 if no tiles are required.

Each structure in the array describes one required tile and has the following fields:

Field	Data Type	Description
X	Long	The horizontal position of the left side of the tile measured from the left of the image in pixels.
Y	Long	The vertical position of the bottom of the tile measured from the bottom of the image in pixels.
WIDTH	Long	The width of the tile in pixels.
HEIGHT	Long	The height of the tile in pixels.
LEVEL	Long	The data resolution, where 0 is the full resolution image. A value of n ($n > 0$) indicates that the resolution is half that of the n-1 level.
DEST	OBJREF	The object reference to the destination object that was used to query for the required tiles.

Table 32-6: IDLIMAGETILE Structure

The X, Y, WIDTH and HEIGHT elements are all relative to the specified LEVEL. For example, say a large image (level 0) has dimensions of 10000 by 10000 pixels. The tile structure [2048, 2048, 1024, 1024, 0] specifies a 1024 by 1024 pixel area where the lower-left corner of the tile is (2048, 2048) pixels from the lower-left corner of the original, level 0 image. This is shown in the left portion of the following figure.

When you zoom out to 50% of the original resolution, you can load the level 1 image (5000 by 5000 pixels), a subsampled version of the large image. Here, the tile [1024, 1024, 1024, 1024, 1] specifies a 1024 by 1024 pixel area of the image with the lower-left corner being (1024, 1024) from the lower-left corner of the image. Both of these tiles have their lower-left corner at the same physical location of the image, but the second tile covers four times the area as it is a lower resolution version of the data.

Figure 32-2: Interaction Between Image Level and Zoom with Equal Tile Sizes

Note ———

See "Image Tiling" (Chapter 4, *Object Programming*) for more information on creating an image pyramid and for tiling examples.

Arguments

View

An object reference to the IDLgrView object used to render the image object. This is required so the visible tiles can be determined.

Image

An object reference to the tiled IDLgrImage object that will be tested to determine which of its tiles are required.

Keywords

ALL_VISIBLE

Set this keyword if QueryRequiredTiles should return all tiles that are visible even if they already have tile data loaded at the required level.

COUNT

Set this keyword equal to a named variable that, on return, contains the number of tiles that are required.

PATH

Set this keyword equal to a vector of object references that uniquely defines the path through the graphics hierarchy used to compute which tiles are visible. Each object specified must contain an alias; tile visibility is computed for the version of the image object (specified by *Image*) that lies at the end of the specified path.

Specifying a unique path through the graphics hierarchy may require multiple objects if multiple aliases are used. If multiple objects are required to define the value of PATH, the objects must be specified in the order they appear in the path, beginning with the object that is closest to the root of the hierarchy.

If this keyword is not set, the path from *Image* to the top of the graphics hierarchy is determined by the PARENT properties of the objects in the hierarchy. In this case, no alias paths are followed.

Note ——————————————————————————————
For more information on aliases, refer to the ALIAS keyword in IDLgrModel::Add.
——————————————————————————————————————

Version History

6.2	Introduced
7.0	Added PATH keyword to QueryRequiredTiles to handle aliases.

IDLgrClipboard::SetProperty

The IDLgrClipboard::SetProperty procedure method sets the value of a property or group of properties for the clipboard buffer.

Syntax

Obj->[IDLgrClipboard::]SetProperty[, *PROPERTY=value*]

Arguments

None

Keywords

Any property listed under "IDLgrClipboard Properties" on page 4266 that contains the word "Yes" in the "Set" column of the properties table can be set using this method. To set the value of a property, specify the property name as a keyword set equal to the appropriate property value.

Version History

5.1	Introduced

IDLgrColorbar

The IDLgrColorbar object consists of a color-ramp with an optional framing box and annotation axis. The object can be horizontal or vertical.

An IDLgrColorbar object is a *composite object*; it is one of the basic drawable elements of the IDL Object Graphics system, and it is not a container for other objects.

This object class is implemented in the IDL language. Its source code can be found in the file idlgrcolorbar__define.pro in the lib subdirectory of the IDL distribution.

Superclasses

IDLgrModel

IDLitComponent

Creation

See "IDLgrColorbar::Init" on page 4314.

Properties

Objects of this class have the following properties. See "IDLgrColorbar Properties" on page 4298 for details on individual properties.

- ALL
- BLUE_VALUES
- COLOR
- DIMENSIONS
- GREEN_VALUES

- • ZCOORD_CONV
- • ZRANGE

In addition, objects of this class inherit:

- • IDLgrModel
- • IDLitComponent

ALL

An anonymous structure containing the values of all of the properties associated with the *state* of this object. State information about the object includes things like color, range, tick direction, etc., but not image, vertex, or connectivity data, or user values.

Note —————————————————————————————

The fields of this structure may change in subsequent releases of IDL.

—————————————————————————————————

Property Type	Structure		
Name String	*not displayed*		
Get: Yes	**Set:** No	**Init:** No	**Registered:** No

BLUE_VALUES

A byte vector containing the blue values for the color palette. Setting this value is the same as specifying the *aBlue* argument to the IDLgrColorbar::Init method.

Property Type	Byte vector		
Name String	*not displayed*		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** No

COLOR

The color to be used as the foreground color for the axis and outline box. The color may be specified as a color lookup table index or as a three-element vector [*red*, *green*, *blue*]. The default is [0, 0, 0].

Property Type	Color		
Name String	*not displayed*		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** No

DIMENSIONS

A two element integer vector [*dx*, *dy*] that specifies the size of the ramp display (not the axis) in pixels. If *dx* > *dy*, the colorbar is drawn horizontally with the axis placed below or above the ramp box depending on the value of the SHOW_AXIS property. If *dx* < *dy*, the colorbar is drawn vertically with the axis placed to the right or left of the ramp box depending on the value of the SHOW_AXIS property. The default value is [16,256].

Property Type	Integer vector		
Name String	*not displayed*		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** No

GREEN_VALUES

A byte vector containing the green values for the color palette. Setting this value is the same as specifying the *aGreen* argument to the IDLgrColorbar::Init method.

Property Type	Byte vector		
Name String	*not displayed*		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** No

HIDE

A Boolean value to indicate whether this object should be drawn:

- 0 = Draw graphic (the default)

- 1 = Do not draw graphic

Property Type	Boolean		
Name String	*not displayed*		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** No

MAJOR

An integer that represents the number of major tick marks. The default is -1, specifying that IDL will compute the number of tickmarks. Setting MAJOR equal to zero suppresses major tickmarks entirely.

Property Type	Integer		
Name String	*not displayed*		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** No

MINOR

An integer representing the number of minor tick marks. The default is -1, specifying that IDL will compute the number of tickmarks. Setting MINOR equal to zero suppresses minor tickmarks entirely.

Property Type	Integer		
Name String	*not displayed*		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** No

PALETTE

An object reference to an instance of the IDLgrPalette object class. If this property is a valid object reference, the colors within the IDLgrPalette are used to specify the colors for the colorbar.

Note ───

Objects specified via this property are not automatically cleaned up when the IDLgrColorbar object is destroyed.

───

Property Type	Object reference		
Name String	*not displayed*		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** No

PARENT

An object reference to the object that contains this colorbar.

Property Type	Object reference		
Name String	*not displayed*		
Get: Yes	**Set:** No	**Init:** No	**Registered:** No

RED_VALUES

A byte vector that contains the red values for the color palette. Setting this value is the same as specifying the *aRed* argument to the IDLgrColorbar::Init method.

Property Type	Byte vector		
Name String	*not displayed*		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** No

SHOW_AXIS

An integer value that indicates whether the axis should be drawn:

- 0 = Do not display axis (the default)
- 1 = Display axis on left side or below the color ramp
- 2 = Display axis on right side or above the color ramp

Property Type	Integer		
Name String	*not displayed*		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** No

SHOW_OUTLINE

A Boolean value indicating whether the colorbar bounds should be outlined:

- 0 = Do not display outline (the default)
- 1 = Display outline

Property Type	Boolean		
Name String	*not displayed*		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** No

SUBTICKLEN

A floating-point scale ratio specifying the length of minor tick marks relative to the length of major tick marks. The default is 0.5, specifying that the minor tick mark is one-half the length of the major tick mark.

Property Type	Floating-point		
Name String	*not displayed*		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** No

THICK

A floating-point value between 1.0 and 10.0, specifying the line thickness used to draw the axis and box outline, in points. Out-of-range values are quietly clamped to the allowed range. The default is 1.0 points.

Property Type	Floating-point		
Name String	*not displayed*		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** No

THREED

A Boolean value that determines whether to create the colorbar as a graphic object that can be fully transformed in three dimensions on initialization. By default, the colorbar always faces the viewer and is drawn at z=0.

Property Type	Boolean		
Name String	*not displayed*		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** No

TICKFORMAT

Either a standard IDL format string (see *"Format Codes"* (Chapter 18, *Application Programming*) for details on format codes) or a string containing the name of a user-supplied function that returns a string to be used to format the axis tick mark labels. The function should accept integer arguments for the direction of the axis, the index of the tick mark, and the value of the tick mark, and should return a string to be used as the tick mark's label. The function may optionally accept a keyword called DATA,

which will be automatically set to the TICKFRMTDATA value. The default TICKFORMAT is '', the null string, which indicates that IDL will determine the appropriate format for each value.

Note ───

If the user-defined function's name does not begin with an open parenthesis, it is interpreted as the name of a callback function to be used to generate tick mark labels. This function is defined with either three or four parameters, depending on whether TICKUNITS is specified. For more information, see "[XYZ]TICKFORMAT" on page 5478.

───

Property Type	String		
Name String	*not displayed*		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** No

TICKFRMTDATA

A user-defined value of any type passed via the DATA keyword to the user-supplied formatting function specified via the TICKFORMAT property, if any. By default, this value is undefined, indicating that the DATA property will be undefined (and furthermore, need not be supported by the user-supplied function). Note that TICKFRMTDATA will not be included in the structure returned via the ALL property to the IDLgrColorbar::GetProperty method.

Property Type	Scalar of any type		
Name String	*not displayed*		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** No

TICKLEN

A floating-point value that specifies the length of each major tick mark, measured in data units. The recommended, and default, tick mark length is 0.2. IDL converts, maintains, and returns this data as double-precision floating-point.

Property Type	Floating-point		
Name String	*not displayed*		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** No

TICKTEXT

An object reference to either a single instance of the IDLgrText object class (with multiple strings) or to a vector of instances of the IDLgrText object class (each with a single string) that specifies the annotations to be assigned to the tick marks. By default, TICKTEXT is set to the NULL object, which indicates that IDL will compute tick annotations based upon the major tick values. The positions and orientation of the provided text object(s) may be overwritten by the colorbar.

Note ───
Objects specified via this property are not automatically cleaned up when the IDLgrColorbar object is destroyed.

──

Property Type	Object reference or object reference vector		
Name String	*not displayed*		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** No

TICKVALUES

A floating-point vector of data values that represent the values at each tick mark. If TICKVALUES is set to 0, the default, IDL computes the tick values based on the axis range and the number of major ticks. IDL converts, maintains, and returns this data as double-precision floating-point.

Property Type	Floating-point vector		
Name String	*not displayed*		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** No

TITLE

An object reference to an instance of the IDLgrText object class to specify the title for the axis. The default is the null object, specifying that no title is drawn. The title will be centered along the axis, even if the text object itself has an associated location.

Note ───
Objects specified via this property are not automatically cleaned up when the IDLgrColorbar object is destroyed.

──

Property Type	Object reference		
Name String	*not displayed*		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** No

XCOORD_CONV

A floating-point vector, $[s_0, s_1]$, of scaling factors used to convert X coordinates from data units to normalized units. The formula for the conversion is as follows:

Normalized$X = s_0 + s_1 *$ Data$X$

Recommended values are:

$[(-X_{min})/(X_{max}-X_{min}), 1/(X_{max}-X_{min})]$

The default is [0.0, 1.0]. IDL converts, maintains, and returns this data as double-precision floating-point.

Property Type	Floating-point vector		
Name String	*not displayed*		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** No

XRANGE

A two-element double-precision floating-point vector of the form [*xmin*, *xmax*] specifying the range of the *x* data coordinates covered by the colorbar.

Property Type	Floating-point vector		
Name String	*not displayed*		
Get: Yes	**Set:** No	**Init:** No	**Registered:** No

YCOORD_CONV

A floating-point vector, $[s_0, s_1]$, of scaling factors that converts Y coordinates from data units to normalized units. The formula for the conversion is as follows:

Normalized$Y = s_0 + s_1 *$ Data$Y$

Recommended values are:

$$[(-Y_{min})/(Y_{max}-Y_{min}), 1/(Y_{max}-Y_{min})]$$

The default is [0.0, 1.0]. IDL converts, maintains, and returns this data as double-precision floating-point.

Property Type	Floating-point vector		
Name String	*not displayed*		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** No

YRANGE

A two-element double-precision floating-point vector of the form [*ymin*, *ymax*] that specifies the range of the *Y* data coordinates covered by the colorbar.

Property Type	Floating-point vector		
Name String	*not displayed*		
Get: Yes	**Set:** No	**Init:** No	**Registered:** No

ZCOORD_CONV

A floating-point vector, $[s_0, s_1]$, of scaling factors that converts Z coordinates from data units to normalized units. The formula for the conversion is as follows:

$$NormalizedZ = s_0 + s_1 * DataZ$$

Recommended values are:

$$[(-Z_{min})/(Z_{max}-Z_{min}), 1/(Z_{max}-Z_{min})]$$

The default is [0.0, 1.0]. IDL converts, maintains, and returns this data as double-precision floating-point.

Property Type	Floating-point vector		
Name String	*not displayed*		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** No

ZRANGE

A two-element double-precision floating-point vector of the form [*zmin*, *zmax*] specifying the range of the *Z* data coordinates covered by the colorbar.

Note

Until the colorbar is drawn to the destination object, the [XYZ]RANGE properties will be zero. Use the ComputeDimensions method on the colorbar object to get the data dimensions of the colorbar prior to a draw operation.

Property Type	Floating-point vector		
Name String	*not displayed*		
Get: Yes	**Set:** No	**Init:** No	**Registered:** No

IDLgrColorbar::Cleanup

The IDLgrColorbar::Cleanup procedure method performs all cleanup on the object.

Note ───

Cleanup methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation and destruction. This means that in most cases, you cannot call the Cleanup method directly. There is one exception to this rule: if you write your own subclass of this class, you can call the Cleanup method from within the Init or Cleanup method of the subclass.

───

Syntax

OBJ_DESTROY,*Obj*

or

Obj->[IDLgrColorbar::]Cleanup   *(In a lifecycle method only.)*

Arguments

None

Keywords

None

Version History

5.1	Introduced

IDLgrColorbar::ComputeDimensions

The IDLgrColorbar::ComputeDimensions function method retrieves the dimensions of a colorbar object for the given destination object. In order to compute the effective dimensions, the object must be inserted into an object graphics hierarchy prior to using this method. The result is a three-element double-precision floating-point vector [*xDim, yDim, zDim*] representing the dimensions of the colorbar object measured in data units.

Syntax

Result = Obj->[IDLgrColorbar::]ComputeDimensions(*DestinationObj*
   [, PATH=*objref(s)*])

Return Value

Returns the dimensions of a colorbar object for the given destination object.

Arguments

DestinationObject

The object reference to a destination object (IDLgrBuffer, IDLgrClipboard, IDLgrPrinter, or IDLgrWindow) for which the dimensions of the colorbar are being requested.

Keywords

PATH

Set this keyword to a single object reference or a vector of object references. This keyword specifies the path in the graphics hierarchy to compute the dimensions. Each path object reference specified with this keyword must contain an alias. The text dimensions are computed for the version of the object falling within that path. If this keyword is not set, the PARENT properties determine the path from the current object to the top of the graphics hierarchy and no alias paths are pursued. If IDLgrColorbar::ComputeDimensions is called from within a Draw method and the PATH keyword is not set, the alias path used to find the object during the draw is used, rather than the PARENT path.

Note ————————————————————————————————————
For more information on aliases, refer to the ALIAS keyword in IDLgrModel::Add.
————————————————————————————————————

Version History

5.1	Introduced

IDLgrColorbar::GetProperty

The IDLgrColorbar::GetProperty procedure method retrieves the value of a property or group of properties for the colorbar.

Syntax

Obj->[IDLgrColorbar::]GetProperty[, *PROPERTY=variable*]

Arguments

None

Keywords

Any property listed under "IDLgrColorbar Properties" on page 4298 that contains the word "Yes" in the "Get" column of the properties table can be retrieved using this method. To retrieve the value of a property, specify the property name as a keyword set equal to a named variable that will contain the value of the property.

Any keyword not recognized is passed to this object's superclass.

Version History

5.1	Introduced

IDLgrColorbar::Init

The IDLgrColorbar::Init function method initializes the colorbar object.

Note ───
Init methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation. This means that in most cases, you cannot call the Init method directly. There is one exception to this rule: if you write your own subclass of this class, you can call the Init method from within the Init method of the subclass.

───

Syntax

Obj = OBJ_NEW('IDLgrColorbar' [, *aRed*, *aGreen*, *aBlue*] [, *PROPERTY=value*])

or

Result = Obj->[IDLgrColorbar::]Init([*aRed, aGreen, aBlue*] [, *PROPERTY=value*])
    (In a lifecycle method only.)

Return Value

When this method is called indirectly, as part of the call to the OBJ_NEW function, the return value is an object reference to the newly-created object.

When called directly within a subclass Init method, the return value is 1 if initialization was successful, or zero otherwise.

Arguments

Note ───
The values specified by the *aRed*, *aGreen*, and *aBlue* arguments are used to initialize the value of the RED_VALUES, GREEN_VALUES, and BLUE_VALUES, properties of the IDLgrColorbar object.

───

Note ───
If *aRed*, *aGreen*, and *aBlue* are not provided, the color palette will default to a 256 entry greyscale ramp.

───

aRed

A vector containing the red values for the color palette. These values should be within the range of 0 < *Value* < 255. The number of elements comprising the *aRed* vector must not exceed 256.

aGreen

A vector containing the green values for the color palette. These values should be within the range of 0 < *Value* < 255. The number of elements comprising the *aGreen* vector must not exceed 256.

aBlue

A vector containing the blue values for the color palette. These values should be within the range of 0 < *Value* < 255. The number of elements comprising the *aBlue* vector must not exceed 256.

Keywords

Any property listed under "IDLgrColorbar Properties" on page 4298 that contains the word "Yes" in the "Init" column of the properties table can be initialized during object creation using this method. To initialize the value of a property, specify the property name as a keyword set equal to the appropriate property value.

All other keywords are passed to the superclass of this object.

Version History

5.1	Introduced

IDLgrColorbar::SetProperty

The IDLgrColorbar::SetProperty procedure method sets the value of a property or group of properties for the colorbar.

Syntax

Obj->[IDLgrColorbar::]SetProperty[, *PROPERTY=value*]

Arguments

None

Keywords

Any property listed under "IDLgrColorbar Properties" on page 4298 that contains the word "Yes" in the "Set" column of the properties table can be set using this method. To set the value of a property, specify the property name as a keyword set equal to the appropriate property value.

Version History

5.1	Introduced

IDLgrContour

The IDLgrContour object draws a contour plot from data stored in a rectangular array or from a set of unstructured points. Both line contours and filled contour plots can be created.

An IDLgrContour object is an *atomic graphic object*; it is one of the basic drawable elements of the IDL Object Graphics system, and it is not a container for other objects.

The object stores the following argument or property in double-precision if the DOUBLE_DATA property is specified, and in single-precision otherwise.

Superclasses

IDLitComponent

Creation

See "IDLgrContour::Init" on page 4356.

Properties

Objects of this class have the following properties. See "IDLgrContour Properties" on page 4320 for details on individual properties.

- ALL
- AM_PM
- C_COLOR
- C_LABEL_INTERVAL
- C_LABEL_OBJECTS
- C_LINESTYLE
- C_USE_LABEL_COLOR
- C_VALUE
- COLOR
- DAYS_OF_WEEK
- DEPTH_TEST_DISABLE

- ALPHA_CHANNEL
- ANISOTROPY
- C_FILL_PATTERN
- C_LABEL_NOGAPS
- C_LABEL_SHOW
- C_THICK
- C_USE_LABEL_ORIENTATION
- CLIP_PLANES
- DATA_VALUES
- DEPTH_OFFSET
- DEPTH_TEST_FUNCTION

- DEPTH_WRITE_DISABLE
- DOUBLE_DATA
- DOUBLE_GEOM
- DOWNHILL
- FILL
- GEOM
- GEOMX
- GEOMY
- GEOMZ

- SHADER
- SHADING
- TICKINTERVAL
- TICKLEN
- USE_TEXT_ALIGNMENTS
- XCOORD_CONV
- XRANGE
- YCOORD_CONV
- YRANGE
- ZCOORD_CONV
- ZRANGE

In addition, objects of this class inherit the properties of all superclasses of this class.

Methods

This class has the following methods:

- IDLgrContour::AdjustLabelOffsets
- IDLgrContour::Cleanup
- IDLgrContour::GetCTM
- IDLgrContour::GetLabelInfo
- IDLgrContour::GetProperty
- IDLgrContour::Init

- IDLgrContour::SetProperty

In addition, this class inherits the methods of its superclasses (if any).

Version History

5.1	Introduced
5.6	Added AM_PM, C_LABEL_INTERVAL, CLIP_PLANES, C_LABEL_OBJECTS, C_LABEL_NOGAPS, C_LABEL_SHOW, C_USE_LABEL_COLOR, C_USE_LABEL_ORIENTATION, DAYS_OF_WEEK, LABEL_FONT, LABEL_FORMAT, LABEL_FRMATDATA, LABEL_UNITS, MONTHS, and USE_TEXT_ALIGNMENTS properties
6.1	Added ALPHA_CHANNEL property
6.4	Added SHADER property

In addition, objects of this class inherit:

- IDLitComponent

ALL

An anonymous structure containing the values of all of the retrievable properties associated with this object except DATA_VALUES and GEOM.

Property Type	Structure		
Name String	*not displayed*		
Get: Yes	**Set:** No	**Init:** No	**Registered:** No

ALPHA_CHANNEL

Set this property to a floating-point value in the range [0.0, 1.0] to specify the opacity of the contour. The default value of 1.0 causes IDL to draw the contours completely opaque. If the value of this property is less than 1.0, then the pixels of the contours are blended with the pixels already on the screen, where the color of the contour is multiplied by the alpha value and the pixels already on the screen are multiplied by 1.0-alpha. Because an object can only be blended with objects already drawn on the screen, the drawing order of the objects must be considered carefully in order to obtain the desired results. This property has no effect on devices using indexed color

mode. If contour colors (C_COLOR property) are supplied, then the value of this property is used for the contour alpha if the C_COLOR property does not contain alpha values (3-channel RGB colors). If the C_COLOR property does contain alpha values (4-channel RGBA colors), then the alpha from each contour color is used. When contour labels (either text or symbols) are used and a label's corresponding value in the C_USE_LABEL_COLOR property is zero, the value of this property is used for the label alpha if contour colors are not provided or if the contour colors are provided and do not contain alpha values. If the alpha values are supplied in the C_COLOR property, then each label uses the alpha from its corresponding C_COLOR contour color. When contour labels (either text or symbols) are used and a label's corresponding value in the C_USE_LABEL_COLOR property is non-zero, then the value of the label object's ALPHA_CHANNEL property is used to draw the label. In other words, C_USE_LABEL_COLOR also implies using the label object's alpha as well as its color.

Note

For more detailed information on alpha channel support for IDL Object Graphics, see "Controlling Object Transparency" (Chapter 2, *Object Programming*).

Property Type	Float-point value		
Name String	*Transparency*		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** Yes

AM_PM

A string vector of two values indicating the names of the AM and PM strings when processing explicitly formatted dates (CAPA, CApA, and CapA format codes) with the LABEL_FORMAT property.

Property Type	String vector		
Name String	*not displayed*		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** No

ANISOTROPY

A three-element floating-point vector [*x, y, z*] that represents the multipliers to be applied to the internally computed correction factors along each axis that account for

anisotropic geometry. Correcting for anisotropy is particularly important for the appropriate representations of downhill tickmarks.

By default, IDL will automatically compute correction factors for anisotropy based on the [XYZ] range of the contour geometry. If the geometry (as provided via the GEOMX, GEOMY, and GEOMZ keywords) falls within the range [*xmin*, *ymin*, *zmin*] to [*xmax*, *ymax*, *zmax*], then the default correction factors are computed as follows:

```
dx = xmax - xmin
dy = ymax - ymin
dz = zmax - zmin
; Get the maximum of the ranges:
maxRange = (dx > dy) > dz
IF (dx EQ 0) THEN xcorrection = 1.0 ELSE $
   xcorrection = maxRange / dx
IF (dy EQ 0) THEN ycorrection = 1.0 ELSE $
   ycorrection = maxRange / dy
IF (dz EQ 0) THEN zcorrection = 1.0 ELSE $
   zcorrection = maxRange / dz
```

This internally computed correction is then multiplied by the corresponding [*x, y, z*] values of the ANISOTROPY property. The default value for this property is [1,1,1]. IDL converts, maintains, and returns this data as double-precision floating-point.

This property is registered as a user-defined property, but it is hidden by default.

Property Type	USERDEF		
Name String	Anistrophy		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** Yes

C_COLOR

A vector of colors to be used to specify the color of each contour level. The vector may be of the form [*n*] where each entry is a color index, or of the form [3,*n*] where each 3-element row is an RGB color, or of the form [4,*n*] where each 4-element row is an RGBA color. To remove contour colors after they have been set, set C_COLOR to a scalar.

If C_COLOR is not specified, the entire contour plot is drawn in the single color provided by the COLOR property, which is the default action. If there are no contour colors, GetProperty returns a value of -1 for this property.

If there are more contour levels than elements in C_COLOR, the elements of C_COLOR are cyclically repeated.

Property Type	USERDEF		
Name String	Colors		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

C_FILL_PATTERN

An array of IDLgrPattern objects that represent the patterns to be applied at each contour level if the FILL property is non-zero. If there are more contour levels than fill patterns, the patterns will be cyclically repeated. If this property is set to any scalar value, all contour levels are filled with a solid color (this is the default). If there are no fill pattern objects stored in this property, GetProperty will return a value of -1.

This property is registered as a user-defined property, but it is hidden by default.

Property Type	USERDEF		
Name String	Fill patterns		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

C_LABEL_INTERVAL

A floating-point vector that indicates the distance (measured parametrically relative to the length of each contour path) between labels for each contour level. If the number of contour levels exceeds the number of provided intervals, the C_LABEL_INTERVAL values will be repeated cyclically. The default is 0.4.

Property Type	Floating-point vector		
Name String	*not displayed*		
Get: Yes	Set: Yes	Init: Yes	Registered: No

C_LABEL_NOGAPS

An integer vector that indicates whether gaps should be computed for the labels at the corresponding contour value. A zero value indicates that gaps will be computed for labels at that contour value; a non-zero value indicates that no gaps will be computed for labels at that contour value. If the number of contour levels exceeds the number of elements in this vector, the C_LABEL_NOGAPS values will be repeated cyclically.

By default, gaps for the labels are computed for all levels (so that a contour line does not pass through the label).

Property Type	Integer vector		
Name String	*not displayed*		
Get: Yes	Set: Yes	Init: Yes	Registered: No

C_LABEL_OBJECTS

An array of object references that provides examples of labels to be drawn for each contour level. The objects specified via this property must inherit from one of the following classes:

- IDLgrSymbol
- IDLgrText

If a single object is provided, and it is an IDLgrText object, each of its strings will correspond to a contour level. If a vector of objects is used, any IDLgrText objects should have only a single string; each object will correspond to a contour level.

By default, with C_LABEL_OBJECTS set equal to a null object, IDL computes text labels that are the string representations of the corresponding contour level values. Note that the objects specified via this property are used as descriptors only. The actual objects drawn as labels are generated by IDL, and may be accessed via the IDLgrContour::GetLabelInfo method. The contour labels will have the same color as the corresponding contour level (see C_COLOR) unless the C_USE_LABEL_COLOR property is specified. The orientation of the label will be automatically computed unless the C_USE_LABEL_ORIENTATION property is specified. The horizontal and vertical alignment of any text labels will default to 0.5 (i.e., centered) unless the USE_TEXT_ALIGNMENTS property is specified.

Note ⎯⎯⎯⎯⎯⎯⎯⎯⎯⎯⎯⎯⎯⎯⎯⎯⎯⎯⎯⎯⎯⎯⎯⎯⎯⎯⎯⎯⎯⎯
The object(s) set via this property will not be destroyed automatically when the contour is destroyed.

⎯⎯⎯

Property Type	Object reference array		
Name String	*not displayed*		
Get: Yes	Set: Yes	Init: Yes	Registered: No

C_LABEL_SHOW

An integer vector that indicates whether labels are shown. For each contour value, if the corresponding value in the C_LABEL_SHOW vector is non-zero, the contour line for that contour value will be labeled. If the number of contour levels exceeds the number of elements in this vector, the C_LABEL_SHOW values will be repeated cyclically. The default is 0 indicating that no contour levels will be labeled.

Property Type	Integer vector		
Name String	*not displayed*		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** No

C_LINESTYLE

An integer array of linestyles that represent the linestyles to be applied at each contour level. The array may be either a vector of integers representing pre-defined linestyles, or an array of 2-element vectors representing a stippling pattern specification. If there are more contour levels than linestyles, the linestyles will be cyclically repeated. If this property is set to any scalar value, all levels are drawn as solid lines (this is the default). If there are no linestyles specified for this property, GetProperty will return a value of -1.

To use a pre-defined line style, set this property equal to one of the following integer values:

0	Solid line (the default)
1	Dotted
2	Dashed
3	Dash dot
4	Dash dot dot dot
5	Long dash
6	No line drawn

This property is registered as a user-defined property, but it is hidden by default.

Property Type	USERDEF		
Name String	Linestyles		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

C_THICK

A floating-point array of line thicknesses that represent the thickness to be applied at each contour level, where each element is a value between 1.0 and 10.0. If there are more contour levels than line thicknesses, the thicknesses will be cyclically repeated. If this property is set to any scalar value, all contour levels are drawn with a line thickness of 1.0 points (this is the default). If there are no thicknesses specified for this property, GetProperty will return a value of -1.

This property is registered as a user-defined property, but it is hidden by default.

Property Type	USERDEF		
Name String	Thicknesses		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

C_USE_LABEL_COLOR

An integer vector that indicates whether the COLOR property value for each of the label objects (for the corresponding contour level) is to be used to draw that label. If the number of contour levels exceeds the number of elements in this vector, the C_USE_LABEL_COLOR values will be repeated cyclically. By default, this value is zero, indicating that the COLOR properties of the label objects will be ignored, and the C_COLOR property for the contour object will be used instead.

Property Type	Integer vector		
Name String	*not displayed*		
Get: Yes	Set: Yes	Init: Yes	Registered: No

Note

When user-defined IDLgrSymbol objects are used for labels in an IDLgrContour object and C_USE_LABEL_COLORS is set to non-zero values, all properties including the color are defined by the object composing the user-defined symbol, and not from the values set on the symbol object itself. For example, a green bow

tie-shaped IDLgrPolyline is assigned to the symbol object, and this symbol object is assigned to the C_LABEL_OBJECTS property. If C_USE_LABEL_COLOR is set, there will be green bow tie shaped labels on the contour lines. If C_USE_LABEL_COLOR is not set, the bow tie color is defined by C_COLOR. Properties defined on the symbol object itself are ignored in all cases.

C_USE_LABEL_ORIENTATION

An integer vector that indicates whether the orientation for each of the label objects (for the corresponding contour level) is to be used when drawing the label. For text, the orientation of the object corresponds to the BASELINE and UPDIR property values; for a symbol, this refers to the default (un-rotated) orientation of the symbol. If the number of contour levels exceeds the number of elements in this vector, the C_USE_LABEL_ORIENTATION values will be repeated cyclically. By default, this value is zero, indicating that orientation of the label object(s) will be set to automatically computed values (to correspond to the direction of the contour paths).

Property Type	Integer vector		
Name String	*not displayed*		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** No

C_VALUE

A floating-point value or a floating-point vector for which contour values are to be drawn. Setting ONLY a scalar value of 0 will cause the default action of even sampling of contour levels across the DATA_VALUES, using the value of the N_LEVELS property to determine the number of samples. IDL will convert any other scalar value to a single element vector containing that value and will then use it as if the user had supplied it as a vector. If there are no values specified for this property, GetProperty will return a value of -1. IDL converts, maintains, and returns this data as double-precision floating-point.

This property is registered as a user-defined property, but it is hidden by default.

Property Type	USERDEF		
Name String	Level values		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** Yes

CLIP_PLANES

A 4-by-*N* floating-point array of dimensions that specifies the coefficients of the clipping planes to be applied to this object. The four coefficients for each clipping plane are of the form [A, B, C, D], where $Ax + By + Cz + D = 0$. Portions of this object that fall in the half space $Ax + By + Cz + D > 0$ will be clipped. By default, the value of this property is a scalar (-1) indicating that no clipping planes are to be applied.

Note ───

The clipping planes specified via this property are applied in addition to the near and far clipping planes associated with the IDLgrView in which this object appears.

───

Note ───

Clipping planes are applied in the data space of this object (prior to the application of any *x*, *y*, or *z* coordinate conversion).

───

Note ───

To determine the maximum number of clipping planes supported by the device, use the MAX_NUM_CLIP_PLANES keyword of the GetDeviceInfo method for the IDLgrBuffer, IDLgrClipboard, IDLgrWindow, and IDLgrVRML objects.

───

Property Type	Floating-point array		
Name String	*not displayed*		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** No

COLOR

The color to be used to draw the contours. The color may be specified as a color lookup table index or as a three-element vector [*red*, *green*, *blue*]. The default is [0,0,0]. This value will be ignored if the C_COLOR property is set to a vector.

In a property sheet, this property appears as a color property.

Property Type	COLOR		
Name String	Color		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** Yes

DATA_VALUES

A floating-point vector or two-dimensional array that specifies the values to be contoured. The property is the same as the *Values* argument described in "IDLgrContour::Init" on page 4356. IDL converts and stores this data as double-precision floating-point if the argument is of type DOUBLE or if the DOUBLE_DATA property is set. Otherwise, the data is stored in single-precision. IDL returns the data as double-precision if it was stored in double-precision.

Property Type	Floating-point vector or array		
Name String	*not displayed*		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** No

DAYS_OF_WEEK

A string vector of 7 values that indicates the names to be used for the days of the week when processing explicitly formatted dates (CDWA, CDwA, and CdwA format codes) with the LABEL_FORMAT property.

Property Type	String vector		
Name String	*not displayed*		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** No

DEPTH_OFFSET

An integer value that specifies an offset in depth to be used when rendering filled primitives. This offset is applied along the viewing axis, with positive values moving the primitive away from the viewer.

The units are "Z-Buffer units," where a value of 1 is used to specify a distance that corresponds to a single step in the device's Z-Buffer.

Use DEPTH_OFFSET to always cause a filled primitive to be rendered slightly deeper than other primitives, independent of model transforms. This is useful for avoiding stitching artifacts caused by rendering lines or polygons on top of other polygons at the same depth.

Note

Use this feature to remove stitching artifacts and not as a means for "layering" complex scenes with multiple DEPTH_OFFSET values. It is safest to use only a DEPTH_OFFSET value of 0, the default, and one other non-zero value, such as 1. Many system-level graphics drivers are not consistent in their handling of DEPTH_OFFSET values, particularly when multiple non-zero values are used. This can lead to portability problems because a set of DEPTH_OFFSET values may produce better results on one machine than on another. Using IDL's software renderer will help improve the cross-platform consistency of scenes that use DEPTH_OFFSET.

Note

DEPTH_OFFSET has no effect unless the FILL property is set.

Property Type	Integer		
Name String	Depth offset		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** Yes

DEPTH_TEST_DISABLE

An integer value that determines whether depth testing is disabled.

- Set this property to 0 (the default) to inherit the value set by the parent model or view. The parent view always enables depth testing. A model may also enable or disable depth testing.

- Set this property to 1 to explicitly disable depth buffer testing while drawing this object.

- Set this property to 2 to explicitly enable depth testing for this object.

Disabling depth testing allows an object to draw itself "on top" of other objects already on the screen, even if the object is located behind them.

Note

Disabling depth testing also disables depth buffer writing. When disabling depth testing, the DEPTH_TEST_FUNCTION and DEPTH_WRITE_DISABLE properties are effectively ignored.

This property is registered as an enumerated list, but it is hidden by default.

Property Type	ENUMLIST		
Name String	*not displayed*		
Get: Yes	Set: Yes	Init: Yes	Registered: No

DEPTH_TEST_FUNCTION

An integer value that determines the depth test function. Set this property to 0 (the default) to inherit the value set by the parent model or view. The parent view always sets a depth test function of LESS. A model may also set a depth test function value. The graphics device compares the object's depth at a particular pixel location with the depth stored in the depth buffer at that same pixel location. If the comparison test passes, the object's pixel is drawn at that location on the screen and the depth buffer is updated (if depth writing is enabled).

Set this property to any of the following values to use the desired function while rendering this object.

- 0 = INHERIT - use value from parent model or view.

- 1 = NEVER - never passes.

- 2 = LESS - passes if the object's depth is less than the depth buffer's value.

- 3 = EQUAL - passes if the object's depth is equal to the depth buffer's value.

- 4 = LESS OR EQUAL - passes if the object's depth is less than or equal to the depth buffer's value.

- 5 = GREATER - passes if the object's depth is greater than or equal to the depth buffer's value.

- 6 = NOT EQUAL - passes if the object's depth is not equal to the depth buffer's value.

- 7 = GREATER OR EQUAL - passes if the object's depth is greater than or equal to the depth buffer's value.

- 8 = ALWAYS - always passes

Less means closer to the viewer.

This property is registered as an enumerated list, but it is hidden by default.

Property Type	ENUMLIST		
Name String	*not displayed*		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** No

DEPTH_WRITE_DISABLE

An integer value that determines whether depth writing is disabled.

- Set this property to 0 (the default) to inherit the value set by the parent model or view. The parent view always enables depth writing. A model may also enable or disable depth writing.

- Set this property to 1 to explicitly disable depth buffer writing while rendering this object.

- Set this property to 2 to explicitly enable depth writing for this object.

Disabling depth writing allows an object to be overdrawn by other objects, even if the object is located in front of them.

Note

If depth testing (see DEPTH_TEST_DISABLE property) is disabled, depth writing is also automatically disabled.

This property is registered as an enumerated list, but it is hidden by default.

Property Type	ENUMLIST		
Name String	*not displayed*		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** No

DOUBLE_DATA

A Boolean value that indicates whether the object is to store data provided by either the *Values* argument or the DATA_VALUES property parameter in double-precision or single-precision floating-point.

- 0 = Single-precision floating-point
- 1 = Double-precision floating-point

IDL converts any value data already stored in the object to the requested precision, if necessary.

Property Type	Boolean		
Name String	*not displayed*		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** No

DOUBLE_GEOM

A Boolean value that indicates whether the object is to store data provided by any of the GEOMX, GEOMY, or GEOMZ property parameters in double-precision or single-precision floating-point.

- 0 = Single-precision floating-point
- 1 = Double-precision floating-point

IDL converts any geometry data already stored in the object to the requested precision, if necessary.

Property Type	Boolean		
Name String	*not displayed*		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** No

DOWNHILL

A Boolean value or enumerated list item that indicates whether downhill tick marks should be rendered as part of each contour level to indicate the downhill direction relative to the contour line.

Value	Property Sheet Value	Description
0	Hide	Do not render downhill tick marks (the default)
1	Show	Render downhill tick marks

Property Type	ENUMLIST		
Name String	Downhill ticks		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** Yes

FILL

A Boolean value that indicates whether the contours should be filled. The default is to draw the contour levels as lines without filling. Filling contour may produce less than satisfactory results if your data contains NaNs, or if the contours are not closed.

Property Type	Boolean		
Name String	Fill contours		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

GEOM

A floating-point array that contains the geometry associated with the contour. IDL returns this data in single-precision floating-point by default or in double-precision floating-point if the DOUBLE_GEOM property is set in the IDLgrContour::Init method.

The shape of the data contained in GEOM depends on the value of the GEOMZ property (and potentially the GEOMX and GEOMY properties). The following rules apply:

- If GEOMZ is a vector of *Z* values $[z_0, z_1, z_2, ...]$ (in which case it is presumed that GEOMX and GEOMY were also set as vectors), GEOM will contain a $3 \times N$ array of *XYZ* values: $[[x_0, y_0, z_0], [x_1, y_1, z_1], ...]$.

- If GEOMZ is a $3 \times N$ array of *XYZ* values $[[x_0, y_0, z_0], [x_1, y_1, z_1], ...]$, GEOM will contain a $3 \times N$ array of *XYZ* values: $[[x_0, y_0, z_0], [x_1, y_1, z_1], ...]$.

- If GEOMZ is an $N \times M$ array of *Z* values $[[z_0, z_1, z_2, ...], [z_N, z_{N+1}, z_{N+2}, ...], ...]$ (in which case it is presumed that GEOMX and GEOMY were also set as $N \times M$ arrays), GEOM will contain a $3 \times N \times M$ array of *XYZ* values: $[[[x_0, y_0, z_0], [x_1, y_1, z_1], ...], [[x_N, y_N, z_N], ...], ...]$

- If GEOMZ is a scalar and the PLANAR property contains a True value (in which case it is presumed that DATA_VALUES was set as an $N \times M$ array), GEOM will contain a $3 \times N \times M$ array of *XYZ* values: $[[[x_0, y_0, z_0], [x_1, y_1, z_1], ...], [[x_N, y_N, z_N], ...], ...]$

- If GEOMZ is a scalar and the PLANAR property contains a False value, GEOM will be undefined.

Property Type	Floating-point		
Name String	*not displayed*		
Get: Yes	**Set:** No	**Init:** No	**Registered:** No

GEOMX

A floating-point vector or two-dimensional array that specifies the X coordinates of the geometry with which the contour values correspond. If X is a vector, it must match the number of elements in the *Values* argument to the IDLgrContour::Init method or DATA_VALUES property value, or it must match the first of the two dimensions of the *Values* argument or DATA_VALUES property value (in which case, the X coordinates will be repeated for each row of data values). IDL converts and maintains this data as double-precision floating-point if the parameter is of type DOUBLE or if the DOUBLE_GEOM property is non-zero. Otherwise, the data is stored in single-precision. IDL returns the data as double-precision if it was stored in double-precision.

Property Type	Floating-point vector or array		
Name String	*not displayed*		
Get: No	**Set:** Yes	**Init:** Yes	**Registered:** No

GEOMY

A floating-point vector or two-dimensional array specifying the Y coordinates of the geometry with which the contour values correspond. If Y is a vector, it must match the number of elements in the *Values* argument to the IDLgrContour::Init method or DATA_VALUES property value, or it must match the second of the two dimensions of the *Values* argument or DATA_VALUES property value (in which case, the Y coordinates will be repeated for each column of data values). IDL converts and maintains this data as double precision floating point if the parameter is of type DOUBLE or if the DOUBLE_GEOM property is non-zero. Otherwise, the data is

stored in single precision. IDL returns the data as double precision if it was stored in double precision.

Property Type	Floating-point vector or array		
Name String	*not displayed*		
Get: No	**Set:** Yes	**Init:** Yes	**Registered:** No

GEOMZ

A floating-point scalar, a vector, or a two-dimensional array specifying the Z coordinates of the geometry with which the contour values correspond.

- If GEOMZ is a scalar and the PLANAR property contains a True value, the resulting contour geometry will be projected onto the plane Z=GEOMZ. If GEOMZ is a scalar, and the PLANAR property is not set, any geometry associated with the contour will be freed.

- If GEOMZ is a vector of Z coordinates, the number of elements in the vector should be the same as the number of elements in DATA_VALUES.

- If GEOMZ is an array and the leading dimension is 3, then the data is treated as a list or array of 3-D vertices. The product of the array dimensions following the 3 should equal the number of DATA_VALUES.

- If GEOMZ is an array and the leading dimension is not 3, then the data is treated as a list or array of single Z coordinates. If the number of dimensions is 2, then the data is treated as a 2-D array of Z values. Otherwise, it is treated as a vector of Z values. In either case, the total number of elements in the array should be the same as the number of DATA_VALUES.

- If GEOMZ is not set, the geometry will be derived from the DATA_VALUES property (if it is set to a two-dimensional array). In this case, the connectivity is implied. The X and Y coordinates match the row and column indices of the array, and the Z coordinates match the data values.

IDL converts and maintains this data as double precision floating point if the parameter is of type DOUBLE or if the DOUBLE_GEOM property is non-zero.

Otherwise, the data is stored in single precision. IDL returns the data as double precision if it was stored in double precision.

Property Type	Floating-point scalar, vector, or array		
Name String	*not displayed*		
Get: No	**Set:** Yes	**Init:** Yes	**Registered:** No

HIDE

A Boolean value or enumerated list item that indicates whether this object should be drawn:

Value	Property Sheet	Description
0	True	Draw graphic (the default)
1	False	Do not draw graphic

Property Type	ENUMLIST		
Name String	Show		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** Yes

LABEL_FONT

An object reference to an IDLgrFont object that describes the default font to be used for contour labels. This font will be used for all text labels automatically generated by IDL (i.e., if C_LABEL_SHOW is set but the corresponding C_LABEL_OBJECTS text object is not provided), or for any text label objects provided via C_LABEL_OBJECTS that do not already have the font property set. The default value for this property is a NULL object reference, indicating that 12 pt. Helvetica will be used.

Note

Objects specified via this property are not automatically cleaned up when the IDLgrContour object is destroyed.

Property Type	Object reference		
Name String	*not displayed*		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** No

LABEL_FORMAT

A string that represents a format string or the name of a function to be used to format the contour labels. If the string begins with an open parenthesis, it is treated as a standard format string. (Refer to the Format Codes in the IDL Reference Guide.) If the string does not begin with an open parenthesis, it is interpreted as the name of a callback function to be used to generate contour level labels.

The callback function is called with three parameters: Axis, Index, and Value, where:

- Axis is simply the value 2 to indicate that values along the Z axis are being formatted. (This allows a single callback routine to be used for both axis labeling and contour labeling.)

- Index is the contour level index (indices start at 0).

- Value is the data value of the current contour level.

Property Type	String		
Name String	*not displayed*		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** No

LABEL_FRMTDATA

A user-defined value of any type passed via the DATA keyword to the user-supplied formatting function specified via the LABEL_FORMAT property, if any. By default, this value is 0, indicating that the DATA keyword will not be set (and furthermore, need not be supported by the user-supplied function).

Note

LABEL_FRMTDATA will not be included in the structure returned via the ALL property to the IDLgrContour::GetProperty method.

Property Type	Scalar of any type		
Name String	*not displayed*		
Get: No	**Set:** No	**Init:** Yes	**Registered:** No

LABEL_UNITS

A string that indicates the units to be used for default contour level labeling.

Valid unit strings include:

- "Numeric"
- "Years"
- "Months"
- "Days"
- "Hours"
- "Minutes"
- "Seconds"
- "Time" - Use this value to indicate that the contour levels correspond to time values; IDL will determine the appropriate label format based upon the range of values covered by the contour Z data.
- "" - The empty string is equivalent to the "Numeric" unit. This is the default.

If any of the time units are utilized, then the contour values are interpreted as Julian date/time values.

Note ───

The singular form of each of the time unit strings is also acceptable (for example, LEVEL_UNITS='Day' is equivalent to LEVEL_UNITS='Days').

───

Property Type	String		
Name String	*not displayed*		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** No

MAX_VALUE

A floating point value that indicates the maximum value to be plotted. Data values greater than this value are treated as missing data. The default is the maximum value of the input Z data. IDL converts, maintains, and returns this data as double-precision floating-point.

Property Type	FLOAT		
Name String	Maximum value		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

MONTHS

A string vector of 12 values indicating the names to be used for the months when processing explicitly formatted dates (CMOA, CMoA, and CmoA format codes) with the C_LABEL_FORMAT keyword.

Property Type	String vector		
Name String	*not displayed*		
Get: Yes	Set: Yes	Init: Yes	Registered: No

MIN_VALUE

A floating-point value that indicates the minimum value to be plotted. Data values less than this value are treated as missing data. The default is the minimum value of the input Z data. IDL converts, maintains, and returns this data as double-precision floating-point.

Property Type	FLOAT		
Name String	Minimum value		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

N_LEVELS

An integer value that indicates the number of contour levels to generate. This property is ignored if the C_VALUE property is set to a vector, in which case, the number of levels is derived from the number of elements in that vector. Set this

property to zero to indicate that IDL should compute a default number of levels based on the range of data values. This is the default.

Property Type	INTEGER		
Name String	Number of levels		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** Yes

PALETTE

An object reference to a palette object (an instance of the IDLgrPalette object class) that defines the color palette of this object. This property is only used if the destination device is using the RGB color model. If so, and a color value for the object is specified as a color index value, the palette set by this property is used to translate the color to RGB space. If the PALETTE property on this object is not set, the destination object PALETTE property is used (which defaults to a grayscale ramp).

Note ───

Objects specified via this property are not automatically cleaned up when the IDLgrContour object is destroyed.

───

This property is registered as a user-defined property, but it is hidden by default.

Property Type	USERDEF		
Name String	Color palette		
Get: No	**Set:** No	**Init:** Yes	**Registered:** Yes

PARENT

An object reference to the object that contains this contour.

Property Type	Object reference		
Name String	*not displayed*		
Get: Yes	**Set:** No	**Init:** No	**Registered:** No

PLANAR

A Boolean value or enumerated list item that indicates whether the contoured data is to be projected onto a plane. This property is ignored if GEOMZ is not a scalar.

Value	Property Sheet Value	Description
0	Planar	Any geometry associated with the contour will be freed
1	Three-D	Projects the contoured data onto a plane at the Z locations provided by the GEOMZ property (the default)

Property Type	ENUMLIST		
Name String	Projection		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** Yes

POLYGONS

An integer array of polygon descriptions that represents the connectivity information for the data to be contoured (as specified in the *Values* argument or the DATA_VALUES property). A polygon description is an integer or long word array of the form: [*n*, i0, i1, ..., i*n*-1], where *n* is the number of vertices that define the polygon, and i0..i*n*-1 are indices into the *X*, *Y*, and *Z* arguments that represent the polygon vertices. To ignore an entry in the POLYGONS array, set the vertex count, *n*, to 0. To end the drawing list, even if additional array space is available, set *n* to -1. If this property is not specified, a single polygon will be generated.

Note

The connectivity array described by POLYGONS allows an individual object to contain more than one polygon. Vertex, normal, and color information can be shared by the multiple polygons. Consequently, the polygon object can represent an entire mesh and compute reasonable normal estimates in most cases.

Property Type	Integer array		
Name String	*not displayed*		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** No

REGISTER_PROPERTIES

A Boolean value that determines whether to register properties available for this object. If this property is set, all properties marked in this properties section as "Registered: Yes" will be registered for display in a property sheet. This property is useful mainly when creating iTools. By default, no properties are registered.

Property Type	Boolean		
Name String	*not displayed*		
Get: No	**Set:** No	**Init:** Yes	**Registered:** No

SHADE_RANGE

A two-element integer array that specifies the range of pixel values (color indices) to use for shading. The first element is the color index for the darkest pixel. The second element is the color index for the brightest pixel. This value is ignored when the contour is drawn to a graphics destination that uses the RGB color model.

Property Type	Integer array		
Name String	*not displayed*		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** No

SHADER

An object reference to an IDLgrShader object (or an object containing IDLgrShader as a superclass). When there is suitable graphics card hardware support, the contour is rendered using the GLSL shader program (executed on the graphics card) instead of using fixed OpenGL properties when initially drawn. (If a suitable graphics card is not present, IDL ignores the shader object when the scene is drawn.) A single IDLgrShader object may be associated with additional contour objects or other graphic objects that have the SHADER property.

Property Type	Object reference		
Name String	*not displayed*		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** No

SHADING

An integer value or enumerated list item that indicates the type of shading to use:

Value	Property Sheet Value	Description
0	Flat	The color has a constant intensity for each face of the contour, based on the normal vector (the default)
1	Gouraud	The colors are interpolated between vertices, and then along scanlines from each of the edge intensities

Property Type	ENUMLIST		
Name String	Shading		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** Yes

TICKINTERVAL

A floating-point value that indicates the distance between downhill tickmarks, in data units. If TICKINTERVAL is not set, or if you explicitly set it to zero, IDL will compute the distance based on the geometry of the contour. IDL converts, maintains, and returns this data as double-precision floating-point.

Property Type	FLOAT		
Name String	Downhill tick interval		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** Yes

TICKLEN

A floating-point value that indicates the length of the downhill tickmarks, in data units. If TICKLEN is not set, or if you explicitly set it to zero, IDL will compute the

length based on the geometry of the contour. IDL converts, maintains, and returns this data as double-precision floating-point

Property Type	FLOAT		
Name String	Downhill tick length		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

USE_TEXT_ALIGNMENTS

A Boolean value that indicates whether, for any IDLgrText labels (as specified via the C_LABEL_OBJECTS property), the ALIGNMENT and VERTICAL_ALIGNMENT property values for the given IDLgrText object(s) are to be used to draw the corresponding labels. By default, this value is zero, indicating that the ALIGNMENT and VERTICAL_ALIGNMENT properties of the label IDLgrText object(s) will be set to default values (0.5 for each, indicating centered labels).

Property Type	Boolean		
Name String	*not displayed*		
Get: Yes	Set: Yes	Init: Yes	Registered: No

XCOORD_CONV

A floating-point vector, $[s_0, s_1]$, of scaling factors used to convert X coordinates from data units to normalized units. The formula for the conversion is as follows:

$$\text{Normalized}X = s_0 + s_1 * \text{Data}X$$

Recommended values are:

$$[(-X_{min})/(X_{max}-X_{min}), 1/(X_{max}-X_{min})]$$

The default is [0.0, 1.0]. IDL converts, maintains, and returns this data as double-precision floating-point.

Property Type	Floating-point vector		
Name String	*not displayed*		
Get: Yes	Set: Yes	Init: Yes	Registered: No

XRANGE

A two-element double-precision floating-point vector of the form [*xmin*, *xmax*] specifying the range of the *X* data coordinates covered by the contour.

Property Type	Floating-point vector		
Name String	*not displayed*		
Get: Yes	Set: No	Init: No	Registered: No

YCOORD_CONV

A floating-point vector, [s_0, s_1], of scaling factors used to convert Y coordinates from data units to normalized units. The formula for the conversion is as follows:

$$\text{Normalized}Y = s_0 + s_1 * \text{Data}Y$$

Recommended values are:

$$[(-Y_{min})/(Y_{max}-Y_{min}), \ 1/(Y_{max}-Y_{min})]$$

The default is [0.0, 1.0]. IDL converts, maintains, and returns this data as double-precision floating-point.

Property Type	Floating-point vector		
Name String	*not displayed*		
Get: Yes	Set: Yes	Init: Yes	Registered: No

YRANGE

A two-element double-precision floating-point vector of the form [*ymin*, *ymax*] that specifies the range of the *Y* data coordinates covered by the contour.

Property Type	Floating-point vector		
Name String	*not displayed*		
Get: Yes	Set: No	Init: No	Registered: No

ZCOORD_CONV

A floating-point vector, [s_0, s_1], of scaling factors that converts Z coordinates from data units to normalized units. The formula for the conversion is as follows:

$$\text{Normalized}Z = s_0 + s_1 * \text{Data}Z$$

Recommended values are:

$$[(-Z_{min})/(Z_{max}-Z_{min}), 1/(Z_{max}-Z_{min})]$$

The default is [0.0, 1.0]. IDL converts, maintains, and returns this data as double-precision floating-point.

Property Type	Floating-point vector		
Name String	*not displayed*		
Get: Yes	Set: Yes	Init: Yes	Registered: No

ZRANGE

A two-element double-precision floating-point vector of the form [*zmin*, *zmax*] that specifies the range of the *Z* data coordinates covered by the contour.

Property Type	Floating-point vector		
Name String	*not displayed*		
Get: Yes	Set: No	Init: No	Registered: No

IDLgrContour::AdjustLabelOffsets

The IDLgrContour::AdjustLabelOffsets procedure method adjusts the offsets at which contour labels are positioned.

Syntax

Obj->[IDLgrContour::]AdjustLabelOffsets, *LevelIndex, LabelOffsets*

Arguments

LevelIndex

The index of the contour level for which the label offsets are being adjusted. This value must be greater than or equal to zero and less than the number of levels (refer to the N_LEVELS property in the IDLgrContour::Init method).

LabelOffsets

A scalar or vector of floating point offsets, [t0, t1, …], that indicate the parametric offsets along the length of each contour line at which each label is to be positioned. The number of elements in this vector must exactly match the number of elements returned in the LABEL_OFFSETS vector retrieved via the IDLgrContour::GetLabelInfo method for the same level.

Keywords

None

Version History

5.1	Introduced

IDLgrContour::Cleanup

The IDLgrContour::Cleanup procedure method performs all cleanup on the object.

Note ───

Cleanup methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation and destruction. This means that in most cases, you cannot call the Cleanup method directly. There is one exception to this rule: if you write your own subclass of this class, you can call the Cleanup method from within the Init or Cleanup method of the subclass.

───

Syntax

OBJ_DESTROY, *Obj*

or

Obj->[IDLgrContour::]Cleanup   *(In a lifecycle method only.)*

Arguments

None

Keywords

None

Version History

5.1	Introduced

IDLgrContour::GetCTM

The IDLgrContour::GetCTM method returns the 4 x 4 double-precision floating-point graphics transform matrix from the current object upward through the graphics tree.

Syntax

Result = Obj->[IDLgrContour::]GetCTM([, DESTINATION=*objref*]
   [, PATH=*objref(s)*] [, TOP=*objref*])

Return Value

Returns the graphics transform matrix from the current object upward through the graphics tree.

Arguments

None

Keywords

DESTINATION

Set this keyword to the object reference of a destination object to specify that the projection matrix for the View object in the current tree be included in the returned transformation matrix. The resulting matrix will transform a point in the data space of the object on which the GetCTM method is called into a normalized coordinate system (-1 to +1 in X, Y, and Z), relative to the View object that contains the surface object.

PATH

Set this keyword to a single object reference or a vector of object references. This keyword specifies the path in the graphics hierarchy to compute the transformation matrix. Each path object reference specified with this keyword must contain an alias. The transformation matrix is computed for the version of the object falling within that path. If this keyword is not set, the PARENT properties determine the path from the current object to the top of the graphics hierarchy and no alias paths are pursued. If IDLgrContour::GetCTM is called from within a Draw method, with the DESTINATION keyword set and the PATH keyword not set, the alias path used to find the object during the draw is used, rather than the PARENT path.

Note

For more information on aliases, refer to the ALIAS keyword in IDLgrModel::Add.

TOP

Set this keyword equal to the object reference to an IDLgrModel object to specify that the returned matrix accumulate from the object on which the GetCTM method is called up to but not including the specified model object.

Version History

5.1	Introduced

IDLgrContour::GetLabelInfo

The IDLgrContour::GetLabelInfo procedure method retrieves information about the labels for a contour. The returned information is only valid until the next time the C_LABEL_INTERVAL or C_LABEL_OBJECTS property is modified using the IDLgrContour::SetProperty method, or the offsets are adjusted using the IDLgrContour::AdjustLabelOffsets method.

Syntax

Obj->[IDLgrContour::]GetLabelInfo, *Destination, LevelIndex*
   [, LABEL_OFFSETS=*variable*] [, LABEL_POLYLINES=*variable*]
   [, LABEL_OBJECTS=*variable*]

Arguments

Destination

A reference to a destination object (such as an IDLgrWindow or IDLgrBuffer object). The contour label information will be computed so that the requested font size is satisfied for this destination device.

LevelIndex

The index of the contour level for which the label information is being requested. This value must be greater than or equal to zero and less than the number of levels (refer to the N_LEVELS keyword in the IDLgrContour::Init method).

Keywords

LABEL_OFFSETS

Set this keyword to a named variable that upon return will contain a vector of floating point offsets, [t0, t1, …], that indicate the parametric offsets along the length of each contour line at which the contour labels are positioned.

LABEL_POLYLINES

Set this keyword to a named variable that upon return will contain a vector of contour polyline indices, $[P_0, P_1, …]$, that indicate which contour lines are labeled. P_i corresponds to the ith contour line.

Note that if a given contour line has more than one label along its perimeter, then the corresponding polyline index may appear more than once in the LABEL_POLYLINES vector.

LABEL_OBJECTS

Set this keyword to a named variable that upon return will contain a vector of objects that represent the labels for each contour label.

Version History

5.1	Introduced

IDLgrContour::GetProperty

The IDLgrContour::GetProperty procedure method retrieves the value of a property or group of properties for the contour.

Syntax

Obj->[IDLgrContour::]GetProperty[, *PROPERTY=variable*]

Arguments

None

Keywords

Any property listed under "IDLgrContour Properties" on page 4320 that contains the word "Yes" in the "Get" column of the properties table can be retrieved using this method. To retrieve the value of a property, specify the property name as a keyword set equal to a named variable that will contain the value of the property.

Any keyword not recognized is passed to this object's superclass.

Version History

5.1	Introduced

IDLgrContour::Init

The IDLgrContour::Init function method initializes the contour object.

Note ──

Init methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation. This means that in most cases, you cannot call the Init method directly. There is one exception to this rule: if you write your own subclass of this class, you can call the Init method from within the Init method of the subclass.

──

Syntax

Obj = OBJ_NEW('IDLgrContour' [, *Values*] [, *PROPERTY=value*])

or

Result = Obj->[IDLgrContour::]Init([*Values*] [, *PROPERTY=value*])   *(In a lifecycle method only.)*

Return Value

When this method is called indirectly, as part of the call to the OBJ_NEW function, the return value is an object reference to the newly-created object.

When called directly within a subclass Init method, the return value is 1 if initialization was successful, or zero otherwise.

Arguments

Values

A vector or two-dimensional array of values to be contoured. If no values are provided, the values will be derived from the GEOMZ property value (if set and the PLANAR property is not set). In this case, the values to be contoured will match the Z coordinates of the provided geometry. IDL converts and maintains this data as double-precision floating-point if the argument is of type DOUBLE or if the DOUBLE_DATA keyword is set. Otherwise, the data is stored in single-precision. IDL returns the data as double-precision if it was stored in double-precision.

Keywords

Any property listed under "IDLgrContour Properties" on page 4320 that contains the word "Yes" in the "Init" column of the properties table can be initialized during object creation using this method. To initialize the value of a property, specify the property name as a keyword set equal to the appropriate property value.

All other keywords are passed to the superclass of this object.

Version History

5.1	Introduced

IDLgrContour::SetProperty

The IDLgrContour::SetProperty procedure method sets the value of a property or group of properties for the contour.

Syntax

Obj->[IDLgrContour::]SetProperty[, *PROPERTY=value*]

Arguments

None

Keywords

Any property listed under "IDLgrContour Properties" on page 4320 that contains the word "Yes" in the "Set" column of the properties table can be set using this method. To set the value of a property, specify the property name as a keyword set equal to the appropriate property value.

Version History

5.1	Introduced

IDLgrFilterChain

An IDLgrFilterChain object is a specialization of the IDL_Container object that is designed to execute a sequence of image filtering shader objects according to their container order. The chain of shader objects must be "image filtering" shaders (those designed to modify an IDLgrImage object). To apply a chain of shaders to an image, set the IDLgrImage SHADER property equal to the filter chain object. Only shader objects (IDLgrShader objects and objects subclassing from IDLgrShader) can be added to the IDLgrFilterChain. See "IDLgrShader" on page 4736 for more information about shader objects.

When the sequence of shaders are executed, the output from the first shader is passed to each subsequent shader in the chain until the last shader is reached, the result of which is drawn to the destination device.

Note —————————————————————————————

This functionality requires support for OpenGL frame buffer object extension in addition to the standard hardware support require by IDLgrShader. See the IDLgrWindow::GetDeviceInfo methods's FRAMEBUFFER_OBJECT_EXTENSION keyword for details).

———————————————————————————————————

Note —————————————————————————————

To control the precision of the temporary storage used to pass data between shaders, use the OUTPUT_DATA_TYPE property of IDLgrShader.

———————————————————————————————————

If the GPU hardware does not provide sufficient support or if FORCE_FILTER is set, the software fallback is used. In such cases, the IDLgrShader::FILTER method (if provided) will be called for each shader in the filter chain. The array returned from FILTER must have the same dimensions as the incoming image. If the returned array from any IDLgrShader in the chain does not meet these requirements IDL draws the image with its original data. See "Providing a Software Alternative to Shaders" (Chapter 14, *Object Programming*) for details.

Warning —————————————————————————————

Setting IDLgrImage RENDER_METHOD=1 (do *not* render image as texture-mapped polygon) disables all shader functionality including the software-based alternative.

———————————————————————————————————

Superclasses

IDL_Container

Creation

See "IDLgrFilterChain::Init" on page 4364.

Properties

Objects of this class have the following properties. See "IDLgrFilterChain Properties" on page 4361 for details on individual properties.

- FORCE_FILTER

In addition, objects of this class inherit the properties of all superclasses of this class.

Methods

This class has the following methods:

- IDLgrFilterChain::Cleanup
- IDLgrFilterChain::GetProperty
- IDLgrFilterChain::Init
- IDLgrFilterChain::SetProperty

In addition, this class inherits the methods of its superclass (IDL_Container).

Examples

See "Image Filter Shaders" (Chapter 14, *Object Programming*) for examples.

Version History

6.4	Introduced

IDLgrFilterChain Properties

IDLgrFilterChain objects have the following properties. Properties with the word "Yes" in the "Get" column of the property table can be retrieved via IDLgrFilterChain::GetProperty. Properties with the word "Yes" in the "Init" column of the property table can be set via IDLgrFilterChain::Init. Properties with the word "Yes" in the "Set" column in the property table can be set via IDLgrFilterChain::SetProperty.

Note —————————————————————————————————————

For a discussion of the property description tables shown below, see "About Object Property Descriptions" on page 3135.

Objects of this class have the following properties.

   •   FORCE_FILTER

In addition, objects of this class inherit the properties of IDL_Container.

FORCE_FILTER

Set this scalar long property to a non-zero value to cause IDL to call the IDLgrShader subclass Filter method on each object in this filter chain, even if there is hardware shader support in the current device. This property overrides the FORCE_FILTER property on the shader objects contained in the filter chain. This is useful for developing and testing the software fallback option on devices that have the hardware support. The default value for this property is zero. This property can only be set at Init time.

Property Type	Integer		
Name String	*not displayed*		
Get: Yes	**Set:** No	**Init:** Yes	**Registered:** No

IDLgrFilterChain::Cleanup

The IDLgrFilterChain::Cleanup procedure method performs all cleanup on the object.

Note ───

Cleanup methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation and destruction. This means that in most cases, you cannot call the Cleanup method directly. There is one exception to this rule: if you write your own subclass of this class, you can call the Cleanup method from within the Init or Cleanup method of the subclass.

Keywords

Any property listed under "IDLgrFilterChain Properties" on page 4361 that contains the word "Yes" in the "Get" column of the properties table can be retrieved using this method. To retrieve the value of a property, specify the property name as a keyword set equal to a named variable that will contain the value of the property.

Any keyword not recognized is passed to this object's superclass.

Version History

6.4	Introduced

IDLgrFilterChain::Init

The IDLgrFilterChain::Init function method initializes the filter chain object.

Note ―――――――――――――――――――――――――――――――――――――――

Init methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation. This means that in most cases, you cannot call the Init method directly. There is one exception to this rule: if you write your own subclass of this class, you can call the Init method from within the Init method of the subclass.

―――

Syntax

Obj = OBJ_NEW('IDLgrFilterChain' [, *PROPERTY=value*])

or

Result = Obj->[IDLgrFilterChain::]Init([, *PROPERTY=value*])   *(In a lifecycle method only.)*

Return Value

When this method is called indirectly, as part of the call to the OBJ_NEW function, the return value is an object reference to the newly-created object.

When called directly within a subclass Init method, the return value is 1 if initialization was successful, or zero otherwise.

Arguments

None

Keywords

Any property listed under "IDLgrFilterChain Properties" on page 4361 that contains the word "Yes" in the "Init" column of the properties table can be initialized during object creation using this method. To initialize the value of a property, specify the property name as a keyword set equal to the appropriate property value.

All other keywords are passed to the superclass of this object.

Version History

6.4	Introduced

IDLgrFilterChain::SetProperty

The IDLgrFilterChain::SetProperty procedure method retrieves the value of a property or group of properties for this object.

Syntax

Obj->[IDLgrFilterChain::]SetProperty[, *PROPERTY=variable*]

Arguments

None

Keywords

Any property listed under "IDLgrFilterChain Properties" on page 4361 that contains the word "Yes" in the "Set" column of the properties table can be set using this method. To set the value of a property, specify the property name as a keyword set equal to the appropriate property value.

Any keyword not recognized is passed to this object's superclass.

6.4	Introduced

IDLgrFont

A font object represents a typeface, style, weight, and point size that may be associated with text objects.

Superclasses

None

Creation

See "IDLgrFont::Init" on page 4374.

Properties

Objects of this class have the following properties. See "IDLgrFont Properties" on page 4369 for details on individual properties.

- ALL
- NAME
- SIZE
- SUBSTITUTE
- THICK
- UVALUE

In addition, objects of this class inherit the properties of all superclasses of this class.

Methods

This class has the following methods:

- IDLgrFont::Cleanup
- IDLgrFont::GetProperty
- IDLgrFont::Init
- IDLgrFont::SetProperty

In addition, this class inherits the methods of its superclasses (if any).

Examples

See "Font Objects" (Chapter 9, *Object Programming*) for examples.

Version History

5.0	Introduced
6.2	Added UVALUE property

IDLgrFont Properties

IDLgrFont objects have the following properties. Properties with the word "Yes" in the "Get" column of the property table can be retrieved via IDLgrFont::GetProperty. Properties with the word "Yes" in the "Init" column of the property table can be set via IDLgrFont::Init. Properties with the word "Yes" in the "Set" column in the property table can be set via IDLgrFont::SetProperty.

Note
For a discussion of the property description tables shown below, see "About Object Property Descriptions" on page 3135.

Objects of this class have the following properties.

- ALL
- NAME
- SIZE
- SUBSTITUTE
- THICK
- UVALUE

ALL

An anonymous structure containing the values of all of the properties associated with the *state* of this object. State information about the object includes things like color, range, tick direction, etc., but not image, vertex, or connectivity data, or user values.

Note
The fields of this structure may change in subsequent releases of IDL.

Property Type	Structure		
Name String	*not displayed*		
Get: Yes	**Set:** No	**Init:** No	**Registered:** No

NAME

A string containing the name of the font used. See "Fontname" on page 4374 for details on constructing font name strings.

Specifying this property is the same as specifying the optional *Fontname* argument to the IDLgrFont::Init method.

Property Type	String		
Name String	*not displayed*		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** No

SIZE

A floating-point value representing the point size of the font. The default is 12.0 points.

Property Type	Floating-point		
Name String	*not displayed*		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** No

SUBSTITUTE

A string that indicates the font to use as a substitute if the specified *Fontname* is not available on the graphics destination. Valid values are only those fonts that are available on all destination objects (the fonts included with IDL). These are: 'Helvetica' (the default), 'Courier', 'Times', 'Symbol', or 'Hershey'.

Property Type	String		
Name String	*not displayed*		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** No

THICK

A floating-point value between 1.0 and 10.0, indicating the line thickness (measured in points) to use for the Hershey vector fonts. Out-of-range values are quietly clamped to the allowed range. The default is 1.0 points.

Property Type	Floating-point		
Name String	*not displayed*		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** No

UVALUE

A value of any type containing any information you wish.

Note ———

Object references or pointers contained in the UVALUE property are *not* automatically cleaned up when the IDLgrFont object is destroyed.

——

Property Type	User Defined		
Name String	*not displayed*		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** No

IDLgrFont::Cleanup

The IDLgrFont::Cleanup procedure method performs all cleanup on the object.

Note ———————————————————————————————

Cleanup methods are special *lifecycle methods*, and as such cannot be called outside
the context of object creation and destruction. This means that in most cases, you
cannot call the Cleanup method directly. There is one exception to this rule: if you
write your own subclass of this class, you can call the Cleanup method from within
the Init or Cleanup method of the subclass.

———————————————————————————————————————

Syntax

OBJ_DESTROY, *Obj*

or

Obj->[IDLgrFont::]Cleanup   *(In a lifecycle method only.)*

Arguments

None

Keywords

None

Version History

5.0	Introduced

IDLgrFont::GetProperty

The IDLgrFont::GetProperty procedure method retrieves the value of a property or group of properties for the font.

Syntax

Obj->[IDLgrFont::]GetProperty[, *PROPERTY=variable*]

Arguments

None

Keywords

Any property listed under "IDLgrFont Properties" on page 4369 that contains the word "Yes" in the "Get" column of the properties table can be retrieved using this method. To retrieve the value of a property, specify the property name as a keyword set equal to a named variable that will contain the value of the property.

Any keyword not recognized is passed to this object's superclass.

Version History

5.0	Introduced

IDLgrFont::Init

The IDLgrFont::Init function method initializes the font object.

Note ───

Init methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation. This means that in most cases, you cannot call the Init method directly. There is one exception to this rule: if you write your own subclass of this class, you can call the Init method from within the Init method of the subclass.

───

Note ───

See "Font Objects" (Chapter 9, *Object Programming*) for information on creating and using font objects.

───

Syntax

Obj = OBJ_NEW('IDLgrFont' [, *Fontname*] [, *PROPERTY=value*])

or

Result = Obj->[IDLgrFont::]Init([*Fontname*] [, *PROPERTY=value*])   *(In a lifecycle method only.)*

Return Value

When this method is called indirectly, as part of the call to the OBJ_NEW function, the return value is an object reference to the newly-created object.

When called directly within a subclass Init method, the return value is 1 if initialization was successful, or zero otherwise.

Arguments

Fontname

A string representing the name of the font to be used. This string should take the form 'fontname*modifier1*modifier2*...*modifierN'. All destination objects support the following fontnames: Helvetica, Courier, Times, Symbol, and Monospace Symbol. (These fonts are included with IDL; you may have other fonts installed on your system as well.)

Note ⎯⎯⎯⎯⎯⎯⎯⎯⎯⎯⎯⎯⎯⎯⎯⎯⎯⎯⎯⎯⎯⎯⎯⎯⎯⎯⎯⎯

The value specified by the *Fontname* argument is used to initialize the value of the NAME property of the IDLgrFont object.

⎯⎯⎯

Valid modifiers for each of these fonts (except Symbol and Monospace Symbol) are:

- *Font weight:* Bold
- *Font angle:* Italic

For example, 'Helvetica*Bold*Italic'.

To select a Hershey vector font, use a fontname of the form: `'Hershey*fontnum'` where `fontnum` is the Hershey font's index number. See "Hershey Vector Font Samples" on page 5604 for descriptions of the Hershey vector fonts.

Note ⎯⎯⎯⎯⎯⎯⎯⎯⎯⎯⎯⎯⎯⎯⎯⎯⎯⎯⎯⎯⎯⎯⎯⎯⎯⎯⎯⎯

Beginning with IDL version 5.1, only TrueType and Hershey fonts are supported in the Object Graphics system. See "Fonts" in Appendix H for details on these font systems.

⎯⎯⎯

Keywords

Any property listed under "IDLgrFont Properties" on page 4369 that contains the word "Yes" in the "Init" column of the properties table can be initialized during object creation using this method. To initialize the value of a property, specify the property name as a keyword set equal to the appropriate property value.

All other keywords are passed to the superclass of this object.

Version History

5.0	Introduced

IDLgrFont::SetProperty

The IDLgrFont::SetProperty procedure method sets the value of a property or group of properties for the font.

Syntax

Obj->[IDLgrFont::]SetProperty[, *PROPERTY=value*]

Arguments

None

Keywords

Any property listed under "IDLgrFont Properties" on page 4369 that contains the word "Yes" in the "Set" column of the properties table can be set using this method. To set the value of a property, specify the property name as a keyword set equal to the appropriate property value.

Version History

5.0	Introduced

IDLgrImage

An image object represents a mapping from a two-dimensional array of data values to a two dimensional array of pixel colors, resulting in a flat 2-D-scaled version of the image, drawn at Z = 0.

An IDLgrImage object is an *atomic graphic object*; it is one of the basic drawable elements of the IDL Object Graphics system, and it is not a container for other objects.

Beginning with IDL 6.2, IDLgrImage renders an image by default using a texture-mapped polygon on graphics devices using the RGB color model, for a significant increase in functionality and performance. IDL continues to use a 2D "bitmap" primitive to draw an image on devices using the indexed color model, since texture mapping is not available on such devices.

Note ———————————————————————————

With the texture-mapping performance improvements of 6.2, interpolation results may differ slightly across graphics devices and from pre-6.2 results. See INTERPOLATE for details.

———————————————————————————————————

Transformations of IDLgrImage Objects

By default, IDLgrImage objects are drawn at Z=0 and are positioned and sized with respect to two points:

```
p1 = [LOCATION(0), LOCATION(1), 0]
p2 = [LOCATION(0) + DIMENSION(0), LOCATION(1) + DIMENSION(1), 0].
```

where LOCATION and DIMENSION are properties of the image object. These two points are transformed in three dimensions, and then projected onto the screen to form the opposite corners of a 2-D rectangle using screen space points designated as p1' and p2':

```
[ [p1'[0], p1'[1]], [[p2'[0], p1'[1]],
   [[p2'[0], p2'[1]], [[p1'[0], p2'[1]] ]
```

The image data is drawn on the display as a 2-D image within this 2-D rectangle whose sides are parallel to the screen sides. The image data is *scaled* in two dimensions (not rotated) to fit into this projected rectangle and then drawn with Z buffering disabled.

To draw an image with the current full 3D transformation (the same way other objects such as polygons are transformed), set the IDLgrImage

TRANSFORM_MODE property to 1. See the IDLgrImage TRANSFORM_MODE property for details.

Objects are drawn to a destination device in the order that they are added (via the Add method) to the model, view, or scene that contains them. By default, image objects do not take into account the depth locations of other objects that may be included in the view object unless you enable depth testing (see "DEPTH_TEST_DISABLE" (*IDL Reference Guide*) for details).

This means that objects that are drawn to the destination object (window or printer) after the image is drawn will appear to be in front of the image, even if they are located behind the image object. Since the image is drawn by default with depth testing disabled, you can think of the image primitive as 'painting' the image onto the screen without regard for other objects that might already have been drawn there.

This behavior can be changed by enabling depth testing to make the image primitive behave like other primitives such as polygons when they are drawn with depth testing enabled.

See "Displaying Multiple Images in Object Graphics" (Chapter 4, *Object Programming*) for an example using the LOCATION property.

Superclasses

IDLitComponent

Creation

See "IDLgrImage::Init" on page 4415.

Properties

Objects of this class have the following properties. See "IDLgrImage Properties" on page 4381 for details on individual properties.

- ALL
- ALPHA_CHANNEL
- BLEND_FUNCTION
- CHANNEL
- CLIP_PLANES
- DATA
- DEPTH_OFFSET
- DEPTH_TEST_DISABLE
- DEPTH_TEST_FUNCTION
- DEPTH_WRITE_DISABLE
- DIMENSIONS
- GREYSCALE

- HIDE
- INTERLEAVE
- INTERPOLATE
- ORDER
- PARENT
- RENDER_METHOD
- SHADER
- SUB_RECT
- TILE_COLOR
- TILE_DIMENSIONS
- TILE_NUM_LEVELS
- TILED_IMAGE_DIMENSIONS
- TRANSFORM_MODE
- XRANGE
- YRANGE
- ZRANGE

- IMAGE_1D
- INTERNAL_DATA_TYPE
- LOCATION
- PALETTE
- REGISTER_PROPERTIES
- RESET_DATA
- SHARE_DATA
- TILE_BORDER_SIZE
- TILE_CURRENT_LEVEL
- TILE_LEVEL_MODE
- TILE_SHOW_BOUNDARIES
- TILING
- XCOORD_CONV
- YCOORD_CONV
- ZCOORD_CONV

In addition, objects of this class inherit the properties of all superclasses of this class.

Methods

This class has the following methods:

- IDLgrImage::Cleanup
- IDLgrImage::DeleteTileData
- IDLgrImage::GetCTM
- IDLgrImage::GetProperty
- IDLgrImage::Init
- IDLgrImage::ReadFilteredData
- IDLgrImage::SetProperty
- IDLgrImage::SetTileData

- IDLgrImage::TileDataLoaded

In addition, this class inherits the methods of its superclasses (if any).

Examples

For image object examples see Chapter 4, "Working with Image Objects" (*Object Programming*). Also see "Mapping an Image onto Elevation Data" (Chapter 3, *Image Processing in IDL*) for a texture mapping example.

Version History

5.0	Introduced
5.6	Added CLIP_PLANES property
6.2	Removed NO_COPY property and documented it as an IDLgrImage::Init keyword.
	Added ALPHA_CHANNEL, DEPTH_OFFSET, RENDER_METHOD, TILE_COLOR, TILE_CURRENT_LEVEL, TILE_DIMENSIONS, TILE_LEVEL_MODE, TILE_NUM_LEVELS, TILE_SHOW_BOUNDARIES, TILED_IMAGE_DIMENSIONS, TILING, and TRANSFORM_MODE properties
	Added DeleteTileData and SetTileData methods
6.4	Added IMAGE_1D, INTERNAL_DATA_TYPE, SHADER, and TILE_BORDER_SIZE properties
	Added ReadFilteredData and TileDataLoaded methods

IDLgrImage Properties

IDLgrImage objects have the following properties in addition to properties inherited from any superclasses. Properties with the word "Yes" in the "Get" column of the property table can be retrieved via IDLgrImage::GetProperty. Properties with the word "Yes" in the "Init" column of the property table can be set via IDLgrImage::Init. Properties with the word "Yes" in the "Set" column in the property table can be set via IDLgrImage::SetProperty.

Note

For a discussion of the property description tables shown below, see "About Object Property Descriptions" on page 3135.

Objects of this class have the following properties. See "IDLgrImage Properties" on page 4381 for details on individual properties.

- ALL
- BLEND_FUNCTION
- CLIP_PLANES
- DEPTH_OFFSET
- DEPTH_TEST_FUNCTION
- DIMENSIONS
- HIDE
- INTERLEAVE
- INTERPOLATE
- ORDER
- PARENT
- RENDER_METHOD
- SHADER
- SUB_RECT
- TILE_COLOR
- TILE_DIMENSIONS
- TILE_NUM_LEVELS

- ALPHA_CHANNEL
- CHANNEL
- DATA
- DEPTH_TEST_DISABLE
- DEPTH_WRITE_DISABLE
- GREYSCALE
- IMAGE_1D
- INTERNAL_DATA_TYPE
- LOCATION
- PALETTE
- REGISTER_PROPERTIES
- RESET_DATA
- SHARE_DATA
- TILE_BORDER_SIZE
- TILE_CURRENT_LEVEL
- TILE_LEVEL_MODE
- TILE_SHOW_BOUNDARIES

- TILED_IMAGE_DIMENSIONS
- TRANSFORM_MODE
- XRANGE
- YRANGE
- ZRANGE

- TILING
- XCOORD_CONV
- YCOORD_CONV
- ZCOORD_CONV

In addition, objects of this class inherit:

- IDLitComponent

ALL

An anonymous structure containing the values of all of the properties associated with the *state* of this object. State information about the object includes things like color, range, tick direction, etc., but not image, vertex, or connectivity data, or user values.

Note ───

The fields of this structure may change in subsequent releases of IDL.

───

Note ───

This structure returns a COLOR property that is consistent with other graphic objects. However, as an image object's color depends on each sample of data, the concept of an overall COLOR is not meaningful for this object and is not used in rendering the object.

───

Property Type	Structure		
Name String	*not displayed*		
Get: Yes	**Set:** No	**Init:** No	**Registered:** No

ALPHA_CHANNEL

A floating-point value in the range [0.0, 1.0] to specify the opacity of the image. The default value of 1.0 causes IDL to draw the image completely opaque. If the value of this property is less than 1.0, then the pixels of the image are blended with the pixels already on the screen, where the image is blended according to the values in the BLEND_FUNCTION property.

Because an object can only be blended with objects already drawn on the screen, the drawing order of the objects must be considered carefully in order to obtain the desired results.

This property has no effect on devices using indexed color model.

If the image data contains an alpha channel, the effective alpha of each pixel is the pixel's alpha multiplied by the value in the ALPHA_CHANNEL property.

Since the BLEND_FUNCTION property contributes (along with the value of the ALPHA_CHANNEL property) to the control of the blending, be sure to set the BLEND_FUNCTION property to the desired value. Its default value is [0,0]. To obtain the same blending function used by other graphic objects using the ALPHA_CHANNEL property, set the BLEND_FUNCTION property to [3,4].

Property Type	Float-point value		
Name String	Opacity		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

BLEND_FUNCTION

A two-element integer vector that controls how the alpha channel values will be interpreted. Set this property equal to a two-element vector [*src*, *dst*] specifying one of the functions listed below for each of the source and destination objects. These are only valid for RGB model destinations. If an alpha channel is not specified in an image, the image's alpha blend factor is assumed to be 1.0. The values of the blending function (V_{src} and V_{dst}) are used in the following equation

$$C_d' = (V_{src} \cdot C_i) + (V_{dst} \cdot C_d)$$

where C_d is the initial color of a pixel on the destination device (the background color), C_i is the color of the pixel in the image, and C_d' is the resulting color of the pixel.

Setting *src* and *dst* in the BLEND_FUNCTION vector to the following values determine how each term in the equation is calculated:

src or dst	V_{src} or V_{dst}	What the function does
0	n/a	Alpha blending is disabled, which is the default setting. $C_d' = C_i$
1	1	The value of V_{src} or V_{dst} in the equation is one, thus the value of the term is the same as the color value.
2	0	The value of V_{src} or V_{dst} in the equation is zero, thus the value of the term is zero.
3	Image$_a$	The value of V_{src} or V_{dst} in the equation is the blend factor of the image's alpha channel.
4	1-Image$_a$	The value of V_{src} or V_{dst} in the equation is one minus the blend factor of the image's alpha channel.

Table 32-7: Values for src and dst in BLEND_FUNCTION

For example, setting BLEND_FUNCTION = [3, 4] creates an image in which you can see through the foreground image to the background to the extent defined by the alpha channel values of the foreground image.

Since the alpha blending operation is dependent on the values of pixels already drawn to the destination for some blending functions, the final result may depend more on the order of drawing the images, and not necessarily on their relative location along the Z axis. IDL draws images in the order that they are stored in the IDLgrModel object that contains them.

This property is registered as a user-defined property, but it is hidden by default.

Property Type	USERDEF		
Name String	Blend function		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** Yes

CHANNEL

A hexadecimal bitmask that defines which color channel(s) to draw. Each bit that is a 1 is drawn; each bit that is a 0 is not drawn. For example, 'ff0000'X represents a Blue channel write. The default is to draw all channels, and is represented by the hexadecimal value 'ffffff'X.

Note ──

This property is ignored for CI destination objects.

──

This property is registered, but it is hidden by default.

Property Type	Integer		
Name String	Color channel		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** Yes

CLIP_PLANES

A 4-by-*N* floating-point array of dimensions [4,N] specifying the coefficients of the clipping planes to be applied to this object. The four coefficients for each clipping plane are of the form [A, B, C, D], where $Ax + By + Cz + D = 0$. Portions of this object that fall in the half space $Ax + By + Cz + D > 0$ will be clipped. By default, the value of this property is a scalar (-1) indicating that no clipping planes are to be applied.

Note ──

The clipping planes specified via this property are applied in addition to the near and far clipping planes associated with the IDLgrView in which this object appears.

Note ──

Clipping planes are applied in the data space of this object (prior to the application of any *x*, *y*, or *z* coordinate conversion).

Note ──

To determine the maximum number of clipping planes supported by the device, use the MAX_NUM_CLIP_PLANES keyword of the GetDeviceInfo method for the IDLgrBuffer, IDLgrClipboard, IDLgrWindow, and IDLgrVRML objects.

──

Property Type	Floating-point array		
Name String	*not displayed*		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** No

DATA

A *n* x *m*, *2 x n x m*, *3 x n* x *m*, or *4 x n* x *m* array (any type) of image data for the object. The *n* and *m* values may be in any position as specified by the INTERLEAVE property.

Specifying this property is the same as specifying the optional *ImageData* argument to the IDLgrImage::Init method.

Property Type	Array of any type		
Name String	*not displayed*		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** No

DEPTH_OFFSET

This property only has an effect when the image is rendered with a texture-mapped polygon and depth testing is enabled.

Set this property to an integer value that specifies an offset in depth to be used when rendering images. This offset is applied along the viewing axis, with positive values moving the image away from the viewer.

The units are "Z-Buffer units," where a value of 1 is used to specify a distance that corresponds to a single step in the device's Z-Buffer.

Use DEPTH_OFFSET to always cause an image to be rendered slightly deeper than other primitives, independent of model transforms. This is useful for avoiding stitching artifacts caused by rendering lines or polygons on top of images at the same depth.

Note ———

Use this feature to remove stitching artifacts and not as a means for "layering" complex scenes with multiple DEPTH_OFFSET values. It is safest to use only a DEPTH_OFFSET value of 0, the default, and one other non-zero value, such as 1. Many system-level graphics drivers are not consistent in their handling of DEPTH_OFFSET values, particularly when multiple non-zero values are used.

This can lead to portability problems because a set of DEPTH_OFFSET values may produce better results on one machine than on another. Using IDL's software renderer will help improve the cross-platform consistency of scenes that use DEPTH_OFFSET. However, software rendering may reduce the rendering performance of images displayed as texture-mapped polygons.

Property Type	Integer		
Name String	Depth offset		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** Yes

DEPTH_TEST_DISABLE

An integer value that determines whether depth testing is disabled.

- Set this property to 0 to inherit the value set by the parent model or view. The parent view always enables depth testing. A model may also enable or disable depth testing.

- Set this property to 1 (the default) to explicitly disable depth buffer testing while drawing this object.

- Set this property to 2 to explicitly enable depth testing for this object.

Disabling depth testing allows an object to draw itself on top of other objects already on the screen, even if the object is located behind them.

Note
To preserve backward compatibility with previous versions of IDL the default value of this property is different from that of other graphic objects using this property.

Note
Disabling depth testing also disables depth buffer writing. When disabling depth testing, the DEPTH_TEST_FUNCTION, DEPTH_OFFSET, and DEPTH_WRITE_DISABLE properties are effectively ignored.

This property is registered as an enumerated list, but it is hidden by default.

Property Type	ENUMLIST		
Name String	*not displayed*		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** No

DEPTH_TEST_FUNCTION

An integer value that determines the depth test function. Set this property to 0 (the default) to inherit the value set by the parent model or view. The parent view always sets a depth test function of LESS. A model may also set a depth test function value. The graphics device compares the object's depth at a particular pixel location with the depth stored in the depth buffer at that same pixel location. If the comparison test passes, the object's pixel is drawn at that location on the screen and the depth buffer is updated (if depth writing is enabled).

Set this property to any of the following values to use the desired function while rendering this object.

- 0 = INHERIT - use value from parent model or view.
- 1 = NEVER - never passes.
- 2 = LESS - passes if the object's depth is less than the depth buffer's value.
- 3 = EQUAL - passes if the object's depth is equal to the depth buffer's value.
- 4 = LESS OR EQUAL - passes if the object's depth is less than or equal to the depth buffer's value.
- 5 = GREATER - passes if the object's depth is greater than or equal to the depth buffer's value.
- 6 = NOT EQUAL - passes if the object's depth is not equal to the depth buffer's value.
- 7 = GREATER OR EQUAL - passes if the object's depth is greater than or equal to the depth buffer's value.
- 8 = ALWAYS - always passes

Less means closer to the viewer.

This property is registered as an enumerated list, but it is hidden by default.

Property Type	ENUMLIST		
Name String	*not displayed*		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** No

DEPTH_WRITE_DISABLE

An integer value that determines whether depth writing is disabled.

- Set this property to 0 (the default) to inherit the value set by the parent model or view. The parent view always enables depth writing. A model may also enable or disable depth writing.

- Set this property to 1 to explicitly disable depth buffer writing while rendering this object.

- Set this property to 2 to explicitly enable depth writing for this object.

Disabling depth writing allows an object to be overdrawn by other objects, even if the object is located in front of them.

This property is registered as an enumerated list, but it is hidden by default.

Property Type	ENUMLIST		
Name String	*not displayed*		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** No

DIMENSIONS

Set this property to a two-element integer vector of the form [*width*, *height*] specifying the dimensions of the rectangle in which the image is to be drawn on the device. The image will be resampled as necessary to fit within this rectangle. The default is derived from the dimensions of the given image data and is measured in pixels. IDL converts, maintains, and returns this data as double-precision floating-point.

Set this property to a scalar value to reset the image dimensions to the implicit dimensions of the data.

This property is registered as a user-defined property, but it is hidden by default.

Property Type	USERDEF		
Name String	Draw dimensions		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** Yes

GREYSCALE

A Boolean value that determines whether the image is drawn through a palette.

0 = Use palette (the default).

1 = Do not use a palette.

This property only has an effect on single-band images. If this property is set to 1 and the destination color model is RGB, both the image palette (if present) and the destination device palette (if present) are bypassed, and the image is drawn in greyscale.

If the destination color model in Indexed, this property has no effect since the image pixels are copied directly to the device and are then translated to RGB by the device palette. The contents of the device palette determine the colors of the image on the display, which will be greyscale only if the device palette contains a grey ramp.

Note —————————————————————————————

Since it is difficult or impossible to map a greyscale image into an arbitrary color palette, this property has no effect on devices using the indexed color model,

Property Type	Boolean		
Name String	Grayscale		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** Yes

HIDE

A Boolean value or enumerated list item that indicates whether this object should be drawn:

Value	Property Sheet Value	Description
0	True	Draw the graphic (the default)
1	False	Do not draw the graphic

Property Type	ENUMLIST		
Name String	Show		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** Yes

IMAGE_1D

A long value that indicates the image data is one-dimensional (1-D) as follows:

Value	Description
0	Not 1-D data (the default). Implies a normal 2-D image.
1	1-D data.

1-D images are useful for creating lookup table texture maps for use in fragment shaders (such as a [3,256] 1-D image used as a 256 entry RGB lookup table). 1-D images cannot be rendered by adding them to an IDLgrModel in a scene, but they can be passed to a shader program using IDLgrShader::SetUniformVariable.

Note ───

You can set this property after an image object has been created, but the data must be of the correct dimensions. If needed, assign new data to the image using the DATA property.

───

An error is generated if this property is set to 1 and the image data array passed to the IDLgrImage is of the wrong dimensions. The accepted array dimensions are as follows where *n* is the number of array elements in the channel:

Interleave	Acceptable Arrays
Pixel	n — monochrome 2 x n — monochrome and Alpha 3 x n — R, G, B 4 x n — R, G, B and Alpha
Planar	n x 2 — monochrome and Alpha n x 3 — R, G, B n x 4 — R, G, B, and Alpha

Property Type	Integer		
Name String	*not displayed*		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** No

INTERLEAVE

An integer value or enumerated list item that indicates the dimension over which color is interleaved for images with more than one channel:

Value	Property Sheet Value	Description
0	Pixel	Pixel interleaved images with dimensions (3, *m*, *n*) - the default
1	Scanline	Scan line interleaved (row interleaved) images with dimensions (*m*, 3, *n*)
2	Planar	Planar interleaved images with dimensions (*m*, *n*, 3)

Note

If an alpha channel is present, the 3s should be replaced by 4s. In a greyscale image with an alpha channel, the 3s should be replaced by 2s.

This property is registered, but it is hidden by default.

Property Type	ENUMLIST		
Name String	Interleaving		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** Yes

INTERNAL_DATA_TYPE

A long value that describes the data format used to store the image in the graphics hardware as a texture map. If floating-point data types are not supported by the graphics hardware, this value is ignored. In practice, this means that settings other than BYTE are generally useful only when using shader programs. Most shader implementations perform their computations in 32-bit float, so the value of this

property determines what precision is used to store the image data before it is converted to float and handed to the shader program. The default value is 0.

Value	Description of Internal Data Types
0	Byte — convert (truncate) and store as Byte. This setting is useful when the image data has a precision of 8 bits per image component or less.
1	Byte — data scaled to Byte
2	Float16 — store and maintain image data consisting of whole numbers in the range of +/- 2048. This is useful because this range uses less texture memory than FLOAT32. The largest values that can be stored with some loss of precision are +/- 65504.
3	Float32 — store whole numbers in the range +/- 16,777,216 without loss of precision and +/- 10^38 with loss of precision. This format is useful if your image data is already in floating point format or if you have integer image data in the range +/- 16,777,216. This type, of course, requires 4 bytes per image pixel component, often 16 bytes per RGBA pixel.

Note

Hardware rendering performance on the GPU can be badly affected if bilinear interpolation (INTERPOLATE=1) is enabled when INTERNAL_DATA_TYPE is set to Float16 or Float32. In some cases, the graphics driver defaults back to software rendering.

The property is applied to data specified with the DATA property/ argument and the TileData argument of the SetTileData method. If no shader program is in effect this property is still used, however it is not recommended setting anything other than 0 unless you fully understand how OpenGL converts the input data to texture data. See "OpenGL Conversion of Image Data to Texture Data" (Chapter 14, *Object Programming*) for details.

When this property is non-zero, the image data provided to the object must be of one of the following types:

Type Code	Description	Values
1	BYTE	8-bit unsigned
2	INT	16-bit signed
4	FLOAT	32-bit float
12	UINT	12-bit unsigned

IDL type codes are listed in "IDL Type Codes and Names" on page 2277 under the SIZE function.

IDL execution halts with an error if any other type is provided. If you wish to change the INTERNAL_DATA_TYPE you must provide new data at the same time via the DATA property.

```
oImage->SetProperty, DATA=imagedata, INTERNAL_DATA_TYPE=2
```

IDL will not generate a warning if you fail to do this, but the image will be converted to a texture incorrectly.

Property Type	Integer		
Name String	*not displayed*		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** No

INTERPOLATE

An integer value or enumerated list item that determines whether to display the IDLgrImage object using bilinear interpolation. The default is to use nearest neighbor interpolation.

Value	Property Sheet Value	Description
0	Nearest neighbor	Surveys the value of the nearest pixel (the default)
1	Bilinear	Surveys the 4 closest pixels

See "Interpolation Methods" (Chapter 5, *Using IDL*) for details.

Property Type	ENUMLIST		
Name String	Interpolation		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** Yes

Note ───

Prior to IDL 6.2, IDL performed image interpolation using its own algorithms in software, if requested with the INTERPOLATE property. With the 6.2 performance enhancements, this interpolation is now performed by any texture-mapping acceleration hardware or fallback software in the vendor-supplied hardware and software. Therefore, interpolation results may differ slightly across graphics devices and from pre-6.2 results. To preserve the exact, but slower interpolation results delivered before IDL 6.2, set the RENDER_METHOD property to 1.

───

LOCATION

A two- or three-element floating-point vector [*x, y*] or [*x, y, z*] specifying the position of the lower lefthand corner of the image, measured in data units. If the vector is of the form [*x, y*], then the *z* value is set equal to zero. The default is [0, 0, 0]. IDL converts, maintains, and returns this data as double-precision floating-point.

On devices using the RGB color model, IDLgrImage renders the image using a texture-mapped polygon, and this polygon is subject to clipping by the near/far clip planes, as defined in the IDLgrView object. To define an arbitrary rotation for an image, see TRANSFORM_MODE.

This property is registered as a user-defined property, but it is hidden by default.

Property Type	USERDEF		
Name String	Location		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** Yes

See "Positioning Image Objects in a View" (Chapter 4, *Object Programming*) for an example using the LOCATION property.

ORDER

A Boolean value or enumerated list item that determines whether to force the rows of the image data to be drawn from top to bottom. By default, image data is drawn from the bottom row up to the top row.

Value	Property Sheet Value	Description
0	Bottom-to-top	Image data is drawn from the bottom row up to the top row (the default)
1	Top-to-bottom	Image data is drawn from the top row down to the bottom row

Property Type	ENUMLIST		
Name String	Row order		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** Yes

PALETTE

An object reference to a palette object (an instance of the IDLgrPalette object class) that specifies the red, green, and blue values of the color lookup table to be associated with the image if it is an indexed color image. This property is ignored if the image is a greyscale or RGB image.

Note

This table is only used when the destination is an RGB model device. The Indexed color model writes the indices directly to the device. In order to ensure that these colors are used when the image is displayed, this palette must be copied to the graphics destination's palette for any graphics destination that uses the Indexed color model.

Warning

If a SHADER is associated with the image object, the palette is ignored.

Note

Objects specified via this property are not automatically cleaned up when the IDLgrImage object is destroyed.

This property is registered as a user-defined property, but it is hidden by default.

Property Type	USERDEF		
Name String	Color palette		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

See the "Examples" section of IDLgrPalette for examples of creating a palette object and assigning it to an image object.

PARENT

An object reference to the object that contains this object.

Property Type	Object reference		
Name String	*not displayed*		
Get: Yes	Set: No	Init: No	Registered: No

REGISTER_PROPERTIES

A Boolean value that determines whether to register properties available for this object. If this property is set, all properties marked in this properties section as "Registered: Yes" will be registered for display in a property sheet. This property is useful mainly when creating iTools. By default, no properties are registered.

Property Type	Boolean		
Name String	*not displayed*		
Get: No	Set: No	Init: Yes	Registered: No

RENDER_METHOD

Set this property to 0 (the default) to cause the image to be rendered using a texture-mapped polygon whenever possible.

Set this property to 1 to cause the image to be rendered using a 2D pixel primitive. This is the mode used in versions of IDL prior to 6.2. When this method is used, the ALPHA_CHANNEL property is ignored and the full 3D transform mode (TRANSFORM_MODE property value 1) is not available.

Warning ───

Setting RENDER_METHOD=1 (do *not* render image as texture-mapped polygon) disables all shader functionality including the software-based alternative. See "IDLgrShader" on page 4736 for details.

───

The texture-mapped mode is more flexible and generally faster on devices with hardware texture mapping support.

This property has no effect on devices using the indexed color model, where the 2D pixel primitive method is always used.

Property Type	ENUMLIST		
Name String	Render method		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

RESET_DATA

A Boolean value that determines whether to treat the data provided via the DATA property as a new data set unique to this object, rather than overwriting data that is shared by other objects.

- 0 = Overwrite data that is shared by other objects (the default).

- 1 = Treat DATA as a new data set unique to this object.

There is no reason to use this property if the object on which the property is being set does not currently share data with another object (that is, if the SHARE_DATA property is not in use). This property has no effect if no new data is provided via the DATA property.

Property Type	Boolean		
Name String	*not displayed*		
Get: No	Set: Yes	Init: Yes	Registered: No

SHADER

An object reference to an IDLgrShader object (or an object containing IDLgrShader as a superclass). When there is suitable graphics card hardware support, the image is rendered using the GLSL shader program (executed on the graphics card) instead of using fixed OpenGL properties when initially drawn. If there is an error while applying the shader program, for example if the GLSL source does not compile, then

the image will be displayed as if there were no shader specified. If a suitable graphics card is not present, IDL uses a software-based alternative if one has been provided in the shader object FILTER method. (See "Providing a Software Alternative to Shaders" (Chapter 14, *Object Programming*) for details.) A single IDLgrShader object may be associated with additional image objects or other graphic objects that have the SHADER property.

Property Type	Object reference		
Name String	*not displayed*		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** No

Note ———————————————————————

If a PALETTE has been set, the palette lookup is done before the fragment shader is executed. Therefore, when the fragment shader reads from the image texture it will be passed 8-bit per channel RGB data (read from the palette), not the original 1-channel image data.

———————————————————————————————

Warning ———————————————————————

If RENDER_METHOD is set to 1 (do *not* display images as texture-mapped polygons) then all shading is disabled. The SHADER property setting is completely ignored and the software fallback will not be used.

———————————————————————————————

SHARE_DATA

An object reference to an object with which data is to be shared by this image. An image may only share data with another image. The SHARE_DATA property is intended for use when data values are not set via an argument to the object's Init method or by setting the object's DATA property.

Note ———————————————————————

Objects specified via this property are not automatically cleaned up when the IDLgrImage object is destroyed.

———————————————————————————————

Property Type	Object reference		
Name String	*not displayed*		
Get: No	**Set:** Yes	**Init:** Yes	**Registered:** No

SUB_RECT

A four-element floating-point vector, [*x*, *y*, *xdim*, *ydim*], specifying the position of the lower left-hand corner and the dimensions of the sub-rectangle to display, in pixel coordinates.

This property is registered as a user-defined property, but it is hidden by default.

Property Type	USERDEF		
Name String	*not displayed*		
Get: Yes	Set: Yes	Init: Yes	Registered: No

TILE_BORDER_SIZE

A scalar long value that sets the size of the tile border. This is useful if the image is being filtered by an IDLgrShader that applies a convolution filter. Data from adjacent tiles is required when filtering the pixels along the edges of a tile. Setting TILE_BORDER_SIZE loads the required pixels from the adjacent tiles into the border of the current tile for computation purposes, but does not display them.

For example, if the convolution kernel size is 5x5, TILE_BORDER_SIZE should be set to 2. When a pixel on the top edge of a tile if being filtered, setting this property to two provides access to the two pixels above the current pixel (from the neighboring tile) and the two pixels below the row. Likewise, if the kernel size is 3x3, TILE_BORDER_SIZE should be set to 1 to access all 9 pixels needed for the kernel.

The border size is subtracted from the TILE_DIMENSIONS making the visible tiles smaller. For example, if TILE_DIMENSIONS is 1024,1024 and TILE_BORDER_SIZE is 2, then the visible portion of the tile will be 1020,1020 (a 2-pixel border at each side of the image reduces the image size by 4).

If TILE_BORDER_SIZE is greater than 0 then the tile data requested by QueryRequiredTiles will include the border and SetTileData will expect the supplied data to include the border. The requested tiles will overlap because of the border.

IDL will automatically tile an image if its dimensions are larger than MAX_TEXTURE_DIMENSIONS returned by GetDeviceInfo (typically larger than 4096, 4096). (TILING need not be set in such a case.) However, if an IDLgrShader applies a convolution filter to such an image, you should still set TILE_BORDER_SIZE so that IDL will have the needed pixels for the convolution operation when handling the internally tiled data.

Default value is 0, the maximum value is TILE_DIMENSIONS / 3.

Property Type	Integer		
Name String	*not displayed*		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** No

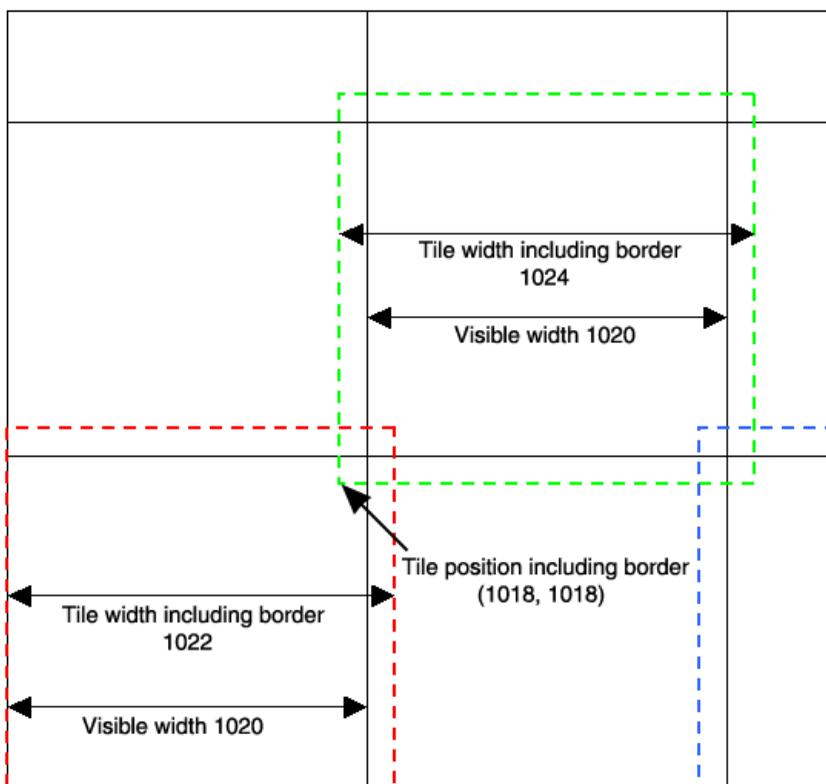
Given TILE_DIMENSIONS of 1024 by 1024 pixels and a TILE_BORDER_SIZE=2, the following figure shows the visible tiles (solid black lines) and the actual tile data that contains pixel from adjacent tiles (dotted lines).


Figure 32-3: Visible Versus Actual Tile Data

TILE_COLOR

Set this property to a three-element vector, [*red*, *green*, *blue*], specifying the color to draw the tile if no data has been set using IDLgrImage::SetTileData. If data has been set for the tile being drawn, or data from another level can be substituted, this property is ignored. The default is [0,0,0] (black).

Property Type	USERDEF		
Name String	*not displayed*		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** No

TILE_CURRENT_LEVEL

Set this property to an integer value that specifies the tile level that the destination object's QueryRequiredTiles method will request and use for drawing. The default is level 0, which is a tile from the full-resolution image. This property only applies when TILE_LEVEL_MODE is 0 (manual).

Property Type	INTEGER		
Name String	*not displayed*		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** No

TILE_DIMENSIONS

Set this property to a two-element integer vector specifying the dimensions of an image tile in the form of [*width*, *height*] in pixel units. The default value is [1024,1024]. Use this property to adjust the tile size to match your application's preferred tile size, if any. If the source of the tiled image data (e.g., image file or file server) has a default tile size, it will be most efficient to set this property to that tile size.

To determine the maximum allowable tile dimensions, use the MAX_TILE_DIMENSIONS keyword to the GetDeviceInfo method on the destination object (window, clipboard, or buffer object) to which the image will be drawn. If you set a TILE_DIMENSIONS value that exceeds the maximum tile dimension supported by the destination object, it will automatically be reduced to the maximum.

Note ───

Tile dimensions that are a power of 2 (e.g., 256, 512, 1024) are more memory efficient.

───

Property Type	USERDEF		
Name String	*not displayed*		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** No

TILE_LEVEL_MODE

Set this property to a scalar integer that defines the tile level selection mode. Use one of the following:

0	Manual mode. The application is responsible for setting the level to be used with TILE_CURRENT_LEVEL. The destination object's QueryRequiredTiles method always asks for and renders tiles at that specified level. This is the default.
	Use this mode if you *do not* have an image pyramid.
1	Automatic mode. The level to be requested and rendered is calculated by IDL based on image magnification or minification (the ratio of image pixels to screen pixels).
	Use this mode if you have an image pyramid and want images of different resolutions to be displayed based on zoom level.

Note ───

See "Adding Tiling to Your Application" (Chapter 4, *Object Programming*) for additional information.

───

Property Type	ENUMLIST		
Name String	*not displayed*		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** No

TILE_NUM_LEVELS

This property automatically calculates the number of image levels (resolution levels), or lets you set an integer value that specifies the number of levels in an image pyramid that can be requested by the destination object's QueryRequiredTiles method. This is calculated automatically or can be set manually as follows:

Automatically calculated	This is automatically calculated when the image is created such that the lowest resolution level is just smaller than the tile size. For example, if the level 0, full-resolution image is 5000 by 5000 and the tile size is 1024 by 1024 pixels: • Level 1 will be 2500 by 2500 • Level 2 will be 1250 by 1250 • Level 3 will be 625 by 625 Thus there are 4 levels (0 to 3), and level 3 is just smaller than the tile size. The default is to automatically calculate the number of levels based on TILED_IMAGE_DIMENSIONS and TILE_DIMENSIONS when the image is created.
Manually set	Set to an integer value specifying the number of levels. For example, setting 2 will result in QueryRequiredTiles requesting levels 0 and 1 as appropriate, and levels 0 and 1 being used for drawing as appropriate. This is useful if there are insufficient levels available in the image pyramid to match the calculated value of TILE_NUM_LEVELS. Set to 0 (zero) to use all available levels.

Note ──
If this property is set to a value higher than the calculated value, it will be ignored, and the calculated value will be used.
──

This property is only used when TILE_LEVEL_MODE is set to 1 (automatic).

Property Type	INTEGER		
Name String	*not displayed*		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** No

TILE_SHOW_BOUNDARIES

Set this property equal to 1 to draw wireframe outlines around the tiles. This is useful while developing applications that use tiling to help visualize where the tiles are within the image. By default, this property is set equal to 0.

Property Type	Boolean		
Name String	Show tile boundaries		
Get: Yes	Set: Yes	Init: Yes	Registered: No

TILED_IMAGE_DIMENSIONS

Set this property to a two-element integer vector [*width*, *height*] specifying the pixel size of the original, full-resolution image that will be tiled. This property must be set when the TILING property set to non-zero value; otherwise, IDL generates an error. The default value is [0,0].

Property Type	USERDEF		
Name String	*not displayed*		
Get: Yes	Set: Yes	Init: Yes	Registered: No

TILING

Set this property to 1 to enable tiling for this image object. The default value is 0 (no tiling). Use the destination object's QueryRequiredTiles method and the IDLgrImage::SetTileData method to determine tile visibility and load the appropriate data. Also, you must set TILED_IMAGE_DIMENSIONS, changing the default value of [0,0] to the actual size of the image to be tiled to avoid generating an error.

Note ────────────────────────────────────
A tiled image cannot be drawn on a destination device using the indexed color model. Also, tiling is not permitted when the image property RENDER_METHOD=1.
────────────────────────────────────

Property Type	BOOLEAN		
Name String	*not displayed*		
Get: Yes	Set: Yes	Init: Yes	Registered: No

Note ───

When tiling is activated, the object does not use any data stored in its DATA property. However, the data are available and will be used if TILING is set to zero.

───

See "Image Tiling" (Chapter 4, *Object Programming*) for details on image tiling.

TRANSFORM_MODE

Set this property to 0 (the default) to cause the image to be rendered into a rectangular region whose sides are always parallel to the window's sides. The rectangular region is defined by two points. The lower left point is specified by the LOCATION property. The upper right point is derived from the LOCATION property and either the DIMENSIONS property or the implicit image dimensions. These two points are transformed by the current model transform and are effectively projected onto a plane located at LOCATION[2] (default 0). The image is then drawn in this region. This is the mode used by versions of IDL prior to 6.2.

Set this property to 1 to cause the image to be rendered into an image rectangle where the entire image rectangle is transformed by the current full three-dimensional model transform. The image is rendered into the resulting rectangle, which may not be aligned with the window boundaries. This allows the image to be drawn with the full flexibility of the current model transform. For more information on transformations, see Transformations of IDLgrImage Objects.

This property has no effect on devices using the indexed color model, where mode 0 is always used.

Property Type	ENUMLIST		
Name String	Transform mode		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

XCOORD_CONV

A floating-point vector, $[s_0, s_1]$, of scaling factors used to convert X coordinates from data units to normalized units. The formula for the conversion is as follows:

$$\text{Normalized}X = s_0 + s_1 * \text{Data}X$$

Recommended values are:

$$[(-X_{min})/(X_{max}-X_{min}), \ 1/(X_{max}-X_{min})]$$

The default is [0.0, 1.0]. IDL converts, maintains, and returns this data as double-precision floating-point.

Property Type	Floating-point vector		
Name String	*not displayed*		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** No

XRANGE

A two-element double-precision floating-point vector of the form [*xmin*, *xmax*] that specifies the range of *x* data coordinates covered by the graphic object.

Property Type	Floating-point vector		
Name String	*not displayed*		
Get: Yes	**Set:** No	**Init:** No	**Registered:** No

YCOORD_CONV

A floating-point vector, $[s_0, s_1]$, of scaling factors used to convert Y coordinates from data units to normalized units. The formula for the conversion is as follows:

$$Normalized Y = s_0 + s_1 * Data Y$$

Recommended values are:

$$[(-Y_{min})/(Y_{max}-Y_{min}), 1/(Y_{max}-Y_{min})]$$

The default is [0.0, 1.0]. IDL converts, maintains, and returns this data as double-precision floating-point.

Property Type	Floating-point vector		
Name String	*not displayed*		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** No

YRANGE

A two-element double-precision floating-point vector of the form [*ymin*, *ymax*] that specifies the range of *y* data coordinates covered by the graphic object.

Property Type	Floating-point vector		
Name String	*not displayed*		
Get: Yes	**Set:** No	**Init:** No	**Registered:** No

ZCOORD_CONV

A floating-point vector, $[s_0, s_1]$, of scaling factors used to convert Z coordinates from data units to normalized units. The formula for the conversion is as follows:

$$\text{Normalized}Z = s_0 + s_1 * \text{Data}Z$$

Recommended values are:

$$[(-Z_{min})/(Z_{max}-Z_{min}), 1/(Z_{max}-Z_{min})]$$

The default is [0.0, 1.0]. IDL converts, maintains, and returns this data as double-precision floating-point.

Property Type	Floating-point vector		
Name String	*not displayed*		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** No

ZRANGE

Two-element double-precision floating-point vector of the form [*zmin*, *zmax*] that specifies the range of *z* data coordinates covered by the graphic object.

Property Type	Floating-point vector		
Name String	*not displayed*		
Get: Yes	**Set:** No	**Init:** No	**Registered:** No

IDLgrImage::Cleanup

The IDLgrImage::Cleanup procedure method performs all cleanup on the object.

Note ————————————————————————————

Cleanup methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation and destruction. This means that in most cases, you cannot call the Cleanup method directly. There is one exception to this rule: if you write your own subclass of this class, you can call the Cleanup method from within the Init or Cleanup method of the subclass.

————————————————————————————————

Syntax

OBJ_DESTROY, *Obj*

or

Obj->[IDLgrImage::]Cleanup   *(In a lifecycle method only.)*

Arguments

None

Keywords

None

Version History

5.0	Introduced

IDLgrImage::DeleteTileData

The IDLgrImage::DeleteTileData procedure method removes tile data from the cache. This is useful to free up cache memory if the application knows a number of tiles will not be displayed again for some time. It could also be used if the image data changes and the old image data should be removed from the cache. If you remove a tile from the cache, a subsequent invocation of QueryRequiredTiles returns the tile if it is visible.

This method deletes tiles even if they were loaded with the NO_FREE keyword set. An error is generated if the tile argument does not specify a valid tile or the level argument specifies an invalid level. If the tile being deleted doesn't have any tile data, no error will be generated.

Syntax

Obj->[IDLgrImage::]DeleteTileData, *TileInfo* [, /ALL]

Arguments

TileInfo

A named structure describing the tile or tiles for which the data is being deleted. This structure contains the following fields:

Field	Data Type	Description
X	Long	The horizontal position of the left side of the tile(s) measured from the left of the image in pixels.
Y	Long	The vertical position of the bottom of the tile(s) measured from the bottom of the image in pixels.
WIDTH	Long	The width of the tile(s) in pixels.
HEIGHT	Long	The height of the tile(s) in pixels.

Table 32-8: IDLIMAGETILE Structure

Field	Data Type	Description
LEVEL	Long	The data resolution, where 0 is the full resolution image. A value of *n* (*n* > 0) indicates that the resolution is half that of the *n*-1 level.
DEST	OBJREF	The object reference to the destination object that is displaying the tiled IDLgrImage.

Table 32-8: IDLIMAGETILE Structure (Continued)

If a number of tiles are to be deleted by passing a region covering multiple tiles then X, Y, WIDTH and HEIGHT must be multiples of the tile size.

Keywords

ALL

Set this keyword to delete all tiles at all levels in the cache for this image. This is useful for clearing the cache when image data changes and new data will be loaded.

The new tile data may now have a different interleave format and number of channels than any tiles previously stored in the object. See IDLgrImage::SetTileData.

Note

The *TileInfo* structure must still be passed, and must contain a valid destination object reference in the Dest field. The other entries can be 0 in this case.

Version History

6.2	Introduced

IDLgrImage::GetCTM

The IDLgrImage::GetCTM function method returns the 4 x 4 double-precision floating-point graphics transform matrix from the current object upward through the graphics tree.

Syntax

Result = Obj->[IDLgrImage::]GetCTM([, DESTINATION=*objref*]
   [, PATH=*objref(s)*] [, TOP=*objref to IDLgrModel object*])

Return Value

Returns the graphics transform matrix from the current object upward through the graphics tree.

Arguments

None

Keywords

DESTINATION

Set this keyword to the object reference of a destination object to specify that the projection matrix for the View object in the current tree be included in the returned transformation matrix. The resulting matrix will transform a point in the data space of the object on which the GetCTM method is called into a normalized coordinate system (-1 to +1 in X, Y, and Z), relative to the View object that contains the image object.

PATH

Set this keyword to a single object reference or a vector of object references. This keyword specifies the path in the graphics hierarchy to compute the transformation matrix. Each path object reference specified with this keyword must contain an alias. The transformation matrix is computed for the version of the object falling within that path. If this keyword is not set, the PARENT properties determine the path from the current object to the top of the graphics hierarchy and no alias paths are pursued. If IDLgrImage::GetCTM is called from within a Draw method, with the DESTINATION keyword set and the PATH keyword not set, the alias path used to find the object during the draw is used, rather than the PARENT path.

Note ——————————————————————————————————
For more information on aliases, refer to the ALIAS keyword in IDLgrModel::Add.
——

TOP

Set this keyword equal to the object reference to an IDLgrModel object to specify
that the returned matrix accumulate from the object on which the GetCTM method is
called up to but not including the specified model object.

Version History

5.0	Introduced

IDLgrImage::GetProperty

The IDLgrImage::GetProperty procedure method retrieves the value of the property or group of properties for the image.

Syntax

Obj->[IDLgrImage::]GetProperty[, *PROPERTY=variable*]

Arguments

None

Keywords

Any property listed under "IDLgrImage Properties" on page 4381 that contains the word "Yes" in the "Get" column of the properties table can be retrieved using this method. To retrieve the value of a property, specify the property name as a keyword set equal to a named variable that will contain the value of the property.

Any keyword not recognized is passed to this object's superclass.

Version History

5.0	Introduced

IDLgrImage::Init

The IDLgrImage::Init function method initializes the image object.

Note ───

Init methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation. This means that in most cases, you cannot call the Init method directly. There is one exception to this rule: if you write your own subclass of this class, you can call the Init method from within the Init method of the subclass.

───

Syntax

Obj = OBJ_NEW('IDLgrImage' [, *ImageData*] [, *PROPERTY=value*] [,NO_COPY])

or

Result = Obj->[IDLgrImage::]Init([*ImageData*] [, *PROPERTY=value*]
   [,NO_COPY])   *(In a lifecycle method only.)*

Return Value

When this method is called indirectly, as part of the call to the OBJ_NEW function, the return value is an object reference to the newly-created object.

When called directly within a subclass Init method, the return value is 1 if initialization was successful, or zero otherwise.

Arguments

ImageData

An array of data values to be displayed as an image. Since by default IDL maintains the image data using the byte type, in most cases the input data values should range from 0 through 255. If this argument is not already of byte type, it is converted to byte type when the image object is created.

Note ───

The INTERNAL_DATA_TYPE property controls the type of data used to store *ImageData*. If the IDLgrImage object has an associated IDLgrShader object, it may be useful to use floating-point values to store the image data.

───

Image objects can have a single channel (one value per pixel—greyscale or color indexed), two channels (greyscale and alpha), three channels (red, green, and blue), or four channels (red, green, blue, and alpha). The alpha channel, if present, determines the transparency of the pixel. The BLEND_FUNCTION property controls the interpretation of the alpha channel values. With channels, the data value of 0 specifies minimum intensity and the data value of 255 specifies maximum intensity. The alpha channel values are also specified in the image data in the range 0 through 255, with an image data value of 0 corresponding to an alpha blend factor of 0 and an image data value of 255 corresponding to an alpha blend factor of 1.0. *ImageData* can be any of the following, where *n* is the width of the image, and *m* is the height:

- An *n* x *m* array of color lookup table indices.

- An *n* x *m* greyscale image, or a 2 x *n* x *m*, *n* x 2 x *m*, or *n* x *m* x 2 greyscale image with an alpha channel. (The alpha channel is ignored if the destination device uses indexed color mode.)

- A 3 x *n* x *m*, *n* x 3 x *m*, or *n* x *m* x 3 RGB image, or a 4 x *n* x *m*, *n* x 4 x *m*, or *n* x *m* x 4 RGB image with an alpha channel.

If the array has more than one channel, the interleave is specified by the INTERLEAVE property.

Note

The value specified by the *ImageData* argument is used to initialize the value of the DATA property of the IDLgrImage object.

Keywords

Any property listed under "IDLgrImage Properties" on page 4381 that contains the word "Yes" in the "Init" column of the properties table can be initialized during object creation using this method. To initialize the value of a property, specify the property name as a keyword set equal to the appropriate property value.

All other keywords are passed to the superclass of this object.

NO_COPY

If this keyword is set to a non-zero value, it relocates the image data from the input variable to the image object, leaving the input variable *ImageData* undefined. Only the *ImageData* argument is affected. The following example illustrates that the data is moved from the input variable.

```
imgdata = BYTSCL(DIST(300))
```

```
oImg = OBJ_NEW('IDLgrImage', imgData, /NO_COPY)
HELP, imgdata
; IDL prints IMGDATA UNDEFINED = <Undefined>
```

If this keyword is omitted, the input image data will be duplicated and a copy will be stored in the object.

Version History

5.0	Introduced
6.2	Added NO_COPY keyword

IDLgrImage::ReadFilteredData

The IDLgrImage::ReadFilteredData function method returns image data after a shader program (contained in an IDLgrShader object or object subclassed from IDLgrShader) has been applied, or after one or more shaders (contained in an IDLgrFilterChain object) have been applied.

Note ──

If there is sufficient hardware support for IDLgrShader programs, this method will complete the shader operations and read the results generated by the graphic card's GPU (Graphic Processing Unit). If there is insufficient support or if software rendering has been specified, the software-based alternative will be used if you have provided one. See "Providing a Software Alternative to Shaders" (Chapter 14, *Object Programming*) for details.

──

Syntax

Result = Obj->[IDLgrImage::]ReadFilteredData(*Dest* [, DATA_TYPE=*value*]
    [, READ_POSITION=*value*] [, TILE=*tileinfo*])

Return Value

Returns an array containing the filtered image data. The returned array is always of dimensions [4, *w*, *h*] where *w* is the width of the returned image and *h* is the height. The data is always pixel interleaved RGBA. The type of the returned data is determined by the DATA_TYPE keyword.

If there was an error this method returns 0.

Arguments

Dest

A object reference to a graphics destination object, (e.g. IDLgrWindow).

Keywords

DATA_TYPE

Set this to one of the following allowable values to specify the data type of the returned data:

0	BYTE (default)
1	INT
2	FLOAT
3	UINT

The output of shader programs is always floating point so if 0, 1, or 3 is specified, the output is clamped to the range of 0.0 to 1.0 and then scaled to fill the requested data type range. If 2 is specified, the data is returned unmodified. The data is converted from floating point to the requested type as follows:

Requested Type	**Conversion from Floating Point (f)**
BYTE (0)	$c = (2^8-1)f$
INT (1)	$c = [(2^{16}-1)f - 1]/2$
FLOAT (2)	$c = f$
UINT (3)	$c = (2^{16}-1)f$

Note

It is very important that this keyword and the IDLgrShader OUTPUT_DATA_TYPE property are set in a consistent manner. For example, suppose you have UINT image data, but OUTPUT_DATA_TYPE is set to BYTE while DATA_TYPE is set to UINT. You will lose accuracy (due to the intermediate BYTE stage). In this example OUTPUT_DATA_TYPE should be set to FLOAT32 (or possibly FLOAT16 if only 10-bits of the UINT are used).

If not set, BYTE data is returned by default.

READ_POSITION

When the IDLgrImage SHADER property has been set to an IDLgrFilterChain object, set this keyword to a scaler long value specifying the zero-based position in the chain from which the data should be read.

For instance, if the filter chain contains a series of 3 shader objects, setting this keyword to one of the following values returns the specified data:

- 0 reads the result without any shaders applied

- 1 reads the result after application of only the first shader

- 2 reads the result after application of the first and second shaders

- 3 reads the result after application of all three shaders

If this keyword isn't set then the default behavior is to return the image data after application of all filtering shaders in the filter chain.

TILE

If the IDLgrImage is tiled (TILING=1) then this keyword must be set to a valid IDLIMAGETILE structure specifying the tile or tiles for which to return filtered data. For example, to retrieve the filtered data for the currently visible tiles call IDLgrWindow::QueryRequiredTiles, /ALL_VISIBLE, then for each tile call ReadFilteredData.

Note ──
Data must be loaded into the tiles using IDLgrImage::SetTileData before doing this.
──

An error will be generated if the image is tiled and this keyword is not set to a valid IDLIMAGETILE structure.

Examples

Create an instance of the example object, shader_rgb_doc, which includes the ability to capture an image and display the results in iImage. Run the example by creating an instance of the object at the IDL command prompt using orgbshader=OBJ_NEW("shader_rgb_doc") or view the file in an IDL Editor window by entering .EDIT shader_rgb_doc__define.

Version History

6.4	Introduced

IDLgrImage::SetProperty

The IDLgrImage::SetProperty procedure method sets the value of the property or group of properties for the image.

Syntax

Obj->[IDLgrImage::]SetProperty[, *PROPERTY=value*] [, /NO_COPY]

Arguments

None

Keywords

Any property listed under "IDLgrImage Properties" on page 4381 that contains the word "Yes" in the "Set" column of the properties table can be set using this method. To set the value of a property, specify the property name as a keyword set equal to the appropriate property value.

NO_COPY

If this keyword is set to a non-zero value, and the DATA property is specified in the same invocation, it relocates the image data from the input variable to the image object, leaving the input DATA property variable undefined. Only the DATA property is affected. The following example illustrates that the data is moved from the input variable.

```
imgdata = BYTSCL(DIST(300))
oImg = OBJ_NEW('IDLgrImage')
oImg->SetProperty, DATA=imgdata, /NO_COPY
HELP, imgdata
; IDL prints IMGDATA UNDEFINED = <Undefined>
```

If this keyword is omitted, the input image data will be duplicated and a copy will be stored in the object.

Version History

5.0	Introduced
6.2	Added NO_COPY keyword

IDLgrImage::SetTileData

The IDLgrImage::SetTileData procedure method stores tile data in the IDLgrImage tile data cache. If a tile has data loaded but not for the required level, the data associated with the next highest available level will be used instead. Otherwise, IDLgrImage renders the tile using the solid color specified by TILE_COLOR. An error is generated if any of the parameters are invalid. All units are in terms of pixels.

All image data tiles stored into the image object with SetTileData must be passed in arrays with consistent dimensions. That is, the number of channels and the interleave format must be the same for all tile data arrays. For example, if one tile is stored in an array with dimensions [3,200,340], then all other tile data arrays must have three dimensions where the first dimension value, the number of channels, is always 3. The other two dimension values, the width and height, can vary to express the tile size.

The first call to SetTileData after the object is created or after a call to DeleteTileData with the ALL keyword set determines the tile data array format to be used for all subsequent tiles. IDL generates an error if a tile data array is submitted with an inconsistent array format.

If data has already been set for the specified tile, it will be replaced by the data in the subsequent call to SetTileData.

Note
When you call IDLgrImage::SetProperty after calling SetTileData, and then draw the tiles, the image data may not be displayed. If you set an image property with SetProperty, IDL may update the image data and delete any tiles that were previously stored with the SetTileData method. If this occurs, set image properties before using SetTileData, or set image properties and then call QueryRequiredTiles to reacquire the tiles before setting and drawing the tiles.

Note
See "Image Tiling" (Chapter 4, *Object Programming*) for information creating an application that uses tiling and code examples.

Syntax

Obj->[IDLgrImage::]SetTileData, *TileInfo, TileData* [, NO_FREE=*value*]

Arguments

TileInfo

A named structure describing the tile or tiles for which the data is being set. The structures returned by the destination object's QueryRequiredTiles method can be passed directly (one at a time) to SetTileData along with the corresponding tile data.

This structure contains the following fields:

Field	Data Type	Description
X	Long	The horizontal position of the left side of the tile(s) measured from the left of the image in pixels.
Y	Long	The vertical position of the bottom of the tile(s) measured from the bottom of the image in pixels.
WIDTH	Long	The width of the tile(s) in pixels.
HEIGHT	Long	The height of the tile(s) in pixels.
LEVEL	Long	The data resolution, where 0 is the full resolution image. A value of n ($n > 0$) indicates that the resolution is half that of the n-1 level.
DEST	OBJREF	The object reference to the destination object that displays the tiled IDLgrImage.

Table 32-9: IDLIMAGETILE Structure

If a region of the image composed of multiple tiles is being set, X, Y, WIDTH, and HEIGHT must be multiples of the tile size (unless the region extends to the edge of the image in which case Width and Height do not need to be a multiple of the tile size).

TileData

The data for the specified tile.

Keywords

NO_FREE

Set this keyword if the tile data should remain loaded for the lifetime of the
IDLgrImage, unless explicitly deleted by the DeleteTileData method. If the tile cache
fills up, IDLgrImage might automatically delete the least recently used tile data from
the cache to make room for new tile data. Setting this keyword prevents the
IDLgrImage from automatically deleting this tile data in this situation.

Version History

6.2	Introduced

IDLgrImage::TileDataLoaded

The IDLgrImage::TileDataLoaded function method tests whether a specified image tile has data loaded.

Syntax

Result = Obj->[IDLgrImage::]TileDataLoaded(*TileInfo)*

Return Value

Returns 1 (one) if the tile has data already loaded, or 0 (zero) otherwise.

Arguments

TileInfo

A named structure describing the tile to be queried. Only one tile at a time can be passed to TileDataLoaded. The structure contains the following fields:

Field	Data Type	Description
X	Long	The horizontal position of the left side of the tile(s) measured from the left of the image in pixels.
Y	Long	The vertical position of the bottom of the tile(s) measured from the bottom of the image in pixels.
WIDTH	Long	The width of the tile(s) in pixels.
HEIGHT	Long	The height of the tile(s) in pixels.
LEVEL	Long	The data resolution, where 0 is the full resolution image. A value of n ($n > 0$) indicates that the resolution is half that of the n-1 level.
DEST	OBJREF	The object reference to the destination object that displays the tiled IDLgrImage.

Table 32-10: IDLIMAGETILE Structure

Keywords

None.

Version History

6.4	Introduced

IDLgrLegend

The IDLgrLegend object provides a simple interface for displaying a legend. The legend itself consists of a (filled and/or framed) box around one or more legend items (arranged in a single column) and an optional title string. Each legend item consists of a glyph patch positioned to the left of a text string. The glyph patch is drawn in a square which is a fraction of the legend label font height. The glyph itself can be in one of two types (see the TYPE keyword). In line type, the glyph is a line segment with line style, thickness and color attributes and an optional symbol object drawn over it. In fill type, the glyph is a square patch drawn with color and optional pattern object attributes.

An IDLgrLegend object is a *composite object*; it is one of the basic drawable elements of the IDL Object Graphics system, and it is not a container for other objects.

This object class is implemented in the IDL language. Its source code can be found in the file `idlgrlegend_ _define.pro` in the `lib` subdirectory of the IDL distribution.

- ZRANGE

In addition, objects of this class inherit the properties of all superclasses of this class.

Methods

This class has the following methods:

- IDLgrLegend::Cleanup
- IDLgrLegend::ComputeDimensions

- IDLgrLegend::GetProperty
- IDLgrLegend::Init
- IDLgrLegend::SetProperty

In addition, this class inherits the methods of its superclasses (if any).

Version History

5.1	Introduced

IDLgrLegend Properties

IDLgrLegend objects have the following properties in addition to properties inherited from any superclasses. Properties with the word "Yes" in the "Get" column of the property table can be retrieved via IDLgrLegend::GetProperty. Properties with the word "Yes" in the "Init" column of the property table can be set via IDLgrLegend::Init. Properties with the word "Yes" in the "Set" column in the property table can be set via IDLgrLegend::SetProperty.

Note ———————————————————————————————————
For a discussion of the property description tables shown below, see "About Object Property Descriptions" on page 3135.

Objects of this class have the following properties.

- ALL
- BORDER_GAP
- COLUMNS
- FILL_COLOR
- FONT
- GAP
- GLYPH_WIDTH
- HIDE
- ITEM_COLOR
- ITEM_LINESTYLE
- ITEM_NAME
- ITEM_OBJECT
- ITEM_THICK
- ITEM_TYPE
- OUTLINE_COLOR
- OUTLINE_THICK
- PARENT
- RECOMPUTE

- SHOW_FILL
- SHOW_OUTLINE
- TEXT_COLOR
- TITLE
- XCOORD_CONV
- XRANGE
- YCOORD_CONV
- YRANGE
- ZCOORD_CONV
- ZRANGE

In addition, objects of this class inherit:

- IDLgrModel
- IDLitComponent

ALL

An anonymous structure containing the values of all of the retrievable properties associated with this object.

Property Type	Structure		
Name String	*not displayed*		
Get: Yes	**Set:** No	**Init:** No	**Registered:** No

BORDER_GAP

A floating-point value to indicate the amount of blank space to be placed around the outside of the glyphs and text items. The units for this property are fractions of the legend label font height. The default is 0.1 (10% of the label font height).

Property Type	Floating-point		
Name String	*not displayed*		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** No

COLUMNS

An integer value to indicate the number of columns the legend items should be displayed in. The default is one column.

Property Type	Integer		
Name String	*not displayed*		
Get: Yes	Set: Yes	Init: Yes	Registered: No

FILL_COLOR

The color to be used to fill the legend background box. The color may be specified as a color lookup table index or as a three-element vector [*red*, *green*, *blue*]. The default is [255,255,255].

Property Type	COLOR		
Name String	*not displayed*		
Get: Yes	Set: Yes	Init: Yes	Registered: No

FONT

An object reference to an instance of an IDLgrFont object class that describes the font to use to draw the legend labels. The default is 12 point Helvetica.

Note
If the default font is in use, retrieving the value of the FONT property (using the GetProperty method) will return a font object that will be destroyed when this legend object is destroyed, leaving a dangling object reference.

Note
Objects specified via this property are not automatically cleaned up when the IDLgrLegend object is destroyed.

Property Type	Object reference		
Name String	*not displayed*		
Get: Yes	Set: Yes	Init: Yes	Registered: No

GAP

A floating-point value that indicates the amount of blank space to be placed vertically between each legend item. The units for this property are fractions of the legend label font height. The default is 0.1 (10% of the label font height). The same gap is placed horizontally between the legend glyph and the legend text string.

Property Type	Floating-point		
Name String	*not displayed*		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** No

GLYPH_WIDTH

A floating-point value to indicate the width of the glyphs, measured as a fraction of the font height. The default is 0.8 (80% of the font height).

Property Type	Floating-point		
Name String	*not displayed*		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** No

HIDE

A Boolean value that indicates whether this object should be drawn:

- 0 = Draw graphic (the default)
- 1 = Do not draw graphic

Property Type	Boolean		
Name String	*not displayed*		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** No

ITEM_COLOR

An array of colors defining the color of each item. The array defines *M* different colors, and should be either of the form [3,*M*] or [*M*]. In the first case, the three

values are used as an RGB triplet, in the second case, the single value is used as a color index value. The default color is [0,0,0].

Property Type	Color array		
Name String	*not displayed*		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** No

ITEM_LINESTYLE

An integer array of integers defining the style of the line to be drawn if the TYPE property is set to zero. The array can be of the form [*M*] or [2,*M*]. The first form selects the linestyle for each legend item from the predefined defaults. To use a pre-defined line style, set this property equal to one of the following integer values:

0	Solid line (the default)
1	Dotted
2	Dashed
3	Dash dot
4	Dash dot dot dot
5	Long dash
6	No line drawn

The second form specifies the stippling pattern explicitly for each legend item (see the LINESTYLE property to IDLgrPolyline::Init for details).

Property Type	Integer array		
Name String	*not displayed*		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** No

ITEM_NAME

An string array representing the names of items in the legend.

Specifying this property is the same as specifying the optional *aItemNames* argument to the IDLgrLegend::Init method.

Property Type	String array		
Name String	*not displayed*		
Get: Yes	Set: Yes	Init: Yes	Registered: No

ITEM_OBJECT

An array of object references of type IDLgrSymbol or IDLgrPattern that represents the shapes of the items in the legend. A symbol object is drawn only if the TYPE property is set to zero. A pattern object is used when drawing the color patch if the TYPE property is set to one. The default object is the NULL object.

Note

If one or more IDlgrSymbol object references are provided, the SIZE property of those objects may be modified by this legend to suit its layout needs.

Note

Objects specified via this property are not automatically cleaned up when the IDLgrLegend object is destroyed.

Property Type	Object reference array		
Name String	*not displayed*		
Get: Yes	Set: Yes	Init: Yes	Registered: No

ITEM_THICK

A floating-point array of floating-point values that define the thickness of each item line, in points, where each element is a value between 1.0 and 10.0. Out-of-range values are quietly clamped to the allowed range. This property is only used if the TYPE property is set to zero. The default is 1.0 points.

Property Type	Floating-point		
Name String	*not displayed*		
Get: Yes	Set: Yes	Init: Yes	Registered: No

ITEM_TYPE

An integer array that defines the type of glyph to be displayed for each item:

- 0 = line type (the default)

- 1 = filled box type

Property Type	Integer array		
Name String	*not displayed*		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** No

OUTLINE_COLOR

The color to be used to draw the legend outline box. The color may be specified as a color lookup table index or as a three-element vector [*red*, *green*, *blue*]. The default is [0,0,0].

Property Type	Color		
Name String	*not displayed*		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** No

OUTLINE_THICK

A floating-point value between 1.0 and 10.0 that defines the thickness of the outline frame, in points. Out-of-range values are quietly clamped to the allowed range. The default is 1.0 points.

Property Type	Floating-point		
Name String	*not displayed*		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** No

PARENT

An object reference to the object that contains this legend.

Property Type	Object reference		
Name String	*not displayed*		
Get: Yes	**Set:** No	**Init:** No	**Registered:** No

RECOMPUTE

A Boolean value that determines whether to recompute the legend dimensions when the legend is redrawn.

- • 0 = Prevent IDL from recomputing legend dimensions (the default).

- • 1 = Recompute the legend dimensions when the legend is redrawn.

Property Type	Boolean		
Name String	*not displayed*		
Get: No	**Set:** Yes	**Init:** No	**Registered:** No

SHOW_FILL

A Boolean value that indicates whether the background should be filled with a color:

- • 0 = Do not fill background (the default)

- • 1 = Fill background

Property Type	Boolean		
Name String	*not displayed*		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** No

SHOW_OUTLINE

A Boolean value indicating whether the outline box should be displayed:

- 0 = Do not display outline (the default)

- 1 = Display outline

Property Type	Boolean		
Name String	*not displayed*		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** No

TEXT_COLOR

The color to be used to draw the legend item text. The color may be specified as a color lookup table index or as a three-element vector [*red*, *green*, *blue*]. The default is [0,0,0].

Property Type	Color		
Name String	*not displayed*		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** No

TITLE

An object reference to an instance of the IDLgrText object class to specify the title for the legend. The default is the null object, specifying that no title is drawn. The title will be centered at the top of the legend, even if the text object itself has an associated location.

Note

Objects specified via this property are not automatically cleaned up when the IDLgrLegend object is destroyed.

Property Type	Object reference		
Name String	*not displayed*		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** No

XCOORD_CONV

A floating-point vector, $[s_0, s_1]$, of scaling factors used to convert X coordinates from data units to normalized units. The formula for the conversion is as follows:

$$Normalized X = s_0 + s_1 * Data X$$

Recommended values are:

$$[(-X_{min})/(X_{max}-X_{min}), 1/(X_{max}-X_{min})]$$

The default is [0.0, 1.0]. IDL converts, maintains, and returns this data as double-precision floating-point.

Property Type	Floating-point vector		
Name String	*not displayed*		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** No

XRANGE

A two-element double-precision floating-point vector of the form [*xmin*, *xmax*] that specifies the range of the *X* data coordinates covered by the legend.

Property Type	Floating-point vector		
Name String	*not displayed*		
Get: Yes	**Set:** No	**Init:** No	**Registered:** No

YCOORD_CONV

A floating-point vector, $[s_0, s_1]$, of scaling factors that convert Y coordinates from data units to normalized units. The formula for the conversion is as follows:

$$Normalized Y = s_0 + s_1 * Data Y$$

Recommended values are:

$$[(-Y_{min})/(Y_{max}-Y_{min}), 1/(Y_{max}-Y_{min})]$$

The default is [0.0, 1.0]. IDL converts, maintains, and returns this data as double-precision floating-point.

Property Type	Floating-point vector		
Name String	*not displayed*		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** No

YRANGE

A two-element double-precision floating-point vector of the form [*ymin*, *ymax*] that specifies the range of the *Y* data coordinates covered by the legend.

Property Type	Floating-point vector		
Name String	*not displayed*		
Get: Yes	**Set:** No	**Init:** No	**Registered:** No

ZCOORD_CONV

A floating-point vector, [s_0, s_1], of scaling factors that convert Z coordinates from data units to normalized units. The formula for the conversion is as follows:

$$Normalized Z = s_0 + s_1 * Data Z$$

Recommended values are:

$$[(-Z_{min})/(Z_{max}-Z_{min}), 1/(Z_{max}-Z_{min})]$$

The default is [0.0, 1.0]. IDL converts, maintains, and returns this data as double-precision floating-point.

Property Type	Floating-point vector		
Name String	*not displayed*		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** No

ZRANGE

A two-element double-precision floating-point vector of the form [*zmin*, *zmax*] that specifies the range of the *Z* data coordinates covered by the legend.

Note

Until the legend is drawn to the destination object, the [XYZ]RANGE properties will be zero. Use the ComputeDimensions method on the legend object to get the data dimensions of the legend prior to a draw operation.

Property Type	Floating-point vector		
Name String	*not displayed*		
Get: Yes	**Set:** No	**Init:** No	**Registered:** No

IDLgrLegend::Cleanup

The IDLgrLegend::Cleanup procedure method performs all cleanup on the object.

Note ──

Cleanup methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation and destruction. This means that in most cases, you cannot call the Cleanup method directly. There is one exception to this rule: if you write your own subclass of this class, you can call the Cleanup method from within the Init or Cleanup method of the subclass.

──

Syntax

OBJ_DESTROY, *Obj*

or

Obj->[IDLgrLegend::]Cleanup   *(In a lifecycle method only.)*

Arguments

None

Keywords

None

Version History

5.1	Introduced

IDLgrLegend::ComputeDimensions

The IDLgrLegend::ComputeDimensions function method retrieves the dimensions of a legend object for the given destination object. In order to compute the effective dimensions, the object must be inserted into an object graphics hierarchy prior to using this method. The result is a three-element double-precision floating-point vector [*xDim, yDim, zDim*] representing the dimensions of the legend object measured in data units.

Syntax

Result = Obj->[IDLgrLegend::]ComputeDimensions(*DestinationObject*
   [, PATH=*objref(s)*])

Return Value

Returns the dimensions of a legend object for the given destination object.

Arguments

DestinationObject

The object reference to a destination object (IDLgrBuffer, IDLgrClipboard, IDLgrPrinter, or IDLgrWindow) for which the dimensions of the legend are being requested.

Keywords

PATH

Set this keyword to a single object reference or a vector of object references. This keyword specifies the path in the graphics hierarchy to compute the dimensions. Each path object reference specified with this keyword must contain an alias. The text dimensions are computed for the version of the object falling within that path. If this keyword is not set, the PARENT properties determine the path from the current object to the top of the graphics hierarchy and no alias paths are pursued. If IDLgrLegend::ComputeDimensions is called from within a Draw method and the PATH keyword is not set, the alias path used to find the object during the draw is used, rather than the PARENT path.

Note ——————————————————————————
For more information on aliases, refer to the ALIAS keyword in IDLgrModel::Add.
——————————————————————————————————

Version History

5.1	Introduced

IDLgrLegend::GetProperty

The IDLgrLegend::GetProperty procedure method retrieves the value of a property or group of properties for the legend.

Syntax

Obj->[IDLgrLegend::]GetProperty[, *PROPERTY=variable*]

Arguments

None

Keywords

Any property listed under "IDLgrLegend Properties" on page 4431 that contains the word "Yes" in the "Get" column of the properties table can be retrieved using this method. To retrieve the value of a property, specify the property name as a keyword set equal to a named variable that will contain the value of the property.

Any keyword not recognized is passed to this object's superclass.

Version History

5.1	Introduced

IDLgrLegend::Init

The IDLgrLegend::Init function method initializes the legend object.

Note
Init methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation. This means that in most cases, you cannot call the Init method directly. There is one exception to this rule: if you write your own subclass of this class, you can call the Init method from within the Init method of the subclass.

Syntax

Obj = OBJ_NEW('IDLgrLegend' [, *aItemNames*] [, *PROPERTY=value*])

or

Result = Obj->[IDLgrLegend::]Init([*aItemNames*] [, *PROPERTY=value*])   *(In a lifecycle method only.)*

Return Value

When this method is called indirectly, as part of the call to the OBJ_NEW function, the return value is an object reference to the newly-created object.

When called directly within a subclass Init method, the return value is 1 if initialization was successful, or zero otherwise.

Arguments

aItemNames

An array of strings to be used as the displayed item label. The length of this array is used to determine the number of items to be displayed. Each item is defined by taking one element from the ITEM_NAME, ITEM_TYPE, ITEM_LINESTYLE, ITEM_THICK, ITEM_COLOR, and ITEM_OBJECT vectors. If the number of items (as defined by the ITEM_NAME array) exceeds any of the attribute vectors, the attribute defaults will be used for any additional items.

Note
The value specified by the *aItemNames* argument is used to initialize the value of the ITEM_NAME property of the IDLgrLegend object.

Keywords

Any property listed under "IDLgrLegend Properties" on page 4431 that contains the word "Yes" in the "Init" column of the properties table can be initialized during object creation using this method. To initialize the value of a property, specify the property name as a keyword set equal to the appropriate property value.

All other keywords are passed to the superclass of this object.

Version History

5.1	Introduced

IDLgrLegend::SetProperty

The IDLgrLegend::SetProperty procedure method sets the value of a property or group of properties for the legend.

Syntax

Obj->[IDLgrLegend::]SetProperty[, *PROPERTY=value*]

Arguments

None

Keywords

Any property listed under "IDLgrLegend Properties" on page 4431 that contains the word "Yes" in the "Set" column of the properties table can be set using this method. To set the value of a property, specify the property name as a keyword set equal to the appropriate property value.

Version History

5.1	Introduced

IDLgrLight

A light object represents a source of illumination for three-dimensional graphic objects. Lights may be either ambient, positional, directional, or spotlights. The first 8 non-ambient type lights encountered in a scene are activated. Any additional non-ambient lights are ignored. Ambient lights do not count toward the limit of 8 active lights. However, an application should define only a single ambient light since only the last ambient light encountered in a scene will be used to define the ambient light properties. If a positional, directional or spotlight type of light is not explicitly created, the default light TYPE is ambient. Lights are not required for objects displayed in two dimensions.

An IDLgrLight object is an *atomic graphic object*; it is one of the basic drawable elements of the IDL Object Graphics system, and it is not a container for other objects.

Superclasses

IDLitComponent

Creation

See "IDLgrLight::Init" on page 4466.

Properties

Objects of this class have the following properties. See "IDLgrLight Properties" on page 4452 for details on individual properties.

- ALL
- ATTENUATION
- COLOR
- CONEANGLE
- DIRECTION
- FOCUS
- HIDE
- INTENSITY
- LIGHT_INDEX

- LOCATION
- PALETTE
- PARENT
- REGISTER_PROPERTIES
- SHADER
- TYPE
- XCOORD_CONV
- YCOORD_CONV
- ZCOORD_CONV

In addition, objects of this class inherit the properties of all superclasses of this class.

Methods

This class has the following methods:

- IDLgrLight::Cleanup
- IDLgrLight::GetCTM
- IDLgrLight::GetProperty
- IDLgrLight::Init
- IDLgrLight::SetProperty

In addition, this class inherits the methods of its superclasses (if any).

Version History

5.0	Introduced
6.4	Added LIGHT_INDEX, SHADER, properties

IDLgrLight Properties

IDLgrLight objects have the following properties in addition to properties inherited from any superclasses. Properties with the word "Yes" in the "Get" column of the property table can be retrieved via IDLgrLight::GetProperty. Properties with the word "Yes" in the "Init" column of the property table can be set via IDLgrLight::Init. Properties with the word "Yes" in the "Set" column in the property table can be set via IDLgrLight::SetProperty.

Note

For a discussion of the property description tables shown below, see "About Object Property Descriptions" on page 3135.

Objects of this class have the following properties.

- ALL
- ATTENUATION
- COLOR
- CONEANGLE
- DIRECTION
- FOCUS
- HIDE
- INTENSITY
- LIGHT_INDEX
- LOCATION
- PALETTE
- PARENT
- REGISTER_PROPERTIES
- SHADER
- TYPE
- XCOORD_CONV
- YCOORD_CONV
- ZCOORD_CONV

In addition, objects of this class inherit:

- IDLitComponent

ALL

An anonymous structure that contains the values of all of the properties associated with the *state* of this object. State information about the object includes things like color, range, tick direction, etc., but not image, vertex, or connectivity data, or user values.

Note —————————————————————————————————————
The fields of this structure may change in subsequent releases of IDL.

Note —————————————————————————————————————
This structure returns ALPHA_CHANNEL, CLIP_PLANES, DEPTH_TEST_DISABLE, DEPTH_TEST_FUNCTION, DEPTH_WRITE_DISABLE, and [XYZ]RANGE properties that are consistent with other graphic objects. However, these properties are not used by the IDLgrLight object.

Property Type	Structure		
Name String	*not displayed*		
Get: Yes	**Set:** No	**Init:** No	**Registered:** No

ATTENUATION

A 3-element floating-point vector of the form [constant, linear, quadratic] that describes the factor by which light intensity is to fall with respect to distance from the light source. ATTENUATION applies only to Positional and Spot lights, as specified by the TYPE property. The overall attenuation factor is computed as follows:

```
attenuation = 1/(constant + linear*distance +
quadratic*distance^2)
```

By default, the values are [1, 0, 0].

This property is registered as a user-defined property, but it is hidden by default.

Property Type	USERDEF		
Name String	Attenuation		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

COLOR

A three-element byte vector specifying the RGB color of the light. The default is [255, 255, 255], which is a white light. The color of a light is ignored when graphics are sent to graphics destinations using the Indexed color model, in which case light intensities are scaled into the range of colors available on the graphics destination.

In a property sheet, this property appears as a color property.

Property Type	COLOR		
Name String	Color		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

CONEANGLE

A floating-point value that specifies the angle (measured in degrees) of coverage for a spotlight. The default is 60.

Property Type	FLOAT		
Name String	Spotlight cone angle		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

DIRECTION

A three-element floating-point vector representing the direction in which a spotlight is to be pointed. The default is [0,0,-1].

Note
For directional lights, the light's parallel rays follow a vector beginning at the position specified by LOCATION and ending at [0, 0, 0].

This property is registered as a user-defined property, but it is hidden by default.

Property Type	USERDEF		
Name String	Spotlight direction		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** Yes

FOCUS

A floating-point value that describes the attenuation of intensity for spotlights as the distance from the center of the cone of coverage increases. This factor is used as an exponent to the cosine of the angle between the direction of the spotlight and the direction from the light to the vertex being lighted. The default is 0.0.

Property Type	FLOAT		
Name String	Spotlight attenuation		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** Yes

HIDE

A Boolean value or enumerated list item that indicates whether this light should be enabled:

Value	Property Sheet Value	Description
0	True	Enable light (the default)
1	False	Disable light

Note

If no lights are present in the view (or if all lights in the view are hidden), an ambient light will be provided by default.

Property Type	ENUMLIST		
Name String	Show		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** Yes

INTENSITY

A floating-point value between 0.0 (darkest) and 1.0 (brightest) that indicates the intensity of the light. The default is 1.0.

Property Type	FLOAT		
Name String	Intensity		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** Yes

LIGHT_INDEX

Use this property to allow a vertex shader program to identify individual light objects in a scene and to locate property information such as color or position associated with the light object. This property is only useful when the IDLgrShader object referenced by the SHADER property has a vertex shader program that does lighting calculations.

Set this property to a scaler integer between the values of -1 and 7, inclusive. If set to -1, IDL ignores this property. Otherwise, each light in a scene, up to the maximum number of 8, should have a unique index value. If any non-ambient light objects share LIGHT_INDEX property values, the object with a shared LIGHT_INDEX value encountered last in the scene deactivates all prior light objects with the same index value.

If you do not set this property, IDL automatically assigns an index value, but this value is unimportant unless you have a shader program performing lighting calculations. If your application is using a shader program, associate the light index with the OpenGL Shading Language (GLSL) light source. For example, if you set the LIGHT_INDEX property on an instance of a diffuse IDLgrLight object to the value of 3, the following GLSL shader language code retrieves the color of that light:

```
Vec4 diffuse_light_color = gl_LightSource[3].diffuse;
```

where `gl_LightSource` is a built-in GLSL uniform variable.

Note ──

IDL does not store ambient lights in the `gl_LightSource` table. In a GLSL shader program, retrieve the color of the IDL ambient light using uniform variable `gl_LightModelProperties.ambient`, the built-in GLSL ambient light uniform variable.

──

See Chapter 14, "Lighting Shaders" (*Object Programming*) for more information about accessing lights in a shader program.

Property Type	Integer		
Name String	*not displayed*		
Get: Yes	Set: Yes	Init: Yes	Registered: No

LOCATION

A floating-point vector of the form [*x, y, z*] describing the position of the light. By default, the position is [0, 0, 0]. IDL converts, maintains, and returns this data as double-precision floating-point.

This property is registered as a user-defined property, but it is hidden by default.

Property Type	USERDEF		
Name String	Location		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

PALETTE

An object reference to a palette object (an instance of the IDLgrPalette object class) that specifies the red, green, and blue values of the color lookup table to be associated with the image if it is an indexed color image. This property is ignored if the image is a greyscale or RGB image.

Note

This table is only used when the destination is an RGB model device. The Indexed color model writes the indices directly to the device. In order to ensure that these colors are used when the image is displayed, this palette must be copied to the graphics destination's palette for any graphics destination that uses the Indexed color model.

Note

Objects specified via this property are not automatically cleaned up when the IDLgrLight object is destroyed.

This property is registered as a user-defined property, but it is hidden by default.

Property Type	USERDEF		
Name String	Color palette		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

PARENT

An object reference to the object that contains this object.

Property Type	Object reference		
Name String	*not displayed*		
Get: Yes	Set: No	Init: No	Registered: No

REGISTER_PROPERTIES

A Boolean value that determines whether to register properties available for this object. If this property is set, all properties marked in this properties section as "Registered: Yes" will be registered for display in a property sheet. This property is useful mainly when creating iTools. By default, no properties are registered.

Property Type	Boolean		
Name String	*not displayed*		
Get: No	Set: No	Init: Yes	Registered: No

SHADER

An object reference to an IDLgrShader object (or an object containing IDLgrShader as a superclass).

Note ───
IDLgrLight ignores this property.
───

Property Type	Object reference		
Name String	*not displayed*		
Get: Yes	Set: Yes	Init: Yes	Registered: No

TYPE

An integer value or an enumerated list item that indicates the type of light. Valid values are:

Value	Property Sheet Value	Description
0	Ambient	An ambient light is a universal light source, which has no direction or position. An ambient light illuminates every surface in the scene equally, which means that no edges are made visible by contrast. Ambient lights control the overall brightness and color of the entire scene. If no value is specified for the TYPE property, an ambient light is created.
1	Positional	A positional light supplies divergent light rays, and will make the edges of surfaces visible by contrast if properly positioned. A positional light source can be located anywhere in the scene.
2	Directional	A directional light supplies parallel light rays. The effect is that of a positional light source located at an infinite distance from scene.
3	Spotlight	A spotlight illuminates only a specific area defined by the light's position, direction, and the cone angle, or angle which the spotlight covers

Property Type	ENUMLIST		
Name String	Type		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** Yes

XCOORD_CONV

A floating-point vector, $[s_0, s_1]$, of scaling factors that convert X coordinates from data units to normalized units. The formula for the conversion is as follows:

Normalized$X = s_0 + s_1 *$ Data$X$

Recommended values are:

$[(-X_{min})/(X_{max}-X_{min}), 1/(X_{max}-X_{min})]$

The default is [0.0, 1.0]. IDL converts, maintains, and returns this data as double-precision floating-point.

Property Type	Double-precision floating-point vector		
Name String	*not displayed*		
Get: Yes	Set: Yes	Init: Yes	Registered: No

YCOORD_CONV

A floating-point vector, $[s_0, s_1]$, of scaling factors that convert Y coordinates from data units to normalized units. The formula for the conversion is as follows:

Normalized$Y = s_0 + s_1 *$ Data$Y$

Recommended values are:

$[(-Y_{min})/(Y_{max}-Y_{min}), 1/(Y_{max}-Y_{min})]$

The default is [0.0, 1.0]. IDL converts, maintains, and returns this data as double-precision floating-point.

Property Type	Double-precision floating-point vector		
Name String	*not displayed*		
Get: Yes	Set: Yes	Init: Yes	Registered: No

ZCOORD_CONV

A floating-point vector, $[s_0, s_1]$, of scaling factors that convert Z coordinates from data units to normalized units. The formula for the conversion is as follows:

Normalized$Z = s_0 + s_1 *$ Data$Z$

Recommended values are:

$$[(-Z_{min})/(Z_{max}-Z_{min}), 1/(Z_{max}-Z_{min})]$$

The default is [0.0, 1.0]. IDL converts, maintains, and returns this data as double-precision floating-point.

Property Type	Double-precision floating-point vector		
Name String	*not displayed*		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** No

IDLgrLight::Cleanup

The IDLgrLight::Cleanup procedure method performs all cleanup on the object.

Note ──

Cleanup methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation and destruction. This means that in most cases, you cannot call the Cleanup method directly. There is one exception to this rule: if you write your own subclass of this class, you can call the Cleanup method from within the Init or Cleanup method of the subclass.

──

Syntax

OBJ_DESTROY, *Obj*

or

Obj->[IDLgrLight::]Cleanup   *(In a lifecycle method only.)*

Arguments

None

Keywords

None

Version History

5.0	Introduced

IDLgrLight::GetCTM

The IDLgrLight::GetCTM function method returns the 4-by-4 double-precision floating-point graphics transform matrix from the current object upward through the graphics tree.

Syntax

Result = Obj->[IDLgrLight::]GetCTM([, DESTINATION=*objref*]
  [, PATH=*objref(s)*] [, TOP=*objref to IDLgrModel object*])

Return Value

Returns the 4-by-4 double-precision floating-point graphics transform matrix from the current object upward through the graphics tree.

Arguments

None

Keywords

DESTINATION

Set this keyword to the object reference of a destination object to specify that the projection matrix for the View object in the current tree be included in the returned transformation matrix. The resulting matrix will transform a point in the data space of the object on which the GetCTM method is called into a normalized coordinate system (-1 to +1 in X, Y, and Z), relative to the View object that contains the light object.

PATH

Set this keyword to a single object reference or a vector of object references. This keyword specifies the path in the graphics hierarchy to compute the transformation matrix. Each path object reference specified with this keyword must contain an alias. The transformation matrix is computed for the version of the object falling within that path. If this keyword is not set, the PARENT properties determine the path from the current object to the top of the graphics hierarchy and no alias paths are pursued. If IDLgrLight::GetCTM is called from within a Draw method, with the DESTINATION keyword set and the PATH keyword not set, the alias path used to find the object during the draw is used, rather than the PARENT path.

Note
> For more information on aliases, refer to the ALIAS keyword in IDLgrModel::Add.

TOP

Set this keyword equal to the object reference to an IDLgrModel object to specify that the returned matrix accumulate from the object on which the GetCTM method is called up to but not including the specified model object.

Version History

5.0	Introduced

IDLgrLight::GetProperty

The IDLgrLight::GetProperty procedure method retrieves the value of a property or group of properties for the light.

Syntax

Obj->[IDLgrLight::]GetProperty[, *PROPERTY=variable*]

Arguments

None

Keywords

Any property listed under "IDLgrLight Properties" on page 4452 that contains the word "Yes" in the "Get" column of the properties table can be retrieved using this method. To retrieve the value of a property, specify the property name as a keyword set equal to a named variable that will contain the value of the property.

Any keyword not recognized is passed to this object's superclass.

Version History

5.0	Introduced

IDLgrLight::Init

The IDLgrLight::Init function method initializes the light object.

Note

Init methods are special *lifecycle methods*, and as such cannot be called outside the
context of object creation. This means that in most cases, you cannot call the Init
method directly. There is one exception to this rule: if you write your own subclass
of this class, you can call the Init method from within the Init method of the
subclass.

Syntax

Obj = OBJ_NEW('IDLgrLight' [, *PROPERTY=value*])

or

Result = Obj->[IDLgrLight::]Init([, *PROPERTY=value*])   *(In a lifecycle method
    only.)*

Return Value

When this method is called indirectly, as part of the call to the OBJ_NEW function,
the return value is an object reference to the newly-created object.

When called directly within a subclass Init method, the return value is 1 if
initialization was successful, or zero otherwise.

Arguments

None

Keywords

Any property listed under "IDLgrLight Properties" on page 4452 that contains the
word "Yes" in the "Init" column of the properties table can be initialized during
object creation using this method. To initialize the value of a property, specify the
property name as a keyword set equal to the appropriate property value.

All other keywords are passed to the superclass of this object.

Version History

5.0	Introduced

IDLgrLight::SetProperty

The IDLgrLight::SetProperty procedure method sets the value of a property or group of properties for the light.

Syntax

Obj->[IDLgrLight::]SetProperty[, *PROPERTY=value*]

Arguments

None

Keywords

Any property listed under "IDLgrLight Properties" on page 4452 that contains the word "Yes" in the "Set" column of the properties table can be set using this method. To set the value of a property, specify the property name as a keyword set equal to the appropriate property value.

Version History

5.0	Introduced

IDLgrModel

A model object represents a graphical item or group of items that can be transformed (rotated, scaled, and/or translated). It serves as a container of other IDLgrModel objects or atomic graphic objects. IDLgrModel applies a transform to the current view tree.

Superclasses

IDL_Container

IDLitComponent

Creation

See "IDLgrModel::Init" on page 4487.

Properties

Objects of this class have the following properties. See "IDLgrModel Properties" on page 4471 for details on individual properties.

- ACTIVE_POSITION
- ALL
- CLIP_PLANES
- DEPTH_TEST_DISABLE
- DEPTH_TEST_FUNCTION
- DEPTH_WRITE_DISABLE
- HIDE
- LIGHTING
- PARENT
- REGISTER_PROPERTIES
- RENDER_METHOD
- SELECT_TARGET
- TRANSFORM

In addition, objects of this class inherit the properties of all superclasses of this class.

Methods

This class has this following methods:

- IDLgrModel::Add
- IDLgrModel::Cleanup
- IDLgrModel::Draw
- IDLgrModel::GetByName
- IDLgrModel::GetCTM
- IDLgrModel::GetProperty
- IDLgrModel::Init
- IDLgrModel::Reset
- IDLgrModel::Rotate
- IDLgrModel::Scale
- IDLgrModel::SetProperty
- IDLgrModel::Translate

In addition, this class inherits the methods of its superclasses (if any).

Version History

5.0	Introduced
5.6	Added CLIP_PLANES property
6.2	Added ACTIVE_POSITION, RENDER_METHOD properties

See Also

"Translating, Rotating and Scaling Objects" (Chapter 3, *Object Programming*)

IDLgrModel Properties

IDLgrModel objects have the following properties in addition to properties inherited from any superclasses. Properties with the word "Yes" in the "Get" column of the property table can be retrieved via IDLgrModel::GetProperty. Properties with the word "Yes" in the "Init" column of the property table can be set via IDLgrModel::Init. Properties with the word "Yes" in the "Set" column in the property table can be set via IDLgrModel::SetProperty.

Note ———
For a discussion of the property description tables shown below, see "About Object Property Descriptions" on page 3135.
——

Objects of this class have the following properties.

- ACTIVE_POSITION
- ALL
- CLIP_PLANES
- DEPTH_TEST_DISABLE
- DEPTH_TEST_FUNCTION
- DEPTH_WRITE_DISABLE
- HIDE
- LIGHTING
- PARENT
- REGISTER_PROPERTIES
- RENDER_METHOD
- SELECT_TARGET
- TRANSFORM

In addition, objects of this class inherit:

- IDL_Container
- IDLitComponent

ACTIVE_POSITION

This scalar integer property is a zero-based index into the model container. It indicates the container index of the object that is drawn by this model when the value of the RENDER_METHOD property is 1.

This property is ignored when the value of the RENDER_METHOD property is not 1.

The default value of this property is 0, indicating the first object in the container.

If this property specifies an index that does not refer to a valid container index, this model object draws nothing when the value of the RENDER_METHOD property is 1. This can happen when the value of the ACTIVE_POSITION property is less than zero, or greater than or equal to the number of objects currently in the container.

This property is registered as an integer, but it is hidden by default.

Property Type	INTEGER		
Name String	Active position		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

ALL

An anonymous structure containing the values of all of the properties associated with this object.

Note

The fields of this structure may change in subsequent releases of IDL.

Property Type	Structure		
Name String	*not displayed*		
Get: Yes	Set: No	Init: No	Registered: No

CLIP_PLANES

An 4-by-*N* floating-point array that specifies the coefficients of the clipping planes to be applied to this object. The four coefficients for each clipping plane are of the form [A, B ,C, D], where $Ax + By + Cz + D = 0$.

Portions of this object that fall in the half space $Ax + By + Cz + D > 0$ will be clipped. By default, the value of this property is a scalar (-1) indicating that no clipping planes are to be applied.

Note ———

The clipping planes specified via this property are applied in addition to the near and far clipping planes associated with the IDLgrView in which this object appears.

Note ———

Note - Clipping planes are applied in the data space of the objects this model contains (prior to the application of this model's transform).

Note ———

To determine the maximum number of clipping planes supported by the device, use the MAX_NUM_CLIP_PLANES property of the GetDeviceInfo method for the IDLgrBuffer, IDLgrClipboard, IDLgrWindow, and IDLgrVRML objects.

This property is registered as a user-defined property, but it is hidden by default.

Property Type	USERDEF		
Name String	Clipping planes		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** Yes

DEPTH_TEST_DISABLE

An integer value that determines whether depth testing is disabled.

- Set this property to 0 (the default) to inherit the value set by the parent model or view. The parent view always enables depth testing. A model may also enable or disable depth testing.

- Set this property to 1 to explicitly disable depth buffer testing while drawing this object.

- Set this property to 2 to explicitly enable depth testing for this object.

Disabling depth testing allows an object to draw itself on top of other objects already on the screen, even if the object is located behind them.

This property is registered as an enumerated list, but it is hidden by default.

Property Type	ENUMLIST		
Name String	Depth Test Disable		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

DEPTH_TEST_FUNCTION

An integer value that determines the depth test function. Set this property to 0 (the default) to inherit the value set by the parent model or view. The parent view always sets a depth test function of LESS. A model may also set a depth test function value. The graphics device compares the object's depth at a particular pixel location with the depth stored in the depth buffer at that same pixel location. If the comparison test passes, the object's pixel is drawn at that location on the screen and the depth buffer is updated (if depth writing is enabled).

Set this property to any of the following values to use the desired function while rendering this object.

- 0 = INHERIT - use value from parent model or view.

- 1 = NEVER - never passes.

- 2 = LESS - passes if the object's depth is less than the depth buffer's value.

- 3 = EQUAL - passes if the object's depth is equal to the depth buffer's value.

- 4 = LESS OR EQUAL - passes if the object's depth is less than or equal to the depth buffer's value.

- 5 = GREATER - passes if the object's depth is greater than or equal to the depth buffer's value.

- 6 = NOT EQUAL - passes if the object's depth is not equal to the depth buffer's value.

- 7 = GREATER OR EQUAL - passes if the object's depth is greater than or equal to the depth buffer's value.

- 8 = ALWAYS - always passes

Less means closer to the viewer.

This property is registered as an enumerated list, but it is hidden by default.

Property Type	ENUMLIST		
Name String	Depth Test Enable		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

DEPTH_WRITE_DISABLE

An integer value that determines whether depth writing is disabled.

- Set this property to 0 (the default) to inherit the value set by the parent model or view. The parent view always enables depth writing. A model may also enable or disable depth writing.

- Set this property to 1 to explicitly disable depth buffer writing while rendering this object.

- Set this property to 2 to explicitly enable depth writing for this object.

Disabling depth writing allows an object to be overdrawn by other objects, even if the object is located in front of them.

This property is registered as an enumerated list, but it is hidden by default.

Property Type	ENUMLIST		
Name String	Depth Write Disable		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

HIDE

A Boolean value or an enumerated list item indicating whether this object should be drawn:

Value	Property Sheet Value	Description
0	True	Draw the model and children (the default)
1	False	Do not draw the model or children

Note ——————————————————————————————————————

HIDE only controls the display attributes of IDLgrModel children since the
IDLgrModel object itself lacks geometry.

Property Type	ENUMLIST		
Name String	Show		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** Yes

LIGHTING

An integer value that indicates whether lighting is to be enabled or disabled for all
atomic graphic objects that have this model as a parent. IDLgrModel objects that
have this model as a parent will not be effected, as they have their own value for this
property. If this value is set to 0, any lights added as children of this model will be
used to illuminate any other models in the view hierarchy that have lighting enabled.

- 0 = Disable lighting

- 1 = Enable single-sided lighting

- 2 = Enable double-sided lighting (the default)

This property is registered as an enumerated list, but it is hidden by default.

Property Type	ENUMLIST		
Name String	Lighting		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** Yes

PARENT

An object reference to the object that contains this object.

Property Type	Object reference		
Name String	*not displayed*		
Get: Yes	**Set:** No	**Init:** No	**Registered:** No

REGISTER_PROPERTIES

A Boolean value that determines whether to register properties available for this object. If this property is set, all properties marked in this properties section as "Registered: Yes" will be registered for display in a property sheet. This property is useful mainly when creating iTools. By default, no properties are registered.

Property Type	Boolean		
Name String	*not displayed*		
Get: No	**Set:** No	**Init:** Yes	**Registered:** No

RENDER_METHOD

This scalar integer property specifies how this model object renders the objects in its container.

If this property is set to a value of 0, the default, the model object draws all objects in its container.

If this property is set to a value of 1, the model object draws only the object specified by the ACTIVE_POSITION property.

This property is registered as an enumerated list, but it is hidden by default.

Property Type	ENUMLIST		
Name String	Render method		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** Yes

See Chapter 10, "Animating Objects" (*Object Programming*) for more information on how to create animation displays when this property is set to 1.

SELECT_TARGET

A Boolean value that tags the model object as the target object to be returned when any object contained by the model is selected via the IDLgrWindow::Select method.

- 0 = Do not tag the model object as the target object (default).
- 1 = Tag the model object as the target object.

By default, an IDLgrModel object cannot be returned as the target of a SELECT operation since it contains no geometry.

This property is registered as a Boolean property, but it is hidden by default.

Property Type	Boolean		
Name String	Select target		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** Yes

TRANSFORM

A 4-by-4 floating-point transformation matrix to be applied to the object. This matrix will be multiplied by its parent's transformation matrix (if the parent has one). The default is the identity matrix. IDL converts, maintains, and returns this data as double-precision floating-point.

This property is registered as a user-defined property, but it is hidden by default.

Property Type	USERDEF		
Name String	Model transform		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** Yes

IDLgrModel::Add

The IDLgrModel::Add procedure method adds a child to this Model.

Syntax

Obj->[IDLgrModel::]Add, *Object* [, /ALIAS] [, POSITION=*index*]

Arguments

Object

An instance of an atomic graphic object or another model object to be added to the model object.

Keywords

ALIAS

Set this keyword to a nonzero value to indicate that an alias—rather than the object itself—is to be added to the model. With this keyword you can add the same object to multiple models without duplicating that object and its children. If this keyword is set, the PARENT keyword on the object being added will not change. Furthermore, if this keyword is set, the object being added will not be destroyed when the model is destroyed.

POSITION

Set this keyword equal to the zero-based index of the position within the container at which the new object should be placed.

Version History

5.0	Introduced

IDLgrModel::Cleanup

The IDLgrModel::Cleanup procedure method performs all cleanup on the object.

Note —————————————————————————

Cleanup methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation and destruction. This means that in most cases, you cannot call the Cleanup method directly. There is one exception to this rule: if you write your own subclass of this class, you can call the Cleanup method from within the Init or Cleanup method of the subclass.

Syntax

OBJ_DESTROY, *Obj*

or

Obj->[IDLgrModel::]Cleanup   *(In a lifecycle method only.)*

Arguments

None

Keywords

None

Version History

5.0	Introduced

IDLgrModel::Draw

The IDLgrModel::Draw procedure method draws the specified picture to the specified graphics destination. *This method is provided for purposes of sub-classing only, and is intended to be called only from the Draw method of a subclass of IDLgrModel.*

Note ——————————————————————————————————

Objects are drawn to the destination device in the order that they are added to the model, view, viewgroup, or scene object that contains them.

———

Syntax

Obj->[IDLgrModel::]Draw, *Destination, Picture*

Arguments

Destination

The destination object (IDLgrBuffer, IDLgrClipboard, IDLgrPrinter, or IDLgrWindow) to which the specified view object will be drawn.

Picture

The view (an instance of an IDLgrView object), viewgroup (an instance of an IDLgrViewgroup object), or scene (an instance of an IDLgrScene object) to be drawn.

Keywords

None

Version History

5.0	Introduced

IDLgrModel::GetByName

The IDLgrModel::GetByName function method finds contained objects by name and returns the object reference to the named object. If the named object is not found, the GetByName function returns a null object reference.

Note

The GetByName function does *not* perform a recursive search through the object hierarchy. If a fully qualified object name is not specified, only the contents of the current container object are inspected for the named object.

Syntax

Result = Obj->[IDLgrModel::]GetByName(*Name*)

Return Value

Returns the object reference to the named object or a null object reference.

Arguments

Name

A string containing the name of the object to be returned.

Object naming syntax is very much like the syntax of a UNIX file system. Objects contained by other objects can include the name of their parent object; this allows you to create a fully qualified name specification. For example, if object1 contains object2, which in turn contains object3, the string specifying the fully qualified object name of object3 would be 'object1/object2/object3'.

Object names are specified relative to the object on which the GetByName method is called. If used at the beginning of the name string, the / character represents the top of an object hierarchy. The string '..' represents the object one level "up" in the hierarchy.

Keywords

None

Version History

5.0	Introduced

IDLgrModel::GetCTM

The IDLgrModel::GetCTM function method returns the 4-by-4 double-precision floating-point graphics transform matrix from the current object upward through the graphics tree.

Syntax

Result = Obj->[IDLgrModel::]GetCTM([, DESTINATION=*objref*]
    [, PATH=*objref(s)*] [, TOP=*objref to IDLgrModel object*])

Return Value

Returns the 4-by-4 double-precision floating-point graphics transform matrix from the current object upward through the graphics tree.

Arguments

None

Keywords

DESTINATION

Set this keyword to the object reference of a destination object to specify that the projection matrix for the View object in the current tree be included in the returned transformation matrix. The resulting matrix will transform a point in the data space of the object on which the GetCTM method is called into a normalized coordinate system (-1 to +1 in X, Y, and Z), relative to the View object that contains the model object.

PATH

Set this keyword to a single object reference or a vector of object references. This keyword specifies the path in the graphics hierarchy to compute the transformation matrix. Each path object reference specified with this keyword must contain an alias. The transformation matrix is computed for the version of the object falling within that path. If this keyword is not set, the PARENT properties determine the path from the current object to the top of the graphics hierarchy and no alias paths are pursued. If IDLgrModel::GetCTM is called from within a Draw method, with the DESTINATION keyword set and the PATH keyword not set, the alias path used to find the object during the draw is used, rather than the PARENT path.

Note ——————————————————————
For more information on aliases, refer to the ALIAS keyword in IDLgrModel::Add.
——————————————————————————————————

TOP

Set this keyword equal to the object reference to an IDLgrModel object to specify
that the returned matrix accumulate from the object on which the GetCTM method is
called up to but not including the specified model object.

Version History

5.0	Introduced

IDLgrModel::GetProperty

The IDLgrModel::GetProperty procedure method retrieves the value of a property or group of properties for the model.

Syntax

Obj->[IDLgrModel::]GetProperty[, *PROPERTY=variable*]

Arguments

None

Keywords

Any property listed under "IDLgrModel Properties" on page 4471 that contains the word "Yes" in the "Get" column of the properties table can be retrieved using this method. To retrieve the value of a property, specify the property name as a keyword set equal to a named variable that will contain the value of the property.

Any keyword not recognized is passed to this object's superclass.

Version History

5.0	Introduced

IDLgrModel::Init

The IDLgrModel::Init procedure method initializes the model object.

Note ───────────────────────────────────

Init methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation. This means that in most cases, you cannot call the Init method directly. There is one exception to this rule: if you write your own subclass of this class, you can call the Init method from within the Init method of the subclass.

───────────────────────────────────────

Syntax

Obj = OBJ_NEW('IDLgrModel' [, *PROPERTY=value*])

or

Result = Obj->[IDLgrModel::]Init([, *PROPERTY=value*])   *(In a lifecycle method only.)*

Return Value

When this method is called indirectly, as part of the call to the OBJ_NEW function, the return value is an object reference to the newly-created object.

When called directly within a subclass Init method, the return value is 1 if initialization was successful, or zero otherwise.

Arguments

None

Keywords

Any property listed under "IDLgrModel Properties" on page 4471 that contains the word "Yes" in the "Init" column of the properties table can be initialized during object creation using this method. To initialize the value of a property, specify the property name as a keyword set equal to the appropriate property value.

All other keywords are passed to the superclass of this object.

Version History

5.0	Introduced

IDLgrModel::Reset

The IDLgrModel::Reset procedure method sets the current transform matrix for the model object to the identity matrix.

Note

Using this method is functionally identical to the following statement:

```
Obj->[IDLgrModel::]SetProperty, TRANSFORM=IDENTITY(4)
```

Syntax

Obj->[IDLgrModel::]Reset

Arguments

None

Keywords

None

Version History

5.0	Introduced

IDLgrModel::Rotate

The IDLgrModel::Rotate procedure method rotates the model about the specified axis by the specified angle. IDL computes and maintains the resulting transform matrix in double-precision floating-point.

Syntax

Obj->[IDLgrModel::]Rotate, *Axis, Angle* [, /PREMULTIPLY]

Arguments

Axis

A three-element vector of the form [*x*, *y*, *z*] describing the axis about which the model is to be rotated.

Angle

The angle (measured in degrees) by which the rotation is to occur.

Keywords

PREMULTIPLY

Set this keyword to cause the rotation matrix specified by *Axis* and *Angle* to be pre-multiplied to the model's transformation matrix. By default, the rotation matrix is post-multiplied.

Version History

5.0	Introduced

IDLgrModel::Scale

The IDLgrModel::Scale procedure method scales the model by the specified scaling factors. IDL computes and maintains the resulting transform matrix in double-precision floating-point.

Syntax

Obj->[IDLgrModel::]Scale, *Sx, Sy, Sz* [, /PREMULTIPLY]

Arguments

Sx, Sy, Sz

The scaling factors in the *x*, *y*, and *z* dimensions by which the model is to be scaled.

Keywords

PREMULTIPLY

Set this keyword to cause the scaling matrix specified by *Sx, Sy, Sz* to be pre-multiplied to the model's transformation matrix. By default, the scaling matrix is post-multiplied.

Version History

5.0	Introduced

IDLgrModel::SetProperty

The IDLgrModel::SetProperty procedure method sets the value of a property or group of properties for the model.

Syntax

Obj->[IDLgrModel::]SetProperty[, *PROPERTY=value*]

Arguments

None

Keywords

Any property listed under "IDLgrModel Properties" on page 4471 that contains the word "Yes" in the "Set" column of the properties table can be set using this method. To set the value of a property, specify the property name as a keyword set equal to the appropriate property value.

Version History

5.0	Introduced

IDLgrModel::Translate

The IDLgrModel::Translate procedure method translates the model by the specified translation offsets. IDL computes and maintains the resulting transform matrix in double-precision floating-point.

Syntax

Obj->[IDLgrModel::]Translate, *Tx, Ty, Tz* [, /PREMULTIPLY]

Arguments

Tx, Ty, Tz

The offsets in *X*, *Y*, and *Z*, respectively, by which the model is to be translated.

Keywords

PREMULTIPLY

Set this keyword to cause the translation matrix specified by *Tx, Ty, Tz* to be pre-multiplied to the model's transformation matrix. By default, the translation matrix is post-multiplied.

Version History

5.0	Introduced

IDLgrMPEG

An IDLgrMPEG object creates an MPEG movie file from an array of image frames.

Note
The MPEG standard does not allow movies with odd numbers of pixels to be created.

Note
MPEG support in IDL requires a special license. For more information, contact your ITT Visual Information Solutions sales representative or technical support.

Note
The IDLffMJPEG2000 object creates and reads Motion JPEG2000 (MJ2) files, and provides more functionality than the MPEG_* routines. Animations can consist of monochrome, RGB or multi-component frames that display individual components, tiles or regions. See "Overview of Motion JPEG2000" (Chapter 6, *Using IDL*) for more information.

Superclasses

IDLitComponent

Creation

See "IDLgrMPEG::Init" on page 4506.

Properties

Objects of this class have the following properties. See "IDLgrMPEG Properties" on page 4497 for details on individual properties.

- ALL
- BITRATE
- DIMENSIONS
- FILENAME
- FORMAT
- FRAME_RATE

- IFRAME_GAP
- INTERLACED
- MOTION_VEC_LENGTH
- QUALITY
- SCALE
- STATISTICS
- TEMP_DIRECTORY

In addition, objects of this class inherit the properties of all superclasses of this class.

Methods

This class has the following methods:

- IDLgrMPEG::Cleanup
- IDLgrMPEG::GetProperty
- IDLgrMPEG::Init
- IDLgrMPEG::Put
- IDLgrMPEG::Save
- IDLgrMPEG::SetProperty

In addition, this class inherits the methods of its superclasses (if any).

Examples

If you have a series of image objects (or simple image arrays), you can combine them into a single MPEG file using the IDLgrMPEG object.

```
PRO mpeg_example

    loops = 4
    increment = 32
    pulseLength = 100
    ;waitSeconds = .01

    ; Put the .MPG file into the system's /TMP directory
    filename = filepath('mpeg_example.mpg', /TMP)

    myDevice = !D.NAME
    SET_PLOT, 'z'
```

```
         DEVICE, SET_RESOLUTION=[500,400]
         mpegObj = OBJ_NEW('IDLgrMPEG')

         FOR i = 0, increment*loops DO BEGIN
            x = 2*!PI/pulseLength * INDGEN(100) + ( i MOD increment )
            PLOT, x, SIN(x), XRANGE=[0,increment], XSTYLE=1, $
               YRANGE=[-!PI/3, !PI/3]
            mpegObj->Put, TVRD(/ORDER)
            ;WAIT, waitSeconds
         ENDFOR

         mpegObj -> Save, FILENAME=filename
         SET_PLOT, myDevice
         PRINT, 'Done writing MPEG file ' + filename
      END
```

Version History

5.1	Introduced

IDLgrMPEG Properties

IDLgrMPEG objects have the following properties in addition to properties inherited from any superclasses. Properties with the word "Yes" in the "Get" column of the property table can be retrieved via IDLgrMPEG::GetProperty. Properties with the word "Yes" in the "Init" column of the property table can be set via IDLgrMPEG::Init. Properties with the word "Yes" in the "Set" column in the property table can be set via IDLgrMPEG::SetProperty.

Note ───

For a discussion of the property description tables shown below, see "About Object Property Descriptions" on page 3135.

───

Objects of this class have the following properties.

- ALL
- BITRATE
- DIMENSIONS
- FILENAME
- FORMAT
- FRAME_RATE
- IFRAME_GAP
- INTERLACED
- MOTION_VEC_LENGTH
- QUALITY
- SCALE
- STATISTICS
- TEMP_DIRECTORY

In addition, objects of this class inherit:

- IDLitComponent

ALL

An anonymous structure containing the values of all of the retrievable properties associated with this object.

Property Type	Structure		
Name String	*not displayed*		
Get: Yes	**Set:** No	**Init:** No	**Registered:** No

BITRATE

A double-precision floating-point value to specify the MPEG movie bit rate. Higher bit rates will create higher quality MPEGs but will increase file size. The following table describes the valid values:

MPEG Version	Range
MPEG 1	0.1 to 104857200.0
MPEG 2	0.1 to 429496729200.0

Table 32-11: BITRATE Value Range

Set this property to 0.0 (the default setting) to indicate that IDL should compute the BITRATE value based upon the value you have specified for the QUALITY property. The value of BITRATE returned by IDLgrMPEG::GetProperty is either the value computed by IDL from the QUALITY value or the last non-zero valid value stored in this property.

Note

Only use the BITRATE property if changing the QUALITY property value does not produce the desired results. It is highly recommended to set the BITRATE to at least several times the frame rate to avoid unusable MPEG files or file generation errors.

Property Type	Floating-point		
Name String	*not displayed*		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** No

DIMENSIONS

A two-element integer array specifying the dimensions (in pixels) of each of the images to be used as frames for the movie. If this property is not specified, the dimensions of the first image loaded will be used. Once IDLgrMPEG::Put has been called, this property can no longer be set.

Note

When creating MPEG files, you must be aware of the capabilities of the MPEG decoder you will be using to view it. Some decoders only support a limited set of sampling and bitrate parameters to normalize computational complexity, buffer size, and memory bandwidth.

FILENAME

A string that represents the name of the file in which the encoded MPEG sequence is to be stored. The default is `'idl.mpg'`.

Property Type	String		
Name String	*not displayed*		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** No

FORMAT

A Boolean value that specifies the type of MPEG encoding to use:

- 0 = MPEG1 (the default)

- 1 = MPEG2

Property Type	Boolean		
Name String	*not displayed*		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** No

FRAME_RATE

An integer value that specifies the frame rate used in creating the MPEG file:

Value	Descriptions
1	23.976 frames/sec: NTSC encapsulated film rate
2	24 frames/sec: Standard international film rate
3	25 frames/sec: PAL video frame rate
4	29.97 frames/sec: NTSC video frame rate
5	30 frames/sec: NTSC drop frame video frame rate (the default)
6	50 frames/sec: Double frame rate/progressive PAL
7	59.94 frames/sec: Double frame rate NTSC
8	60 frames/sec: Double frame rate NTSC drop frame video

Table 32-12: FRAME_RATE Values

Property Type	Integer		
Name String	*not displayed*		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** No

IFRAME_GAP

A positive integer value that specifies the number of frames between I frames to be created in the MPEG file. I frames are full-quality image frames that may have a number of predicted or interpolated frames between them.

Set this property to 0 (the default setting) to indicate that IDL should compute the IFRAME_GAP value based upon the value you have specified for the QUALITY property. The value of IFRAME_GAP returned by IDLgrMPEG::GetProperty is either the value computed by IDL from the QUALITY value or the last non-zero valid value stored in this property.

Note ───

Only use the IFRAME_GAP property if changing the QUALITY property value does not produce the desired results.

───

Property Type	Integer		
Name String	*not displayed*		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** No

INTERLACED

A Boolean value that indicates whether frames in the encoded MPEG file should be interlaced.

- 0 = Non-interlaced (the default)
- 1 = Interlaced

When interlacing is set, the video data is written to the file by writing the odd-numbered scan lines first, followed by the even-numbered scan lines. This format is used to provide smoother screen refreshing on slower display devices. You may need to generate an interlaced file if the intended playback device requires interlaced video data. Most modern MPEG playback devices can handle non-interlaced (progressive scan) video.

Property Type	Boolean		
Name String	*not displayed*		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** No

MOTION_VEC_LENGTH

An integer value that specifies the length of the motion vectors to be used to generate predictive frames. The following table describes the valid values:

Value	Description
1	Small motion vectors.
2	Medium motion vectors.
3	Large motion vectors.

Table 32-13: MOTION_VEC_LENGTH Values

0 (the default setting) indicates that IDL should compute the MOTION_VEC_LENGTH value based upon the value you have specified for the QUALITY property. The value of MOTION_VEC_LENGTH returned by IDLgrMPEG::GetProperty is either the value computed by IDL from the QUALITY value or the last non-zero value stored in this property.

Note ───
Only use the MOTION_VEC_LENGTH property if changing the QUALITY value does not produce the desired results.
───

Property Type	Integer		
Name String	*not displayed*		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** No

QUALITY

An integer value between 0 (low quality) and 100 (high quality), inclusive, that specifies the quality at which the MPEG stream is to be stored. Higher quality values result in lower rates of time compression and less motion prediction which provide higher quality MPEGs but with substantially larger file size. Lower quality factors may result in longer MPEG generation times. The default is 50.

Note ───
Since MPEG uses JPEG (lossy) compression, the original picture quality cannot be reproduced even when setting QUALITY to its highest setting.
───

Property Type	Integer		
Name String	*not displayed*		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** No

SCALE

A two-element floating-point vector, [*xscale*, *yscale*], indicating the scale factors to be stored with the MPEG file as hints for playback. The default is [1.0, 1.0],

indicating that the movie should be played back at the dimensions of the stored image frames.

Property Type	Floating-point vector		
Name String	*not displayed*		
Get: Yes	Set: Yes	Init: Yes	Registered: No

STATISTICS

A Boolean value that determines whether to save statistical information about MPEG encoding for the supplied image frames in a file when the IDLgrMPEG::Save method is called. The information will be saved in a file with a name that matches that specified by the FILENAME property, with the extension ".stat".

- 0 = Statistics are not saved (the default).

- 1 = Save statistics.

Property Type	Boolean		
Name String	*not displayed*		
Get: Yes	Set: Yes	Init: Yes	Registered: No

TEMP_DIRECTORY

A string value that specifies the directory in which to place temporary files while creating the MPEG movie file. The default value is platform specific.

Property Type	String		
Name String	*not displayed*		
Get: No	Set: No	Init: Yes	Registered: No

IDLgrMPEG::Cleanup

The IDLgrMPEG::Cleanup procedure method performs all cleanup on the object.

Note —————————————————————————————

Cleanup methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation and destruction. This means that in most cases, you cannot call the Cleanup method directly. There is one exception to this rule: if you write your own subclass of this class, you can call the Cleanup method from within the Init or Cleanup method of the subclass.

Syntax

OBJ_DESTROY, *Obj*

or

Obj->[IDLgrMPEG::]Cleanup   *(In a lifecycle method only.)*

Arguments

None

Keywords

None

Version History

5.1	Introduced

IDLgrMPEG::GetProperty

The IDLgrMPEG::GetProperty procedure method retrieves the value of a property or group of properties for the MPEG object.

Syntax

Obj->[IDLgrMPEG::]GetProperty[, *PROPERTY=variable*]

Arguments

None

Keywords

Any property listed under "IDLgrMPEG Properties" on page 4497 that contains the word "Yes" in the "Get" column of the properties table can be retrieved using this method. To retrieve the value of a property, specify the property name as a keyword set equal to a named variable that will contain the value of the property.

Any keyword not recognized is passed to this object's superclass.

Version History

5.1	Introduced

IDLgrMPEG::Init

The IDLgrMPEG::Init function method initializes the MPEG object.

Note

Init methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation. This means that in most cases, you cannot call the Init method directly. There is one exception to this rule: if you write your own subclass of this class, you can call the Init method from within the Init method of the subclass.

Note

MPEG support in IDL requires a special license. For more information, contact your ITT Visual Information Solutions sales representative or technical support.

Syntax

Obj = OBJ_NEW('IDLgrMPEG' [, *PROPERTY=value*])

or

Result = Obj->[IDLgrMPEG::]Init([, *PROPERTY=value*])   *(In a lifecycle method only.)*

Return Value

When this method is called indirectly, as part of the call to the OBJ_NEW function, the return value is an object reference to the newly-created object.

When called directly within a subclass Init method, the return value is 1 if initialization was successful, or zero otherwise.

Arguments

None

Keywords

Any property listed under "IDLgrMPEG Properties" on page 4497 that contains the word "Yes" in the "Init" column of the properties table can be initialized during object creation using this method. To initialize the value of a property, specify the property name as a keyword set equal to the appropriate property value.

All other keywords are passed to the superclass of this object.

Version History

5.1	Introduced

IDLgrMPEG::Put

The IDLgrMPEG::Put procedure method puts a given image into the MPEG sequence at the specified frame. Note that all images in a given MPEG movie must have matching dimensions. If no dimensions were explicitly specified when the MPEG object was initialized, the dimensions will be set according to the dimensions of the first image.

Syntax

Obj->[IDLgrMPEG::]Put, *Image*[, *Frame*]

Arguments

Image

An instance of an IDLgrImage object or a *m* x *n* or 3 x *m* x *n* array representing the image to be loaded at the given frame.

Frame

An integer specifying the index of the frame at which the image is to be added. Frame indices start at zero. If *Frame* is not supplied, the frame number used will be one more than the last frame that was put. Frame number need not be consecutive; in case of a gap in frame numbers, the frame before the gap is repeated to fill the space.

Keywords

None

Version History

5.1	Introduced

IDLgrMPEG::Save

The IDLgrMPEG::Save procedure method encodes and saves the MPEG sequence to the specified filename.

Note ───

The MPEG standard does not allow movies with odd numbers of pixels to be created.

───

Syntax

Obj->[IDLgrMPEG::]Save [, FILENAME=*string*]

Arguments

None

Keywords

FILENAME

Set this keyword to a string representing the name of the file in which the encoded MPEG sequence is to be stored. The default is idl.mpg.

Version History

5.1	Introduced
Pre 6.1	Deprecated CREATOR_TYPE keyword

For more information on deprecated features, see Appendix I, "Obsolete Features".

IDLgrMPEG::SetProperty

The IDLgrMPEG::SetProperty procedure method sets the value of a property or group of properties for the MPEG object.

Syntax

Obj->[IDLgrMPEG::]SetProperty[, *PROPERTY=value*]

Arguments

None

Keywords

Any property listed under "IDLgrMPEG Properties" on page 4497 that contains the word "Yes" in the "Set" column of the properties table can be set using this method. To set the value of a property, specify the property name as a keyword set equal to the appropriate property value.

Version History

5.1	Introduced

IDLgrPalette

A palette object represents a color lookup table that maps indices to red, green, and blue values.

Superclasses

None

Creation

See "IDLgrPalette::Init" on page 4527.

Properties

Objects of this class have the following properties. See "IDLgrPalette Properties" on page 4520 for details on individual properties.

- ALL
- BLUE_VALUES
- BOTTOM_STRETCH
- GAMMA
- GREEN_VALUES
- NAME
- N_COLORS
- RED_VALUES
- TOP_STRETCH
- UVALUE

In addition, objects of this class inherit the properties of all superclasses of this class.

Methods

This class has this following methods:

- IDLgrPalette::Cleanup
- IDLgrPalette::GetRGB

- IDLgrPalette::GetProperty
- IDLgrPalette::Init
- IDLgrPalette::LoadCT
- IDLgrPalette::NearestColor
- IDLgrPalette::SetRGB
- IDLgrPalette::SetProperty

In addition, this class inherits the methods of its superclasses (if any).

Examples

This section contains the following examples:

- — accesses the palette associated with an indexed image and passes the palette data to an IDLgrPalette object
- — loads a pre-defined color table into a palette object and then modifies this color table to highlight image features

Displaying Indexed Images with Object Graphics

An indexed image contains up to 256 colors, typically defined by a color table associated with the image. The value of each pixel relates to a color within the associated color table. Combinations of the primary colors (red, green, and blue) make up the colors within the color table. Most indexed images are stored as byte and therefore do not require scaling prior to display.

The following example imports an indexed image from the `avhrr.png` image file. This indexed image is a satellite photograph of the world. Complete the following steps for a detailed description of the process.

Example Code

See `displayindexedimage_object.pro` in the `examples/doc/objects` subdirectory of the IDL installation directory for code that duplicates this example. Run the example procedure by entering `displayindexedimage` at the IDL command prompt or view the file in an IDL Editor window by entering `displayindexedimage.pro`.

1. Determine the path to the `avhrr.png` file:

```
file = FILEPATH('avhrr.png', $
   SUBDIRECTORY = ['examples', 'data'])
```

2. Use QUERY_IMAGE to query the file to determine image parameters:

    ```
    queryStatus = QUERY_IMAGE(file, imageInfo)
    ```

3. Output the results of the file query:

    ```
    PRINT, 'Query Status = ', queryStatus
    HELP, imageInfo, /STRUCTURE
    ```

    The following text appears in the Output Log:

    ```
    Query Status =            1
    ** Structure <141d0b0>, 7 tags, length=36, refs=1:
       CHANNELS      LONG      1
       DIMENSIONS    LONG      Array[2]
       HAS_PALETTE   INT       1
       IMAGE_INDEX   LONG      0
       NUM_IMAGES    LONG      1
       PIXEL_TYPE    INT       1
       TYPE          STRING    'PNG'
    ```

4. Set the image size parameter from the query information:

    ```
    imageSize = imageInfo.dimensions
    ```

    The HAS_PALETTE tag has a value of 1. Thus, the image has a palette (color table), which is also contained within the file. The color table is made up of its three primary components (the red component, the green component, and the blue component).

5. Use READ_IMAGE to import the image and its associated color table from the file:

    ```
    image = READ_IMAGE(file, red, green, blue)
    ```

6. Initialize the display objects:

    ```
    oWindow = OBJ_NEW('IDLgrWindow', RETAIN = 2, $
       DIMENSIONS = imageSize, TITLE = 'An Indexed Image')
    oView = OBJ_NEW('IDLgrView', $
       VIEWPLANE_RECT = [0., 0., imageSize])
    oModel = OBJ_NEW('IDLgrModel')
    ```

7. Initialize the image's palette object:

    ```
    oPalette = OBJ_NEW('IDLgrPalette', red, green, blue)
    ```

8. Initialize the image object with the resulting palette object:

    ```
    oImage = OBJ_NEW('IDLgrImage', image, $
       PALETTE = oPalette)
    ```

9. Add the image object to the model, which is added to the view, then display the view in the window:

```
oModel -> Add, oImage
oView -> Add, oModel
oWindow -> Draw, oView
```

10. Use the colorbar object to display the associated color table in another window:

```
oCbWindow = OBJ_NEW('IDLgrWindow', RETAIN = 2, $
   DIMENSIONS = [256, 48], $
   TITLE = 'Original Color Table')
oCbView = OBJ_NEW('IDLgrView', $
   VIEWPLANE_RECT = [0., 0., 256., 48.])
oCbModel = OBJ_NEW('IDLgrModel')
oColorbar = OBJ_NEW('IDLgrColorbar', PALETTE = oPalette, $
   DIMENSIONS = [256, 16], SHOW_AXIS = 1)
oCbModel -> Add, oColorbar
oCbView -> Add, oCbModel
oCbWindow -> Draw, oCbView
```

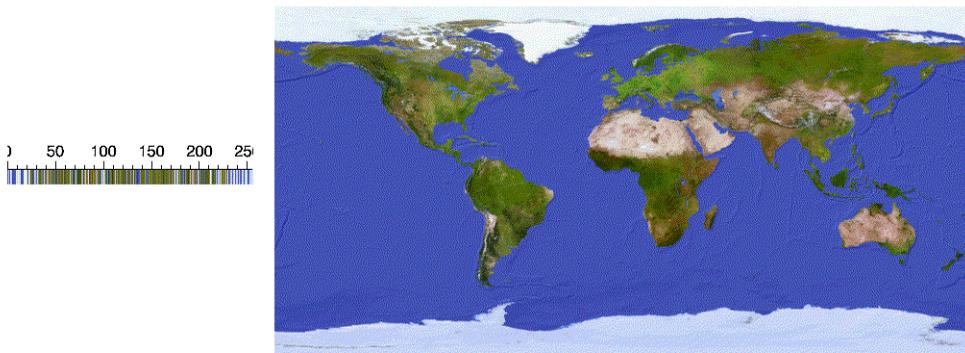
The following figure shows the resulting indexed image and its color table.


Figure 32-4: Indexed Image and Associated Color Table in Object Graphics

The data values within the image are indexed to specific colors within the table. You can change the color table associated with this image to show how an indexed image is dependent upon its related color tables.

11. Change the palette (color table) to the EOS B pre-defined color table:

```
oPalette -> LoadCT, 27
```

12. Redisplay the image in another window to show the palette change:

```
oWindow = OBJ_NEW('IDLgrWindow', RETAIN = 2, $
   DIMENSIONS = imageSize, TITLE = 'An Indexed Image')
oWindow -> Draw, oView
```

13. Redisplay the colorbar in another window to show the palette change:

```
oCbWindow = OBJ_NEW('IDLgrWindow', RETAIN = 2, $
   DIMENSIONS = [256, 48], $
   TITLE = 'EOS B Color Table')
oCbWindow -> Draw, oCbView
```

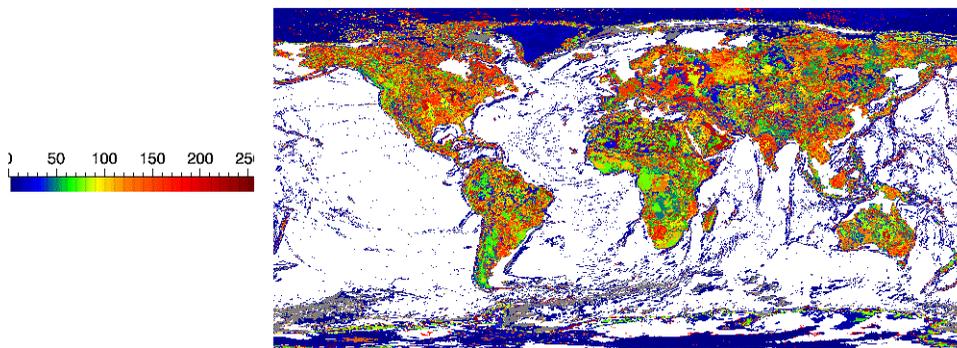
The following figure shows the indexed image with the EOS B color table.


Figure 32-5: Indexed Image and EOS B Color Table in Object Graphics

14. Clean up the object references. When working with objects always remember to clean up any object references with the OBJ_DESTROY routine. Since the view contains all the other objects, except for the window (which is destroyed by the user), you only need to use OBJ_DESTROY on the view object.

```
OBJ_DESTROY, [oView, oCbVeiw, oPalette]
```

Highlighting Features with Color in Object Graphics

This example shows how to create a color table to highlight image features using Object Graphics. Complete the following steps for a detailed description of the process.

Example Code

See `highlightfeatures_object.pro` in the `examples/doc/objects` subdirectory of the IDL installation directory for code that duplicates this example. Run the example procedure by entering `highlightfeatures_object` at the IDL command prompt or view the file in an IDL Editor window by entering `highlightfeatures_object.pro`.

1. Determine the path to the `mineral.png` file:

```
mineralFile = FILEPATH('mineral.png', $
    SUBDIRECTORY = ['examples', 'data'])
```

2. Import the image and its associated color table into IDL:

```
mineralImage = READ_PNG(mineralFile, red, green, blue)
```

3. Determine the size of the imported image:

```
mineralSize = SIZE(mineralImage, /DIMENSIONS)
```

4. Initialize objects necessary for a graphics display:

```
oWindow = OBJ_NEW('IDLgrWindow', RETAIN = 2, $
    DIMENSIONS = [mineralSize[0], mineralSize[1]], $
    TITLE = 'mineral.png')
oView = OBJ_NEW('IDLgrView', VIEWPLANE_RECT = [0., 0., $
    mineralSize[0], mineralSize[1]])
oModel = OBJ_NEW('IDLgrModel')
```

5. Initialize a palette object containing the image's associated color table and apply the palette to the image objects:

```
oPalette = OBJ_NEW('IDLgrPalette', red, green, blue)
oImage = OBJ_NEW('IDLgrImage', mineralImage, $
    PALETTE = oPalette)
```

The objects are then added to the view, which is displayed in the window.

6. Add the image to the model, then add the model to the view:

```
oModel -> Add, oImage
oView -> Add, oModel
```

Draw the view in the window:

```
oWindow -> Draw, oView
```

This scanning electron microscope image shows mineral deposits in a sample of polished granite and gneiss. The associated color table is a reverse grayscale.

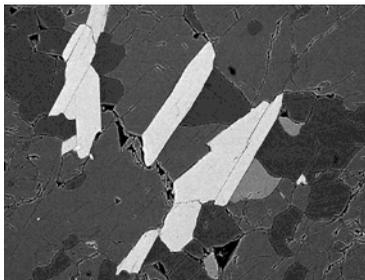
The following figure shows that the associated color table highlights the gneiss very well, but the other features are not very clear. The other features can be defined with IDL's pre-defined color table, RAINBOW.


Figure 32-6: Mineral Image and Default Color Table (Object Graphics)

The palette can easily be modified to show the RAINBOW pre-defined color table in another instance of the window object.

7. Update palette with RAINBOW color table and then display the image with this color table in another instance window of the window object:

```
oPalette -> LoadCT, 13
oWindow = OBJ_NEW('IDLgrWindow', RETAIN = 2, $
   DIMENSIONS = [mineralSize[0], mineralSize[1]], $
   TITLE = 'RAINBOW Color')
oWindow -> Draw, oView
```

The following figure shows that the yellow, cyan, and red sections are now apparent, but the cracks are no longer visible. Details within the yellow areas

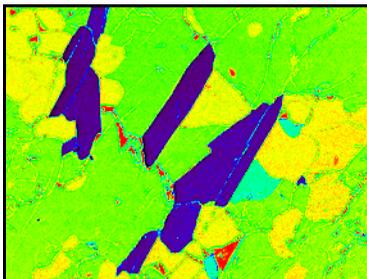
and the green background are also difficult to distinguish. These features can be highlighted by designing your own color table.


Figure 32-7: Mineral Image and RAINBOW Color Table (Object Graphics)

The features within the image are at specific ranges in between 0 and 255. Instead of a progressive color table, specific colors can be defined to be constant over these ranges. Any contrasting colors can be used, but the easiest to derive are the additive and subtractive primary colors used in the previous section.

8. Define colors for a new color table:

```
colorLevel = [[0, 0, 0], $ ; black
    [255, 0, 0], $ ; red
    [255, 255, 0], $ ; yellow
    [0, 255, 0], $ ; green
    [0, 255, 255], $ ; cyan
    [0, 0, 255], $ ; blue
    [255, 0, 255], $ ; magenta
    [255, 255, 255]] ; white
```

9. Create a new color table that contains eight levels, including the highest end boundary by first deriving levels for each color in the new color table:

```
numberOfLevels = CEIL(!D.TABLE_SIZE/8.)
level = INDGEN(!D.TABLE_SIZE)/numberOfLevels
```

10. Place each color level into its appropriate range.

```
newRed = colorLevel[0, level]
newGreen = colorLevel[1, level]
newBlue = colorLevel[2, level]
```

11. Include the last color in the last level:

```
newRed[!D.TABLE_SIZE - 1] = 255
```

```
newGreen[!D.TABLE_SIZE - 1] = 255
newBlue[!D.TABLE_SIZE - 1] = 255
```

12. Apply the new color table to the palette object:

```
oPalette -> SetProperty, RED_VALUES = newRed, $
    GREEN_VALUES = newGreen, BLUE_VALUES = newBlue
```

13. Display the image with this color table in another window:

```
oWindow = OBJ_NEW('IDLgrWindow', RETAIN = 2, $
    DIMENSIONS = [mineralSize[0], mineralSize[1]], $
    TITLE = 'Cube Corner Colors')
oWindow -> Draw, oView
```

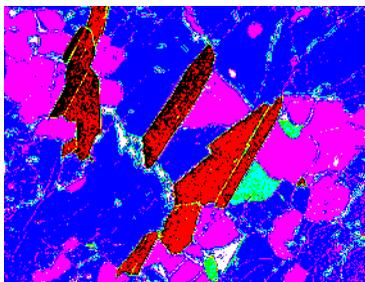
The following figure shows that each image feature is readily distinguishable.


Figure 32-8: Mineral Image and Derived Color Table (Object Graphics)

14. Clean up object references. When working with objects always remember to clean up any object references with the OBJ_DESTROY routine. Since the view contains all the other objects, except for the window (which is destroyed by the user), you only need to use OBJ_DESTROY on the view and the palette object:

```
OBJ_DESTROY, [oView, oPalette]
```

Version History

5.0	Introduced
6.2	Added UVALE and NAME properties

IDLgrPalette Properties

IDLgrPalette objects have the following properties in addition to properties inherited from any superclasses. Properties with the word "Yes" in the "Get" column of the property table can be retrieved via IDLgrPalette::GetProperty. Properties with the word "Yes" in the "Init" column of the property table can be set via IDLgrPalette::Init. Properties with the word "Yes" in the "Set" column in the property table can be set via IDLgrPalette::SetProperty.

Note

For a discussion of the property description tables shown below, see "About Object Property Descriptions" on page 3135.

Objects of this class have the following properties.

- ALL
- BLUE_VALUES
- BOTTOM_STRETCH
- GAMMA
- GREEN_VALUES
- NAME
- N_COLORS
- RED_VALUES
- TOP_STRETCH
- UVALUE

ALL

An anonymous structure that contains the values of all of the properties associated with the *state* of this object. State information about the object includes things like color, range, tick direction, etc., but not image, vertex, or connectivity data, or user values.

Note

The fields of this structure may change in subsequent releases of IDL.

Property Type	Structure		
Name String	*not displayed*		
Get: Yes	**Set:** No	**Init:** No	**Registered:** No

BLUE_VALUES

A byte vector containing the blue values for the color palette. Setting this value is the same as specifying the *aBlue* argument to the IDLgrPalette::Init method.

Property Type	Byte vector		
Name String	*not displayed*		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** No

BOTTOM_STRETCH

An integer value in the range of $0 \leq Value \leq 100$ to indicate what percentage of the palette entries at the bottom of the palette should be filled with the value of the first palette entry. The entire range of red, green, and blue values will be compressed to fit within the range of palette entries beginning at this entry and ending at the entry specified by the value of the TOP_STRETCH property. The default is 0 (zero).

Property Type	Integer		
Name String	*not displayed*		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** No

GAMMA

A floating-point value that indicates the gamma value to be applied to the color palette. This value should be in the range of $0.1 \leq Gamma \leq 10.0$. The default is 1.0.

Property Type	Floating-point		
Name String	*not displayed*		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** No

GREEN_VALUES

A byte vector containing the green values for the color palette. Setting this value is the same as specifying the *aGreen* argument to the IDLgrPalette::Init method.

Property Type	Byte-vector		
Name String	*not displayed*		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** No

NAME

A string giving the human-readable name of this object.

Property Type	STRING		
Name String	Name		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** No

N_COLORS

An integer value that determines the number of elements in the color palette.

Property Type	Integer		
Name String	*not displayed*		
Get: Yes	**Set:** No	**Init:** No	**Registered:** No

RED_VALUES

A byte vector containing the red values for the color palette. Setting this value is the same as specifying the *aRed* argument to the IDLgrPalette::Init method.

Property Type	Byte vector		
Name String	*not displayed*		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** No

TOP_STRETCH

A floating-point value in the range of $0 \le$ *Value* ≤ 100 to indicate what percentage of the palette entries at the top of the palette should be filled with the value of the last palette entry. The entire range of red, green, and blue values will be compressed to fit within the range of palette entries beginning at the entry specified by the value of the BOTTOM_STRETCH property and ending at this entry. The default is 0 (zero).

Property Type	Floating-point		
Name String	*not displayed*		
Get: Yes	Set: Yes	Init: Yes	Registered: No

UVALUE

A value of any type containing any information you wish.

Note ————————————————————————————————————

Object references or pointers contained in the UVALUE property are *not* automatically cleaned up when the IDLgrPalette object is destroyed.

Property Type	User Defined		
Name String	*not displayed*		
Get: Yes	Set: Yes	Init: Yes	Registered: No

IDLgrPalette::Cleanup

The IDLgrPalette::Cleanup procedure method performs all cleanup on the object.

Note ───

Cleanup methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation and destruction. This means that in most cases, you cannot call the Cleanup method directly. There is one exception to this rule: if you write your own subclass of this class, you can call the Cleanup method from within the Init or Cleanup method of the subclass.

───

Syntax

OBJ_DESTROY, *Obj*

or

Obj->[IDLgrPalette::]Cleanup   *(In a lifecycle method only.)*

Arguments

None

5.0	Introduced

IDLgrPalette::GetRGB

The IDLgrPalette::GetRGB function method returns the RGB values contained in the palette at the given index. The returned value is a three-element vector of the form [red, green, blue].

Syntax

Result = Obj->[IDLgrPalette::]GetRGB(*Index*)

Return Value

Returns the RGB values contained in the palette at the given index.

Arguments

Index

The index whose RGB values are desired. This value should be in the range of $0 \le Index <$ N_COLORS, where N_COLORS is the number of elements in the color palette, as returned by the N_COLORS keyword to the IDLgrPalette:GetProperty method.

Keywords

None

Version History

5.0	Introduced

IDLgrPalette::GetProperty

The IDLgrPalette::GetProperty procedure method retrieves the value of a property or group of properties for the palette.

Syntax

Obj->[IDLgrPalette::]GetProperty[, *PROPERTY=variable*]

Arguments

None

Keywords

Any property listed under "IDLgrPalette Properties" on page 4520 that contains the word "Yes" in the "Get" column of the properties table can be retrieved using this method. To retrieve the value of a property, specify the property name as a keyword set equal to a named variable that will contain the value of the property.

Any keyword not recognized is passed to this object's superclass.

Version History

5.0	Introduced

IDLgrPalette::Init

The IDLgrPalette::Init function method initializes a palette object.

Note

Init methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation. This means that in most cases, you cannot call the Init method directly. There is one exception to this rule: if you write your own subclass of this class, you can call the Init method from within the Init method of the subclass.

Syntax

Obj = OBJ_NEW('IDLgrPalette', *aRed*, *aGreen*, *aBlue* [, *PROPERTY=value*])

or

Result = Obj->[IDLgrPalette::]Init([*aRed*, *aGreen*, *aBlue*] [, *PROPERTY=value*])
    (In a lifecycle method only.)

Return Value

When this method is called indirectly, as part of the call to the OBJ_NEW function, the return value is an object reference to the newly-created object.

When called directly within a subclass Init method, the return value is 1 if initialization was successful, or zero otherwise.

Arguments

Note

The values specified by the *aRed*, *aGreen*, and *aBlue* arguments are used to initialize the value of the RED_VALUES, GREEN_VALUES, and BLUE_VALUES, properties of the IDLgrPalette object.

aRed

A vector containing the red values for the color palette. These values should be within the range of $0 \leq Value \leq 255$. The number of elements comprising the *aRed* vector must not exceed 256.

aGreen

A vector containing the green values for the color palette. These values should be within the range of $0 \leq \text{Value} \leq 255$. The number of elements comprising the *aGreen* vector must not exceed 256.

aBlue

A vector containing the blue values for the color palette. These values should be within the range of $0 \leq \text{Value} \leq 255$. The number of elements comprising the *aBlue* vector must not exceed 256.

Keywords

Any property listed under "IDLgrPalette Properties" on page 4520 that contains the word "Yes" in the "Init" column of the properties table can be initialized during object creation using this method. To initialize the value of a property, specify the property name as a keyword set equal to the appropriate property value.

All other keywords are passed to the superclass of this object.

Version History

5.0	Introduced

IDLgrPalette::LoadCT

The IDLgrPalette::LoadCT procedure method loads one of the IDL predefined color tables into an IDLgrPalette object.

Syntax

Obj->[IDLgrPalette::]LoadCT, *TableNum* [, FILE=*colortable filename*]

Arguments

TableNum

The number of the pre-defined IDL color table to load, from 0 to 40.

Keywords

FILE

Set this keyword to the name of a colortable file to be used instead of the file `colors1.tbl` in the IDL distribution. The MODIFYCT procedure can be used to create and modify colortable files.

Version History

5.0	Introduced

IDLgrPalette::NearestColor

The IDLgrPalette::NearestColor function method returns the index of the color in the palette that best matches the given RGB values.

Syntax

Result = Obj->[IDLgrPalette::]NearestColor(*Red*, *Green*, *Blue*)

Return Value

Returns the index of the color in the palette that best matches the given RGB values.

Arguments

Red

The red value of the color that should be matched. This value should be within the range of $0 \leq \text{Value} \leq 255$.

Green

The green value of the color that should be matched. This value should be within the range of $0 \leq \text{Value} \leq 255$.

Blue

The blue value of the color that should be matched. This value should be within the range of $0 \leq \text{Value} \leq 255$.

Keywords

None

Version History

5.0	Introduced

IDLgrPalette::SetRGB

The IDLgrPalette::SetRGB procedure method sets the color values at a specified index in the palette to the specified Red, Green and Blue values.

Syntax

Obj->[IDLgrPalette::]SetRGB, *Index*, *Red*, *Green*, *Blue*

Arguments

Index

The index within the Palette object to be set. This value should be in the range of 0 ≤ *Value* < N_COLORS.

Red

The red value to set in the color palette.

Green

The green value to set in the color palette.

Blue

The blue value to set in the color palette.

Keywords

None

Version History

5.0	Introduced

IDLgrPalette::SetProperty

The IDLgrPalette::SetProperty procedure method sets the value of a property or group of properties for the palette.

Syntax

Obj->[IDLgrPalette::]SetProperty[, *PROPERTY=value*]

Arguments

None

Keywords

Any property listed under "IDLgrPalette Properties" on page 4520 that contains the word "Yes" in the "Set" column of the properties table can be set using this method. To set the value of a property, specify the property name as a keyword set equal to the appropriate property value.

Version History

5.0	Introduced

IDLgrPattern

A pattern object describes which pixels are filled and which are left blank when an area is filled. Pattern objects are used by setting the FILL_PATTERN property of a polygon object equal to the object reference of the pattern object.

Superclasses

None

Creation

See "IDLgrPattern::Init" on page 4541.

Properties

Objects of this class have the following properties. See "IDLgrPattern Properties" on page 4535 for details on individual properties.

- ALL
- NAME
- ORIENTATION
- PATTERN
- SPACING
- STYLE
- THICK
- UVALUE

Methods

This class has this following methods:

- IDLgrPattern::Cleanup
- IDLgrPattern::GetProperty
- IDLgrPattern::Init
- IDLgrPattern::SetProperty

In addition, this class inherits the methods of its superclasses (if any).

Version History

5.0	Introduced
6.2	Added UVALUE and NAME properties

IDLgrPattern Properties

IDLgrPattern objects have the following properties. Properties with the word "Yes" in the "Get" column of the property table can be retrieved via IDLgrPattern::GetProperty. Properties with the word "Yes" in the "Init" column of the property table can be set via IDLgrPattern::Init. Properties with the word "Yes" in the "Set" column in the property table can be set via IDLgrPattern::SetProperty.

Note ———————————————————————————————————————

For a discussion of the property description tables shown below, see "About Object Property Descriptions" on page 3135.

——

Objects of this class have the following properties.

- ALL
- NAME
- ORIENTATION
- PATTERN
- SPACING
- STYLE
- THICK
- UVALUE

ALL

An anonymous structure containing the values of all of the properties associated with the *state* of this object. State information about the object includes things like color, range, tick direction, etc., but not image, vertex, or connectivity data, or user values.

Note ———————————————————————————————————————

The fields of this structure may change in subsequent releases of IDL.

——

Property Type	Structure		
Name String	*not displayed*		
Get: Yes	**Set:** No	**Init:** No	**Registered:** No

NAME

A string giving the human-readable name of this object.

Property Type	STRING		
Name String	Name		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** No

ORIENTATION

An integer representing the angle (measured in degrees counterclockwise from the horizontal) of the lines used in a Line Fill. This property is ignored unless the *Style* argument (or STYLE property) is set to one.

Property Type	Integer		
Name String	*not displayed*		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** No

PATTERN

A 32 x 32 bit array (bitmap) describing the pattern that will be tiled over a polygon when a pattern fill is used. The bitmap must be configured as a 4 x 32 "bitmap byte array" as created by the CVTTOBM function. Each bit that is a 1 is drawn, each bit that is 0 is not drawn. Each bit in this array represents a 1 point by 1 point square area of pixels on the destination device. This property is ignored unless the *Style* argument (or STYLE property) is set to 2.

Property Type	Integer array		
Name String	*not displayed*		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** No

SPACING

A floating-point value representing the distance (measured in points) between the lines used for a Line Fill. This property is ignored unless the *Style* argument (or STYLE property) is set to 1. The default is 2.0 points.

Property Type	Floating-point		
Name String	*not displayed*		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** No

STYLE

An integer value that specifies the type of pattern, as follows:

- 0 = Solid (default)
- 1 = Line Fill
- 2 = Pattern

Specifying this property is the same as specifying the optional *Style* argument to the IDLgrPattern::Init method.

Property Type	Integer		
Name String	*not displayed*		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** No

THICK

A floating-point value between 1.0 and 10.0 that specifies the line thickness to be used to draw the pattern lines for a Line Fill, in points. Out-of-range values are quietly clamped to the allowed range. The default is 1.0 points. This property is ignored unless the *Style* argument or STYLE property is set to 1.

Property Type	Floating-point		
Name String	*not displayed*		
Get: No	**Set:** No	**Init:** Yes	**Registered:** No

UVALUE

A value of any type containing any information you wish.

Note ——

Object references or pointers contained in the UVALUE property are *not* automatically cleaned up when the IDLgrPattern object is destroyed.

——

Property Type	User Defined		
Name String	*not displayed*		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** No

IDLgrPattern::Cleanup

The IDLgrPattern::Cleanup procedure method performs all cleanup on the object.

Note —————————————————————————

Cleanup methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation and destruction. This means that in most cases, you cannot call the Cleanup method directly. There is one exception to this rule: if you write your own subclass of this class, you can call the Cleanup method from within the Init or Cleanup method of the subclass.

Syntax

OBJ_DESTROY, *Obj*

or

Obj->[IDLgrPattern::]Cleanup   *(In a lifecycle method only.)*

Arguments

None

Keywords

None

Version History

5.0	Introduced

IDLgrPattern::GetProperty

The IDLgrPattern::GetProperty procedure method retrieves the value of a property or group of properties for the pattern.

Syntax

Obj->[IDLgrPattern::]GetProperty[, *PROPERTY=variable*]

Arguments

None

Keywords

Any property listed under "IDLgrPattern Properties" on page 4535 that contains the word "Yes" in the "Get" column of the properties table can be retrieved using this method. To retrieve the value of a property, specify the property name as a keyword set equal to a named variable that will contain the value of the property.

Version History

5.0	Introduced

IDLgrPattern::Init

The IDLgrPattern::Init function method initializes the pattern object.

Note ───

Init methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation. This means that in most cases, you cannot call the Init method directly. There is one exception to this rule: if you write your own subclass of this class, you can call the Init method from within the Init method of the subclass.

───

Syntax

Obj = OBJ_NEW('IDLgrPattern' [, *Style*] [, *PROPERTY=value*])

or

Result = Obj->[IDLgrPattern::]Init([*Style*] [, *PROPERTY=value*])   *(In a lifecycle method only.)*

Return Value

When this method is called indirectly, as part of the call to the OBJ_NEW function, the return value is an object reference to the newly-created object.

When called directly within a subclass Init method, the return value is 1 if initialization was successful, or zero otherwise.

Arguments

Style

A integer value representing the type of pattern. Valid values are:

- 0 = Solid color (default)
- 1 = Line Fill
- 2 = Pattern

Note ───

The value specified by the *Style* argument is used to initialize the value of the STYLE property of the IDLgrPattern object.

───

Keywords

Any property listed under "IDLgrPattern Properties" on page 4535 that contains the word "Yes" in the "Init" column of the properties table can be initialized during object creation using this method. To initialize the value of a property, specify the property name as a keyword set equal to the appropriate property value.

Version History

5.0	Introduced

IDLgrPattern::SetProperty

The IDLgrPattern::SetProperty procedure method sets the value of a property or group of properties for the pattern.

Syntax

Obj->[IDLgrPattern::]SetProperty[, *PROPERTY=value*]

Arguments

None

Keywords

Any property listed under "IDLgrPattern Properties" on page 4535 that contains the word "Yes" in the "Set" column of the properties table can be set using this method. To set the value of a property, specify the property name as a keyword set equal to the appropriate property value.

Version History

5.0	Introduced

IDLgrPlot

A plot object creates a set of polylines connecting data points in two-dimensional space.

An IDLgrPlot object is an *atomic graphic object*; it is one of the basic drawable elements of the IDL Object Graphics system, and it is not a container for other objects.

Note
See IDLgrAxis for information on configuring plot axes.

Superclasses

IDLitComponent

Creation

See "IDLgrPlot::Init" on page 4569.

Properties

Objects of this class have the following properties. See "IDLgrPlot Properties" on page 4546 for details on individual properties.

- ALL
- CLIP_PLANES
- DATA
- DATAY
- DEPTH_TEST_FUNCTION
- DOUBLE
- HISTOGRAM
- MAX_VALUE
- NSUM
- PARENT
- REGISTER_PROPERTIES

- ALPHA_CHANNEL
- COLOR
- DATAX
- DEPTH_TEST_DISABLE
- DEPTH_WRITE_DISABLE
- HIDE
- LINESTYLE
- MIN_VALUE
- PALETTE
- POLAR
- RESET_DATA

- SHADER
- SYMBOL
- USE_ZVALUE
- XCOORD_CONV
- YCOORD_CONV
- ZCOORD_CONV
- ZVALUE

- SHARE_DATA
- THICK
- VERT_COLORS
- XRANGE
- YRANGE
- ZRANGE

In addition, objects of this class inherit the properties of all superclasses of this class.

Methods

This class has the following methods:

- IDLgrPlot::Cleanup
- IDLgrPlot::GetCTM
- IDLgrPlot::GetProperty
- IDLgrPlot::GetVertexAttributeData
- IDLgrPlot::Init
- IDLgrPlot::SetProperty
- IDLgrPlot::SetVertexAttributeData

In addition, this class inherits the methods of its superclasses (if any).

Version History

5.0	Introduced
5.6	Added CLIP_PLANES property
6.1	Added ALPHA_CHANNEL property
6.4	Added SHADER property
	Added GetVertexAttributeData, SetVertexAttributeData methods

IDLgrPlot Properties

IDLgrPlot objects have the following properties in addition to properties inherited
from any superclasses. Properties with the word "Yes" in the "Get" column of the
property table can be retrieved via IDLgrPlot::GetProperty. Properties with the word
"Yes" in the "Init" column of the property table can be set via IDLgrPlot::Init.
Properties with the word "Yes" in the "Set" column in the property table can be set
via IDLgrPlot::SetProperty.

Note
For a discussion of the property description tables shown below, see "About Object
Property Descriptions" on page 3135.

Objects of this class have the following properties. See "IDLgrPlot Properties" on
page 4546 for details on individual properties.

- ALL
- ALPHA_CHANNEL
- CLIP_PLANES
- COLOR
- DATA
- DATAX
- DATAY
- DEPTH_TEST_DISABLE

- XCOORD_CONV
- XRANGE
- YCOORD_CONV
- YRANGE

- ZCOORD_CONV
- ZVALUE
- ZRANGE

In addition, objects of this class inherit:

- IDLitComponent

ALL

An anonymous structure containing the values of all of the properties associated with the *state* of this object. State information about the object includes things like color, range, tick direction, etc., but not image, vertex, or connectivity data, or user values.

Note —————————————————————————————————————

The fields of this structure may change in subsequent releases of IDL.

——

Property Type	Structure		
Name String	*not displayed*		
Get: Yes	**Set:** No	**Init:** No	**Registered:** No

ALPHA_CHANNEL

A floating-point value in the range [0.0, 1.0] to specify the opacity of the plot. The default value of 1.0 causes IDL to draw the plot completely opaque. If the value of this property is less than 1.0, then the pixels of the plot are blended with the pixels already on the screen, where the color of the plot is multiplied by the alpha value and the pixels already on the screen are multiplied by 1.0-alpha. Because an object can only be blended with objects already drawn on the screen, the drawing order of the objects must be considered carefully in order to obtain the desired results.

This property has no effect on devices using indexed color mode. If 3-channel (RGB) VERT_COLORS are supplied, then the value of this property is used for the alpha at each vertex when drawing the plot line. If 4-channel (RGBA) VERT_COLORS are supplied, then the alpha from each vertex color is used for the alpha at each vertex when drawing the plot line.

When a plot is drawn with symbols, the symbol's color and alpha values are always used to draw the symbols unless VERT_COLORS are supplied. If the VERT_COLORS are RGB, then the alpha value of the symbol is used to draw the

symbol. If the VERT_COLORS are RGBA, then the alpha from the vertex color is used to draw the symbol.

Note ———————————————————————————————————————
For more detailed information on alpha channel support for IDL Object Graphics, see "Controlling Object Transparency" (Chapter 2, *Object Programming*).

———

Property Type	Float-point value		
Name String	*Transparency*		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** Yes

CLIP_PLANES

A 4-by-*N* floating-point array that specifies the coefficients of the clipping planes to be applied to this object. The four coefficients for each clipping plane are of the form [A, B, C, D], where $Ax + By + Cz + D = 0$. Portions of this object that fall in the half space $Ax + By + Cz + D > 0$ will be clipped. By default, the value of this property is a scalar (-1) indicating that no clipping planes are to be applied.

Note ———————————————————————————————————————
The clipping planes specified via this property are applied in addition to the near and far clipping planes associated with the IDLgrView in which this object appears.

Note ———————————————————————————————————————
Clipping planes are applied in the data space of this object (prior to the application of any *x*, *y*, or *z* coordinate conversion).

Note ———————————————————————————————————————
To determine the maximum number of clipping planes supported by the device, use the MAX_NUM_CLIP_PLANES keyword of the GetDeviceInfo method for the IDLgrBuffer, IDLgrClipboard, IDLgrWindow, and IDLgrVRML objects.

———

Property Type	Floating-point array		
Name String	*not displayed*		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** No

COLOR

The color to be used as the foreground color for this plot. The color may be specified as a color lookup table index or as a three-element vector [*red*, *green*, *blue*]. The default is [0, 0, 0].

In a property sheet, this property appears as a color property.

Property Type	COLOR		
Name String	Color		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** Yes

DATA

The plot data of any type in a 3 x *n* array, [*DataX*, *DataY*, *DataZ*].

Property Type	Array of any type		
Name String	*not displayed*		
Get: Yes	**Set:** No	**Init:** No	**Registered:** No

DATAX

A vector of any type that specifies the X values to be plotted.

Specifying this property is the same as specifying the optional *X* argument to the IDLgrPlot::Init method

Property Type	Vector of any type		
Name String	*not displayed*		
Get: No	**Set:** Yes	**Init:** Yes	**Registered:** No

DATAY

A vector of any type that specifies the Y values to be plotted.

Specifying this property is the same as specifying the optional *X* argument to the
IDLgrPlot::Init method.

Property Type	Vector of any type		
Name String	*not displayed*		
Get: No	**Set:** Yes	**Init:** Yes	**Registered:** No

DEPTH_TEST_DISABLE

An integer value that determines whether depth testing is disabled.

- Set this property to 0 (the default) to inherit the value set by the parent model or view. The parent view always enables depth testing. A model may also enable or disable depth testing.

- Set this property to 1 to explicitly disable depth buffer testing while drawing this object.

- Set this property to 2 to explicitly enable depth testing for this object.

Disabling depth testing allows an object to draw itself "on top" of other objects already on the screen, even if the object is located behind them.

Note

Disabling depth testing also disables depth buffer writing. When disabling depth testing, the DEPTH_TEST_FUNCTION and DEPTH_WRITE_DISABLE properties are effectively ignored.

This property is registered as an enumerated list, but it is hidden by default.

Property Type	ENUMLIST		
Name String	*not displayed*		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** No

DEPTH_TEST_FUNCTION

An integer value that determines the depth test function. Set this property to 0 (the default) to inherit the value set by the parent model or view. The parent view always sets a depth test function of LESS. A model may also set a depth test function value. The graphics device compares the object's depth at a particular pixel location with the depth stored in the depth buffer at that same pixel location. If the comparison test

passes, the object's pixel is drawn at that location on the screen and the depth buffer is updated (if depth writing is enabled).

Set this property to any of the following values to use the desired function while rendering this object.

- 0 = INHERIT - use value from parent model or view.
- 1 = NEVER - never passes.
- 2 = LESS - passes if the object's depth is less than the depth buffer's value.
- 3 = EQUAL - passes if the object's depth is equal to the depth buffer's value.
- 4 = LESS OR EQUAL - passes if the object's depth is less than or equal to the depth buffer's value.
- 5 = GREATER - passes if the object's depth is greater than or equal to the depth buffer's value.
- 6 = NOT EQUAL - passes if the object's depth is not equal to the depth buffer's value.
- 7 = GREATER OR EQUAL - passes if the object's depth is greater than or equal to the depth buffer's value.
- 8 = ALWAYS - always passes

Less means closer to the viewer.

This property is registered as an enumerated list, but it is hidden by default.

Property Type	ENUMLIST		
Name String	*not displayed*		
Get: Yes	Set: Yes	Init: Yes	Registered: No

DEPTH_WRITE_DISABLE

An integer value that determines whether depth writing is disabled.

- Set this property to 0 (the default) to inherit the value set by the parent model or view. The parent view always enables depth writing. A model may also enable or disable depth writing.
- Set this property to 1 to explicitly disable depth buffer writing while rendering this object.
- Set this property to 2 to explicitly enable depth writing for this object.

Disabling depth writing allows an object to be overdrawn by other objects, even if the object is located in front of them.

Note ───

If depth testing (see DEPTH_TEST_DISABLE property) is disabled, depth writing is also automatically disabled.

───

This property is registered as an enumerated list, but it is hidden by default.

Property Type	ENUMLIST		
Name String	*not displayed*		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** No

DOUBLE

A Boolean value that indicates whether data provided by any of the input arguments will be stored in this object as using double-precision floating-point format.

- Set this property equal to 1 to convert input data to double-precision floating-point format.

- Set this property equal to 0 to convert input data to single-precision floating-point format.

- If you do not specify a value for this property, no data type conversion will be performed, and the data will be stored with its original precision.

Setting this property may be desirable if the data consists of large integers that cannot be accurately represented in single-precision floating-point arithmetic. This property is also automatically set to 1 if any of the input arguments are stored using a variable of type DOUBLE.

Property Type	Boolean		
Name String	*not displayed*		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** No

HIDE

A Boolean value or enumerated list item that indicates whether this object should be drawn:

Value	Property Sheet Value	Description
0	True	Draw graphic (the default)
1	False	Do not draw graphic

Property Type	ENUMLIST		
Name String	Show		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** Yes

HISTOGRAM

A Boolean value that determines whether to use only horizontal and vertical lines to connect the plotted points.

- 0 = The points are connected using a single straight line (the default).

- 1 = Use only horizontal and vertical lines to connect the plotted points.

Property Type	Boolean		
Name String	Histogram plot		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** Yes

LINESTYLE

An integer value that indicates the line style to be used to draw the plot lines. The value can be either an integer value specifying a pre-defined line style, or a two-element vector specifying a stippling pattern.

To use a pre-defined line style, set this property equal to one of the following integer values:

0	Solid line (the default)
1	Dotted

2	Dashed
3	Dash dot
4	Dash dot dot dot
5	Long dash
6	No line drawn

To define your own stippling pattern, specify a two-element vector [*repeat*, *bitmask*], where *repeat* indicates the number of times consecutive runs of 1's or 0's in the *bitmask* should be repeated. (That is, if three consecutive 0's appear in the *bitmask* and the value of *repeat* is 2, then the line that is drawn will have six consecutive bits turned off.) The value of *repeat* must be in the range $1 \leq repeat \leq 255$.

The *bitmask* indicates which pixels are drawn and which are not along the length of the line. *Bitmask* is most conveniently specified as a 16-bit hexadecimal value.

For example, LINESTYLE = [2, 'F0F0'X] describes a dashed line (8 bits on, 8 bits off, 8 bits on, 8 bits off).

In a property sheet, this property appears as follows:

Property Type	Linestyle		
Name String	Line style		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** Yes

MAX_VALUE

A double-precision floating-point value that determines the maximum value to be plotted. When this property is set, data values greater than the value of MAX_VALUE are treated as missing data and are not plotted. Note that the IEEE

floating-point value NaN is also treated as missing data. IDL converts, maintains, and returns this data as double-precision floating-point.

Property Type	FLOAT		
Name String	Maximum value		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** Yes

MIN_VALUE

A double-precision floating-point value that determines the minimum value to be plotted. If this property is present, data values less than the value of MIN_VALUE are treated as missing data and are not plotted. Note that the IEEE floating-point value NaN is also treated as missing data. IDL converts, maintains, and returns this data as double-precision floating-point.

Property Type	FLOAT		
Name String	Minimum value		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** Yes

NSUM

An integer value representing the number of data points to average when plotting. If NSUM is larger than 1, every group of NSUM points is averaged to produce one plotted point. If there are M data points, then M/NSUM points are plotted.

Property Type	Integer		
Name String	Points to average		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** Yes

PALETTE

An object reference to a palette object (an instance of the IDLgrPalette object class). This property is only used if the destination device is using the RGB color model. If so, and a color value for the object is specified as a color index value, the palette set by this property is used to translate the color to RGB space. If the PALETTE property on this object is not set, the destination object PALETTE property is used (which defaults to a grayscale ramp).

Note ───
Objects specified via this property are not automatically cleaned up when the
IDLgrPlot object is destroyed.
───

This property is registered as a user-defined property, but it is hidden by default.

Property Type	USERDEF		
Name String	Color palette		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

PARENT

An object reference to the object that contains this object.

Property Type	Object reference		
Name String	*not displayed*		
Get: Yes	Set: No	Init: No	Registered: No

POLAR

A Boolean value that determines whether to create a polar plot. The *X* and *Y*
arguments must both be present. The *X* argument represents the radius, and the *Y*
argument represents the angle expressed in radians.

Property Type	Boolean		
Name String	Polar plot		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

REGISTER_PROPERTIES

A Boolean value that determines whether to register properties available for this
object. If this property is set, all properties marked in this properties section as

"Registered: Yes" will be registered for display in a property sheet. This property is useful mainly when creating iTools. By default, no properties are registered.

Property Type	Boolean		
Name String	*not displayed*		
Get: No	Set: No	Init: Yes	Registered: No

RESET_DATA

A Boolean value that determines whether to treat the data provided via one of the DATA[XY] properties as a new data set unique to this object, rather than overwriting data that is shared by other objects. There is no reason to use this property if the object on which the property is being set does not currently share data with another object (that is, if the SHARE_DATA property is not in use). This property has no effect if no new data is provided via a DATA property.

Property Type	Boolean		
Name String	*not displayed*		
Get: No	Set: Yes	Init: Yes	Registered: No

SHADER

An object reference to an IDLgrShader object (or an object containing IDLgrShader as a superclass). When there is suitable graphics card hardware support, the plot is rendered using the GLSL shader program (executed on the graphics card) instead of using fixed OpenGL properties when initially drawn. (If a suitable graphics card is not present, IDL ignores the shader object when the scene is drawn.) A single IDLgrShader object may be associated with additional plot objects or other graphic objects that have the SHADER property.

Property Type	Object reference		
Name String	*not displayed*		
Get: Yes	Set: Yes	Init: Yes	Registered: No

SHARE_DATA

An object reference to an object with which data is to be shared by this plot. A plot may only share data with another plot. The SHARE_DATA property is intended for

use when data values are not set via an argument to the object's Init method or by
setting the object's DATA property.

Note ───

Objects specified via this property are not automatically cleaned up when the
IDLgrPlot object is destroyed.

───

Property Type	Object reference		
Name String	*not displayed*		
Get: No	**Set:** Yes	**Init:** Yes	**Registered:** No

SYMBOL

An object reference vector containing instances of the IDLgrSymbol object class.
Each symbol in the vector will be drawn at the corresponding plotted point. If there
are more points than elements in SYMBOL, the elements of the SYMBOL vector are
cyclically repeated. By default, no symbols are drawn. To remove symbols from a
plot, set the SYMBOL property equal to a null object reference.

Note ───

Objects specified via this property are not automatically cleaned up when the
IDLgrPlot object is destroyed.

───

Property Type	Object reference vector		
Name String	*not displayed*		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** No

THICK

A floating-point value between 1.0 and 10.0, specifying the line thickness to be used
to draw the plotted lines, in points. Out-of-range values are quietly clamped to the
allowed range. The default is 1.0 points.

In a property sheet, this property appears as follows:

Property Type	Thickness		
Name String	Thickness		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** Yes

USE_ZVALUE

A Boolean value that determines whether to use the current ZVALUE. The plot is considered three-dimensional if this property is set.

Property Type	Boolean		
Name String	*not displayed*		
Get: No	**Set:** No	**Init:** Yes	**Registered:** No

VERT_COLORS

A vector of colors to be used to specify the color of the plot segment between each vertex. The vector may be of the form [n] where each entry is a color index, or of the form [3,n] where each 3-element row is an RGB color, or of the form [4,n] where each 4-element row is an RGBA color. To remove vertex colors after they have been set, set VERT_COLORS to a scalar.

If VERT_COLORS is not specified, the entire plot is drawn in the single color provided by the COLOR property, which is the default action.

If there are more vertices than elements in VERT_COLORS, the elements of VERT_COLORS are cyclically repeated.

When VERT_COLORS is used with symbols, the vertex colors and vertex alpha override any colors and alpha specified by the symbol object or any colors and alpha specified by graphic atoms contained in a user-defined symbol.

Property Type	USERDEF		
Name String	Vertex colors		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** Yes

XCOORD_CONV

A floating-point vector, $[s_0, s_1]$, of scaling factors used to convert X coordinates from data units to normalized units. The formula for the conversion is as follows:

$$Normalized X = s_0 + s_1 * Data X$$

Recommended values are:

$$[(-X_{min})/(X_{max}-X_{min}), 1/(X_{max}-X_{min})]$$

The default is [0.0, 1.0]. IDL converts, maintains, and returns this data as double-precision floating-point.

Property Type	Floating-point vector		
Name String	*not displayed*		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** No

XRANGE

A two-element floating-point vector of the form [*xmin*, *xmax*] specifying the range of *x* data coordinates covered by the graphic object. The plot line is *clipped* to the XRANGE values specified, but data points that lie outside the specified range are not removed. (Set the MAX_VALUE and MIN_VALUE properties if data outside the range should be removed.) If this property is not specified, the minimum and maximum data values are used. IDL converts, maintains, and returns this data as double-precision floating-point.

Property Type	Floating-point vector		
Name String	*not displayed*		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** No

YCOORD_CONV

A floating-point vector, [s_0, s_1], of scaling factors used to convert Y coordinates from data units to normalized units. The formula for the conversion is as follows:

Normalized$Y = s_0 + s_1$ * Data$Y$

Recommended values are:

[(-Y_{min})/(Y_{max}-Y_{min}), 1/(Y_{max}-Y_{min})]

The default is [0.0, 1.0]. IDL converts, maintains, and returns this data as double-precision floating-point.

Property Type	Floating-point vector		
Name String	*not displayed*		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** No

YRANGE

A two-element floating-point vector of the form [*ymin*, *ymax*] specifying the range of *y* data values covered by the graphic object. The plot line is *clipped* to the YRANGE values specified, but data points that lie outside the specified range are not removed. (Set the MAX_VALUE and MIN_VALUE properties if data outside the range should be removed.) If this property is not specified, the minimum and maximum data values are used. IDL converts, maintains, and returns this data as double-precision floating-point.

Property Type	Floating-point vector		
Name String	*not displayed*		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** No

ZCOORD_CONV

A floating-point vector, [s_0, s_1], of scaling factors used to convert Z coordinates from data units to normalized units. The formula for the conversion is as follows:

Normalized$Z = s_0 + s_1$ * Data$Z$

The default is [0.0, 1.0]. IDL converts, maintains, and returns this data as double-precision floating-point.

Property Type	Floating-point vector		
Name String	*not displayed*		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** No

ZRANGE

A two-element floating-point vector of the form [*zmin, zmax*] specifying the range of *z* data values covered by the graphic object. The plot line is *clipped* to the ZRANGE values specified, but data points that lie outside the specified range are not removed. (Set the MAX_VALUE and MIN_VALUE properties if data outside the range should be removed.) IDL maintains and returns this property in double-precision floating-point.

Note ───
The XRANGE and YRANGE properties can also be retrieved via the GetProperty method; ZRANGE, however, can only be retrieved, not initialized (Init method) or set (SetProperty method).
───

Property Type	Floating-point vector		
Name String	*not displayed*		
Get: Yes	**Set:** No	**Init:** No	**Registered:** No

ZVALUE

A floating-point value to be used as the Z coordinate for the entire plot. By default, 0.0 is used as the Z coordinate.

Note ───
The USE_ZVALUE property needs to be set in order for ZVALUE to take effect.
───

Property Type	Floating-point		
Name String	*not displayed*		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** No

IDLgrPlot::Cleanup

The IDLgrPlot::Cleanup procedure method performs all cleanup on the object.

Note

Cleanup methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation and destruction. This means that in most cases, you cannot call the Cleanup method directly. There is one exception to this rule: if you write your own subclass of this class, you can call the Cleanup method from within the Init or Cleanup method of the subclass.

Syntax

OBJ_DESTROY, *Obj*

or

Obj->[IDLgrPlot::]Cleanup   *(In a lifecycle method only.)*

Arguments

None

Keywords

None

Version History

5.0	Introduced

IDLgrPlot::GetCTM

The IDLgrPlot::GetCTM function method returns the 4-by-4 double-precision floating-point graphics transform matrix from the current object upward through the graphics tree.

Syntax

Result = Obj->[IDLgrPlot::]GetCTM([, DESTINATION=*objref*] [, PATH=*objref(s)*] [, TOP=*objref to IDLgrModel object*])

Return Value

Returns the 4-by-4 double-precision floating-point graphics transform matrix from the current object upward through the graphics tree.

Arguments

None

Keywords

DESTINATION

Set this keyword to the object reference of a destination object to specify that the projection matrix for the View object in the current tree be included in the returned transformation matrix. The resulting matrix will transform a point in the data space of the object on which the GetCTM method is called into a normalized coordinate system (-1 to +1 in X, Y, and Z), relative to the View object that contains the plot object.

PATH

Set this keyword to a single object reference or a vector of object references. This keyword specifies the path in the graphics hierarchy to compute the transformation matrix. Each path object reference specified with this keyword must contain an alias. The transformation matrix is computed for the version of the object falling within that path. If this keyword is not set, the PARENT properties determine the path from the current object to the top of the graphics hierarchy and no alias paths are pursued. If IDLgrPlot::GetCTM is called from within a Draw method, with the DESTINATION keyword set and the PATH keyword not set, the alias path used to find the object during the draw is used, rather than the PARENT path.

Note ─────────────

For more information on aliases, refer to the ALIAS keyword in IDLgrModel::Add.
─────────────────────────────────

TOP

Set this keyword equal to the object reference to an IDLgrModel object to specify that the returned matrix accumulate from the object on which the GetCTM method is called up to but not including the specified model object.

Version History

5.0	Introduced

IDLgrPlot::GetProperty

The IDLgrPlot::GetProperty procedure method retrieves the value of the property or group of properties for the plot.

Syntax

Obj->[IDLgrPlot::]GetProperty[, *PROPERTY=variable*]

Arguments

None

Keywords

Any property listed under "IDLgrPlot Properties" on page 4546 that contains the word "Yes" in the "Get" column of the properties table can be retrieved using this method. To retrieve the value of a property, specify the property name as a keyword set equal to a named variable that will contain the value of the property.

Any keyword not recognized is passed to this object's superclass.

Version History

5.0	Introduced

IDLgrPlot::GetVertexAttributeData

The IDLgrPlot::GetVertexAttributeData procedure method retrieves the data associated with a named attribute variable containing per-vertex attribute data. See "Attribute Variables" (Chapter 14, *Object Programming*) for more information. This method is useful when a shader program defined by an IDLgrShader object modifies the vertices of an object. See Chapter 14, "Advanced Rendering Using Shader Objects" (*Object Programming*) for more information.

Syntax

Obj->[IDLgrPlot::]GetVertexAttributeData, *Name, Value*

Arguments

Name

Specifies a case-sensitive string name of the attribute variable to retrieve.

Note

If the *Name* argument specifies an attribute variable that was never defined and stored in the plot object using SetVertexAttributeData, then the variable specified in the *Value* parameter will be set to an undefined variable.

Value

Specifies a variable that contains the current value of the vertex data attribute variable. The variable is stored in this parameter in exactly the same format as that used when it was defined using IDLgrPlot::SetVertexAttributeData.

Keywords

None

Examples

See "Vertex Shaders" (Chapter 14, *Object Programming*).

Version History

6.4	Introduced

See Also

IDLgrPlot::SetVertexAttributeData

IDLgrPlot::Init

The IDLgrPlot::Init function method initializes the plot object.

Note
Init methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation. This means that in most cases, you cannot call the Init method directly. There is one exception to this rule: if you write your own subclass of this class, you can call the Init method from within the Init method of the subclass.

Syntax

Obj = OBJ_NEW('IDLgrPlot' [, [*X*,] *Y*] [, *PROPERTY=value*])

or

Result = Obj->[IDLgrPlot::]Init([[*X*,] *Y*] [, *PROPERTY=value*])   *(In a lifecycle method only.)*

Return Value

When this method is called indirectly, as part of the call to the OBJ_NEW function, the return value is an object reference to the newly-created object.

When called directly within a subclass Init method, the return value is 1 if initialization was successful, or zero otherwise.

Arguments

Note
The values specified by the *X* and *Y* arguments are used to initialize the values of the DATAX and DATAY properties of the IDLgrPlot object.

X

A vector representing the abscissa values to be plotted. If *X* is provided, *Y* is plotted as a function of *X*. The value for this argument is double-precision floating-point if the DOUBLE keyword is set or the input value is of type DOUBLE. Otherwise it is converted to single-precision floating-point.

Y

The ordinate data to be plotted. The value for this argument is double-precision floating-point if the DOUBLE keyword is set or the input value is of type DOUBLE. Otherwise it is converted to single-precision floating-point.

Keywords

Any property listed under "IDLgrPlot Properties" on page 4546 that contains the word "Yes" in the "Init" column of the properties table can be initialized during object creation using this method. To initialize the value of a property, specify the property name as a keyword set equal to the appropriate property value.

All other keywords are passed to the superclass of this object.

Version History

5.0	Introduced

IDLgrPlot::SetProperty

The IDLgrPlot::SetProperty procedure method sets the value of the property or group of properties for the plot.

Syntax

Obj->[IDLgrPlot::]SetProperty[, *PROPERTY=value*]

Arguments

None

Keywords

Any property listed under "IDLgrPlot Properties" on page 4546 that contains the word "Yes" in the "Set" column of the properties table can be set using this method. To set the value of a property, specify the property name as a keyword set equal to the appropriate property value.

Version History

5.0	Introduced

IDLgrPlot::SetVertexAttributeData

The IDLgrPlot::SetVertexAttributeData procedure method passes a set of per-vertex attribute data to a vertex shader program. When an IDLgrShader object is associated with the plot via the SHADER property, this attribute data is made available, a vertex's worth at a time, to the vertex shader program as it processes each vertex in the plot. If there are more vertices in the plot than there are vertex attributes, the list of vertex attributes is reused until all the vertices are drawn. See "Attribute Variables" (Chapter 14, *Object Programming*) for a general introduction to attribute variables. Also see the chapter, "Advanced Rendering Using Shader Objects" (*Object Programming*) for additional shader program information and examples.

IDL stores the *Name* and *Value* of the vertex attribute data variable with this plot object the first time this method is called. When SetVertexAttributeData is called again using the same *Name* argument, the vertex attribute data variable is updated with the current contents of *Value*. Once a vertex attribute data variable is associated with this object, there is no way to remove the reference. The shader program ignores any vertex attribute data variable defined for this object but not declared in the shader program.

The attribute data may consist of 1 to 4 elements per vertex. The data is passed to the vertex shader program via a shader program variable with the attribute qualifier. The attribute variable may be of GLSL type float, vec2, vec3, vec4, mat2, mat3, or mat4. Internally, the mat2 type is treated as two vec2 attribute variables, mat3 as three vec3 attribute variables, and mat4 as four vec4 attribute variables.

If the attribute variable is larger than the data passed to it, the shader program pads the missing elements as follows. A missing second or third element is set to 0.0. A missing fourth element is set to 1.0.

For example, the IDL application has a set of vertex attribute data where there is an x-offset and a y-offset for each vertex. The vertex program defines an attribute variable using a vec4 type so that it can be used in 4x4 general transformations. The IDL program stores the x- and y-offset information in a [2, *n*] array and sets the value of the attribute variable to this array. As the shader program runs, for each vertex it assigns the two values from the corresponding row of the IDL array to the first two elements in the vec4 attribute variable. It also sets the third value to 0.0 and the fourth value to 1.0, thus expanding the 2-element data to a general 3-D point in homogenous coordinate space, suited for 4x4 general transforms.

Note

A minimum of 16 vertex attribute data variables can be passed to the shader vertex program (use IDLgrWindow::GetDeviceInfo to determine the exact number). IDL

uses one vertex attribute variable, leaving the remainder for user programs. For maximum shader program portability, define 15 or fewer attribute variables.

Syntax

Obj->[IDLgrPlot::]SetVertexAttributeData, *Name, Value*

Arguments

Name

Specifies a case-sensitive string name of the attribute variable.

Value

Specifies an IDL array of any numeric type. The array must be of the form [*n*], [*a*,*n*], or [*a*,*a*,*n*] where *a* is 1,2,3, or 4 and *n* is the number of vertex attribute elements. IDL will halt with an error if you assign IDL strings, structures, pointers, object references, and undefined variables to *Value*. IDL converts all numeric types to 32-bit float when submitting the data to the shader program.

Keywords

None

Examples

Suppose there is large set of point sample data, along with a set of initial velocity vectors for each point. You want to display an animation of these points as each point moves along its own velocity vector as a function of time. Without a shader program, you would normally have to recalculate the position of each point and replace all the vertices in an IDLgrPolygon (STYLE=0) object with the recomputed values for each animation frame, which would be inefficient with a large number of points.

However, with a vertex shader program and vertex attribute data, you can move the points around using the graphics card's GPU instead of recalculating and moving a lot of data around on the system CPU.

The interesting parts of the IDL code are:

```
; Define the original vertices at time=0.
oPolygon->SetProperty, DATA=vertices
```

```
; Set [3,n] array.
oPolygon->SetVertexAttributeData, 'velocity', velocities
FOR t=0.0, 100.0, 0.01 DO BEGIN  ;; time samples
   oShader->SetUniformVariable, 'time', t
   oWindow->Draw
ENDFOR
```

And the interesting parts of the vertex shader program are:

```
attribute vec3 velocity;
uniform float time;
void main () {
   vec4 vert;
   vert = gl_Vertex + vec4(velocity * time, 0.0);
   gl_Position = gl_ModelViewProjectMatrix * vert;
}
```

See "Vertex Shaders" (Chapter 14, *Object Programming*) for more information and examples.

IDLgrPlot::GetVertexAttributeData

IDLgrPolygon

A polygon object represents one or more polygons that share a given set of vertices and rendering attributes. All polygons must be convex—that is, a line connecting any pair of vertices on the polygon cannot fall outside the polygon. Concave polygons can be converted to a set of convex polygons using the IDLgrTessellator object.

An IDLgrPolygon object is an *atomic graphic object*; it is one of the basic drawable elements of the IDL Object Graphics system, and it is not a container for other objects.

Superclasses

IDLitComponent

Creation

See "IDLgrPolygon::Init" on page 4610.

Properties

Objects of this class have the following properties. See "IDLgrPolygon Properties" on page 4578 for details on individual properties.

- ALL
- AMBIENT
- CLIP_PLANES
- DATA
- DEPTH_TEST_DISABLE
- DEPTH_WRITE_DISABLE
- DOUBLE
- FILL_PATTERN
- HIDE
- NORMALS
- PARENT
- REGISTER_PROPERTIES

- ALPHA_CHANNEL
- BOTTOM
- COLOR
- DEPTH_OFFSET
- DEPTH_TEST_FUNCTION
- DIFFUSE
- EMISSION
- HIDDEN_LINES
- LINESTYLE
- PALETTE
- POLYGONS
- REJECT

- SHADER
- SHARE_DATA
- SPECULAR
- TEXTURE_COORD
- TEXTURE_MAP
- VERT_COLORS
- XRANGE
- YRANGE
- ZERO_OPACITY_SKIP

- SHADE_RANGE
- SHADING
- SHININESS
- STYLE
- TEXTURE_INTERP
- THICK
- XCOORD_CONV
- YCOORD_CONV
- ZCOORD_CONV
- ZRANGE

In addition, objects of this class inherit the properties of all superclasses of this class.

Methods

This class has the following methods:

- IDLgrPolygon::Cleanup
- IDLgrPolygon::GetCTM
- IDLgrPolygon::GetMultiTextureCoord
- IDLgrPolygon::GetProperty
- IDLgrPolygon::GetVertexAttributeData
- IDLgrPolygon::Init
- IDLgrPolygon::SetMultiTextureCoord
- IDLgrPolygon::SetProperty
- IDLgrPolygon::SetVertexAttributeData

In addition, this class inherits the methods of its superclasses (if any).

Version History

5.0	Introduced
5.6	Added CLIP_PLANES property
6.1	Added ALPHA_CHANNEL, AMBIENT, DIFFUSE, EMISSION, SHININESS, and SPECULAR properties
6.4	Added the SHADER property
	Added GetVertexAttributeData, SetVertexAttributeData, GetMultiTextureCoord, and SetMultiTextureCoord methods

IDLgrPolygon Properties

IDLgrPolygon objects have the following properties in addition to properties inherited from any superclasses. Properties with the word "Yes" in the "Get" column of the property table can be retrieved via IDLgrPolygon::GetProperty. Properties with the word "Yes" in the "Init" column of the property table can be set via IDLgrPolygon::Init. Properties with the word "Yes" in the "Set" column in the property table can be set via IDLgrPolygon::SetProperty.

Note ───
For a discussion of the property description tables shown below, see "About Object Property Descriptions" on page 3135.

In addition, objects of this class inherit:

- IDLitComponent

ALL

An anonymous structure containing the values of all of the properties associated with the *state* of this object. State information about the object includes things like color, range, tick direction, etc., but not image, vertex, or connectivity data, or user values.

Note

The fields of this structure may change in subsequent releases of IDL.

Property Type	Structure		
Name String	*not displayed*		
Get: Yes	**Set:** No	**Init:** No	**Registered:** No

ALPHA_CHANNEL

Set this property to a floating-point value in the range [0.0, 1.0] to specify the opacity of the polygon. The default value of 1.0 causes IDL to draw the polygon completely opaque. If the value of this property is less than 1.0, then the pixels of the polygon are blended with the pixels already on the screen. The color of the polygon is multiplied by the alpha value and the pixels already on the screen are multiplied by 1.0-alpha.

Because an object can only be blended with objects already drawn on the screen, the drawing order of the objects must be considered carefully in order to obtain the desired results. Note that since a single polygon object may contain many polygons, the ordering of the polygons within the object (POLYGONS property) must be considered as well.

This property has no effect on devices using indexed color mode.

If VERT_COLORS are supplied, then the value of this property is used for the vertex color alpha if the VERT_COLORS do not contain alpha values (3-channel RGB

colors). If the VERT_COLORS do contain alpha values (4-channel RGBA colors), then the alpha for each vertex color is used.

When used with textures, the ALPHA_CHANNEL value controls the opacity of the polygon in the same manner as when not using a texture. If the texture contains alpha information, the effective alpha of each texel is the texel's alpha multiplied by the polygon's alpha value (ALPHA_CHANNEL property).

Note ───

For more detailed information on alpha channel support for IDL Object Graphics, see "Controlling Object Transparency" (Chapter 2, *Object Programming*).

───

Property Type	Float-point value		
Name String	*Transparency*		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** Yes

AMBIENT

Set this property to a three-element vector [*red*, *green*, *blue*] to specify the ambient reflective color of the object. The default is black or [0,0,0], which specifies that the value of the COLOR property determines the ambient reflective color of the object. Setting an ambient color other than black makes the object use that color for ambient reflectance. Ambient reflectance affects the overall color of the object and is most noticeable where the object is not directly lit by a light source. This property has no effect on devices using indexed color mode.

Property Type	COLOR		
Name String	*Ambient reflective color*		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** Yes

BOTTOM

A scalar or three-element vector [*red*, *green*, *blue*] specifying the color used for drawing the backs of the polygons. (The back of a polygon is the side opposite the normal direction). Set this property to a scalar to draw the backs of the polygons with the same color as the front. If set to a scalar, IDL returns the default value of -1 if the property is retrieved with GetProperty. Setting a bottom color is only supported when the destination device uses RGB color mode.

In a property sheet, this property appears as a color property.

Property Type	COLOR		
Name String	Bottom color		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** Yes

CLIP_PLANES

A 4-by-*N* floating-point array that specifies the coefficients of the clipping planes to be applied to this object. The four coefficients for each clipping plane are of the form [A, B, C, D], where $Ax + By + Cz + D = 0$. Portions of this object that fall in the half space $Ax + By + Cz + D > 0$ will be clipped. By default, the value of this property is a scalar (-1) indicating that no clipping planes are to be applied.

Note ───────────────────────────────
The clipping planes specified via this property are applied in addition to the near and far clipping planes associated with the IDLgrView in which this object appears.
───────────────────────────────

Note ───────────────────────────────
Clipping planes are applied in the data space of this object (prior to the application of any *x*, *y*, or *z* coordinate conversion).
───────────────────────────────

Note ───────────────────────────────
To determine the maximum number of clipping planes supported by the device, use the MAX_NUM_CLIP_PLANES property of the GetDeviceInfo method for the IDLgrBuffer, IDLgrClipboard, IDLgrWindow, and IDLgrVRML objects.
───────────────────────────────

Property Type	Floating-point array		
Name String	*not displayed*		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** No

COLOR

A color index or a three-element vector [*red*, *green*, *blue*] specifying the color used to draw polygons. The default color is [0, 0, 0] (black). If the TEXTURE_MAP property is used, the final color is modulated by the texture map pixel values. This property is ignored if the VERT_COLORS property is provided.

In a property sheet, this property appears as a color property.

Property Type	COLOR		
Name String	Color		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

DATA

A *2*-by-*n* or a *3*-by-*n* array of any type which defines, respectively, the 2-D or 3-D vertex data. This property is stored as double precision floating point values if the property variable is of type DOUBLE or if the DOUBLE property parameter is also specified, otherwise it is converted to single precision floating point.

Specifying this property is the same as specifying the optional *X*, *Y*, and *Z* arguments to the IDLgrPolygon::Init method.

Property Type	Array of any type		
Name String	*not displayed*		
Get: Yes	Set: Yes	Init: Yes	Registered: No

DEPTH_OFFSET

An integer value that specifies an offset in depth to be used when rendering filled primitives. This offset is applied along the viewing axis, with positive values moving the primitive away from the viewer.

The units are "Z-Buffer units," where a value of 1 is used to specify a distance that corresponds to a single step in the device's Z-Buffer.

Use DEPTH_OFFSET to always cause a filled primitive to be rendered slightly deeper than other primitives, independent of model transforms. This is useful for avoiding stitching artifacts caused by rendering lines or polygons on top of other polygons at the same depth.

Note —————————————————————————————————

Use this feature to remove stitching artifacts and not as a means for "layering" complex scenes with multiple DEPTH_OFFSET values. It is safest to use only a DEPTH_OFFSET value of 0, the default, and one other non-zero value, such as 1. Many system-level graphics drivers are not consistent in their handling of DEPTH_OFFSET values, particularly when multiple non-zero values are used. This can lead to portability problems because a set of DEPTH_OFFSET values may

produce better results on one machine than on another. Using IDL's software renderer will help improve the cross-platform consistency of scenes that use DEPTH_OFFSET.

Note

DEPTH_OFFEST has no effect unless the value of the STYLE property is 2 (Filled).

Property Type	Integer		
Name String	Depth offset		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** Yes

DEPTH_TEST_DISABLE

An integer value that determines whether depth testing is disabled.

- Set this property to 0 (the default) to inherit the value set by the parent model or view. The parent view always enables depth testing. A model may also enable or disable depth testing.

- Set this property to 1 to explicitly disable depth buffer testing while drawing this object.

- Set this property to 2 to explicitly enable depth testing for this object.

Disabling depth testing allows an object to draw itself "on top" of other objects already on the screen, even if the object is located behind them.

Note

Disabling depth testing also disables depth buffer writing. When disabling depth testing, the DEPTH_TEST_FUNCTION and DEPTH_WRITE_DISABLE properties are effectively ignored.

This property is registered as an enumerated list, but it is hidden by default.

Property Type	ENUMLIST		
Name String	*not displayed*		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** No

DEPTH_TEST_FUNCTION

An integer value that determines the depth test function. Set this property to 0 (the default) to inherit the value set by the parent model or view. The parent view always sets a depth test function of LESS. A model may also set a depth test function value. The graphics device compares the object's depth at a particular pixel location with the depth stored in the depth buffer at that same pixel location. If the comparison test passes, the object's pixel is drawn at that location on the screen and the depth buffer is updated (if depth writing is enabled).

Set this property to any of the following values to use the desired function while rendering this object.

- 0 = INHERIT - use value from parent model or view.

- 1 = NEVER - never passes.

- 2 = LESS - passes if the object's depth is less than the depth buffer's value.

- 3 = EQUAL - passes if the object's depth is equal to the depth buffer's value.

- 4 = LESS OR EQUAL - passes if the object's depth is less than or equal to the depth buffer's value.

- 5 = GREATER - passes if the object's depth is greater than or equal to the depth buffer's value.

- 6 = NOT EQUAL - passes if the object's depth is not equal to the depth buffer's value.

- 7 = GREATER OR EQUAL - passes if the object's depth is greater than or equal to the depth buffer's value.

- 8 = ALWAYS - always passes

Less means closer to the viewer.

This property is registered as an enumerated list, but it is hidden by default.

Property Type	ENUMLIST		
Name String	*not displayed*		
Get: Yes	Set: Yes	Init: Yes	Registered: No

DEPTH_WRITE_DISABLE

An integer value that determines whether depth writing is disabled.

- Set this property to 0 (the default) to inherit the value set by the parent model or view. The parent view always enables depth writing. A model may also enable or disable depth writing.

- Set this property to 1 to explicitly disable depth buffer writing while rendering this object.

- Set this property to 2 to explicitly enable depth writing for this object.

Disabling depth writing allows an object to be overdrawn by other objects, even if the object is located in front of them.

Note

If depth testing (see DEPTH_TEST_DISABLE property) is disabled, depth writing is also automatically disabled.

This property is registered as an enumerated list, but it is hidden by default.

Property Type	ENUMLIST		
Name String	*not displayed*		
Get: Yes	Set: Yes	Init: Yes	Registered: No

DIFFUSE

Set this property to a three-element vector [*red*, *green*, *blue*] to specify the diffuse reflectance color of the object. The default is black or [0,0,0], which specifies that the value of the COLOR property determines the diffuse reflective color of the object. Setting a diffuse color other than black makes the object use that color for diffuse reflectance. Diffuse reflectance is an important factor in determining the color of the object and is affected by the color and angle of the light sources in a scene. This property has no effect on devices using indexed color mode.

Property Type	COLOR		
Name String	*Diffuse reflective color*		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

DOUBLE

A Boolean value that indicates whether data provided by any of the input arguments will be stored in this object as using double-precision floating-point format.

- Set this property equal to 1 to convert input data to double-precision floating-point format.

- Set this property equal to 0 to convert input data to single-precision floating-point format.

- If you do not specify a value for this property, no data type conversion will be performed, and the data will be stored with its original precision.

Setting this property may be desirable if the data consists of large integers that cannot be accurately represented in single-precision floating-point arithmetic. This property is also automatically set to 1 if any of the input arguments are stored using a variable of type DOUBLE.

Property Type	Boolean		
Name String	*not displayed*		
Get: Yes	Set: Yes	Init: Yes	Registered: No

EMISSION

Set this property to a three-element vector [*red*, *green*, *blue*] to specify the emissive color of the object. The default is black or [0,0,0], which specifies that the object contributes no additional color in an emissive sense. Setting an emission color other than black makes the object appear as if it were emitting that color. This property is used to simulate light sources or other objects that emit light in a scene. This property has no effect on devices using indexed color mode.

Property Type	COLOR		
Name String	*Emissive color*		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

FILL_PATTERN

An object reference to an IDLgrPattern object (or an array of IDLgrPattern objects) that specifies the fill pattern to use for filling the polygons. By default, FILL_PATTERN is set to a null object reference, specifying a solid fill.

Note ──

Objects specified via this property are not automatically cleaned up when the IDLgrPolygon object is destroyed.

──

Property Type	Object reference		
Name String	*not displayed*		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** No

HIDDEN_LINES

A Boolean value that determines whether to draw point and wireframe surfaces using hidden line (point) removal. By default, hidden line removal is disabled.

Property Type	Boolean		
Name String	Remove hidden		
Get: No	**Set:** Nos	**Init:** Yes	**Registered:** Yes

HIDE

A Boolean value or enumerated list item that indicates whether this object should be drawn:

Value	Property Sheet Value	Description
0	True	Draw graphic (the default)
1	False	Do not draw graphic

Property Type	ENUMLIST		
Name String	Show		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** Yes

LINESTYLE

An integer value that indicates the line style that should be used to draw the polygon. The value can be either an integer value specifying a pre-defined line style, or a two-element vector specifying a stippling pattern.

To use a pre-defined line style, set this property equal to one of the following integer values:

0	Solid line (the default)
1	Dotted
2	Dashed
3	Dash dot
4	Dash dot dot dot
5	Long dash
6	No line drawn

To define your own stippling pattern, specify a two-element vector [*repeat*, *bitmask*], where *repeat* indicates the number of times consecutive runs of 1's or 0's in the *bitmask* should be repeated. (That is, if three consecutive 0's appear in the *bitmask* and the value of *repeat* is 2, then the line that is drawn will have six consecutive bits turned off.) The value of *repeat* must be in the range $1 \le repeat \le 255$.

The *bitmask* indicates which pixels are drawn and which are not along the length of the line. *Bitmask* is most conveniently specified as a 16-bit hexadecimal value.

For example, LINESTYLE = [2, 'F0F0'X] describes a dashed line (8 bits on, 8 bits off, 8 bits on, 8 bits off).

In a property sheet, this property appears as follows:

Property Type	Linestyle		
Name String	Line style		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** Yes

NORMALS

A *3*-by-*n* floating-point array of unit polygon normals at each vertex. If this property is not set, vertex normals are computed by averaging shared polygon normals at each vertex. Normals are computed using the Right Hand Rule; that is, if the polygon is

facing the viewer, vertices are taken in counterclockwise order. To remove previously specified normals, set NORMALS to a scalar.

Note

Computing normals is a computationally expensive operation. Rendering speed increases significantly if you supply the surface normals explicitly. You can compute the array of polygon normals used by this property automatically. See "COMPUTE_MESH_NORMALS" on page 335 for details.

Once you use the NORMALS property in a call to IDLgrPolygon::Init or IDLgrPolygon::SetProperty, you are responsible for that IDLgrPolygon's normals from then on. IDL will not calculate that IDLgrPolygon's normals for you automatically, even if you draw the IDLgrPolygon after vertices or connectivity have been changed.

If you do not use the NORMALS property, IDL calculates normals the first time it draws the IDLgrPolygon. IDL reuses those normals for subsequent draws unless it determines that a fresh recalculation of normals is required, such as if the vertices of the IDLgrPolygon are changed, or you supply new normals via the NORMALS property.

Property Type	Floating-point array		
Name String	*not displayed*		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** No

PALETTE

An object reference to a palette object (an instance of the IDLgrPalette object class). This property is only used if the destination device is using the RGB color model. If so, and a color value for the object is specified as a color index value, the palette set by this property is used to translate the color to RGB space. If the PALETTE property on this object is not set, the destination object PALETTE property is used (which defaults to a grayscale ramp).

Note

Objects specified via this property are not automatically cleaned up when the IDLgrPolygon object is destroyed.

This property is registered as a user-defined property, but it is hidden by default.

Property Type	USERDEF		
Name String	Color palette		
Get: No	Set: No	Init: Yes	Registered: Yes

PARENT

An object reference to the object that contains this object.

Property Type	Object reference		
Name String	*not displayed*		
Get: Yes	Set: No	Init: No	Registered: No

POLYGONS

An integer array of one or more polygon descriptions. IDL converts and stores this array as 32-bit signed integers. Set this property to a scalar to remove a polygon description array from the object, returning it to its initial empty state. When this property does not contain an array of polygon descriptions, IDL draws a single polygon using the vertices in the order they appear in the vertex list (see the DATA property).

For details on using this property, see "Creating Polygon and Polyline Objects" (Chapter 8, *Object Programming*).

Property Type	Integer array		
Name String	*not displayed*		
Get: Yes	Set: Yes	Init: Yes	Registered: No

REGISTER_PROPERTIES

A Boolean value that determines whether to register properties available for this object. If this property is set, all properties marked in this properties section as

"Registered: Yes" will be registered for display in a property sheet. This property is useful mainly when creating iTools. By default, no properties are registered.

Property Type	Boolean		
Name String	*not displayed*		
Get: No	**Set:** No	**Init:** Yes	**Registered:** No

REJECT

An integer value or an enumerated list item that rejects polygons as being hidden depending on the orientation of their normals. Select from one of the following values:

Value	Property Sheet Value	Description
0	None	No polygons are hidden
1	Normals point away	Polygons whose normals point away from the viewer are hidden
2	Normals point toward	Polygons whose normals point toward the viewer are hidden

Set this property to zero to draw all polygons regardless of the direction of their normals.

Note

The REJECT property has no effect on non-filled polygons (where STYLE is 0 or 1).

Property Type	ENUMLIST		
Name String	Polygon rejection		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** Yes

RESET_DATA

A Boolean value that determines whether to treat the data provided via the DATA property as a new data set unique to this object, rather than overwriting data that is shared by other objects. There is no reason to use this property if the object on which

the property is being set does not currently share data with another object (that is, if the SHARE_DATA property is not in use). This property has no effect if no new data is provided via the DATA property.

Property Type	Boolean		
Name String	*not displayed*		
Get: No	**Set:** Yes	**Init:** Yes	**Registered:** No

SHADE_RANGE

A two-element integer array that specifies the range of pixel values (color indices) to use for shading. The first element is the color index for the darkest pixel. The second element is the color index for the brightest pixel. The default is [0, 255]. This property is ignored when the polygons are drawn to a graphics destination that uses the RGB color model.

Property Type	Integer array		
Name String	*not displayed*		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** No

SHADER

An object reference to an IDLgrShader object (or an object containing IDLgrShader as a superclass). When there is suitable graphics card hardware support, the polygon is rendered using the GLSL shader program (executed on the graphics card) instead of using fixed OpenGL properties when initially drawn. (If a suitable graphics card is not present, IDL ignores the shader object when the scene is drawn.) A single IDLgrShader object may be associated with additional polygon objects or other graphic objects that have the SHADER property.

Property Type	Object reference		
Name String	*not displayed*		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** No

SHADING

An integer value or an enumerated list item that represents the type of shading to use:

Value	Property Sheet Value	Description
0	Flat	The color of the first vertex in each polygon is used to define the color for the entire polygon. The color has a constant intensity based upon the normal vector (the default).
1	Gouraud	The colors along each line are interpolated between vertex colors, and then along scanlines from each of the edge intensities.

Gouraud shading may be slower than flat shading, but results in a smoother appearance.

Property Type	ENUMLIST		
Name String	Shading		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** Yes

SHARE_DATA

An object reference to an object with which data is to be shared by this polygon(s). Polygons may only share data with another polygons object or a polyline. The SHARE_DATA property is intended for use when data values are not set via an argument to the object's Init method or by setting the object's DATA property.

Note ───

Objects specified via this property are not automatically cleaned up when the IDLgrPolygon object is destroyed.

──

Property Type	Object reference		
Name String	*not displayed*		
Get: No	**Set:** Yes	**Init:** Yes	**Registered:** No

SHININESS

Set this property to a floating-point value between 0.0 and 128.0, inclusive. The default value is 25.0. Higher values of shininess concentrate specular highlights into smaller and brighter areas, while lower values will spread out specular highlights over a wider area and make them appear dimmer.

Property Type	FLOAT		
Name String	*Shininess*		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** Yes

SPECULAR

Set this property to a three-element vector [*red*, *green*, *blue*] to specify the color of the specular highlights of an object. The default is white or [255,255,255]. This property is used to simulate and control reflective highlights on an object. This property has no effect on devices using indexed color mode.

Property Type	COLOR		
Name String	*Specular highlight color*		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** Yes

STYLE

An integer value or an enumerated list item that specifies how the polygon should be drawn:

Value	Property Sheet Value	Description
0	Points	Only vertices are drawn, using either COLOR or VERT_COLORS
1	Lines	Each polygon is outlined by connecting vertices
2	Filled	The polygon faces are shaded (the default)

Property Type	ENUMLIST		
Name String	Style		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** Yes

TEXTURE_COORD

A 2 by *n* array containing the texture map coordinates, where *n* is the number of polygon vertices. Each two-element entry in this array specifies the texture coordinates for the corresponding vertex in the vertex list. One texture coordinate pair should exist for each vertex. Use this property in conjunction with the TEXTURE_MAP property to wrap images over 2-D and 3-D polygons. Default coordinates are not provided.

Texture coordinates are normalized. This means that the *m* x *n* image object specified via the TEXTURE_MAP property is mapped into the range [0.0, 0.0] to [1.0, 1.0]. If texture coordinates outside the range [0.0, 0.0] to [1.0, 1.0] are specified, the image object is tiled into the larger range.

For example, suppose the image object specified via TEXTURE_MAP is a 256 x 256 array, and we want to map the image into a square two units on each side. To completely fill the square with a single copy of the image:

```
TEXTURE_COORD = [[0,0], [1,0], [1,1], [0,1]]
```

To fill the square with four tiled copies of the image:

```
TEXTURE_COORD = [[0,0], [2,0], [2,2], [0,2]]
```

Property Type	Floating-point array		
Name String	*not displayed*		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** No

TEXTURE_INTERP

A Boolean value or an enumerated list item that indicates whether bilinear sampling is to be used for texture mapping an image onto the polygon(s).

Value	Property Sheet Value	Description
0	Nearest neighbor	Surveys the value of the nearest pixel (the default)
1	Bilinear	Surveys the 4 closest pixels

Note ───
See "Interpolation Methods" (Chapter 5, *Using IDL*) for details.
──

Property Type	ENUMLIST		
Name String	Texture interpolation		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** Yes

TEXTURE_MAP

An object reference to an IDLgrImage object to be texture mapped onto the polygons. The tiling or mapping of the texture is defined expressly by TEXTURE_COORD. If this property is omitted, polygons are filled with the color specified by the COLOR or VERT_COLORS property. If both TEXTURE_MAP and COLORS or VERT_COLORS properties exist, the color of the texture is modulated by the base color of the object. (This means that for the clearest display of the texture image, the COLOR property should be set equal to [255,255,255].) To remove a texture map, set TEXTURE_MAP equal to a null object reference.

Setting TEXTURE_MAP to the object reference of an IDLgrImage that contains an alpha channel allows you to create a transparent IDLgrPolygon object. If an alpha channel is present in the IDLgrImage object, IDL blends the texture using the blend

function src=alpha and dst=1 – alpha, which corresponds to a BLEND_FUNCTION of (3,4) as described for the IDLgrImage object.

If the width and/or height of the provided image is not an exact power of two, then the texture map will consist of the given image pixel values resampled to the nearest larger dimensions that are exact powers of two.

Note
Texture mapping is disabled when rendering to a destination object that uses Indexed color mode.

Note
Texture mapping is applied to all styles that are set by the STYLE property.

Note
Objects specified via this property are not automatically cleaned up when the IDLgrPolygon object is destroyed.

This property is registered as a user-defined property, but it is hidden by default.

Property Type	USERDEF		
Name String	Texture map		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** Yes

THICK

A floating-point value between 1.0 and 10.0, specifying the size of the points or the thickness of the lines to be drawn when STYLE is set to either 0 (Points) or 1 (Lines), in points. Out-of-range values are quietly clamped to the allowed range. The default is 1.0 points.

Note
The value of this property is ignored if STYLE is set to 2 (Filled).

In a property sheet, this property appears as follows:

Property Type	Thickness		
Name String	Thickness		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

VERT_COLORS

A vector of colors used to specify the color of a polygon vertex. The vector may be of the form [*n*] where each entry is a color index, or of the form [3,*n*] where each 3-element row is an RGB color, or of the form [4,*n*] where each 4-element row is an RGBA color. To remove vertex colors after they have been set, set VERT_COLORS to a scalar.

If VERT_COLORS is not specified, the entire polygon is drawn in the single color provided by the COLOR property, which is the default action.

If SHADING is set to 0 (Flat, the default) the color of a polygon is the color of the first vertex of that polygon. Color is interpolated between vertices if SHADING is set to 1 (Gouraud).

If there are more vertices than elements in VERT_COLORS, the elements of VERT_COLORS are cyclically repeated.

Note

If the polygon object is being rendered on a destination device that uses the Indexed color model, and the view that contains the polygon also contains one or more light objects, the VERT_COLORS property is ignored and the SHADE_RANGE property is used instead.

This property is registered as a user-defined property, but it is hidden by default.

Property Type	USERDEF		
Name String	Vertex colors		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

XCOORD_CONV

A floating-point vector, $[s_0, s_1]$, of scaling factors used to convert X coordinates from data units to normalized units. The formula for the conversion is as follows:

$$\text{Normalized}X = s_0 + s_1 * \text{Data}X$$

Recommended values are:

$$[(-X_{min})/(X_{max}-X_{min}), 1/(X_{max}-X_{min})]$$

The default is [0.0, 1.0]. IDL converts, maintains, and returns this data as double-precision floating-point.

Property Type	Floating-point vector		
Name String	*not displayed*		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** No

XRANGE

A two-element floating-point vector of the form [*xmin*, *xmax*] that specifies the range of *x* data coordinates covered by the graphic object. IDL maintains and returns this property in double-precision floating-point.

Property Type	Floating-point vector		
Name String	*not displayed*		
Get: Yes	**Set:** No	**Init:** No	**Registered:** No

YCOORD_CONV

A floating-point vector, $[s_0, s_1]$, of scaling factors used to convert Y coordinates from data units to normalized units. The formula for the conversion is as follows:

$$\text{Normalized}Y = s_0 + s_1 * \text{Data}Y$$

Recommended values are:

$$[(-Y_{min})/(Y_{max}-Y_{min}), 1/(Y_{max}-Y_{min})]$$

The default is [0.0, 1.0]. IDL converts, maintains, and returns this data as double-precision floating-point.

Property Type	Floating-point vector		
Name String	*not displayed*		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** No

YRANGE

A two-element floating-point vector of the form [*ymin*, *ymax*] that specifies the range of *y* data coordinates covered by the graphic object. IDL maintains and returns this property in double-precision floating-point.

Property Type	Floating-point vector		
Name String	*not displayed*		
Get: Yes	**Set:** No	**Init:** No	**Registered:** No

ZCOORD_CONV

A floating point vector, [s_0, s_1], of scaling factors used to convert Z coordinates from data units to normalized units. The formula for the conversion is as follows:

$$\text{Normalized}Z = s_0 + s_1 * \text{Data}Z$$

Recommended values are:

$$[(-Z_{min})/(Z_{max}\text{-}Z_{min}),\ 1/(Z_{max}\text{-}Z_{min})]$$

The default is [0.0, 1.0]. IDL converts, maintains, and returns this data as double-precision floating-point.

Property Type	Floating-point vector		
Name String	*not displayed*		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** No

ZERO_OPACITY_SKIP

A Boolean value that makes it possible to gain finer control over the rendering of textured polygon pixels (texels) with an opacity of 0 in the texture map. Texels with zero opacity do not affect the color of a screen pixel since they have no opacity.

- • 1 = Any texels are "skipped" and not rendered at all (the default).

- • 0 = The Z-buffer is updated for these pixels and the display image is not affected as noted above.

By updating the Z-buffer without updating the display image, the polygon can be used as a *clipping* surface for other graphics primitives drawn after the current graphics object. The default value for this property is 1.

Note ───

This property has no effect if no texture map is used or if the texture map in use does not contain an opacity channel.

───

Property Type	Boolean		
Name String	Skip zero opacity		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

ZRANGE

A two-element floating-point vector of the form [*zmin*, *zmax*] that specifies the range of *z* data coordinates covered by the graphic object. IDL maintains and returns this property in double-precision floating-point.

Property Type	Floating-point vector		
Name String	*not displayed*		
Get: Yes	Set: No	Init: No	Registered: No

IDLgrPolygon::Cleanup

The IDLgrPolygon::Cleanup procedure method performs all cleanup on the object.

Note ——————————————————————————————————

Cleanup methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation and destruction. This means that in most cases, you cannot call the Cleanup method directly. There is one exception to this rule: if you write your own subclass of this class, you can call the Cleanup method from within the Init or Cleanup method of the subclass.

Syntax

OBJ_DESTROY, *Obj*

or

Obj->[IDLgrPolygon::]Cleanup   *(In a lifecycle method only.)*

Arguments

None

Keywords

None

Version History

5.0	Introduced

IDLgrPolygon::GetCTM

The IDLgrPolygon::GetCTM The IDLgrPolygon::GetCTM function method returns the 4-by-4 double-precision floating-point graphics transform matrix from the current object upward through the graphics tree.

Syntax

Result = Obj->[IDLgrPolygon::]GetCTM([, DESTINATION=*objref*]
  [, PATH=*objref(s)*] [, TOP=*objref to IDLgrModel object*])

Return Value

Returns the 4-by-4 double-precision floating-point graphics transform matrix from the current object upward through the graphics tree.

Arguments

None

Keywords

DESTINATION

Set this keyword to the object reference of a destination object to specify that the projection matrix for the View object in the current tree be included in the returned transformation matrix. The resulting matrix will transform a point in the data space of the object on which the GetCTM method is called into a normalized coordinate system (-1 to +1 in X, Y, and Z), relative to the View object that contains the polygon object.

PATH

Set this keyword to a single object reference or a vector of object references. This keyword specifies the path in the graphics hierarchy to compute the transformation matrix. Each path object reference specified with this keyword must contain an alias. The transformation matrix is computed for the version of the object falling within that path. If this keyword is not set, the PARENT properties determine the path from the current object to the top of the graphics hierarchy and no alias paths are pursued. If IDLgrPolygonl::GetCTM is called from within a Draw method, with the DESTINATION keyword set and the PATH keyword not set, the alias path used to find the object during the draw is used, rather than the PARENT path.

Note

For more information on aliases, refer to the ALIAS keyword in IDLgrModel::Add.

TOP

Set this keyword equal to the object reference to an IDLgrModel object to specify that the returned matrix accumulate from the object on which the GetCTM method is called up to but not including the specified model object.

Version History

5.0	Introduced

IDLgrPolygon::GetMultiTextureCoord

The IDLgrPolygon::GetMultiTextureCoord returns the texture coordinates associated with a given *Unit*. This method is useful when a shader program defined by an IDLgrShader object applies more than a single texture to an object. See Chapter 14, "Advanced Rendering Using Shader Objects" (*Object Programming*) for more information.

Syntax

Obj->[IDLgrPolygon::]GetMultiTextureCoord, *Unit*, *TexCoord*

Arguments

Unit

This scalar numeric value specifies the texture unit. Texture units are used primarily with multi-texturing and allow OpenGL to handle multiple textures and multiple sets of texture coordinates and parameters. This value should be greater than or equal to zero and less than the MAX_VERTEX_TEXTURE_IMAGE_UNITS (for vertex shaders) or MAX_TEXTURE_IMAGE_UNITS (for fragment shaders). These values can be returned by IDLgrWindow::GetDeviceInfo.

Note ————
If the specified *Unit* value was never defined and stored in the polygon object using IDLgrPolygon::SetMultiTextureCoord, then the variable specified in the *TexCoord* parameter will be set to an undefined variable.

TexCoord

Specifies a variable that contains the current texture coordinates associated with the specified *Unit*. Texture coordinates are stored in this parameter as single precision floating point numbers.

Keywords

None

Examples

See "Multi-texture Shaders" (Chapter 14, *Object Programming*)

Version History

6.4	Introduced

See Also

IDLgrPolygon::SetMultiTextureCoord

IDLgrPolygon::GetProperty

The IDLgrPolygon::GetProperty procedure method retrieves the value of the property or group of properties for the polygons.

Syntax

Obj->[IDLgrPolygon::]GetProperty[, *PROPERTY=variable*]

Arguments

There are no arguments for this methods.

Keywords

Any property listed under "IDLgrPolygon Properties" on page 4578 that contains the word "Yes" in the "Get" column of the properties table can be retrieved using this method. To retrieve the value of a property, specify the property name as a keyword set equal to a named variable that will contain the value of the property.

Any keyword not recognized is passed to this object's superclass.

Version History

5.0	Introduced

IDLgrPolygon::GetVertexAttributeData

The IDLgrPolygon::GetVertexAttributeData procedure method retrieves the data associated with a named attribute variable containing per-vertex attribute data. See "Attribute Variables" (Chapter 14, *Object Programming*) for general attribute variable information. This method is useful when a shader program defined by an IDLgrShader object modifies the vertices of an object. See Chapter 14, "Advanced Rendering Using Shader Objects" (*Object Programming*) for more information.

Syntax

Obj->[IDLgrPolygon::]GetVertexAttributeData, *Name, Value*

Arguments

Name

Specifies a case-sensitive string name of the attribute variable to retrieve.

Note

If the *Name* argument specifies an attribute variable that was never defined and stored in the polygon object using SetVertexAttributeData, then the variable specified in the *Value* parameter will be set to an undefined variable.

Value

Specifies a variable that contains the current value of the vertex data attribute variable. The variable is stored in this parameter in exactly the same format as that used when it was defined using IDLgrPolygon::SetVertexAttributeData.

Keywords

None

Examples

See "Vertex Shaders" (Chapter 14, *Object Programming*).

Version History

6.4	Introduced

See Also

IDLgrPolygon::SetVertexAttributeData

IDLgrPolygon::Init

The IDLgrPolygon::Init function method initializes the polygons object.

Note

Init methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation. This means that in most cases, you cannot call the Init method directly. There is one exception to this rule: if you write your own subclass of this class, you can call the Init method from within the Init method of the subclass.

Syntax

Obj = OBJ_NEW('IDLgrPolygon' [, *X* [, *Y*[, *Z*]]] [, *PROPERTY=value*])

or

Result = Obj->[IDLgrPolygon::]Init([*X*, [*Y*, [*Z*]]] [, *PROPERTY=value*])   *(In a lifecycle method only.)*

Return Value

When this method is called indirectly, as part of the call to the OBJ_NEW function, the return value is an object reference to the newly-created object.

When called directly within a subclass Init method, the return value is 1 if initialization was successful, or zero otherwise.

Arguments

Note

The values specified by the *X*, *Y*, and *Z* arguments are used to initialize the value of the DATA property of the IDLgrPolygon object.

X

A vector argument providing the X coordinates of the vertices. The vector must contain at least three elements. If the Y and Z arguments are not provided, X must be an array of either two or three vectors (i.e., [2,*] or [3,*]), in which case, X[0,*] specifies the X values, X[1,*] specifies the Y values, and X[2,*] specifies the Z values.

This argument is stored as double precision floating point values if the argument variable is of type DOUBLE or if the DOUBLE property is non-zero, otherwise it is converted to single precision floating point.

Y

A vector argument providing the Y coordinates of the vertices. The vector must contain at least three elements. This argument is stored as double precision floating point values if the argument variable is of type DOUBLE or if the DOUBLE property is non-zero, otherwise it is converted to single precision floating point.

Z

A vector argument providing the Z coordinates of the vertices. The vector must contain at least three elements. This argument is stored as double precision floating point values if the argument variable is of type DOUBLE or if the DOUBLE property is non-zero, otherwise it is converted to single precision floating point.

Keywords

Any property listed under "IDLgrPolygon Properties" on page 4578 that contains the word "Yes" in the "Init" column of the properties table can be initialized during object creation using this method. To initialize the value of a property, specify the property name as a keyword set equal to the appropriate property value.

All other keywords are passed to the superclass of this object.

Examples

See "Mapping an Image onto a Sphere" (Chapter 3, *Image Processing in IDL*) and Chapter 8, "Polygon and Polyline Objects" (*Object Programming*).

Version History

5.0	Introduced

IDLgrPolygon::SetMultiTextureCoord

The IDLgrPolygon::SetMultiTextureCoord procedure method passes texture coordinates to a shader program when the shader program applies more than one texture to an object. The shader program accesses these texture coordinates by using the GLSL predefined uniform variable gl_MultiTexCoord*n*, where *n* corresponds to the *Unit* parameter in this method. This method is useful when a shader program defined by an IDLgrShader object applies more than a single texture to an object. See Chapter 14, "Advanced Rendering Using Shader Objects" (*Object Programming*) for more information.

Syntax

Obj->[IDLgrPolygon::]SetMultiTextureCoord, *Unit*, *TexCoord*

Arguments

Unit

This scalar numeric value specifies the texture unit. Texture units are used primarily with multi-texturing and allow OpenGL to handle multiple textures and multiple sets of texture coordinates and parameters. This value should be greater than or equal to zero and less than the MAX_VERTEX_TEXTURE_IMAGE_UNITS (for vertex shaders) or MAX_TEXTURE_IMAGE_UNITS (for fragment shaders). These values can be returned by IDLgrWindow::GetDeviceInfo. The behavior is undefined for any other setting.

Unit 0 is used by the TEXTURE_COORD property on IDLgrPolygon. Using unit 0 in this method overrides any texture coordinates specified with the TEXTURE_COORD property. Therefore, the TEXTURE_COORD property can be used instead of this method if *Unit* is 0.

TexCoord

This data has exactly the same form as the TEXTURE_COORD property. IDL converts and maintains this data as single precision floating point. IDL displays an error message and does not draw the object if the number of texture coordinates provided in this parameter is not the same as the number of vertices in the polygon.

IDL stores the texture coordinates in the instance of the graphic object when the application calls this method for the first time with a given *Unit* parameter. If the application calls this method again with a *Unit* number used in a previous call to this

method, IDL replaces the corresponding stored texture coordinates with the contents of the *TexCoord* parameter.

There is no way to remove texture coordinates from an instance of a graphics object. If texture coordinates are associated with a particular texture unit, and the shader program does not reference that unit, the texture coordinates are effectively ignored by the shader program.

Keywords

IDLgrPolygon::GetMultiTextureCoord

IDLgrPolygon::SetProperty

The IDLgrPolygon::SetProperty procedure method sets the value of the property or group of properties for the polygons.

Syntax

Obj->[IDLgrPolygon::]SetProperty[, *PROPERTY=value*]

Arguments

None

Keywords

Any property listed under "IDLgrPolygon Properties" on page 4578 that contains the word "Yes" in the "Set" column of the properties table can be set using this method. To set the value of a property, specify the property name as a keyword set equal to the appropriate property value.

Version History

5.0	Introduced

IDLgrPolygon::SetVertexAttributeData

The IDLgrPolygon::SetVertexAttributeData procedure method passes a set of per-vertex attribute data to a vertex shader program. When an IDLgrShader object is associated with the polygon via the SHADER property, this attribute data is made available, a vertex's worth at a time, to the vertex shader program as it processes each vertex in the polygon. If there are more vertices in the polygon than there are vertex attributes, the list of vertex attributes is reused until all the vertices are drawn. See "Attribute Variables" (Chapter 14, *Object Programming*) for a general introduction to attribute variables. Also see the chapter, "Advanced Rendering Using Shader Objects" (*Object Programming*) for additional shader program information and examples.

IDL stores the *Name* and *Value* of the vertex attribute data variable with this polygon object the first time this method is called. When SetVertexAttributeData is called again using the same *Name* argument, the vertex attribute data variable is updated with the current contents of *Value*. Once a vertex attribute data variable is associated with this object, there is no way to remove the reference. The shader program ignores any vertex attribute data variable defined for this object but not declared in the shader program.

The attribute data may consist of 1 to 4 elements per vertex. The data is passed to the vertex shader program via a shader program variable with the attribute qualifier. The attribute variable may be of GLSL type `float`, `vec2`, `vec3`, `vec4`, `mat2`, `mat3`, or `mat4`. Internally, the `mat2` type is treated as two `vec2` attribute variables, `mat3` as three `vec3` attribute variables, and `mat4` as four `vec4` attribute variables.

If the attribute variable is larger than the data passed to it, the shader program pads the missing elements as follows. A missing second or third element is set to 0.0. A missing fourth element is set to 1.0.

For example, the IDL application has a set of vertex attribute data where there is an x-offset and a y-offset for each vertex. The vertex program defines an attribute variable using a `vec4` type so that it can be used in 4x4 general transformations. The IDL program stores the x- and y-offset information in a [2, *n*] array and sets the value of the attribute variable to this array. As the shader program runs, for each vertex it assigns the two values from the corresponding row of the IDL array to the first two elements in the `vec4` attribute variable. It also sets the third value to 0.0 and the fourth value to 1.0, thus expanding the 2-element data to a general 3-D point in homogenous coordinate space, suited for 4x4 general transforms.

Note

A minimum of 16 vertex attribute data variables can be passed to the shader vertex program (use IDLgrWindow::GetDeviceInfo to determine the exact number). IDL

uses one vertex attribute variable, leaving the remainder for user programs. For maximum shader program portability, define 15 or fewer attribute variables.

Syntax

Obj->[IDLgrPolygon::]SetVertexAttributeData, *Name, Value*

Arguments

Name

Specifies a case-sensitive string name of the attribute variable.

Value

Specifies an IDL array of any numeric type. The array must be of the form [*n*], [*a*,*n*], or [*a*,*a*,*n*] where *a* is 1,2,3, or 4 and *n* is the number of vertex attribute elements. IDL will halt with an error if you assign IDL strings, structures, pointers, object references, and undefined variables to *Value*. IDL converts all numeric types to 32-bit float when submitting the data to the shader program.

Keywords

None

Examples

Suppose there is large set of point sample data, along with a set of initial velocity vectors for each point. You want to display an animation of these points as each point moves along its own velocity vector as a function of time. Without a shader program, you would normally have to recalculate the position of each point and replace all the vertices in an IDLgrPolygon (STYLE=0) object with the recomputed values for each animation frame, which would be inefficient with a large number of points.

However, with a vertex shader program and vertex attribute data, you can move the points around using the graphics card's GPU instead of recalculating and moving a lot of data around on the system CPU.

The interesting parts of the IDL code are:

```
; Define the original vertices at time=0.
oPolygon->SetProperty, DATA=vertices
```

```
; Set [3,n] array.
oPolygon->SetVertexAttributeData, 'velocity', velocities
FOR t=0.0, 100.0, 0.01 DO BEGIN  ;; time samples
   oShader->SetUniformVariable, 'time', t
   oWindow->Draw
ENDFOR
```

And the interesting parts of the vertex shader program are:

```
attribute vec3 velocity;
uniform float time;
void main () {
   vec4 vert;
   vert = gl_Vertex + vec4(velocity * time, 0.0);
   gl_Position = gl_ModelViewProjectMatrix * vert;
}
```

See "Vertex Shaders" (Chapter 14, *Object Programming*) for more information and examples.

IDLgrPolygon::GetVertexAttributeData

IDLgrPolyline

A polyline object represents one or more polylines that share a set of vertices and rendering attributes.

An IDLgrPolyline object is an *atomic graphic object*; it is one of the basic drawable elements of the IDL Object Graphics system, and it is not a container for other objects.

Superclasses

IDLitComponent

Creation

See "IDLgrPolyline::Init" on page 4646.

Properties

Objects of this class have the following properties. See "IDLgrPolyline Properties" on page 4620 for details on individual properties.

- ALL
- CLIP_PLANES
- DATA
- DEPTH_TEST_FUNCTION
- DOUBLE
- LABEL_NOGAPS
- LABEL_OBJECTS
- LABEL_USE_VERTEX_COLOR
- PALETTE
- POLYLINES
- RESET_DATA
- SHADING
- SYMBOL

- ALPHA_CHANNEL
- COLOR
- DEPTH_TEST_DISABLE
- DEPTH_WRITE_DISABLE
- HIDE
- LABEL_OFFSETS
- LABEL_POLYLINES
- LINESTYLE
- PARENT
- REGISTER_PROPERTIES
- SHADER
- SHARE_DATA
- THICK

- USE_LABEL_COLOR
- USE_LABEL_ORIENTATION
- USE_TEXT_ALIGNMENTS
- VERT_COLORS
- XCOORD_CONV
- XRANGE
- YCOORD_CONV
- YRANGE
- ZCOORD_CONV

In addition, objects of this class inherit the properties of all superclasses of this class.

Methods

This class has the following methods:

- IDLgrPolyline::Cleanup
- IDLgrPolyline::GetCTM
- IDLgrPolyline::GetProperty
- IDLgrPolyline::GetVertexAttributeData
- IDLgrPolyline::Init
- IDLgrPolyline::SetProperty
- IDLgrPolyline::SetVertexAttributeData

In addition, this class inherits the methods of its superclasses (if any).

5.6	Added CLIP_PLANES, LABEL_NOGAPS, LABEL_POLYLINES, LABEL_OFFSETS, LABEL_OBJECTS, LABEL_USE_VERTEX_COLOR, USE_LABEL_COLOR, USE_LABEL_ORIENTATION, USE_TEXT_ALIGNMENTS properties
6.1	Added ALPHA_CHANNEL property
6.4	Added the SHADER property Added GetVertexAttributeData, SetVertexAttributeData

IDLgrPolyline Properties

IDLgrPolyline objects have the following properties in addition to properties inherited from any superclasses. Properties with the word "Yes" in the "Get" column of the property table can be retrieved via IDLgrPolyline::GetProperty. Properties with the word "Yes" in the "Init" column of the property table can be set via IDLgrPolyline::Init. Properties with the word "Yes" in the "Set" column in the property table can be set via IDLgrPolyline::SetProperty.

Note
For a discussion of the property description tables shown below, see "About Object Property Descriptions" on page 3135.

Objects of this class have the following properties.

- ALL
- CLIP_PLANES
- DATA
- DEPTH_TEST_FUNCTION
- DOUBLE
- LABEL_NOGAPS
- LABEL_OBJECTS
- LABEL_USE_VERTEX_COLOR
- PALETTE
- POLYLINES
- RESET_DATA
- SHADING

- REGISTER_PROPERTIES
- SHADER
- SHARE_DATA
- THICK
- USE_LABEL_ORIENTATION
- VERT_COLORS
- XRANGE
- YRANGE

In addition, objects of this class inherit:

- IDLitComponent

ALL

An anonymous structure containing the values of all of the properties associated with the *state* of this object. State information about the object includes things like color, range, tick direction, etc., but not image, vertex, or connectivity data, or user values.

Note ————————————————————————————

The fields of this structure may change in subsequent releases of IDL.

_____

Property Type	Structure		
Name String	*not displayed*		
Get: Yes	**Set:** No	**Init:** No	**Registered:** No

ALPHA_CHANNEL

A floating-point value in the range [0.0, 1.0] to specify the opacity of the polyline. The default value of 1.0 causes IDL to draw the line completely opaque. If the value of this property is less than 1.0, then the pixels of the polyline are blended with the pixels already on the screen, where the color of the polyline is multiplied by the alpha value and the pixels already on the screen are multiplied by 1.0-alpha.

Because an object can only be blended with objects already drawn on the screen, the drawing order of the objects must be considered carefully in order to obtain the desired results. Note that since a single polyline object may contain many polylines, or because a line may draw in back or in front of itself, the ordering of the polylines within the object (POLYLINES property) must be considered as well.

This property has no effect on devices using indexed color mode.

If 3-channel (RGB) VERT_COLORS are supplied, then the value of this property is used for the alpha at each vertex to draw the line. If 4-channel (RGBA) VERT_COLORS are supplied, then the alpha from each vertex color is used for the alpha at each vertex to draw the line.

When a polyline is drawn with symbols, the symbol's color and alpha values are always used to draw the symbols unless VERT_COLORS are supplied. If the VERT_COLORS are RGB, then the alpha value of the symbol is used to draw the

symbol. If the VERT_COLORS are RGBA, then the alpha from the vertex color is used to draw the symbol.

When used with labels, the value of this property is used as the alpha channel value for a label if its corresponding value in the USE_LABEL_COLOR property is zero and the value of LABEL_USE_VERTEX_COLOR is zero.

If a label's corresponding value in the USE_LABEL_COLOR property is zero and the LABEL_USE_VERTEX_COLOR property is non-zero, then the label is drawn with the alpha value from its corresponding vertex color, if the alpha values are included in the vertex colors. If the vertex colors do not include alpha values, the value of this property is used as the alpha value for the label.

If a label's corresponding value in the USE_LABEL_COLOR property is non-zero, then the value of the label object's ALPHA_CHANNEL property is used to draw the label. In other words, USE_LABEL_COLOR also implies using the label object's alpha as well as its color.

Note ———————————————————————————

For more detailed information on alpha channel support for IDL Object Graphics, see "Controlling Object Transparency" (Chapter 2, *Object Programming*).

———————————————————————————————————

Property Type	Float-point value		
Name String	*Transparency*		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** Yes

CLIP_PLANES

A 4-by-*N* floating-point array of dimensions that specifies the coefficients of the clipping planes to be applied to this object. The four coefficients for each clipping plane are of the form [A, B, C, D], where $Ax + By + Cz + D = 0$. Portions of this object that fall in the half space $Ax + By + Cz + D > 0$ will be clipped. By default, the value of this property is a scalar (-1) indicating that no clipping planes are to be applied.

Note ———————————————————————————

The clipping planes specified via this property are applied in addition to the near and far clipping planes associated with the IDLgrView in which this object appears.

———————————————————————————————————

Note

Clipping planes are applied in the data space of this object (prior to the application of any *x*, *y*, or *z* coordinate conversion).

Note

To determine the maximum number of clipping planes supported by the device, use the MAX_NUM_CLIP_PLANES property of the GetDeviceInfo method for the IDLgrBuffer, IDLgrClipboard, IDLgrWindow, and IDLgrVRML objects.

Property Type	Floating-point array		
Name String			
Get: Yes	Set: Yes	Init: Yes	Registered: No

COLOR

A color index or a three-element vector [*red*, *green*, *blue*] specifying the color used to draw polylines. The default color is [0, 0, 0] (black). This property is ignored if the VERT_COLORS property is provided.

In a property sheet, this property appears as a color property.

Property Type	COLOR		
Name String	Color		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

DATA

A 2-by-*n* or a 3-by-*n* floating-point array which defines, respectively, the 2-D or 3-D vertex data. This property is converted to double-precision floating-point values if the DOUBLE property is set. Otherwise, it is converted to single-precision floating-point.

Specifying this property is the same as specifying the optional *X*, *Y*, and *Z* arguments to the IDLgrPolyline::Init method.

Property Type	Floating-point array		
Name String	*not displayed*		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** No

DEPTH_TEST_DISABLE

An integer value that determines whether depth testing is disabled.

- Set this property to 0 (the default) to inherit the value set by the parent model or view. The parent view always enables depth testing. A model may also enable or disable depth testing.

- Set this property to 1 to explicitly disable depth buffer testing while drawing this object.

- Set this property to 2 to explicitly enable depth testing for this object.

Disabling depth testing allows an object to draw itself "on top" of other objects already on the screen, even if the object is located behind them.

Note
Disabling depth testing also disables depth buffer writing. When disabling depth testing, the DEPTH_TEST_FUNCTION and DEPTH_WRITE_DISABLE properties are effectively ignored.

This property is registered as an enumerated list, but it is hidden by default.

Property Type	ENUMLIST		
Name String	*not displayed*		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** No

DEPTH_TEST_FUNCTION

An integer value that determines the depth test function. Set this property to 0 (the default) to inherit the value set by the parent model or view. The parent view always sets a depth test function of LESS. A model may also set a depth test function value. The graphics device compares the object's depth at a particular pixel location with the depth stored in the depth buffer at that same pixel location. If the comparison test

passes, the object's pixel is drawn at that location on the screen and the depth buffer is updated (if depth writing is enabled).

Set this property to any of the following values to use the desired function while rendering this object.

- 0 = INHERIT - use value from parent model or view.
- 1 = NEVER - never passes.
- 2 = LESS - passes if the object's depth is less than the depth buffer's value.
- 3 = EQUAL - passes if the object's depth is equal to the depth buffer's value.
- 4 = LESS OR EQUAL - passes if the object's depth is less than or equal to the depth buffer's value.
- 5 = GREATER - passes if the object's depth is greater than or equal to the depth buffer's value.
- 6 = NOT EQUAL - passes if the object's depth is not equal to the depth buffer's value.
- 7 = GREATER OR EQUAL - passes if the object's depth is greater than or equal to the depth buffer's value.
- 8 = ALWAYS - always passes

Less means closer to the viewer.

This property is registered as an enumerated list, but it is hidden by default.

Property Type	ENUMLIST		
Name String	*not displayed*		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** No

DEPTH_WRITE_DISABLE

An integer value that determines whether depth writing is disabled.

- Set this property to 0 (the default) to inherit the value set by the parent model or view. The parent view always enables depth writing. A model may also enable or disable depth writing.
- Set this property to 1 to explicitly disable depth buffer writing while rendering this object.
- Set this property to 2 to explicitly enable depth writing for this object.

Disabling depth writing allows an object to be overdrawn by other objects, even if the object is located in front of them.

Note ───

If depth testing (see DEPTH_TEST_DISABLE property) is disabled, depth writing is also automatically disabled.

───

This property is registered as an enumerated list, but it is hidden by default.

Property Type	ENUMLIST		
Name String	*not displayed*		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** No

DOUBLE

A Boolean value that indicates whether data provided by any of the input arguments will be stored in this object as using double-precision floating-point format.

- Set this property equal to 1 to convert input data to double-precision floating-point format.

- Set this property equal to 0 to convert input data to single-precision floating-point format.

- If you do not specify a value for this property, no data type conversion will be performed, and the data will be stored with its original precision.

Setting this property may be desirable if the data consists of large integers that cannot be accurately represented in single-precision floating-point arithmetic. This property is also automatically set to 1 if any of the input arguments are stored using a variable of type DOUBLE.

Property Type	Boolean		
Name String	*not displayed*		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** No

HIDE

A Boolean value or enumerated list item indicating whether this object should be drawn:

Value	Property Sheet Value	Description
0	True	Draw graphic (the default)
1	False	Do not draw graphic

Property Type	ENUMLIST		
Name String	Show		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** Yes

LABEL_NOGAPS

An integer vector of values indicating whether gaps should be computed for the corresponding label. A zero value indicates that a gap will be computed for the labels; a non-zero value indicates that no gap will be computed for the label. If the number of labels exceeds the number of elements in this vector, the LABEL_NOGAPS values will be repeated cyclically. By default, gaps are computed for all labels (so that the polyline does not pass through the label).

Property Type	Integer vector		
Name String	*not displayed*		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** No

LABEL_OFFSETS

A scalar or vector of floating-point offsets, [t0, t1, …], that indicate the parametric offsets along the length of each polyline (specified via the LABEL_POLYLINES property) at which each label (as specified via the LABEL_OBJECTS property) would be positioned. If LABEL_OFFSETS is set to a scalar less than zero, then the offsets will be automatically computed to be evenly distributed along the length of the polyline. If a scalar value greater than or equal to zero is provided, it is used for all labels. If a vector is provided, the number of offsets must match the number of

labels provided via LABEL_OBJECTS. By default, this property is set to the scalar, -1, indicating that the label offsets will be automatically computed.

Property Type	Floating-point vector		
Name String	*not displayed*		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** No

LABEL_OBJECTS

An object reference (or vector of object references) to specify the labels to be drawn along the polyline path(s). The objects specified via this property must inherit from one of the following classes:

- IDLgrSymbol
- IDLgrText

If a single object is provided, and it is an IDLgrText object, each of its strings will correspond to a label. If a vector of objects is used, any IDLgrText objects should have only a single string; each object will correspond to a label.

If one or more IDLgrText objects are provided, the LOCATION property of the provided text object(s) may be overwritten; position is determined according to the values provided via the LABEL_OFFSETS property. The labels will have the same color as the corresponding polyline (see the COLOR property) unless the USE_LABEL_COLOR property is specified. The orientation of the label objects USE_LABEL_ORIENTATION property is specified. The horizontal and vertical alignment for any text labels will each default to 0.5 (i.e., centered) unless the USE_TEXT_ALIGNMENTS property is specified.

Note ————————————————————————————————————
The objects provided via this property will not be destroyed automatically when this IDLgrPolyline is destroyed.
————————————————————————————————————

Property Type	Object reference		
Name String	*not displayed*		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** No

LABEL_POLYLINES

An integer or integer vector of polyline indices, [P0, P1, …], that indicate which polylines are to be labeled. Pi corresponds to the ith polyline specified via the POLYLINES property. This property is intended to be used in conjunction with the LABEL_OBJECTS property. If a scalar is provided, all labels will be drawn along the single indicated polyline. If a vector is provided, the number of polyline indices must match the number of labels provided via LABEL_OBJECTS.

By default, this property is set to the scalar, 0, indicating that only the first polyline will be labeled.

Note ———————————————————————————————

If a given polyline has more than one label, then the corresponding polyline index may appear more than once in the LABEL_POLYLINES vector.

Property Type	Integer or integer vector		
Name String	*not displayed*		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** No

LABEL_USE_VERTEX_COLOR

An integer value that indicates whether labels should be colored according to the vertex coloring (if the VERT_COLORS property is set).

- A non-zero value = labels should be colored according to the vertex coloring

- Zero (the default) = the label will be drawn using the color specified via the COLOR property of the polyline object (unless the USE_LABEL_COLOR property is set).

Property Type	Integer		
Name String	*not displayed*		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** No

LINESTYLE

An integer or array value that indicates the line style to be used to draw the polyline. The value can be either an integer value specifying a pre-defined line style, or a two-element vector specifying a stippling pattern.

To use a pre-defined line style, set this property equal to one of the following integer values:

0	Solid line (the default)
1	Dotted
2	Dashed
3	Dash dot
4	Dash dot dot dot
5	Long dash
6	No line drawn

To define your own stippling pattern, specify a two-element vector [*repeat*, *bitmask*], where *repeat* indicates the number of times consecutive runs of 1's or 0's in the *bitmask* should be repeated. (That is, if three consecutive 0's appear in the *bitmask* and the value of *repeat* is 2, then the line that is drawn will have six consecutive bits turned off.) The value of *repeat* must be in the range $1 \le repeat \le 255$.

The *bitmask* indicates which pixels are drawn and which are not along the length of the line. *Bitmask* is most conveniently specified as a 16-bit hexadecimal value.

For example, LINESTYLE = [2, 'F0F0'X] describes a dashed line (8 bits on, 8 bits off, 8 bits on, 8 bits off).

In a property sheet, this property appears as follows:

Property Type	Linestyle		
Name String	Line style		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** Yes

PALETTE

An object reference to a palette object (an instance of the IDLgrPalette object class) that defines the color palette of this object. This property is only used if the destination device is using the RGB color model. If so, and a color value for the object is specified as a color index value, the palette set by this property is used to translate the color to RGB space. If the PALETTE property on this object is not set, the destination object PALETTE property is used (which defaults to a grayscale ramp).

Note
Objects specified via this property are not automatically cleaned up when the IDLgrPolyline object is destroyed.

This property is registered as a user-defined property, but it is hidden by default.

Property Type	USERDEF		
Name String	Color palette		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** Yes

PARENT

An object reference to the object that contains this object.

Property Type	Object reference		
Name String	*not displayed*		
Get: Yes	**Set:** No	**Init:** No	**Registered:** No

POLYLINES

An integer array of one or more polyline descriptions. IDL converts and stores this array as 32-bit signed integers. Set this property to a scalar to remove a polyline description array from the object, returning it to its initial empty state. When this property does not contain an array of polyline descriptions, IDL draws a single polyline using the vertices in the order they appear in the vertex list (see the DATA property).

For details on using this property, see "Creating Polygon and Polyline Objects" (Chapter 8, *Object Programming*).

Property Type	Integer array		
Name String	*not displayed*		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** No

REGISTER_PROPERTIES

A Boolean value that determines whether to register properties available for this object. If this property is set, all properties marked in this properties section as "Registered: Yes" will be registered for display in a property sheet. This property is useful mainly when creating iTools. By default, no properties are registered.

Property Type	Boolean		
Name String	*not displayed*		
Get: No	**Set:** No	**Init:** Yes	**Registered:** No

RESET_DATA

A Boolean value that determines whether to treat the data provided via one of the DATA property as a new data set unique to this object, rather than overwriting data that is shared by other objects. There is no reason to use this property if the object on which the property is being set does not currently share data with another object (that is, if the SHARE_DATA property is not in use). This property has no effect if no new data is provided via the DATA property.

Property Type	Boolean		
Name String	*not displayed*		
Get: No	**Set:** Yes	**Init:** Yes	**Registered:** No

SHADER

An object reference to an IDLgrShader object (or an object containing IDLgrShader as a superclass). When there is suitable graphics card hardware support, the polyline is rendered using the GLSL shader program (executed on the graphics card) instead of using fixed OpenGL properties when initially drawn. (If a suitable graphics card is not present, IDL ignores the shader object when the scene is drawn.) A single

IDLgrShader object may be associated with additional polyline objects or other graphic objects that have the SHADER property.

Property Type	Object reference		
Name String	*not displayed*		
Get: Yes	Set: Yes	Init: Yes	Registered: No

SHADING

An integer value or enumerated list item representing the type of shading to use:

Value	Property Sheet Value	Description
0	Flat	The color of the second vertex in a line segment is used to define the color for the entire line segment. The color has a constant intensity based upon the normal vector (the default).
1	Gouraud	The colors along each line are interpolated between vertex colors

Property Type	ENUMLIST		
Name String	Shading		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

SHARE_DATA

An object reference to an object whose data is to be shared by this polyline. A polyline may only share data with a polygon object or another polyline. The SHARE_DATA property is intended for use when data values are not set via an argument to the object's Init method or by setting the object's DATA property.

Note

Objects specified via this property are not automatically cleaned up when the IDLgrPolyline object is destroyed.

Property Type	Object reference		
Name String	*not displayed*		
Get: No	**Set:** Yes	**Init:** Yes	**Registered:** No

SYMBOL

An object reference vector containing one or more instances of the IDLgrSymbol object class to indicate the plotting symbols to be used at each vertex of the polyline. If there are more vertices than elements in SYMBOL, the elements of the SYMBOL vector are cyclically repeated. By default, no symbols are drawn. To remove symbols from a polyline, set SYMBOL to a scalar.

Note
Objects specified via this property are not automatically cleaned up when the IDLgrPolyline object is destroyed.

Property Type	Object reference vector		
Name String	*not displayed*		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** No

THICK

A floating-point value between 1.0 and 10.0, specifying the line thickness to be used to draw the polyline, in points. Out-of-range values are quietly clamped to the allowed range. The default is 1.0 points.

In a property sheet, this property appears as follows:

Property Type	Thickness		
Name String	Thickness		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** Yes

USE_LABEL_COLOR

An integer vector of values to indicate whether the COLOR property value for the corresponding label object is to be used to draw that label. If the number of labels exceeds the number of elements in this vector, the USE_LABEL_COLOR values will be repeated cyclically. By default, this value is zero, indicating that the COLOR property of each label object will be ignored, and the COLOR property for the polyline object will be used instead.

Property Type	Integer vector		
Name String	*not displayed*		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** No

USE_LABEL_ORIENTATION

An integer vector of values to indicate whether the orientation of the corresponding label object is to be used to draw that label. For IDLgrText objects, this refers to the BASELINE and UPDIR property values. For IDLgrSymbol objects, this refers to the default (un-rotated) orientation of the symbol. If the number of labels exceeds the number of elements in this vector, the USE_LABEL_ORIENTATION values will be repeated cyclically. By default, USE_LABEL_ORIENTATION is zero, indicating

that the orientation will be automatically computed so that the baseline is parallel to the polyline, and the updir is perpendicular to the polyline.

Property Type	Integer vector		
Name String	*not displayed*		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** No

USE_TEXT_ALIGNMENTS

A Boolean value that indicates whether, for any IDLgrText labels (as specified via the LABEL_OBJECTS property), the ALIGNMENT and VERTICAL_ALIGNMENT property values for the given IDLgrText object(s) are to be used to draw those labels. By default, this value is zero, indicating that the ALIGNMENT and VERTICAL_ALIGNMENT properties of the IDLgrText object(s) will be overwritten with default values (0.5 for each, indicating centered labels).

Property Type	Boolean		
Name String	*not displayed*		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** No

VERT_COLORS

A vector of colors to be used to specify the color of the line segment between each vertex. The vector may be of the form [*n*] where each entry is a color index, or of the form [3,*n*] where each 3-element row is an RGB color, or of the form [4,*n*] where each 4-element row is an RGBA color. To remove vertex colors after they have been set, set VERT_COLORS to a scalar.

If VERT_COLORS is not specified, the entire polyline is drawn in the single color provided by the COLOR property, which is the default action.

If SHADING is set to 0 (Flat, the default) the color of a line segment is the color of the second vertex of that line segment. Color is interpolated between vertices if SHADING is set to 1 (Gouraud).

If there are more vertices than elements in VERT_COLORS, the elements of VERT_COLORS are cyclically repeated.

When VERT_COLORS is used with symbols, the vertex colors and vertex alpha override any colors and alpha specified by the symbol object or any colors and alpha specified by graphic atoms contained in a user-defined symbol.

When VERT_COLORS is used with labels, the application of the color and alpha of the labels is controlled by the USE_LABEL_COLOR and LABEL_USE_VERTEX_COLOR properties.

Property Type	USERDEF		
Name String	Vertex colors		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

XCOORD_CONV

A floating-point vector, $[s_0, s_1]$, of scaling factors used to convert X coordinates from data units to normalized units. The formula for the conversion is as follows:

$$Normalized X = s_0 + s_1 * Data X$$

Recommended values are:

$$[(-X_{min})/(X_{max}-X_{min}), 1/(X_{max}-X_{min})]$$

The default is [0.0, 1.0]. IDL converts, maintains, and returns this data as double-precision floating-point.

Property Type	Floating-point vector		
Name String	*not displayed*		
Get: Yes	Set: Yes	Init: Yes	Registered: No

XRANGE

A two-element floating-point vector of the form [*xmin*, *xmax*] that specifies the range of *x* data coordinates covered by the graphic object. IDL maintains and returns this property in double-precision floating-point.

Property Type	Floating-point vector		
Name String	*not displayed*		
Get: Yes	Set: No	Init: No	Registered: No

YCOORD_CONV

A floating-point vector, [s_0, s_1], of scaling factors used to convert Y coordinates from data units to normalized units. The formula for the conversion is as follows:

$$Normalized Y = s_0 + s_1 * Data Y$$

Recommended values are:

[($-Y_{min}$)/(Y_{max}-Y_{min}), 1/(Y_{max}-Y_{min})]

The default is [0.0, 1.0]. IDL converts, maintains, and returns this data as double-precision floating-point.

Property Type	Floating-point vector		
Name String	*not displayed*		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** No

YRANGE

A two-element floating-point vector of the form [*ymin*, *ymax*] that specifies the range of *y* data coordinates covered by the graphic object. IDL maintains and returns this property in double-precision floating-point.

Property Type	Floating-point vector		
Name String	*not displayed*		
Get: Yes	**Set:** No	**Init:** No	**Registered:** No

ZCOORD_CONV

A floating-point vector, [s_0, s_1], of scaling factors used to convert Z coordinates from data units to normalized units. The formula for the conversion is as follows:

$$Normalized Z = s_0 + s_1 * Data Z$$

Recommended values are:

[($-Z_{min}$)/(Z_{max}-Z_{min}), 1/(Z_{max}-Z_{min})]

The default is [0.0, 1.0]. IDL converts, maintains, and returns this data as double-precision floating-point.

Property Type	Floating-point vector		
Name String	*not displayed*		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** No

ZRANGE

A two-element floating-point vector of the form [*zmin*, *zmax*] that specifies the range of *z* data coordinates covered by the graphic object. IDL maintains and returns this property in double-precision floating-point.

Property Type	Floating-point vector		
Name String	*not displayed*		
Get: Yes	**Set:** No	**Init:** No	**Registered:** No

IDLgrPolyline::Cleanup

The IDLgrPolyline::Cleanup procedure method performs all cleanup on the object.

Note ───

Cleanup methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation and destruction. This means that in most cases, you cannot call the Cleanup method directly. There is one exception to this rule: if you write your own subclass of this class, you can call the Cleanup method from within the Init or Cleanup method of the subclass.

───

Syntax

OBJ_DESTROY, *Obj*

or

Obj->[IDLgrPolyline::]Cleanup   *(In a lifecycle method only.)*

Arguments

None

Keywords

None

Version History

5.0	Introduced

IDLgrPolyline::GetCTM

The IDLgrPolyline::GetCTM function method returns the 4-by-4 double-precision floating-point graphics transform matrix from the current object upward through the graphics tree.

Syntax

Result = Obj->[IDLgrPolyline::]GetCTM([, DESTINATION=*objref*]
   [, PATH=*objref(s)*] [, TOP=*objref to IDLgrModel object*])

Return Value

Returns the 4-by-4 double-precision floating-point graphics transform matrix from the current object upward through the graphics tree.

Arguments

None

Keywords

DESTINATION

Set this keyword to the object reference of a destination object to specify that the projection matrix for the View object in the current tree be included in the returned transformation matrix. The resulting matrix will transform a point in the data space of the object on which the GetCTM method is called into a normalized coordinate system (-1 to +1 in X, Y, and Z), relative to the View object that contains the polyline object.

PATH

Set this keyword to a single object reference or a vector of object references. This keyword specifies the path in the graphics hierarchy to compute the transformation matrix. Each path object reference specified with this keyword must contain an alias. The transformation matrix is computed for the version of the object falling within that path. If this keyword is not set, the PARENT properties determine the path from the current object to the top of the graphics hierarchy and no alias paths are pursued. If IDLgrPolyline::GetCTM is called from within a Draw method, with the DESTINATION keyword set and the PATH keyword not set, the alias path used to find the object during the draw is used, rather than the PARENT path.

Note ───

For more information on aliases, refer to the ALIAS keyword in IDLgrModel::Add.

───

TOP

Set this keyword equal to the object reference to an IDLgrModel object to specify that the returned matrix accumulate from the object on which the GetCTM method is called up to but not including the specified model object.

Version History

5.0	Introduced

IDLgrPolyline::GetProperty

The IDLgrPolyline::GetProperty procedure method retrieves the value of a property or group of properties for the polylines.

Syntax

Obj->[IDLgrPolyline::]GetProperty[, *PROPERTY=variable*]

Arguments

None

Keywords

Any property listed under "IDLgrPolyline Properties" on page 4620 that contains the word "Yes" in the "Get" column of the properties table can be retrieved using this method. To retrieve the value of a property, specify the property name as a keyword set equal to a named variable that will contain the value of the property.

Any keyword not recognized is passed to this object's superclass.

Version History

5.0	Introduced

IDLgrPolyline::GetVertexAttributeData

The IDLgrPolyline::GetVertexAttributeData procedure method retrieves the data associated with a named attribute variable containing per-vertex attribute data. See "Attribute Variables" (Chapter 14, *Object Programming*). This method is useful when a shader program defined by an IDLgrShader object modifies the vertices of an object. See Chapter 14, "Advanced Rendering Using Shader Objects" (*Object Programming*) for more information.

Syntax

Obj->[IDLgrPolyline::]GetVertexAttributeData, *Name, Value*

Arguments

Name

Specifies a case-sensitive string name of the attribute variable to retrieve.

Note

If the *Name* argument specifies an attribute variable that was never defined and stored in the polyline object using SetVertexAttributeData, then the variable specified in the *Value* parameter will be set to an undefined variable.

Value

Specifies a variable that contains the current value of the vertex data attribute variable. The variable is stored in this parameter in exactly the same format as that used when it was defined using IDLgrPolyline::SetVertexAttributeData.

Keywords

None

Examples

See "Vertex Shaders" (Chapter 14, *Object Programming*).

Version History

6.4	Introduced

See Also

IDLgrPolyline::SetVertexAttributeData

IDLgrPolyline::Init

The IDLgrPolyline::Init function method initializes the polylines object.

Note

Init methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation. This means that in most cases, you cannot call the Init method directly. There is one exception to this rule: if you write your own subclass of this class, you can call the Init method from within the Init method of the subclass.

Syntax

Obj = OBJ_NEW('IDLgrPolyline' [, *X* [, *Y*[, *Z*]]] [, *PROPERTY=value*])

or

Result = Obj->[IDLgrPolyline::]Init([*X*, [*Y*, [*Z*]]] [, *PROPERTY=value*])   *(In a lifecycle method only.)*

Return Value

When this method is called indirectly, as part of the call to the OBJ_NEW function, the return value is an object reference to the newly-created object.

When called directly within a subclass Init method, the return value is 1 if initialization was successful, or zero otherwise.

Arguments

Note

The values specified by the *X*, *Y*, and *Z* arguments are used to initialize the value of the DATA property of the IDLgrPolyline object.

X

A vector providing the X components of the points to be connected. If the Y and Z arguments are not provided, X must be an array of either two or three vectors (i.e., [2,*] or [3,*]), in which case, X[0,*] specifies the X values, X[1,*] specifies the Y values, and X[2,*] specifies the Z values. This argument is stored as double precision floating point values if the argument variable is of type DOUBLE or if the DOUBLE property is non-zero, otherwise it is stored as single precision floating point.

Y

A vector providing the Y coordinates of the points to be connected. This argument is stored as double precision floating point values if the argument variable is of type DOUBLE or if the DOUBLE property is non-zero, otherwise it is stored as single precision floating point.

Z

A vector providing the Z coordinates of the points to be connected. This argument is stored as double precision floating point values if the argument variable is of type DOUBLE or if the DOUBLE property is non-zero, otherwise it is stored as single precision floating point.

Keywords

Any property listed under "IDLgrPolyline Properties" on page 4620 that contains the word "Yes" in the "Init" column of the properties table can be initialized during object creation using this method. To initialize the value of a property, specify the property name as a keyword set equal to the appropriate property value.

All other keywords are passed to the superclass of this object.

Version History

5.0	Introduced

IDLgrPolyline::SetProperty

The IDLgrPolylines::SetProperty procedure method sets the value of a property or group of properties for the polylines.

Syntax

Obj->[IDLgrPolyline::]SetProperty[, *PROPERTY=value*]

Arguments

None

Keywords

Any property listed under "IDLgrPolyline Properties" on page 4620 that contains the word "Yes" in the "Set" column of the properties table can be set using this method. To set the value of a property, specify the property name as a keyword set equal to the appropriate property value.

Version History

5.0	Introduced

IDLgrPolyline::SetVertexAttributeData

The IDLgrPolyline::SetVertexAttributeData procedure method passes a set of per-vertex attribute data to a vertex shader program. When an IDLgrShader object is associated with the polyline via the SHADER property, this attribute data is made available, a vertex's worth at a time, to the vertex shader program as it processes each vertex in the polyline. If there are more vertices in the polyline than there are vertex attributes, the list of vertex attributes is reused until all the vertices are drawn. See "Attribute Variables" (Chapter 14, *Object Programming*) for a general introduction to attribute variables. Also see the chapter, "Advanced Rendering Using Shader Objects" (*Object Programming*) for additional shader program information and examples.

IDL stores the *Name* and *Value* of the vertex attribute data variable with this polyline object the first time this method is called. When SetVertexAttributeData is called again using the same *Name* argument, the vertex attribute data variable is updated with the current contents of *Value*. Once a vertex attribute data variable is associated with this object, there is no way to remove the reference. The shader program ignores any vertex attribute data variable defined for this object but not declared in the shader program.

The attribute data may consist of 1 to 4 elements per vertex. The data is passed to the vertex shader program via a shader program variable with the attribute qualifier. The attribute variable may be of GLSL type `float`, `vec2`, `vec3`, `vec4`, `mat2`, `mat3`, or `mat4`. Internally, the `mat2` type is treated as two `vec2` attribute variables, `mat3` as three `vec3` attribute variables, and `mat4` as four `vec4` attribute variables.

If the attribute variable is larger than the data passed to it, the shader program pads the missing elements as follows. A missing second or third element is set to 0.0. A missing fourth element is set to 1.0.

For example, the IDL application has a set of vertex attribute data where there is an x-offset and a y-offset for each vertex. The vertex program defines an attribute variable using a `vec4` type so that it can be used in 4x4 general transformations. The IDL program stores the x- and y-offset information in a [2, *n*] array and sets the value of the attribute variable to this array. As the shader program runs, for each vertex it assigns the two values from the corresponding row of the IDL array to the first two elements in the `vec4` attribute variable. It also sets the third value to 0.0 and the fourth value to 1.0, thus expanding the 2-element data to a general 3-D point in homogenous coordinate space, suited for 4x4 general transforms.

Note

A minimum of 16 vertex attribute data variables can be passed to the shader vertex program (use IDLgrWindow::GetDeviceInfo to determine the exact number). IDL

uses one vertex attribute variable, leaving the remainder for user programs. For maximum shader program portability, define 15 or fewer attribute variables.

Syntax

Obj->[IDLgrPolyline::]SetVertexAttributeData, *Name, Value*

Arguments

Name

Specifies a case-sensitive string name of the attribute variable.

Value

Specifies an IDL array of any numeric type. The array must be of the form [*n*], [*a,n*], or [*a,a,n*] where *a* is 1,2,3, or 4 and *n* is the number of vertex attribute elements. IDL will halt with an error if you assign IDL strings, structures, pointers, object references, and undefined variables to *Value*. IDL converts all numeric types to 32-bit float when submitting the data to the shader program.

Keywords

None

Examples

Suppose there is large set of point sample data, along with a set of initial velocity vectors for each point. You want to display an animation of these points as each point moves along its own velocity vector as a function of time. Without a shader program, you would normally have to recalculate the position of each point and replace all the vertices in an IDLgrPolygon (STYLE=0) object with the recomputed values for each animation frame, which would be inefficient with a large number of points.

However, with a vertex shader program and vertex attribute data, you can move the points around using the graphics card's GPU instead of recalculating and moving a lot of data around on the system CPU.

The interesting parts of the IDL code are:

```
; Define the original vertices at time=0.
oPolygon->SetProperty, DATA=vertices
```

```
; Set [3,n] array.
oPolygon->SetVertexAttributeData, 'velocity', velocities
FOR t=0.0, 100.0, 0.01 DO BEGIN  ;; time samples
   oShader->SetUniformVariable, 'time', t
   oWindow->Draw
ENDFOR
```

And the interesting parts of the vertex shader program are:

```
attribute vec3 velocity;
uniform float time;
void main () {
   vec4 vert;
   vert = gl_Vertex + vec4(velocity * time, 0.0);
   gl_Position = gl_ModelViewProjectMatrix * vert;
}
```

See "Vertex Shaders" (*Object Programming*) for more information and examples.

IDLgrPolyline::GetVertexAttributeData

IDLgrPrinter

A printer object represents a hardcopy graphics destination. When a printer object is created, the printer device to which it refers is the default system printer. To change the printer, utilize the printer dialogs (see "DIALOG_PRINTJOB" on page 637 and "DIALOG_PRINTERSETUP" on page 635.)

Note ————————————————————————————————————
Objects or subclasses of this type can not be saved or restored.

Superclasses

None

Creation

See "IDLgrPrinter::Init" on page 4674.

Properties

Objects of this class have the following properties. See "IDLgrPrinter Properties" on page 4656 for details on individual properties.

- ALL
- COLOR_MODEL
- DIMENSIONS
- GAMMA
- GRAPHICS_TREE
- LANDSCAPE
- N_COLORS
- N_COPIES
- NAME
- PALETTE
- PRINT_QUALITY
- PRINTER_NAME

- QUALITY
- REGISTER_PROPERTIES
- RESOLUTION
- UNITS

In addition, objects of this class inherit the properties of all superclasses of this class.

Methods

This class has the following methods:

- IDLgrPrinter::Cleanup
- IDLgrPrinter::Draw
- IDLgrPrinter::GetContiguousPixels
- IDLgrPrinter::GetFontnames
- IDLgrPrinter::GetProperty
- IDLgrPrinter::GetTextDimensions
- IDLgrPrinter::Init
- IDLgrPrinter::NewDocument
- IDLgrPrinter::NewPage
- IDLgrPrinter::QueryRequiredTiles
- IDLgrPrinter::SetProperty

In addition, this class inherits the methods of its superclasses (if any).

Examples

See Chapter 12, "Displaying, Copying and Printing Objects" (*Object Programming*) for information on the IDLgrPrinter object. See "Positioning Objects Within a Page" (Chapter 12, *Object Programming*) for additional examples that define the locations of objects within the hardcopy page.

The following example demonstrates the process of printing the contents of an IDL graphics display object (a buffer or a window) to an IDLgrPrinter object. The resolution of the printed page is based on the resolution of the screen. The model object in the printer object must be scaled to maintain the same size as displayed on

the screen. The location of the view must also be changed to center the display on the page.

```
PRO PrintingAnImage

; Determine the path to the "convec.dat" file.
convecFile = FILEPATH('convec.dat', $

6.2	Added QueryRequiredTiles method
	Added PRINTER_NAME property and revised NAME property

IDLgrPrinter Properties

IDLgrPrinter objects have the following properties in addition to properties inherited from any superclasses. Properties with the word "Yes" in the "Get" column of the property table can be retrieved via IDLgrPrinter::GetProperty. Properties with the word "Yes" in the "Init" column of the property table can be set via IDLgrPrinter::Init. Properties with the word "Yes" in the "Set" column in the property table can be set via IDLgrPrinter::SetProperty.

Note ──

For a discussion of the property description tables shown below, see "About Object Property Descriptions" on page 3135.

──

Objects of this class have the following properties.

- ALL
- COLOR_MODEL
- DIMENSIONS
- GAMMA
- GRAPHICS_TREE
- LANDSCAPE
- N_COLORS
- N_COPIES
- NAME
- PALETTE
- PRINT_QUALITY
- PRINTER_NAME
- QUALITY
- REGISTER_PROPERTIES
- RESOLUTION
- UNITS

ALL

An anonymous structure containing the values of all of the properties associated with the *state* of this object. State information about the object includes things like color, range, tick direction, etc., but not image, vertex, or connectivity data, or user values.

Note

The fields of this structure may change in subsequent releases of IDL.

Property Type	Structure		
Name String	*not displayed*		
Get: Yes	**Set:** No	**Init:** No	**Registered:** No

COLOR_MODEL

An integer value or an enumerated list item that determines the color model to be used for the printer buffer:

Value	Property Sheet Value	Description
0	RGB	RGB (default)
1	Indexed	Color Index

Property Type	ENUMLIST		
Name String	Color model		
Get: Yes	**Set:** No	**Init:** Yes	**Registered:** Yes

DIMENSIONS

A two-element integer vector of the form [*width*, *height*] specifying the overall drawable area that may be printed on a page. By default, the dimensions are measured in device units (refer to the UNITS property).

Property Type	Integer vector		
Name String	*not displayed*		
Get: Yes	**Set:** No	**Init:** No	**Registered:** No

GAMMA

An object reference to an IDLgrPalette object whose entries will be used as the gamma correction table for color printing. Gamma correction only applies if COLOR_MODEL=1 (Indexed).

When the color palette (specified via the PALETTE property) is loaded for the printer, if a gamma correction table is provided, then each of the [R,G,B] entries in the color palette will be translated through the gamma correction table. For example, at color index *i*:

```
correctedRed[i] = gammaRed[paletteRed[i]]
correctedGreen[i] = gammaGreen[paletteGreen[i]]
correctedBlue[i] = gammaBlue[paletteBlue[i]]
```

Note
Objects specified via this property are not automatically cleaned up when the IDLgrPrinter object is destroyed.

Property Type	Object reference		
Name String	*not displayed*		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** No

GRAPHICS_TREE

An object reference of type IDLgrScene, IDLgrViewgroup, or IDLgrView that specifies the graphics tree of this object. If this property is set to a valid object reference, calling the Draw method on the destination object with no arguments will cause the object reference associated with this property to be drawn. If this object is valid and the destination object is destroyed, this object reference will be destroyed as well. By default the GRAPHICS_TREE property is set equal to the null-object.

Property Type	Object reference		
Name String	*not displayed*		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** No

LANDSCAPE

A Boolean value that indicates whether to produce hardcopy output in landscape mode. The default value of zero indicates Portrait mode.

Note ――

The printer driver may not support the LANDSCAPE option; in general, it is best to use the printer dialogs to set orientation.

――

Property Type	Boolean		
Name String	*not displayed*		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** No

N_COLORS

An integer value that indicates the number of colors (between 2 and 256) to be used if the COLOR_MODEL is set to Indexed (1). This property is ignored if the COLOR_MODEL is set to RGB (0).

Property Type	Integer		
Name String	Number of colors		
Get: Yes	**Set:** No	**Init:** Yes	**Registered:** Yes

N_COPIES

An integer that determines the number of copies of print data to be generated. The default is 1 copy.

Note ――

Your specific printer driver may not support the N_COPIES option. You can also use the printer dialogs to set the number of copies.

――

Property Type	Integer		
Name String	*not displayed*		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** No

NAME

A string giving the human-readable name of this object. This property is initialized to the network name of the printer unless another value is set during initialization.

Property Type	String		
Name String	*not displayed*		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** No

PALETTE

An object reference to a palette object (an instance of the IDLgrPalette object class) to specify the red, green, and blue values that are to be loaded into the graphics destination's color lookup table if the Indexed color model is used.

Note

Objects specified via this property are not automatically cleaned up when the IDLgrPrinter object is destroyed.

This property is registered as a user-defined property, but it is hidden by default.

Property Type	USERDEF		
Name String	Color palette		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** Yes

PRINT_QUALITY

An integer value indicating the print quality at which graphics are to be drawn to the printer. Note that the print quality is independent of the rendering quality (as set by the QUALITY property). Valid values are:

- $0 = $ Low
- $1 = $ Normal (this is the default)
- $2 = $ High

Generally, setting the print quality to a lower value will increase the speed of the printing job, but decrease the resolution; setting it to a higher value will cause the printing job to take more time, but will increase the resolution.

Note

Some printer drivers may not be able to support different printing qualities. In these cases, the setting of the PRINT_QUALITY property will be quietly ignored.

Property Type	Integer		
Name String	*not displayed*		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** No

PRINTER_NAME

A string containing the network name of the printer, (*e.g.,* `'\\BORG\HpJet'`).

Property Type	String		
Name String	*not displayed*		
Get: Yes	**Set:** No	**Init:** No	**Registered:** No

QUALITY

An integer value or enumerated list item that indicates the rendering quality at which graphics are to be drawn to this destination. Note that the rendering quality is independent of the print quality (as set by the PRINT_QUALITY property). Valid values are:

Value	Property Sheet Value	Description
0	Low	Low quality
1	Medium	Medium quality
2	High	High quality (the default)

Property Type	ENUMLIST		
Name String	Draw quality		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** Yes

REGISTER_PROPERTIES

A Boolean value that determines whether to register properties available for this object. If this property is set, all properties marked in this properties section as

"Registered: Yes" will be registered for display in a property sheet. This property is useful mainly when creating iTools. By default, no properties are registered.

Property Type	Boolean		
Name String	*not displayed*		
Get: No	**Set:** No	**Init:** Yes	**Registered:** No

RESOLUTION

A floating-point vector of the form [*xres*, *yres*] defining the pixel resolution, measured in centimeters per pixel. This value is stored in double precision.

Property Type	FLOAT		
Name String	Resolution		
Get: Yes	**Set:** No	**Init:** No	**Registered:** Yes

UNITS

An integer value that indicates the units of measure for the DIMENSIONS property. Valid values are:

- 0 = Device (default)
- 1 = Inches
- 2 = Centimeters
- 3 = Normalized: relative to the drawable area on a page.

Note

If you change the value of the UNITS property (using the SetProperty method), IDL will convert the current value of the DIMENSIONS property to the new units.

Property Type	Integer		
Name String	*not displayed*		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** No

IDLgrPrinter::Cleanup

The IDLgrPrinter::Cleanup procedure method performs all cleanup on the object. If a document is open (that is, if graphics have been draw to the printer), the document is closed and the pending graphics are sent to the current printer.

Note _____

Cleanup methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation and destruction. This means that in most cases, you cannot call the Cleanup method directly. There is one exception to this rule: if you write your own subclass of this class, you can call the Cleanup method from within the Init or Cleanup method of the subclass.

Syntax

OBJ_DESTROY, *Obj*

or

Obj->[IDLgrPrinter::]Cleanup   *(In a lifecycle method only.)*

Arguments

None

Keywords

None

Version History

5.0	Introduced

IDLgrPrinter::Draw

The IDLgrPrinter::Draw procedure method draws the given picture to this graphics destination.

Printing in Bitmap or Vector Graphic Mode

The IDLgrPrinter::Draw method VECTOR keyword generates output in bitmap or vector format. The following table shows the keyword options and results for each platform.

Keyword Settings	Windows Printer Output	UNIX File Type
VECTOR = 0	Bitmap (BMP)	Encapsulated PostScript (EPS) file (e.g. xprinter.eps)
VECTOR = 1	Enhanced MetaFile (EMF)	Encapsulated PostScript (EPS) file (e.g. xprinter.eps)

Table 32-14: File Types Produced by IDLgrPrinter Draw Method

Because Windows printer output is usually sent directly to the printer, EMF and BMP files are not viewable. On UNIX, the printer output is usually directed to a file named xprinter.eps by default.

Note ──

Objects are drawn to the destination device in the order that they are added to the model, view, viewgroup, or scene object that contains them when VECT_SORTING=0. Otherwise, objects are drawn to the destination device based on their average depth value. See "Bitmap and Vector Graphic Output" (Chapter 12, *Object Programming*) for more information on bitmap and vector output.

──

Syntax

Obj->[IDLgrPrinter::]Draw [, *Picture*] [, VECT_SORTING={ 0 | 1 }]
   [, VECT_TEXT_RENDER_METHOD={ 0 | 1 }] [, VECTOR={ 0 | 1 }]

Arguments

Picture

The view (an instance of an IDLgrView object), viewgroup (an instance of an IDLgrViewgroup object), or scene (an instance of an IDLgrScene object) to be drawn.

Keywords

VECT_SORTING

This keyword has an effect only when generating vector output (VECTOR=1).

This keyword controls the way object primitives in a picture appear in the destination. Valid values are:

- 0 = disable sorting. This causes the object primitives to appear in the vector output file in the same order they are drawn on the display device. This is the order in which they appear in the graphics tree.

- 1 = enable sorting (default). Objects are ordered from back to front based on each primitive object's average depth value.

Note

Objects that intersect each other, IDLgrImage objects (which do not update the depth buffer), and objects contained within transparent views may not sort correctly. See "Controlling What is Displayed in Vector Graphics" (Chapter 12, *Object Programming*) for details.

VECT_TEXT_RENDER_METHOD

This keyword has an effect only when generating vector output (VECTOR=1).

This keyword controls the way text is rendered in a vector graphic file. Valid values are:

- 0 = render text as text primitives (default). Use the output device's text primitives when rendering text.

- 1 = render text as primitives composed of triangles. Render text in the vector file as a series of filled triangles. This produces text that closely matches the text on the display device, but the output file size is larger.

Note ───────────────────────────────────────

When using the IDLgrPrinter object under UNIX, the Xprinter output is regarded as write-only. As there is no support for 3-D text, IDL always generates filled triangles when rendering text in the Xprinter output. On Windows, the vector output is always Enhanced MetaFile (EMF) file format. Because printer output is usually sent directly to the printer the EMF file cannot be seen by the user.

───────────────────────────────────────

Note ───────────────────────────────────────

See "Text Rendering in Vector Graphics" (Chapter 12, *Object Programming*) for more information.

───────────────────────────────────────

VECTOR

Set this keyword to indicate the type of graphics primitives generated. Valid values are:

- 0 = generate bitmap graphics (default). Render the scene to a buffer and then copy the buffer to the printer in bitmap format. The bitmap retains the quality of the original image.

- 1 = generate vector graphics. Render the scene using simple vector operations that result in a representation of the scene that is scalable to the printer. The vector representation, which is sent to the printer, does not retain all the attributes of the original image.

Note ───────────────────────────────────────

Transparent objects in a view are not rendered in vector graphic files. Semi-transparent objects are rendered fully opaque. See "Bitmap and Vector Graphic Output" (Chapter 12, *Object Programming*) for a complete discussion of when to output to bitmap or vector graphics based on picture content.

───────────────────────────────────────

Version History

5.0	Introduced
6.1	Added VECT_SORTING, VECT_TEXT_RENDER_METHOD keywords

IDLgrPrinter::GetContiguousPixels

The IDLgrPrinter::GetContiguousPixels function method returns an array of long integers whose length is equal to the number of colors available in the index color mode (that is, the value of the N_COLORS property).

The returned array marks contiguous pixels with the ranking of the range's size. This means that within the array, the elements in the largest available range are set to zero, the elements in the second-largest range are set to one, etc. Use this range to set an appropriate colormap for use with the SHADE_RANGE property of the IDLgrSurface and IDLgrPolygon object classes.

To get the largest contiguous range, you could use the following IDL command:

```
result = obj->GetContiguousPixels()
Range0 = WHERE(result EQ 0)
```

A contiguous region in the colormap can be increasing or decreasing in values. The following would be considered contiguous:

```
[0,1,2,3,4]
[4,3,2,1,0]
```

Syntax

Result = Obj->[IDLgrPrinter::]GetContiguousPixels()

Return Value

Returns an array of long integers whose length is equal to the number of colors available in the index color mode.

Arguments

None

Keywords

None

Version History

5.0	Introduced

IDLgrPrinter::GetFontnames

The IDLgrPrinter::GetFontnames function method returns the list of available fonts that can be used in IDLgrFont objects. This method will only return the names of the available TrueType fonts. Hershey fonts will not be returned; see Appendix H, "Fonts" for more information.

Syntax

Result = Obj->[IDLgrPrinter::]GetFontnames(*FamilyName* [, IDL_FONTS={0 | 1 | 2}] [, STYLES=*string*])

Return Value

Returns the list of available fonts that can be used in IDLgrFont objects.

Arguments

FamilyName

A string representing the name of the font family to which all of the returned fonts must belong. The string may be a fully specified family name—such as "Helvetica". You can use both "*" and "?" as wildcard characters, matching any number of characters or one character respectively. To return all available family names, use "*".

Keywords

IDL_FONTS

Set this keyword to specify where to search for fonts that IDL may use. Set IDL_FONT to 1 to select only fonts installed by IDL and to 2 to select only fonts detected in the host operating system. The default value is 0, specifying that both IDL and operating system fonts should be returned.

STYLES

Set this keyword to a string specifying the styles that are to be matched by the returned font names. You can set STYLES to a fully specified style string, such as "Bold Italic". If you set STYLES to the null string, ' ', only fontnames without style modifiers will be returned. You can use both "*" and "?" as wildcard characters, matching any number of characters or one character respectively. The default value is

the string, "*", which returns all fontnames containing the *FamilyName* argument, with or without style modifiers.

Version History

5.0	Introduced

IDLgrPrinter::GetProperty

The IDLgrPrinter::GetProperty procedure method retrieves the value of a property or group of properties for the printer.

Syntax

Obj->[IDLgrPrinter::]GetProperty[, *PROPERTY=variable*]

Arguments

None

Keywords

Any property listed under "IDLgrPrinter Properties" on page 4656 that contains the word "Yes" in the "Get" column of the properties table can be retrieved using this method. To retrieve the value of a property, specify the property name as a keyword set equal to a named variable that will contain the value of the property.

Any keyword not recognized is passed to this object's superclass.

Version History

5.0	Introduced

IDLgrPrinter::GetTextDimensions

The IDLgrPrinter::GetTextDimensions function method retrieves the dimensions of a text or axis object that will be rendered in a window. In order to compute the effective text dimensions, the object must be inserted into an object graphics hierarchy prior to using this method. The result is a 3-element double-precision floating-point vector [*xDim*, *yDim*, *zDim*] representing the dimensions of the text or axis object, measured in data units. If the object specified is an axis object, the result encompasses the tick labels and the title of the axis (if any).

Note

The returned results take into account the setting of the IDLgrText RECOMPUTE_DIMENSIONS property.

Syntax

Result = Obj->[IDLgrPrinter::]GetTextDimensions(*TextObj* [, DESCENT=*variable*]
   [, PATH=*objref(s)*])

Return Value

Returns a 3-element double-precision floating-point vector [*xDim*, *yDim*, *zDim*] representing the dimensions of the text or axis object, measured in data units.

Arguments

TextObj

The object reference to a text or axis object for which the text dimensions are requested.

Keywords

DESCENT

Set this keyword equal to a named variable that will contain an array of double-precision floating-point values (one for each string in the IDLgrText object). The values represent the distance to travel (parallel to the UPDIR vector) from the text baseline to reach the bottom of the lowest descender in the string. All values will be negative numbers, or zero. This keyword is valid only if *TextObj* is an IDLgrText object.

PATH

Set this keyword to a single object reference or a vector of object references. This keyword specifies the path in the graphics hierarchy to compute the text dimensions. Each path object reference specified with this keyword must contain an alias. The text dimensions are computed for the version of the object falling within that path. If this keyword is not set, the PARENT properties determine the path from the current object to the top of the graphics hierarchy and no alias paths are pursued. If IDLgrPrinter::GetTextDimensions is called from within a Draw method and the PATH keyword is not set, the alias path used to find the object during the draw is used, rather than the PARENT path.

Note —————————————————————————————————

For more information on aliases, refer to the ALIAS keyword in IDLgrModel::Add.

Version History

5.0	Introduced

IDLgrPrinter::Init

The IDLgrPrinter::Init function method initializes the printer object.

Note

Init methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation. This means that in most cases, you cannot call the Init method directly. There is one exception to this rule: if you write your own subclass of this class, you can call the Init method from within the Init method of the subclass.

Syntax

Obj = OBJ_NEW('IDLgrPrinter' [, *PROPERTY=value*])

or

Result = Obj->[IDLgrPrinter::]Init([, *PROPERTY=value*])   *(In a lifecycle method only.)*

Return Value

When this method is called indirectly, as part of the call to the OBJ_NEW function, the return value is an object reference to the newly-created object.

When called directly within a subclass Init method, the return value is 1 if initialization was successful, or zero otherwise.

Arguments

None

Keywords

Any property listed under "IDLgrPrinter Properties" on page 4656 that contains the word "Yes" in the "Init" column of the properties table can be initialized during object creation using this method. To initialize the value of a property, specify the property name as a keyword set equal to the appropriate property value.

All other keywords are passed to the superclass of this object.

Version History

5.0	Introduced

IDLgrPrinter::NewDocument

The IDLgrPrinter::NewDocument procedure method closes the current document (a page or group of pages), which causes any pending output to be sent to the printer, finishing the printer job.

Syntax

Obj->[IDLgrPrinter::]NewDocument

Arguments

None

Keywords

None

Version History

5.0	Introduced

IDLgrPrinter::NewPage

The IDLgrPrinter::NewPage procedure method issues a new page command to the printer.

Syntax

Obj->[IDLgrPrinter::]NewPage

Arguments

None

Keywords

None

Version History

5.0	Introduced

IDLgrPrinter::QueryRequiredTiles

The IDLgrPrinter::QueryRequiredTiles function method is used in conjunction with an IDLgrImage object that supports tiling. Initially, this type of IDLgrImage object contains no data. Call this method to determine what data to load into this destination object based on which tiles are visible in a view. Pass the results to IDLgrImage::SetTileData to load the required portion of the tiled image. When the Draw method is called, the destination object contains the image tiles that are the results of this method's query.

Note

Printer support of tiled images is not available in vector mode (when the IDLgrPrinter::Draw method VECTOR keyword is set to 1). The bitmap mode (VECTOR=0) must be used.

This method returns an array of named structures containing information about the tiles that are required, or a scalar integer with the value 0 if no tiles are required. The application can check that COUNT is greater than 0 before accessing the returned array.

Note

Printers are normally a higher resolution than a monitor; therefore higher resolution levels will be requested when calling QueryRequiredTiles on an IDLgrPrinter. QueryRequiredTiles on IDLgrPrinter also considers the value in the IDL_GR_TILECACHESIZE preference when calculating the required level. If the data for the required tiles at the required level will not fit in IDL_GR_TILECACHESIZE, the next-lower resolution level will be tried. This is repeated until a level that fits is found and this is returned by QueryRequiredTiles. This can be overridden by setting TILE_LEVEL_MODE to 0 (manual) and setting the required level in TILE_CURRENT_LEVEL on the tiled IDLgrImage before calling QueryRequiredTiles. However, if the total data exceeds IDL_GR_TILECACHESIZE, then some tiles will print blank. If there is sufficient RAM in the system, IDL_GR_TILECACHESIZE can be increased to enable higher-resolution printing. Setting 0 will allow an unlimited amount of tile data to be set, but note that printing may fail if all physical RAM is used.

Note

If the device is in Color Index mode (COLOR_MODEL=1) or the image has RENDER_METHOD=1 set, then IDL will generate an error as tiling is not supported under these circumstances.

Syntax

Result = Obj->[IDLgrPrinter::]QueryRequiredTiles(*View*, *Image*
   [, ALL_VISIBLE=*value*] [, COUNT=*variable*] [, PATH=*objref(s)*])

Return Value

Returns an array of named structures containing information about the tiles that are
required, or a scalar integer with the value 0 if no tiles are required.

Each structure in the array describes one required tile and has the following fields:

Field	Data Type	Description
X	Long	The horizontal position of the left side of the tile measured from the left of the image in pixels.
Y	Long	The vertical position of the bottom of the tile measured from the bottom of the image in pixels.
WIDTH	Long	The width of the tile in pixels.
HEIGHT	Long	The height of the tile in pixels.
LEVEL	Long	The data resolution, where 0 is the full resolution image. A value of *n* (*n* > 0) indicates that the resolution is half that of the *n*-1 level.
DEST	OBJREF	The object reference to the destination object that was used to query for the required tiles.

Table 32-15: IDLIMAGETILE Structure

The X, Y, WIDTH and HEIGHT elements are all relative to the specified LEVEL.
For example, say a large image (level 0) has dimensions of 10000 by 10000 pixels.
The tile structure [2048, 2048, 1024, 1024, 0] specifies a 1024 by 1024 pixel area
where the lower-left corner of the tile is (2048, 2048) pixels from the lower-left
corner of the original, level 0 image. This is shown in the left portion of the following
figure.

When you zoom out to 50% of the original resolution, you can load the level 1 image
(5000 by 5000 pixels), a subsampled version of the large image. Here, the tile [1024,
1024, 1024, 1024, 1] specifies a 1024 by 1024 pixel area of the image with the lower-
left corner being (1024, 1024) from the lower-left corner of the image. Both of these

tiles have their lower-left corner at the same physical location of the image, but the second tile covers four times the area as it is a lower resolution version of the data.

Figure 32-9: Interaction Between Image Level and Zoom with Equal Tile Sizes

Note ───
See "Image Tiling" (Chapter 4, *Object Programming*) for more information on creating an image pyramid and for tiling examples.
───

Arguments

View

An object reference to the IDLgrView object used to render the image object. This is required so the visible tiles can be determined.

Image

An object reference to the tiled IDLgrImage object that will be tested to determine which of its tiles are required.

Keywords

ALL_VISIBLE

Set this keyword if QueryRequiredTiles should return all tiles that are visible even if they already have tile data loaded at the required level.

COUNT

Set this keyword equal to a named variable that, on return, contains the number of tiles that are required.

PATH

Set this keyword equal to a vector of object references that uniquely defines the path through the graphics hierarchy used to compute which tiles are visible. Each object specified must contain an alias; tile visibility is computed for the version of the image object (specified by *Image*) that lies at the end of the specified path.

Specifying a unique path through the graphics hierarchy may require multiple objects if multiple aliases are used. If multiple objects are required to define the value of PATH, the objects must be specified in the order they appear in the path, beginning with the object that is closest to the root of the hierarchy.

If this keyword is not set, the path from *Image* to the top of the graphics hierarchy is determined by the PARENT properties of the objects in the hierarchy. In this case, no alias paths are followed.

Note ───

For more information on aliases, refer to the ALIAS keyword in IDLgrModel::Add.

───

Version History

6.2	Introduced
7.0	Added PATH keyword to QueryRequiredTiles to handle aliases.

IDLgrPrinter::SetProperty

The IDLgrPrinter::SetProperty procedure method sets the value of a property or group of properties for the printer.

Syntax

Obj->[IDLgrPrinter::]SetProperty[, *PROPERTY=value*]

Arguments

None

Keywords

Any property listed under "IDLgrPrinter Properties" on page 4656 that contains the word "Yes" in the "Set" column of the properties table can be set using this method. To set the value of a property, specify the property name as a keyword set equal to the appropriate property value.

Version History

5.0	Introduced

IDLgrROI

The IDLgrROI object class is an object graphics representation of a region of interest.

Superclasses

IDLanROI

IDLitComponent

Creation

See "IDLgrROI::Init" on page 4699.

Properties

Objects of this class have the following properties. See "IDLgrROI Properties" on page 4685 for details on individual properties.

- ALL
- ALPHA_CHANNEL
- CLIP_PLANES
- COLOR
- DEPTH_TEST_DISABLE
- DEPTH_TEST_FUNCTION
- DEPTH_WRITE_DISABLE
- DOUBLE
- HIDE
- LINESTYLE
- PALETTE
- PARENT
- REGISTER_PROPERTIES
- SHADER
- STYLE
- SYMBOL

- THICK
- XCOORD_CONV
- XRANGE
- YCOORD_CONV
- YRANGE
- ZCOORD_CONV
- ZRANGE

In addition, objects of this class inherit the properties of all superclasses of this class.

Methods

The IDLgrROI object class has the following methods:

- IDLgrROI::Cleanup
- IDLgrROI::GetProperty
- IDLgrROI::Init
- IDLgrROI::PickVertex
- IDLgrROI::SetProperty

In addition, this class inherits the methods of its superclasses (if any).

Version History

5.3	Introduced
5.6	Added CLIP_PLANES property
6.1	Added ALPHA_CHANNEL property
6.4	Added SHADER property

IDLgrROI Properties

IDLgrROI objects have the following properties in addition to properties inherited from any superclasses. Properties with the word "Yes" in the "Get" column of the property table can be retrieved via IDLgrROI::GetProperty. Properties with the word "Yes" in the "Init" column of the property table can be set via IDLgrROI::Init. Properties with the word "Yes" in the "Set" column in the property table can be set via IDLgrROI::SetProperty.

Note

For a discussion of the property description tables shown below, see "About Object Property Descriptions" on page 3135.

Objects of this class have the following properties.

- ALL
- ALPHA_CHANNEL
- CLIP_PLANES
- COLOR
- DEPTH_TEST_DISABLE
- DEPTH_TEST_FUNCTION
- DEPTH_WRITE_DISABLE
- DOUBLE
- HIDE
- LINESTYLE
- PALETTE
- PARENT
- REGISTER_PROPERTIES
- SHADER
- STYLE
- SYMBOL
- THICK
- XCOORD_CONV

- XRANGE
- YCOORD_CONV
- YRANGE
- ZCOORD_CONV
- ZRANGE

In addition, objects of this class inherit:

- IDLanROI
- IDLitComponent

ALL

An anonymous structure with the values of all of the properties associated with the state of this object. State information about the object may include things like color, line style, etc., but not vertex data or user values.

Note
The fields in this structure may change in subsequent releases of IDL.

Property Type	Structure		
Name String	*not displayed*		
Get: Yes	**Set:** No	**Init:** No	**Registered:** No

ALPHA_CHANNEL

A floating-point value in the range [0.0, 1.0] to specify the opacity of the ROI. The default value of 1.0 causes IDL to draw the ROI completely opaque. If the value of this property is less than 1.0, then the pixels of the ROI are blended with the pixels already on the screen, where the color of the ROI is multiplied by the alpha value and the pixels already on the screen are multiplied by 1.0-alpha.

Because an object can only be blended with objects already drawn on the screen, the drawing order of the objects must be considered carefully in order to obtain the desired results.

This property has no effect on devices using indexed color mode.

When the ROI is drawn with symbols, the symbol color and alpha values are always used to draw the symbols.

Note ———————————————————————————————————
For more detailed information on alpha channel support for IDL Object Graphics,
see "Controlling Object Transparency" (Chapter 2, *Object Programming*).

Property Type	Float-point value		
Name String	*Transparency*		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** Yes

CLIP_PLANES

A 4-by-*N* floating-point array that specifies the coefficients of the clipping planes to
be applied to this object. The four coefficients for each clipping plane are of the form
[A, B, C, D], where $Ax + By + Cz + D = 0$. Portions of this object that fall in the half
space $Ax + By + Cz + D > 0$ will be clipped. By default, the value of this property is a
scalar (-1) indicating that no clipping planes are to be applied.

Note ———————————————————————————————————
The clipping planes specified via this property are applied in addition to the near
and far clipping planes associated with the IDLgrView in which this object appears.

Note ———————————————————————————————————
Clipping planes are applied in the data space of this object (prior to the application
of any *x*, *y*, or *z* coordinate conversion).

Note ———————————————————————————————————
To determine the maximum number of clipping planes supported by the device, use
the MAX_NUM_CLIP_PLANES property of the GetDeviceInfo method for the
IDLgrBuffer, IDLgrClipboard, IDLgrWindow, and IDLgrVRML objects.

Property Type	Floating-point array		
Name String	*not displayed*		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** No

COLOR

A color index or a three-element vector [*red*, *green*, *blue*] specifying the color used to
draw the region. The default color is [0, 0, 0].

In a property sheet, this property appears as a color property.

Property Type	COLOR		
Name String	Color		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** Yes

DEPTH_TEST_DISABLE

An integer value that determines whether depth testing is disabled.

- Set this property to 0 (the default) to inherit the value set by the parent model or view. The parent view always enables depth testing. A model may also enable or disable depth testing.

- Set this property to 1 to explicitly disable depth buffer testing while drawing this object.

- Set this property to 2 to explicitly enable depth testing for this object.

Disabling depth testing allows an object to draw itself "on top" of other objects already on the screen, even if the object is located behind them.

Note

Disabling depth testing also disables depth buffer writing. When disabling depth testing, the DEPTH_TEST_FUNCTION and DEPTH_WRITE_DISABLE properties are effectively ignored.

This property is registered as an enumerated list, but it is hidden by default.

Property Type	ENUMLIST		
Name String	*not displayed*		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** No

DEPTH_TEST_FUNCTION

An integer value that determines the depth test function. Set this property to 0 (the default) to inherit the value set by the parent model or view. The parent view always sets a depth test function of LESS. A model may also set a depth test function value. The graphics device compares the object's depth at a particular pixel location with the depth stored in the depth buffer at that same pixel location. If the comparison test

passes, the object's pixel is drawn at that location on the screen and the depth buffer is updated (if depth writing is enabled).

Set this property to any of the following values to use the desired function while rendering this object.

- 0 = INHERIT - use value from parent model or view.

- 1 = NEVER - never passes.

- 2 = LESS - passes if the object's depth is less than the depth buffer's value.

- 3 = EQUAL - passes if the object's depth is equal to the depth buffer's value.

- 4 = LESS OR EQUAL - passes if the object's depth is less than or equal to the depth buffer's value.

- 5 = GREATER - passes if the object's depth is greater than or equal to the depth buffer's value.

- 6 = NOT EQUAL - passes if the object's depth is not equal to the depth buffer's value.

- 7 = GREATER OR EQUAL - passes if the object's depth is greater than or equal to the depth buffer's value.

- 8 = ALWAYS - always passes

Less means closer to the viewer.

This property is registered as an enumerated list, but it is hidden by default.

Property Type	ENUMLIST		
Name String	*not displayed*		
Get: Yes	Set: Yes	Init: Yes	Registered: No

DEPTH_WRITE_DISABLE

An integer value that determines whether depth writing is disabled.

- Set this property to 0 (the default) to inherit the value set by the parent model or view. The parent view always enables depth writing. A model may also enable or disable depth writing.

- Set this property to 1 to explicitly disable depth buffer writing while rendering this object.

- Set this property to 2 to explicitly enable depth writing for this object.

Disabling depth writing allows an object to be overdrawn by other objects, even if the object is located in front of them.

Note ───

If depth testing (see DEPTH_TEST_DISABLE property) is disabled, depth writing is also automatically disabled.

───

This property is registered as an enumerated list, but it is hidden by default.

Property Type	ENUMLIST		
Name String	*not displayed*		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** No

DOUBLE

A Boolean value that indicates whether data provided by any of the input arguments will be stored in this object as using double-precision floating-point format.

- Set this property equal to 1 to convert input data to double-precision floating-point format.

- Set this property equal to 0 to convert input data to single-precision floating-point format.

- If you do not specify a value for this property, no data type conversion will be performed, and the data will be stored with its original precision.

Setting this property may be desirable if the data consists of large integers that cannot be accurately represented in single-precision floating-point arithmetic. This property is also automatically set to 1 if any of the input arguments are stored using a variable of type DOUBLE.

Property Type	Boolean		
Name String	*not displayed*		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** No

HIDE

A Boolean value or enumerated list item indicating whether this region should be drawn:

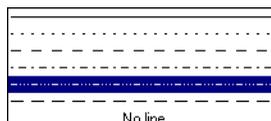
Value	Property Sheet Value	Description
0	True	Draw the region (the default)
1	False	Do not draw the region

Property Type	ENUMLIST		
Name String	Show		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** Yes

LINESTYLE

An integer that indicates the line style to be used to draw the region. The value can be either an integer value specifying a pre-defined line style, or a two-element vector specifying a stippling pattern. To use a pre-defined line style, set this property equal to one of the following integer values:

0	Solid line (the default)
1	Dotted
2	Dashed
3	Dash dot
4	Dash dot dot dot
5	Long dash
6	No line drawn

In a property sheet, this property appears as follows:


Property Type	ENUMLIST		
Name String	*not displayed*		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** Yes

PALETTE

An object reference to a palette object (an instance of the IDLgrPalette object class) that defines the color palette of this object. This property is only used for Object Graphics destinations using the RGB color model. In this case, if the color value for the region is specified as a color index value, this palette is used to look up the color for the region. If the PALETTE property is not set, the destination object PALETTE property is used, which defaults to a gray scale ramp.

Note ──

Objects specified via this property are not automatically cleaned up when the IDLgrROI object is destroyed.

──

This property is registered as a user-defined property, but it is hidden by default.

Property Type	USERDEF		
Name String	Color palette		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** Yes

PARENT

An object reference to the object that contains this object.

Property Type	Object reference		
Name String	*not displayed*		
Get: Yes	**Set:** No	**Init:** No	**Registered:** No

REGISTER_PROPERTIES

A Boolean value that determines whether to register properties available for this object. If this property is set, all properties marked in this properties section as

"Registered: Yes" will be registered for display in a property sheet. This property is useful mainly when creating iTools. By default, no properties are registered.

Property Type	Boolean		
Name String	*not displayed*		
Get: No	Set: No	Init: Yes	Registered: No

SHADER

An object reference to an IDLgrShader object (or an object containing IDLgrShader as a superclass). When there is suitable graphics card hardware support, the ROI is rendered using the GLSL shader program (executed on the graphics card) instead of using fixed OpenGL properties when initially drawn. (If a suitable graphics card is not present, IDL ignores the shader object when the scene is drawn.) A single IDLgrShader object may be associated with additional ROI objects or other graphic objects that have the SHADER property.

Property Type	Object reference		
Name String	*not displayed*		
Get: Yes	Set: Yes	Init: Yes	Registered: No

STYLE

An integer value that indicates the geometrical primitive to use to represent the region when displayed. Valid values include:

- 0 = points
- 1 = open polyline
- 2 = closed polyline (the default)

Property Type	Integer		
Name String	*not displayed*		
Get: Yes	Set: Yes	Init: Yes	Registered: No

SYMBOL

An object reference to an IDLgrSymbol object for the symbol used for display when STYLE = 0 (points). By default, a dot is used.

Note

Objects specified via this property are not automatically cleaned up when the IDLgrROI object is destroyed.

Property Type	Object reference		
Name String	*not displayed*		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** No

THICK

A floating-point value between 1.0 and 10.0, specifying the size of the points, or the thickness of the lines, measured in points. Out-of-range values are quietly clamped to the allowed range. The default is 1.0 points.

In a property sheet, this property appears as follows:

Property Type	THICKNESS		
Name String	Thickness		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** Yes

XCOORD_CONV

A vector, $[s_0, s_1]$, of scaling factors used to convert *X* coordinates from data units to normalized units. The formula for the conversion is as follows:

Normalized$X = s_0 + s_1*$Data$X$

Recommended values are:

$$[(-X_{min})/(X_{max} - X_{min}),\ 1.0/(X_{max} - X_{min})\ ]$$

IDL converts, maintains, and returns this data as double-precision floating-point.

Property Type	Double-precision floating-point vector		
Name String	*not displayed*		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** No

XRANGE

A two-element floating-point vector of the form [*xmin*, *xmax*] that specifies the range of *x* data coordinates covered by the graphic object. IDL maintains and returns this property in double-precision floating-point.

Property Type	Floating-point vector		
Name String	*not displayed*		
Get: Yes	**Set:** No	**Init:** No	**Registered:** No

YCOORD_CONV

A floating-point vector, [s_0, s_1], of scaling factors used to convert *Y* coordinates from data units to normalized units. The formula for the conversion is as follows:

$$Normalized Y = s_0 + s_1 * Data Y$$

Recommended values are:

$$[(-Y_{min})/(Y_{max} - Y_{min}),\ 1.0/(Y_{max} - Y_{min})\ ]$$

IDL converts, maintains, and returns this data as double-precision floating-point.

Property Type	Floating-point vector		
Name String	*not displayed*		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** No

YRANGE

A two-element floating-point vector of the form [*ymin*, *ymax*] that specifies the range of *y* data coordinates covered by the graphic object. IDL maintains and returns this property in double-precision floating-point.

Property Type	Floating-point vector		
Name String	*not displayed*		
Get: Yes	**Set:** No	**Init:** No	**Registered:** No

ZCOORD_CONV

A floating-point vector, [s_0, s_1], of scaling factors used to convert *Z* coordinates from data units to normalized units. The formula for the conversion is as follows:

$$Normalized Z = s_0 + s_1 * Data Z$$

Recommended values are:

$$[(-Z_{min})/(Z_{max} - Z_{min}), 1.0/(Z_{max} - Z_{min})]$$

IDL converts, maintains, and returns this data as double-precision floating-point.

Property Type	Floating-point vector		
Name String	*not displayed*		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** No

ZRANGE

A two-element floating-point vector of the form [*zmin*, *zmax*] that specifies the range of *z* data coordinates covered by the graphic object. IDL maintains and returns this property in double-precision floating-point.

Property Type	Floating-point vector		
Name String	*not displayed*		
Get: Yes	**Set:** No	**Init:** No	**Registered:** No

IDLgrROI::Cleanup

The IDLgrROI::Cleanup procedure method performs all cleanup for a region of interest object.

Note ———

Cleanup methods are special life cycle methods, and as such cannot be called outside the context of object creation and destruction. This means that in most cases, you cannot call the Cleanup method directly. There is one exception to this rule: if you write your own subclass of this class, you can call the Cleanup method from within the Init or Cleanup method of the subclass.

Syntax

OBJ_DESTROY, *Obj*

or

Obj->[IDLgrROI::]Cleanup   *(In a lifecycle method only.)*

Arguments

None

Keywords

None

Version History

5.3	Introduced

IDLgrROI::GetProperty

The IDLgrROI::GetProperty procedure method retrieves the value of a property or group of properties for the Object Graphics region.

Syntax

Obj->[IDLgrROI::]GetProperty[, *PROPERTY=variable*]

Arguments

None

Keywords

Any property listed under "IDLgrROI Properties" on page 4685 that contains the word "Yes" in the "Get" column of the properties table can be retrieved using this method. To retrieve the value of a property, specify the property name as a keyword set equal to a named variable that will contain the value of the property.

Any keyword not recognized is passed to this object's superclass.

Version History

5.3	Introduced

IDLgrROI::Init

The IDLgrROI::Init function method initializes an Object Graphics region of interest.

Note ──

Init methods are special life cycle methods, and as such cannot be called outside the context of object creation. This means that in most cases, you cannot call the Init method directly. There is one exception to this rule: if you write your own subclass of this class, you can call the Init method from within the Init method of the subclass.

──

Syntax

Obj = OBJ_NEW('IDLgrROI' [, *X*[, *Y*[, *Z*]]] [, *PROPERTY=value*])

or

Result = Obj->[IDLgrROI::]Init([*X*[, *Y*[, *Z*]]] [, *PROPERTY=value*])   *(In a lifecycle method only.)*

Return Value

When this method is called indirectly, as part of the call to the OBJ_NEW function, the return value is an object reference to the newly-created object.

When called directly within a subclass Init method, the return value is 1 if initialization was successful, or zero otherwise.

Arguments

X

A vector providing the X components of the vertices for the region. If the Y and Z arguments are not specified, X must be a two-dimensional array with the leading dimension either 2 or 3 ([2, *] or [3, *]), in which case, X[0, *] represents the X values, X[1, *] represents the Y values, and X[2, *] represents the Z values. This argument is stored as double precision floating point values if the argument variable is of type DOUBLE or if the DOUBLE property is non-zero. Otherwise it is converted and stored as single precision floating point.

Y

A vector providing the Y components of the vertices. This argument is stored as double precision floating point values if the argument variable is of type DOUBLE or if the DOUBLE property is non-zero. Otherwise it is converted and stored as single precision floating point.

Z

A scalar or vector providing the Z components of the vertices. If not provided, Z values default to 0.0. This argument is stored as double precision floating point values if the argument variable is of type DOUBLE or if the DOUBLE property is non-zero. Otherwise it is converted and stored as single precision floating point.

Keywords

Any property listed under "IDLgrROI Properties" on page 4685 that contains the word "Yes" in the "Init" column of the properties table can be initialized during object creation using this method. To initialize the value of a property, specify the property name as a keyword set equal to the appropriate property value.

All other keywords are passed to the superclass of this object.

Version History

5.3	Introduced

IDLgrROI::PickVertex

The IDLgrROI::PickVertex function method picks a vertex of the region which, when projected onto the given destination device, is nearest to the given 2-D device coordinate.

Syntax

Result = Obj->[IDLgrROI::]PickVertex(*Dest*, *View*, *Point* [, PATH=*objref*])

Return Value

Returns the index of the nearest region vertex. If two or more vertices are equally nearest to the point, the smallest index of those vertices is returned.

Arguments

Dest

An object reference to an IDLgrWindow or IDLgrBuffer for which the pick is to occur.

View

An object reference to the IDLgrView containing this region.

Point

A two-element vector, [*x*, *y*], representing the device location used for picking a nearest vertex.

Keywords

PATH

Set this keyword to a single object reference or a vector of object references. This keyword specifies the path in the graphics hierarchy to map the device position to a location in the data space of the region. Each path object reference specified with this keyword must contain an alias. The selected vertex is computed for the version of the object falling within the specified path. If this keyword is not set, the parent properties determine the path from the current object to the top of the graphics hierarchy and no alias paths are pursued.

Version History

5.3	Introduced

IDLgrROI::SetProperty

The IDLgrROI::SetProperty procedure method sets the value of a property or group of properties for the Object Graphics region.

Syntax

Obj->[IDLgrROI::]SetProperty[, *PROPERTY=value*]

Arguments

None

Keywords

Any property listed under "IDLgrROI Properties" on page 4685 that contains the word "Yes" in the "Set" column of the properties table can be set using this method. To set the value of a property, specify the property name as a keyword set equal to the appropriate property value.

Version History

5.3	Introduced

IDLgrROIGroup

The IDLgrROIGroup object class is an Object Graphics representation of a group of regions of interest.

Superclasses

IDLanROIGroup.

IDLitComponent

Creation

See "IDLgrROIGroup::Init" on page 4717.

Properties

Objects of this class have the following properties. See "IDLgrROIGroup Properties" on page 4706 for details on individual properties.

- ALL
- CLIP_PLANES
- DEPTH_TEST_DISABLE
- DEPTH_TEST_FUNCTION
- DEPTH_WRITE_DISABLE
- HIDE
- PARENT
- SHADER
- XCOORD_CONV
- XRANGE
- YCOORD_CONV
- YRANGE
- ZCOORD_CONV
- ZRANGE

In addition, objects of this class inherit the properties of all superclasses of this class.

Methods

The IDLgrROIGroup class has the following methods:

- IDLgrROIGroup::Add
- IDLgrROIGroup::Cleanup
- IDLgrROIGroup::GetProperty
- IDLgrROIGroup::Init
- IDLgrROIGroup::PickRegion
- IDLgrROIGroup::Remove
- IDLgrROIGroup::SetProperty

In addition, this class inherits the methods of its superclasses (if any).

Version History

5.3	Introduced
5.6	Added CLIP_PLANES property
6.4	Added SHADER property
	Added Remove method

IDLgrROIGroup Properties

IDLgrROIGroup objects have the following properties in addition to properties inherited from any superclasses. Properties with the word "Yes" in the "Get" column of the property table can be retrieved via IDLgrROIGroup::GetProperty. Properties with the word "Yes" in the "Init" column of the property table can be set via IDLgrROIGroup::Init. Properties with the word "Yes" in the "Set" column in the property table can be set via IDLgrROIGroup::SetProperty.

Note ───

For a discussion of the property description tables shown below, see "About Object Property Descriptions" on page 3135.

───

Objects of this class have the following properties.

- ALL
- CLIP_PLANES
- DEPTH_TEST_DISABLE
- DEPTH_TEST_FUNCTION
- DEPTH_WRITE_DISABLE
- HIDE
- PARENT
- SHADER
- XCOORD_CONV
- XRANGE
- YCOORD_CONV
- YRANGE
- ZCOORD_CONV
- ZRANGE

In addition, objects of this class inherit:

- IDLanROIGroup.
- IDLitComponent

ALL

An anonymous structure with the values of all of the properties associated with the state of this object.

Note ———————————————————————————————————————
The fields in this structure may change in subsequent releases of IDL.

Note ———————————————————————————————————————
This structure returns ALPHA_CHANNEL and COLOR properties that are consistent with other graphic objects. However, neither property is used by the IDLgrROIGroup object.

Property Type	Structure		
Name String	*not displayed*		
Get: Yes	**Set:** No	**Init:** No	**Registered:** No

CLIP_PLANES

A 4-by-*N* floating-point array that specifies the coefficients of the clipping planes to be applied to this object. The four coefficients for each clipping plane are of the form [A, B, C, D], where $Ax + By + Cz + D = 0$. Portions of this object that fall in the half space $Ax + By + Cz + D > 0$ will be clipped. By default, the value of this property is a scalar (-1) indicating that no clipping planes are to be applied.

Note ———————————————————————————————————————
The clipping planes specified via this property are applied in addition to the near and far clipping planes associated with the IDLgrView in which this object appears.

Note ———————————————————————————————————————
Clipping planes are applied in the data space of this object (prior to the application of any x, y, or z coordinate conversion).

Note ———————————————————————————————————————
To determine the maximum number of clipping planes supported by the device, use the MAX_NUM_CLIP_PLANES property of the GetDeviceInfo method for the IDLgrBuffer, IDLgrClipboard, IDLgrWindow, and IDLgrVRML objects.

Property Type	Floating-point array		
Name String	*not displayed*		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** No

DEPTH_TEST_DISABLE

An integer value that determines whether depth testing is disabled.

- Set this property to 0 (the default) to inherit the value set by the parent model or view. The parent view always enables depth testing. A model may also enable or disable depth testing.

- Set this property to 1 to explicitly disable depth buffer testing while drawing this object.

- Set this property to 2 to explicitly enable depth testing for this object.

Disabling depth testing allows an object to draw itself "on top" of other objects already on the screen, even if the object is located behind them.

Note

Disabling depth testing also disables depth buffer writing. When disabling depth testing, the DEPTH_TEST_FUNCTION and DEPTH_WRITE_DISABLE properties are effectively ignored.

This property is registered as an enumerated list, but it is hidden by default.

Property Type	ENUMLIST		
Name String	*not displayed*		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** No

DEPTH_TEST_FUNCTION

An integer value that determines the depth test function. Set this property to 0 (the default) to inherit the value set by the parent model or view. The parent view always sets a depth test function of LESS. A model may also set a depth test function value. The graphics device compares the object's depth at a particular pixel location with the depth stored in the depth buffer at that same pixel location. If the comparison test passes, the object's pixel is drawn at that location on the screen and the depth buffer is updated (if depth writing is enabled).

Set this property to any of the following values to use the desired function while rendering this object.

- 0 = INHERIT - use value from parent model or view.

- 1 = NEVER - never passes.

- 2 = LESS - passes if the object's depth is less than the depth buffer's value.

- 3 = EQUAL - passes if the object's depth is equal to the depth buffer's value.

- 4 = LESS OR EQUAL - passes if the object's depth is less than or equal to the depth buffer's value.

- 5 = GREATER - passes if the object's depth is greater than or equal to the depth buffer's value.

- 6 = NOT EQUAL - passes if the object's depth is not equal to the depth buffer's value.

- 7 = GREATER OR EQUAL - passes if the object's depth is greater than or equal to the depth buffer's value.

- 8 = ALWAYS - always passes

Less means closer to the viewer.

This property is registered as an enumerated list, but it is hidden by default.

Property Type	ENUMLIST		
Name String	*not displayed*		
Get: Yes	Set: Yes	Init: Yes	Registered: No

DEPTH_WRITE_DISABLE

An integer value that determines whether depth writing is disabled.

- Set this property to 0 (the default) to inherit the value set by the parent model or view. The parent view always enables depth writing. A model may also enable or disable depth writing.

- Set this property to 1 to explicitly disable depth buffer writing while rendering this object.

- Set this property to 2 to explicitly enable depth writing for this object.

Disabling depth writing allows an object to be overdrawn by other objects, even if the object is located in front of them.

This property is registered as an enumerated list, but it is hidden by default.

Property Type	ENUMLIST		
Name String	*not displayed*		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** No

HIDE

A Boolean value indicating whether this region group should be drawn:

- 0 = draw the region group (the default)

- 1 = do not draw the region group.

Property Type	BOOLEAN		
Name String	*not displayed*		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** Yes

PARENT

An object reference to the object that contains this object.

Property Type	Object reference		
Name String	*not displayed*		
Get: Yes	**Set:** No	**Init:** No	**Registered:** No

SHADER

An object reference to an IDLgrShader object (or an object containing IDLgrShader as a superclass). When there is suitable graphics card hardware support, the ROI group is rendered using the GLSL shader program (executed on the graphics card) instead of using fixed OpenGL properties when initially drawn. (If a suitable graphics card is not present, IDL ignores the shader object when the scene is drawn.) A single

IDLgrShader object may be associated with additional ROI group objects or other graphic objects that have the SHADER property.

Property Type	Object reference		
Name String	*not displayed*		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** No

XCOORD_CONV

A floating-point vector, $[s_0, s_1]$, of scaling factors used to convert *X* coordinates from data units to normalized units. The formula for the conversion is as follows:

Normalized$X = s_0 + s_1*$Data$X$

Recommended values are:

$[(-X_{min})/(X_{max} - X_{min}), 1.0/(X_{max} - X_{min})\ ]$

IDL converts, maintains, and returns this data as double-precision floating-point.

Property Type	Floating-point vector		
Name String	*not displayed*		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** No

XRANGE

A two-element floating-point vector of the form [*xmin*, *xmax*] that specifies the range of *x* data coordinates covered by the graphic object. IDL maintains and returns this property in double-precision floating-point.

Property Type	Floating-point vector		
Name String	*not displayed*		
Get: Yes	**Set:** No	**Init:** No	**Registered:** No

YCOORD_CONV

A floating-point vector, $[s_0, s_1]$, of scaling factors used to convert *Y* coordinates from data units to normalized units. The formula for the conversion is as follows:

Normalized$Y = s_0 + s_1*$Data$Y$

Recommended values are:

$$[(-Y_{min})/(Y_{max} - Y_{min}), 1.0/(Y_{max} - Y_{min})]$$

IDL converts, maintains, and returns this data as double-precision floating-point.

Property Type	Floating-point vector		
Name String	*not displayed*		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** No

YRANGE

A two-element floating-point vector of the form [*ymin*, *ymax*] that specifies the range of *y* data coordinates covered by the graphic object. IDL maintains and returns this property in double-precision floating-point.

Property Type	Floating-point vector		
Name String	*not displayed*		
Get: Yes	**Set:** No	**Init:** No	**Registered:** No

ZCOORD_CONV

A floating-point vector, $[s_0, s_1]$, of scaling factors used to convert *Z* coordinates from data units to normalized units. The formula for the conversion is as follows:

$$NormalizedZ = s_0 + s_1 * DataZ$$

Recommended values are:

$$[(-Z_{min})/(Z_{max} - Z_{min}), 1.0/(Z_{max} - Z_{min})]$$

IDL converts, maintains, and returns this data as double-precision floating-point.

Property Type	Floating-point vector		
Name String	*not displayed*		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** No

ZRANGE

A two-element floating-point vector of the form [*zmin*, *zmax*] that specifies the range of *z* data coordinates covered by the graphic object. IDL maintains and returns this property in double-precision floating-point.

Property Type	Floating-point vector		
Name String	*not displayed*		
Get: Yes	Set: No	Init: No	Registered: No

IDLgrROIGroup::Add

The IDLgrROIGroup::Add procedure method adds a region to the region group. Only objects of the IDLgrROI class may be added to the group. The regions in the group must all be of the same type: all points, all paths, or all polygons.

Syntax

Obj->[IDLgrROIGroup::]Add, *ROI*

Arguments

ROI

A reference to an instance of the IDLgrROI object class representing the region of interest to add to the group.

Keywords

Accepts all keywords accepted by the IDLanROIGroup::Add method.

Version History

5.3	Introduced

IDLgrROIGroup::Cleanup

The IDLgrROIGroup::Cleanup procedure method performs all cleanup for an Object Graphics region of interest group object.

Note ——

Cleanup methods are special life cycle methods, and as such cannot be called outside the context of object creation and destruction. This means that in most cases, you cannot call the Cleanup method directly. There is one exception to this rule: if you write your own subclass of this class, you can call the Cleanup method from within the Init or Cleanup method of the subclass.

Syntax

OBJ_DESTROY, *Obj*

or

Obj->[IDLgrROIGroup::]Cleanup   *(In a lifecycle method only.)*

Arguments

None

Keywords

None

Version History

5.3	Introduced

IDLgrROIGroup::GetProperty

The IDLgrROIGroup::Get Property procedure method retrieves the value of a property or group of properties for the region group.

Syntax

Obj->[IDLgrROIGroup::]GetProperty[, *PROPERTY=variable*]

Arguments

None

Keywords

Any property listed under "IDLgrROIGroup Properties" on page 4706 that contains the word "Yes" in the "Get" column of the properties table can be retrieved using this method. To retrieve the value of a property, specify the property name as a keyword set equal to a named variable that will contain the value of the property.

Any keyword not recognized is passed to this object's superclass.

Version History

5.3	Introduced

IDLgrROIGroup::Init

The IDLgrROIGroup::Init function method initializes an Object Graphics region of interest group object.

Note

Init methods are special life cycle methods, and as such cannot be called outside the context of object creation. This means that in most cases, you cannot call the Init method directly. There is one exception to this rule: if you write your own subclass of this class, you can call the Init method from within the Init method of the subclass.

Syntax

Obj = OBJ_NEW('IDLgrROIGroup' [, *PROPERTY=value*])

or

Result = Obj->[IDLgrROIGroup::]Init([, *PROPERTY=value*])   *(In a lifecycle method only.)*

Note

Keywords can be used in either form. They are omitted in the second form for brevity.

Return Value

When this method is called indirectly, as part of the call to the OBJ_NEW function, the return value is an object reference to the newly-created object.

When called directly within a subclass Init method, the return value is 1 if initialization was successful, or zero otherwise.

Arguments

None

Keywords

Any property listed under "IDLgrROIGroup Properties" on page 4706 that contains the word "Yes" in the "Init" column of the properties table can be initialized during

object creation using this method. To initialize the value of a property, specify the property name as a keyword set equal to the appropriate property value.

All other keywords are passed to the superclass of this object.

Version History

5.3	Introduced

IDLgrROIGroup::PickRegion

The IDLgrROIGroup::PickRegion function method picks a region within the group which, when projected onto the given destination device, is nearest to the given 2-D device coordinate.

Syntax

Result = Obj->[IDLgrROIGroup::]PickRegion(*Dest*, *View*, *Point* [, PATH=*objref*])

Return Value

Returns the object reference of the nearest region. If two or more regions are equally nearest to the point, the one that was added to the region group first is returned.

Arguments

Dest

An object reference to an IDLgrWindow or IDLgrBuffer for which the pick is to occur.

View

An object reference to the IDLgrView containing this region.

Point

A two-element vector, [*x*, *y*], representing the device location to use for picking a nearest region.

Keywords

PATH

Set this keyword to a single object reference or a vector of object references. This keyword specifies the path in the graphics hierarchy to map the device position to a location in the data space of the region. Each path object reference specified with this keyword must contain an alias. The selected region is computed for the version of the object falling within the specified path. If this keyword is not set, the parent properties determine the path from the current object to the top of the graphics hierarchy and no alias paths are pursued.

Version History

5.3	Introduced

IDLgrROIGroup::Remove

The IDLgrROIGroup::Remove procedure method removes an object from the ROI group.

Syntax

Obj->[IDLgrROIGroup::]Remove [, *Child_object*] [, POSITION=*index*] [, /ALL]

Arguments

Child_object

An object reference or array of object references for the objects to be removed from the ROI group. If *Child_object* is not provided (and neither the ALL nor POSITION keyword are set), the first object in the ROI group will be removed.

Keywords

ALL

Set this keyword to remove all objects from the ROI group. If this keyword is set, the *Child_object* argument is not required.

POSITION

Set this keyword equal to the zero-based index of the object to be removed. If the *Child_object* argument is supplied, this keyword is ignored.

Version History

6.4	Introduced

IDLgrROIGroup::SetProperty

The IDLgrROIGroup::Set Property procedure method sets the value of a property or group of properties for the region group.

Syntax

Obj->[IDLgrROIGroup::]SetProperty[, *PROPERTY=value*]

Arguments

None

Keywords

Any property listed under "IDLgrROIGroup Properties" on page 4706 that contains the word "Yes" in the "Set" column of the properties table can be set using this method. To set the value of a property, specify the property name as a keyword set equal to the appropriate property value.

Version History

5.3	Introduced

IDLgrScene

A scene object represents the entire scene to be drawn and serves as a container of IDLgrView or IDLgrViewgroup objects.

Superclasses

IDL_Container

IDLitComponent

Creation

See "IDLgrScene::Init" on page 4733.

Properties

Objects of this class have the following properties. See "IDLgrScene Properties" on page 4725 for details on individual properties.

- ALL
- COLOR
- HIDE
- REGISTER_PROPERTIES
- TRANSPARENT

In addition, objects of this class inherit the properties of all superclasses of this class.

Methods

This class has the following methods:

- IDLgrScene::Add
- IDLgrScene::Cleanup
- IDLgrScene::GetByName
- IDLgrScene::GetProperty
- IDLgrScene::Init
- IDLgrScene::SetProperty

In addition, this class inherits the methods of its superclasses (if any).

Version History

5.0	Introduced

IDLgrScene Properties

IDLgrScene objects have the following properties in addition to properties inherited from any superclasses. Properties with the word "Yes" in the "Get" column of the property table can be retrieved via IDLgrScene::GetProperty. Properties with the word "Yes" in the "Init" column of the property table can be set via IDLgrScene::Init. Properties with the word "Yes" in the "Set" column in the property table can be set via IDLgrScene::SetProperty.

Note

For a discussion of the property description tables shown below, see "About Object Property Descriptions" on page 3135.

Objects of this class have the following properties.

- ALL
- COLOR
- HIDE
- REGISTER_PROPERTIES
- TRANSPARENT

In addition, objects of this class inherit:

- IDL_Container
- IDLitComponent

ALL

An anonymous structure containing the values of all of the properties associated with the *state* of this object. State information about the object includes things like color, range, tick direction, etc., but not image, vertex, or connectivity data, or user values.

Note

The fields of this structure may change in subsequent releases of IDL.

Property Type	Structure		
Name String	*not displayed*		
Get: Yes	Set: No	Init: No	Registered: No

COLOR

The color to which the scene should be erased before drawing. The color may be specified as a color lookup table index or a three-element vector [*red*, *green*, *blue*].

In a property sheet, this property appears as a color property.

Property Type	COLOR		
Name String	Background color		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** Yes

HIDE

A Boolean value or an enumerated list item indicating whether this object should be drawn:

Value	Property Sheet Value	Description
0	True	Draw graphic (the default)
1	False	Do not draw graphic

Property Type	ENUMLIST		
Name String	Show		
Get: No	**Set:** No	**Init:** Yes	**Registered:** Yes

REGISTER_PROPERTIES

A Boolean value that determines whether to register properties available for this object. If this property is set, all properties marked in this properties section as "Registered: Yes" will be registered for display in a property sheet. This property is useful mainly when creating iTools. By default, no properties are registered.

For IDLgrScene, the available properties (and their iTool data types) are:

- HIDE (Boolean)

Property Type	Boolean		
Name String	*not displayed*		
Get: No	Set: No	Init: Yes	Registered: No

TRANSPARENT

A Boolean value that determines whether to disable window clearing. If this property is not set, the destination object in use by the scene is automatically erased when the scene is initialized.

Property Type	BOOLEAN		
Name String	Transparent		
Get: Yes	Set: Yes	Init: No	Registered: Yes

IDLgrScene::Add

The IDLgrScene::Add function method verifies that the added item is an instance of an IDLgrView or IDLgrViewgroup object. If it is, IDLgrScene:Add adds the view or viewgroup to the specified scene.

Syntax

Obj->[IDLgrScene::]Add, *View* [, POSITION=*index*]

Arguments

View

An instance of the IDLgrView or IDLgrViewgroup object class.

Keywords

POSITION

Set this keyword equal to the zero-based index of the position within the container at which the new object should be placed.

Version History

5.0	Introduced

IDLgrScene::Cleanup

The IDLgrScene::Cleanup procedure method performs all cleanup on the object.

Note

Cleanup methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation and destruction. This means that in most cases, you cannot call the Cleanup method directly. There is one exception to this rule: if you write your own subclass of this class, you can call the Cleanup method from within the Init or Cleanup method of the subclass.

Syntax

OBJ_DESTROY, *Obj*

or

Obj->[IDLgrScene::]Cleanup   *(In a lifecycle method only.)*

Arguments

None

Keywords

None

Version History

5.0	Introduced

IDLgrScene::GetByName

The IDLgrScene::GetByName function method finds contained objects by name and returns the object reference to the named object. If the named object is not found, the GetByName function returns a null object reference.

Note

The GetByName function does *not* perform a recursive search through the object hierarchy. If a fully qualified object name is not specified, only the contents of the current container object are inspected for the named object.

Syntax

Result = Obj->[IDLgrScene::]GetByName(*Name*)

Return Value

Returns the object reference to the named object. If the named object is not found, returns a null object reference.

Arguments

Name

A string containing the name of the object to be returned.

Object naming syntax is very much like the syntax of a UNIX filesystem. Objects contained by other objects can include the name of their parent object; this allows you to create a fully qualified name specification. For example, if object1 contains object2, which in turn contains object3, the string specifying the fully qualified object name of object3 would be 'object1/object2/object3'.

Object names are specified relative to the object on which the GetByName method is called. If used at the beginning of the name string, the / character represents the top of an object hierarchy. The string '..' represents the object one level "up" in the hierarchy.

Keywords

None

Version History

5.0	Introduced

IDLgrScene::GetProperty

The IDLgrScene::GetProperty procedure method retrieves the value of a property or group of properties for the contour.

Syntax

Obj->[IDLgrScene::]GetProperty[, *PROPERTY=variable*]

Arguments

None

Keywords

Any property listed under "IDLgrScene Properties" on page 4725 that contains the word "Yes" in the "Get" column of the properties table can be retrieved using this method. To retrieve the value of a property, specify the property name as a keyword set equal to a named variable that will contain the value of the property.

Any keyword not recognized is passed to this object's superclass.

Version History

5.0	Introduced

IDLgrScene::Init

The IDLgrScene::Init function method initializes the scene object.

Note

Init methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation. This means that in most cases, you cannot call the Init method directly. There is one exception to this rule: if you write your own subclass of this class, you can call the Init method from within the Init method of the subclass.

Syntax

Obj = OBJ_NEW('IDLgrScene' [, *PROPERTY=value*])

or

Result = Obj->[IDLgrScene::]Init([, *PROPERTY=value*])   *(In a lifecycle method only.)*

Return Value

When this method is called indirectly, as part of the call to the OBJ_NEW function, the return value is an object reference to the newly-created object.

When called directly within a subclass Init method, the return value is 1 if initialization was successful, or zero otherwise.

Arguments

None

Keywords

Any property listed under "IDLgrScene Properties" on page 4725 that contains the word "Yes" in the "Init" column of the properties table can be initialized during object creation using this method. To initialize the value of a property, specify the property name as a keyword set equal to the appropriate property value.

All other keywords are passed to the superclass of this object.

Version History

5.0	Introduced

IDLgrScene::SetProperty

The IDLgrScene::SetProperty procedure method sets the value of a property or group of properties for the buffer.

Syntax

Obj->[IDLgrScene::]SetProperty[, *PROPERTY=value*]

Arguments

None

Keywords

Any property listed under "IDLgrScene Properties" on page 4725 that contains the word "Yes" in the "Set" column of the properties table can be set using this method. To set the value of a property, specify the property name as a keyword set equal to the appropriate property value.

Version History

5.0	Introduced

IDLgrShader

A *shader object* provides access to the hardware-based processing power available on some modern graphics cards. This allows computationally intensive image processing operations to be delegated to the Graphics Processing Unit (GPU) of a suitable graphics card, dramatically increasing performance and interactivity. A shader program can perform image filtering operations, complex lighting and shading calculations, interactive blending of multiple textures, animation of object vertices, or any combination of these.

See "Hardware Requirements for Shaders" (*Object Programming*) for information on graphics cards and how to determine whether the graphics card supports this shader functionality. If there is not sufficient support for the shader program, IDL draws the scene graph as if there was no shader object present.

Note ───

See Chapter 14, "Advanced Rendering Using Shader Objects" (*Object Programming*) for valuable overview information about using shader programs with IDL and for a wide range of examples.

───

Warning ───────────────────────────────────────

Setting IDLgrImage RENDER_METHOD=1 (do *not* render image as texture-mapped polygon) disables all shader functionality including the software-based alternative.

───

Superclasses

Objects of this class have no superclass.

Creation

See IDLgrShader::Init.

Properties

Objects of this class have the following properties. See "IDLgrShader Properties" on page 4738 for details on individual properties.

- CACHE_RESULT
- FORCE_FILTER

- FRAGMENT_PROGRAM_FILENAME
- FRAGMENT_PROGRAM_STRING
- OUTPUT_DATA_TYPE
- VERTEX_PROGRAM_FILENAME
- VERTEX_PROGRAM_STRING

In addition, objects of this class inherit the properties of all superclasses of this class, if any.

Methods

This class has the following methods:

- IDLgrShader::Cleanup
- IDLgrShader::Filter
- IDLgrShader::GetProperty
- IDLgrShader::GetUniformVariable
- IDLgrShader::Init
- IDLgrShader::SetProperty
- IDLgrShader::SetUniformVariable

In addition, this class inherits the methods of its superclasses, if any.

Examples

See Chapter 14, "Advanced Rendering Using Shader Objects" (*Object Programming*).

Version History

6.4	Introduced

IDLgrShader Properties

IDLgrShader objects have the following properties in addition to properties inherited from any superclasses. Properties with the word "Yes" in the "Get" column of the property table can be retrieved via IDLgrShader::GetProperty. Properties with the word "Yes" in the "Init" column of the property table can be set via IDLgrShader::Init. Properties with the word "Yes" in the "Set" column in the property table can be set via IDLgrShader::SetProperty.

Note ————————————————————————————————————

For a discussion of the property description tables shown below, see "About Object Property Descriptions" on page 3135.

———

Objects of this class have the following properties:

- CACHE_RESULT
- FORCE_FILTER
- FRAGMENT_PROGRAM_FILENAME
- FRAGMENT_PROGRAM_STRING
- OUTPUT_DATA_TYPE
- VERTEX_PROGRAM_FILENAME
- VERTEX_PROGRAM_STRING

CACHE_RESULT

If a shader object is associated with an IDLgrImage object, you may set this property to determine whether a shader program is executed every time Draw is called as follows:

Value	Description
0	The default. Apply the shader each time Draw is called. This is suitable for applications with a fast graphics card or one that is interactively updated by uniform variable parameter changes. (Re-caching the image each time the shader is changed carries a performance penalty.)
Non-zero	Cache the result of applying the shader and use this cached result in subsequent renderings. This setting is appropriate for slow graphics cards or applications that requires fast redraw capabilities such as when panning or zooming.

If a software fallback is in use or the image is part of an IDLgrFilterChain, the value of this property is ignored and the result of applying the shader is always cached. This property is ignored if the shader object is associated with any object other than IDLgrImage. The default value is 0.

Note ───────

Your graphics card must support FRAMEBUFFER_OBJECT_EXTENSION when you request caching (CACHE_RESULT=1). You can determine this support using IDLgrWindow::GetDeviceInfo.

───────

Property Type	Integer		
Name String	*not displayed*		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** No

FORCE_FILTER

Set this scalar long property to a non-zero value to cause IDL to call the IDLgrShader subclass Filter method, even if the graphics hardware supports shaders. This is useful for developing and testing the software fallback option on devices that have the

hardware support. The default value for this property is zero. This property can only be set at Init time.

Property Type	Integer		
Name String	*not displayed*		
Get: Yes	**Set:** No	**Init:** Yes	**Registered:** No

FRAGMENT_PROGRAM_FILENAME

This property is a scalar string containing the complete filepath specifying a text file that contains the fragment program text. If specified, IDL ignores the FRAGMENT_PROGRAM_STRING property. If the file does not exist when IDL draws the scene using this shader, IDL reports an informational error and continues drawing without the shader program.

Property Type	String		
Name String	*not displayed*		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** No

FRAGMENT_PROGRAM_STRING

This property is a scalar string that contains the fragment program text. If your application maintains the program as an array of strings, one for each program line, use STRJOIN to create a single string that is suitable for this property. Specify a newline string (10B) as the delimiter in STRJOIN so that the shader program compiler can report a useful line number in any compilation error messages. For example:

```
programString = STRJOIN(pgmStrings, STRING(10B))
```

Property Type	String		
Name String	*not displayed*		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** No

OUTPUT_DATA_TYPE

This property controls the precision of data storage used for an interim image when the following conditions apply to the shader object:

- • It is associated with an IDLgrImage object

- • It is being executed on the GPU of the graphics card (suitable hardware is available)

- • It is either contained in an IDLgrFilterChain object or CACHE_RESULT=1.

This scalar long property may be set to one of the following values:

Value	Description
1	BYTE
2	FLOAT16
3	FLOAT32 (the default)

When the IDLgrShader is in an IDLgrFilterChain, OUTPUT_DATA_TYPE specifies the precision of the temporary storage used to pass data from one shader to the next in the chain. When CACHE_RESULT is set to 1, OUTPUT_DATA_TYPE specifies the precision of the cache used to store the result of the shader operation.

Note ───
If you will be capturing the image data during or after applying the shaders, the OUTPUT_DATA_TYPE property and the DATA_TYPE keyword of IDLgrImage::ReadFilteredData should have consistent values.
───

Note ───
For best performance use the lowest precision possible without loss of data.
───

The default value is 3.

Property Type	Integer		
Name String	*not displayed*		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** No

VERTEX_PROGRAM_STRING

This property is a scalar string that contains the vertex program text. If your application maintains the program as an array of strings, one for each program line, use STRJOIN to create a single string that is suitable for this property. Specify a newline string (10B) as the delimiter in STRJOIN so that the shader program compiler can report a useful line number in any compilation error messages. For example:

```
programString = STRJOIN(pgmStrings, STRING(10B))
```

Property Type	String		
Name String	*not displayed*		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** No

VERTEX_PROGRAM_FILENAME

This property is a scalar string containing the complete filepath specifying a text file that contains the vertex program text. If specified, IDL ignores the VERTEX_PROGRAM_STRING property. If the file does not exist when IDL draws the scene using this shader, IDL reports an informational error and continues drawing without the shader program.

Property Type	String		
Name String	*not displayed*		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** No

IDLgrShader::Cleanup

The IDLgrShader::Cleanup procedure method performs all cleanup on the object.

Note ————————————————————————————————————

Cleanup methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation and destruction. This means that in most cases, you cannot call the Cleanup method directly. There is one exception to this rule: if you write your own subclass of this class, you can call the Cleanup method from within the Init or Cleanup method of the subclass.

Syntax

OBJ_DESTROY, *Obj*

or

Obj->[IDLgrShader::]Cleanup   *(In a lifecycle method only.)*

Arguments

None

Keywords

None

Version History

6.4	Introduced

IDLgrShader::Filter

The IDLgrShader::Filter function method, implemented only in an IDLgrShader subclass, provides a way to implement a software-based fallback for an image filtering shader program when the graphics card hardware does not support shading language.

This function is only available for shader objects associated with IDLgrImage objects, and is activated only when the required hardware support is not present or when the FORCE_FILTER property of the shader object or IDLgrFilterChain object is set to a non-zero value.

Note ───

Never call this method directly. It is called automatically in response to changes requiring a re-draw of the scene, including IDLgrShader::SetUniformVariable updates.

───

This method should not be included in a subclassed shader object attached to texture mapped IDLgrSurface or IDLgrPolygon object (where an image is associated via the TEXTURE_MAP property). A software fallback option is not available in such cases.

Syntax

Result = Obj->[IDLgrShader subclass::]Filter(*Image*)

Return Value

Returns an IDL array containing the resulting filtered image. The array must have the same dimensions and type as the incoming image. If the returned array does not meet these requirements, IDL ignores the array and draws the image with its original data.

This method should apply the desired operation to the image data and return that data as its function return value. IDL clamps the returned image data to the range [0.0, 1.0] and converts this range into the pixel component range appropriate for the device. In most cases, this is [0, 255].

Arguments

Image

An array containing the image data. This array is always of type FLOAT and contains RGBA components arranged in PIXEL_INTERLEAVE format, [4, *cols*, *rows*].

Keywords

None.

Examples

The following code segment shows an implementation of the Filter method in an object, shader_rgb_doc, that subclasses from IDLgrShader. Within the method, access the RGBA floating-point, pixel-interleaved data in *Image*. Alter the intensity of each red, green, and blue channel based on values (*s*) contained in the uniform variable (*scl*). Return the filtered image. See "Altering RGB Levels Using a Shader" (Chapter 14, *Object Programming*) for expository details.

```
Function shader_rgb_doc::Filter, Image

newImage=Image
self->GetUniformVariable, 'scl', s
newImage[0,*,*] *= s[0]
newImage[1,*,*] *= s[1]
newImage[2,*,*] *= s[2]

RETURN, newImage

END
```

Example Code

See shader_rgb_doc__define.pro for the complete, working example, which is located in the examples/doc/shaders subdirectory of the IDL distribution. Run the example by creating an instance of the object at the IDL command prompt using orgbshader=OBJ_NEW("shader_rgb_doc") or view the file in an IDL Editor window by entering shader_rgb_doc__define.pro.

IDLgrShader::SetUniformVariable

IDLgrShader::GetProperty

The IDLgrShader::GetProperty procedure method returns the value of a property or group of properties for the shader.

Syntax

Obj->[IDLgrShader::]GetProperty[, *PROPERTY=value*]

Arguments

None

Keywords

Any property listed under "IDLgrShader Properties" on page 4738 that contains the word "Yes" in the "Get" column of the properties table can be retrieved using this method. To retrieve the value of a property, specify the property name as a keyword set equal to a named variable that will contain the value of the property.

Version History

6.4	Introduced

IDLgrShader::GetUniformVariable

The IDLgrShader::GetUniformVariable procedure method returns the value of a named uniform variable. A uniform variable provides a way to pass small amounts of data to a shader program. It can enable interactivity by linking user interface control changes to program updates.

The GetUniformVariable method is typically called inside the IDLgrShader::Filter method, which is used to provide a software-based alternative to a hardware-based image processing shader program. See "Examples" on page 4745 for such a sample program.

Note

For information about uniform variables, see "Uniform Variables" (Chapter 14, *Object Programming*).

Syntax

Obj->[IDLgrShader::]GetUniformVariable, *Name, Value*

Arguments

Name

Specifies a case-sensitive string name of the uniform variable to retrieve.

Note

If the *Name* argument specifies a uniform variable that was never defined and stored in the shader object using SetUniformVariable, then the variable specified in the *Value* parameter will be set to an undefined variable.

Value

Specifies a variable that contains the current value of the uniform variable. The variable is stored in this parameter in exactly the same format as that used when it was defined using IDLgrShader::SetUniformVariable.

Keywords

None.

Version History

6.4	Introduced

See Also

IDLgrShader::SetUniformVariable

IDLgrShader::Init

The IDLgrShader::Init function method initializes the shader object.

Note

Init methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation. This means that in most cases, you cannot call the Init method directly. There is one exception to this rule: if you write your own subclass of this class, you can call the Init method from within the Init method of the subclass.

Syntax

Obj = OBJ_NEW('IDLgrShader' [, *PROPERTY=value*])

or

Result = Obj->[IDLgrShader::]Init([, *PROPERTY=value*])   *(In a lifecycle method only.)*

Return Value

When this method is called indirectly, as part of the call to the OBJ_NEW function, the return value is an object reference to the newly-created object.

When called directly within a subclass Init method, the return value is 1 if initialization was successful, or zero otherwise.

Arguments

None.

Keywords

Any property listed under "IDLgrShader Properties" on page 4738 that contains the word "Yes" in the "Init" column of the properties table can be initialized during object creation using this method. To initialize the value of a property, specify the property name as a keyword set equal to the appropriate property value.

Version History

6.4	Introduced

IDLgrShader::SetProperty

The IDLgrShader::SetProperty procedure method sets the value of a property or group of properties for the shader.

Syntax

Obj->[IDLgrShader::]SetProperty[, *PROPERTY=value*]

Arguments

None

Keywords

Any property listed under "IDLgrShader Properties" on page 4738 that contains the word "Yes" in the "Set" column of the properties table can be set using this method. To set the value of a property, specify the property name as a keyword set equal to the appropriate property value.

Version History

6.4	Introduced

IDLgrShader::SetUniformVariable

The IDLgrShader::SetUniformVariable procedure method assigns a value to a named uniform variable. A uniform variable provides a way to pass small amounts of data to a shader program. It can enable interactivity by linking user interface control changes to shader program updates.

IDL stores the *Name* and *Value* of the uniform variable with the instance of the associated IDLgrShader object the first time this method is called. When SetUniformVariable is called again using the same *Name* argument, the uniform variable is updated with the current contents of *Value*. Once a uniform variable is associated with a shader object, there is no way to remove the reference. Any uniform variable that is defined, but not used in the shader program is simply ignored.

Note

For information about uniform variables, see "Uniform Variables" (Chapter 14, *Object Programming*).

The fragment shader program will support a minimum of 64 uniform variables (use IDLgrWindow::GetDeviceInfo to determine the exact number). For maximum shader program portability, define 64 or fewer variables.

In the case of a shader object associated with an IDLgrImage, or an IDLgrPolygon or IDLgrSurface with an associated TEXTURE_MAP image, you do not need to use SetUniformVariable to pass the image data to the shader program if multi-texturing is not occurring. The reserved uniform variable, _IDL_ImageTexture, automatically contains the texture map data associated with the primary IDLgrImage object. See "Reserved Uniform Variables" (Chapter 14, *Object Programming*) for details.

Note

If a shader object is associated with more than a single graphic object, any changes to a uniform variable will be applied to all associated objects. To avoid this, copy and associate an individual instance of a shader object with each individual graphic objects.

Syntax

Obj->[IDLgrShader::]SetUniformVariable, *Name, Value*]

Arguments

Name

Specifies a case-sensitive string name of the uniform variable.

Value

Defines an IDL simple scalar value, array or an IDLgrImage object reference to be associated with *Name*. IDL strings, structures, pointers, and undefined variables are not allowed and will cause an error that halts execution. IDL converts all integer types to 32-bit long and converts all floating types to 32-bit float before submitting the data to the shader program.

If this argument is set to a 1-D or 2-D IDLgrImage object reference (the only type of object reference permitted), IDL loads the image data into an OpenGL texture that can be accessed using the uniform variable specified. This uniform variable must be defined as GLSL type *sampler1D* or *sampler2D* in the shader program.

If the dimensions of the IDLgrImage are not a power of 2 then the image will be padded to the next largest power of 2. If the dimensions of the IDLgrImage are larger than MAX_TEXTURE_DIMENSIONS (returned by GetDeviceInfo) then the image will be scaled down to MAX_TEXTURE_DIMENSIONS. Keep this in mind when generating texture coordinates to access the texture map. The IDLgrImage passed to SetUniformVariable cannot be tiled.

Keywords

None.

Version History

6.4	Introduced

IDLgrShader::GetUniformVariable

IDLgrShaderBytscl

A shader byte-scale object is a subclass of IDLgrShader that can be associated with an IDLgrImage object via the SHADER property. This object lets you quickly perform a BYTSCL operation on the image data as it is drawn to the screen, taking advantage of the advanced processing power of the hardware-based OpenGL Shading Language (GLSL) if an appropriate graphics card is available. See "Hardware Requirements for Shaders" (Chapter 14, *Object Programming*) for details. Otherwise, this object performs the byte-scale operation using a software-based alternative. See Chapter 14, "Advanced Rendering Using Shader Objects" (*Object Programming*) for more information about shader objects.

Use the IN_RANGE and OUT_RANGE property values to control the byte-scaling parameters, which can be independently applied to each channel of image data. This object performs the byte-scaling operation in floating-point format and does not call the IDL BYTSCL function.

If the image data is other than byte or 8-bits per channel, set the IDLgrImage INTERNAL_DATA_TYPE property to avoid having your data truncated to byte.

Warning ―――――――――――――――――――――――――――――
Setting IDLgrImage RENDER_METHOD=1 (do *not* render image as texture-mapped polygon) disables all shader functionality including the software-based alternative.
―――――――――――――――――――――――――――――――――――

This object class is implemented in the IDL language. Its source code can be found in the file `idlgrshaderbytscl__define.pro` in the `lib` subdirectory of the IDL distribution.

Superclasses

IDLgrShader

Creation

See IDLgrShaderBytscl::Init.

Properties

Objects of this class have the following properties. See "IDLgrShaderBytscl Properties" on page 4758 for details on individual properties.

- IN_RANGE

- OUT_RANGE

- UNITS_IN_RANGE

In addition, objects of this class inherit the properties of all superclasses of this class.

Methods

This class has the following methods:

- IDLgrShaderBytscl::Cleanup

- IDLgrShaderBytscl::GetProperty

- IDLgrShaderBytscl::Init

- IDLgrShaderBytscl::SetProperty

In addition, this class inherits the methods of its superclass (IDLgrShader).

Examples

The following example creates an object that inherits from the IDLgrShaderBytscl object, loads grayscale image data and lets you interactively adjust the input and output data ranges using two sliders. Note that when using the IDLgrShaderBytscl object with non-byte data, you should set the IDLgrImage INTERNAL_DATA_TYPE property to avoid having your data truncated to a byte (0-255) range.

Example Code

See `shader_bytscl_doc__define.pro` for the complete, working example, which is located in the `examples/doc/shaders` subdirectory of the IDL distribution. Run the example by creating an instance of the object at the IDL command prompt using `obytsclshader=OBJ_NEW("shader_bytscl_doc")` or view the file in an IDL Editor window by entering `shader_bytscl_doc__define.pro`.

IDLgrShaderBytscl Properties

IDLgrShaderBytscl objects have the following properties in addition to properties inherited from any superclasses. Properties with the word "Yes" in the "Get" column of the property table can be retrieved via "IDLgrShaderBytscl::GetProperty" on page 4762. Properties with the word "Yes" in the "Init" column of the property table can be set via "IDLgrShaderBytscl::Init" on page 4763. Properties with the word "Yes" in the "Set" column in the property table can be set via "IDLgrShaderBytscl::SetProperty" on page 4765.

Note

For a discussion of the property description tables shown below, see "About Object Property Descriptions" on page 3135.

Objects of this class have the following properties.

- IN_RANGE
- OUT_RANGE
- UNITS_IN_RANGE

In addition, objects of this class inherit the properties of:

- "IDLgrShader" on page 4736

IN_RANGE

A 2x*n* floating-point array that describes the MIN and MAX values for the byte-scaling operation for each of the *n* channels in the input image. See the BYTSCL function for more detail. See the UNITS_IN_RANGE property for this object to determine the units and scaling to use for setting this property.

Since the IDLgrShader::Filter method receives RGBA data from IDL, this object expands this property into a [2,4] floating-point array. The UNITS_IN_RANGE property value determines how incoming values are scaled before being expanded as follows:

- [a,b] — expands to [[a,b],[a,b],[a,b],[0,1]] (single LUM channel repeated in RGB, Alpha channel set to full range)
- [[a,b],[c,d]] expands to [[a,b],[a,b],[a,b],[c,d]] (LUM with Alpha channel specified)
- [[a,b],[c,d],[e,f]] expands to [[a,b],[c,d],[e,f],[0,1]] (RGB copied exactly, Alpha channel set to full range)

- • [[a,b],[c,d],[e,f],[g,h]] expands to [[a,b],[c,d],[e,f],[g,h]] (entire range is specified)

The default values are [0.0, 1.0] for each channel. In all cases, the MAX value must be greater than the MIN value.

Property Type	Float array		
Name String	*not displayed*		
Get: Yes	Set: Yes	Init: Yes	Registered: No

OUT_RANGE

A 2x*n* floating-point array that describes the bottom and top range values for the output of the byte-scaling operation for each of the *n* channels in the image data. The top value corresponds to the TOP keyword used in the IDL BYTSCL function. For example, if the provided values are [40,80], the data will be scaled into byte data in the range 40 - 80, inclusive. For compatibility with the IDL BYTSCL function, the minimum and maximum values for this property should be specified in the range [0, 255].

Since the IDLgrShader::Filter method returns RGBA data to IDL, this object expands this property into a [2,4] floating-point array as follows:

- • [a,b] — expands to [[a,b],[a,b],[a,b],[0,1]] (single LUM channel repeated in RGB, Alpha channel set to full range)

- • [[a,b],[c,d]] expands to [[a,b],[a,b],[a,b],[c,d]] (LUM with Alpha channel specified)

- • [[a,b],[c,d],[e,f]] expands to [[a,b],[c,d],[e,f],[0,1]] (RGB copied exactly, Alpha channel set to full range)

- • [[a,b],[c,d],[e,f],[g,h]] expands to [[a,b],[c,d],[e,f],[g,h]] (entire range is specified)

Before performing the byte-scaling operation, these values are scaled into the floating-point range [0,1].

The default values are [0,255] for each color channel and [0,1] for the alpha channel.

Property Type	Float array		
Name String	*not displayed*		
Get: Yes	Set: Yes	Init: Yes	Registered: No

UNITS_IN_RANGE

A scalar integer that represents the units used to express the minimum and maximum values specified by the IN_RANGE property. This value usually corresponds to the data type of the data stored in the image object. The allowed values, which correspond to IDL *type codes*, are:

Value (type code)	Data Units	IN_RANGE Values must be in this range:
0	Normalized	• [0.0, 1.0] for BYTE and UINT • [-1.0, 1.0] for INT • Any range for FLOAT.
1	BYTE	[0, 255]
2	INT	[-32768, 32767]
4	FLOAT	Any floating-point range
12	UINT	[0, 65535]

The default value is 0.

Property Type	Integer		
Name String	*not displayed*		
Get: Yes	**Set:** Yes	**Init:** No	**Registered:** No

IDLgrShaderBytscl::Cleanup

The IDLgrShaderBytscl::Cleanup procedure method performs all cleanup on the object.

Note ───

Cleanup methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation and destruction. This means that in most cases, you cannot call the Cleanup method directly. There is one exception to this rule: if you write your own subclass of this class, you can call the Cleanup method from within the Init or Cleanup method of the subclass.

──

Syntax

OBJ_DESTROY, *Obj*

or

Obj->[IDLgrShaderBytscl::]Cleanup   *(In a lifecycle method only.)*

Arguments

None

Keywords

None

Version History

6.4	Introduced

IDLgrShaderBytscl::GetProperty

The IDLgrShaderBytscl::GetProperty procedure method returns the value of a
property or group of properties for the shader.

Syntax

Obj->[IDLgrShaderBytscl::]GetProperty[, *PROPERTY=value*]

Arguments

None

Keywords

Any property listed under "IDLgrShaderBytscl Properties" on page 4758 that
contains the word "Yes" in the "Get" column of the properties table can be retrieved
using this method. To retrieve the value of a property, specify the property name as a
keyword set equal to a named variable that will contain the value of the property.

Version History

6.4	Introduced

IDLgrShaderBytscl::Init

The IDLgrShaderBytscl::Init function method initializes the surface object.

Note

Init methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation. This means that in most cases, you cannot call the Init method directly. There is one exception to this rule: if you write your own subclass of this class, you can call the Init method from within the Init method of the subclass.

Syntax

Obj = OBJ_NEW('IDLgrShaderBytscl' [, *PROPERTY=value*])

or

Result = Obj->[IDLgrShaderBytscl::]Init([, *PROPERTY=value*])   *(In a lifecycle method only.)*

Return Value

When this method is called indirectly, as part of the call to the OBJ_NEW function, the return value is an object reference to the newly-created object.

When called directly within a subclass Init method, the return value is 1 if initialization was successful, or zero otherwise.

Arguments

None.

Keywords

Any property listed under "IDLgrShaderBytscl Properties" on page 4758 that contains the word "Yes" in the "Init" column of the properties table can be initialized during object creation using this method. To initialize the value of a property, specify the property name as a keyword set equal to the appropriate property value.

Version History

6.4	Introduced

IDLgrShaderBytscl::SetProperty

The IDLgrShaderBytscl::SetProperty procedure method sets the value of a property or group of properties for the shader.

Syntax

Obj->[IDLgrShaderBytscl::]SetProperty[, *PROPERTY=value*]

Arguments

None

Keywords

Any property listed under "IDLgrShaderBytscl Properties" on page 4758 that contains the word "Yes" in the "Set" column of the properties table can be set using this method. To set the value of a property, specify the property name as a keyword set equal to the appropriate property value.

Version History

6.4	Introduced

IDLgrShaderConvol3

A convolution shader object is a subclass of IDLgrShader that can be associated with an IDLgrImage object via the SHADER property to perform general 3x3 convolution operations such as smoothing and edge detection on the image data as it is drawn to the screen. If hardware shader support is available, IDL will use it. Otherwise, this object performs the operation using a software-based alternative.

IDLgrShaderConvol3 performs the convolution operation on each channel independently, using either a predefined convolution KERNEL or a user-specified kernel.

Since the hardware shader programs require data in floating-point format, this function converts the input data into the floating-point range of [0,1], applies the scaling, and then maps the scaled data into the device's output range.

The reserved uniform variable `_IDL_ImageStep` is set by the IDLgrImage object before calling the shader program. This GLSL type `vec2` variable contains the texture coordinate offsets needed to locate adjacent texels in both the *x* and *y* dimensions. These offsets are useful to shader programs that implement convolution kernels because it is necessary to use neighboring texels in these computations. See "Reserved Uniform Variables" (Chapter 14, *Object Programming*) for more information about reserved uniform variables.

Warning

Setting IDLgrImage RENDER_METHOD=1 (do *not* render image as texture-mapped polygon) disables all shader functionality including the software-based alternative.

This object class is implemented in the IDL language. Its source code can be found in the file `idlgrshaderconvol3__define.pro` in the `lib` subdirectory of the IDL distribution.

Superclasses

IDLgrShader

Creation

See IDLgrShaderConvol3::Init.

Properties

Objects of this class have the following properties. See "IDLgrShaderConvol3 Properties" on page 4769 for details on individual properties.

- • BASE_BLEND_FACTOR
- • CONVOL_BLEND_FACTOR
- • KERNEL

In addition, objects of this class inherit the properties of all superclasses of this class.

Methods

This class has the following methods:

- • IDLgrShaderConvol3::Cleanup
- • IDLgrShaderConvol3::GetProperty
- • IDLgrShaderConvol3::Init
- • IDLgrShaderConvol3::SetProperty

In addition, this class inherits the methods of its superclass (IDLgrShader).

Examples

The following example creates four instances of the IDLgrShaderConvol3 object and lets you apply one or more shaders to an image by modifying the IDLgrFilterChain object. See "Filter Chain Shaders" (Chapter 14, *Object Programming*) for more information about the IDLgrShaderConvol3 object and this example.

Example Code ————————————————————————

See `shader_filterchain_doc__define.pro` for the complete, working example, which is located in the `examples/doc/shaders` subdirectory of the IDL distribution. Run the example by creating entering `o=OBJ_NEW('shader_filterchain_doc')` at the IDL command prompt or view the file in an IDL Editor window by entering `.edit shader_filterchain_doc__define.pro`.

IDLgrShaderConvol3 Properties

IDLgrShaderConvol3 objects have the following properties in addition to properties inherited from any superclasses. Properties with the word "Yes" in the "Get" column of the property table can be retrieved via IDLgrShaderConvol3::GetProperty. Properties with the word "Yes" in the "Init" column of the property table can be set via IDLgrShaderConvol3::Init. Properties with the word "Yes" in the "Set" column in the property table can be set via IDLgrShaderConvol3::SetProperty.

Note ──

For a discussion of the property description tables shown below, see "About Object Property Descriptions" on page 3135.

──

Objects of this class have the following properties.

- BASE_BLEND_FACTOR
- CONVOL_BLEND_FACTOR
- KERNEL

In addition, objects of this class inherit the properties of "IDLgrShader" on page 4736.

BASE_BLEND_FACTOR

A scalar single-precision floating-point value in the range of [0.0, 1.0] with a default value of 0.0. Setting this property to a numeric value outside of this range results in an error. This property controls the amount of the base image that is added to the kernel output, controlled by the CONVOL_BLEND_FACTOR property, in the final resulting image. The default value of 0.0 implies that no part of the base image is added to the final image.

Note ──

Some convolution kernels work best when combining the kernel output with the original base image. The sharpen convolution kernel (KERNEL=2) is a good example. The default value of 0.0, causes no contribution of the base image with the kernel output, while a value of 1.0 adds all of the base image to the kernel output.

──

Property Type	Float		
Name String	*not displayed*		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** No

CONVOL_BLEND_FACTOR

A scalar single-precision floating-point value in the range [0.0, 1.0]. This property controls the amount of the convolution kernel output that is added to the base image, controlled by the BASE_BLEND_FACTOR property, in the final resulting image. Setting this property to a numeric value outside of the 0.0 to 1.0 range results in an error. The default value is 1.0, which implies that all of the convolution output is added to the final image.

Property Type	Float		
Name String	*not displayed*		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** No

KERNEL

Either a scalar integer value indicating a pre-defined kernel, or a 9-element numerical array (that will be converted to a 3x3 floating-point array) containing a custom kernel. The predefined kernels are:

Value	Description
0	Identity (performs no operation on the image) - the default
1	Smooth
2	Sharpen
3	Edge Detection (vertical and horizontal)

The default value, 0, selects the "identity" kernel, which passes the image through without modification. This property may also be set with a 9-element numeric array. IDL converts this array to single-precision floating-point. Setting this property with any value other than a pre-defined kernel or a 9-element numeric array results in an error.

If this property is set with a scalar integer, GetProperty returns the same scalar integer. If this property is set with a 9-element numeric array, GetProperty returns a 9-element floating-point array.

Property Type	Integer or Array		
Name String	*not displayed*		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** No

IDLgrShaderConvol3::Cleanup

The IDLgrShaderConvol3::Cleanup procedure method performs all cleanup on the object.

Note ───

Cleanup methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation and destruction. This means that in most cases, you cannot call the Cleanup method directly. There is one exception to this rule: if you write your own subclass of this class, you can call the Cleanup method from within the Init or Cleanup method of the subclass.

───

Syntax

OBJ_DESTROY, *Obj*

or

Obj->[IDLgrShaderConvol3::]Cleanup   *(In a lifecycle method only.)*

Arguments

None

Keywords

None

Version History

6.4	Introduced

IDLgrShaderConvol3::GetProperty

The IDLgrShaderConvol3::GetProperty procedure method returns the value of a property or group of properties for the shader.

Syntax

Obj->[IDLgrShaderConvol3::]GetProperty[, *PROPERTY=value*]

Arguments

None

Keywords

Any property listed under "IDLgrShaderConvol3 Properties" on page 4769 that contains the word "Yes" in the "Get" column of the properties table can be retrieved using this method. To retrieve the value of a property, specify the property name as a keyword set equal to a named variable that will contain the value of the property.

Version History

6.4	Introduced

IDLgrShaderConvol3::Init

The IDLgrShaderConvol3::Init function method initializes the surface object.

Note

Init methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation. This means that in most cases, you cannot call the Init method directly. There is one exception to this rule: if you write your own subclass of this class, you can call the Init method from within the Init method of the subclass.

Syntax

Obj = OBJ_NEW('IDLgrShaderConvol3' [, *PROPERTY=value*])

or

Result = *Obj*->[IDLgrShaderConvol3::]Init([, *PROPERTY=value*])　　*(In a lifecycle method only.)*

Return Value

When this method is called indirectly, as part of the call to the OBJ_NEW function, the return value is an object reference to the newly-created object.

When called directly within a subclass Init method, the return value is 1 if initialization was successful, or zero otherwise.

Arguments

None.

Keywords

Any property listed under "IDLgrShaderConvol3 Properties" on page 4769 that contains the word "Yes" in the "Init" column of the properties table can be initialized during object creation using this method. To initialize the value of a property, specify the property name as a keyword set equal to the appropriate property value.

Version History

6.4	Introduced

IDLgrShaderConvol3::SetProperty

The IDLgrShaderConvol3::SetProperty procedure method sets the value of a property or group of properties for the shader.

Syntax

Obj->[IDLgrShaderConvol3::]SetProperty[, *PROPERTY=value*]

Arguments

None

Keywords

Any property listed under "IDLgrShaderConvol3 Properties" on page 4769 that contains the word "Yes" in the "Set" column of the properties table can be set using this method. To set the value of a property, specify the property name as a keyword set equal to the appropriate property value.

IDLgrSurface

A surface object represents a shaded or vector representation of a mesh grid.

An IDLgrSurface object is an *atomic graphic object*; it is one of the basic drawable elements of the IDL Object Graphics system, and it is not a container for other objects.

Superclasses

IDLitComponent

Creation

See "IDLgrSurface::Init" on page 4816.

Properties

Objects of this class have the following properties. See "IDLgrSurface Properties" on page 4780 for details on individual properties.

- ALL
- AMBIENT
- CLIP_PLANES
- DATA
- DATAY
- DEPTH_OFFSET
- DEPTH_TEST_FUNCTION
- DIFFUSE
- EMISSION
- HIDDEN_LINES
- LINESTYLE
- MIN_VALUE
- PARENT
- RESET_DATA

- ALPHA_CHANNEL
- BOTTOM
- COLOR
- DATAX
- DATAZ
- DEPTH_TEST_DISABLE
- DEPTH_WRITE_DISABLE
- DOUBLE
- EXTENDED_LEGO
- HIDE
- MAX_VALUE
- PALETTE
- REGISTER_PROPERTIES
- SHADE_RANGE

- SHADER
- SHARE_DATA
- SHOW_SKIRT
- SPECULAR
- TEXTURE_COORD
- TEXTURE_INTERP
- THICK
- VERT_COLORS
- XRANGE
- YRANGE
- ZERO_OPACITY_SKIP

- SHADING
- SHININESS
- SKIRT
- STYLE
- TEXTURE_HIGHRES
- TEXTURE_MAP
- USE_TRIANGLES
- XCOORD_CONV
- YCOORD_CONV
- ZCOORD_CONV
- ZRANGE

In addition, objects of this class inherit the properties of all superclasses of this class.

Methods

This class has the following methods:

- IDLgrSurface::Cleanup
- IDLgrSurface::GetCTM
- IDLgrSurface::GetMultiTextureCoord
- IDLgrSurface::GetProperty
- IDLgrSurface::GetVertexAttributeData
- IDLgrSurface::Init
- IDLgrSurface::SetProperty
- IDLgrSurface::SetMultiTextureCoord
- IDLgrSurface::SetVertexAttributeData

In addition, this class inherits the methods of its superclasses (if any).

Examples

See "Mapping an Image onto Elevation Data" (Chapter 3, *Image Processing in IDL*) for a texture mapping example and Chapter 6, "Working with Surface Objects" (*Object Programming*) for additional examples.

Version History

5.0	Introduced
5.6	Added CLIP_PLANES property
6.1	Added ALPHA_CHANNEL, AMBIENT, DIFFUSE, EMISSION, SHININESS, and SPECULAR properties
6.4	Added SHADER property
	Added GetVertexAttributeData, SetVertexAttributeData, Get MultiTextureCoord, and SetMultiTextureCoord methods

IDLgrSurface Properties

IDLgrSurface objects have the following properties in addition to properties inherited from any superclasses. Properties with the word "Yes" in the "Get" column of the property table can be retrieved via IDLgrSurface::GetProperty. Properties with the word "Yes" in the "Init" column of the property table can be set via IDLgrSurface::Init. Properties with the word "Yes" in the "Set" column in the property table can be set via IDLgrSurface::SetProperty.

Note
For a discussion of the property description tables shown below, see "About Object Property Descriptions" on page 3135.

Objects of this class have the following properties.

- ALL
- AMBIENT
- CLIP_PLANES
- DATA
- DATAY
- DEPTH_OFFSET
- DEPTH_TEST_FUNCTION
- DIFFUSE
- EMISSION
- HIDDEN_LINES
- LINESTYLE
- MIN_VALUE

- XCOORD_CONV
- XRANGE
- YCOORD_CONV
- YRANGE
- ZCOORD_CONV
- ZERO_OPACITY_SKIP
- ZRANGE

In addition, objects of this class inherit:

- IDLitComponent

ALL

An anonymous structure containing the values of all of the properties associated with the *state* of this object. State information about the object includes things like color, range, tick direction, etc., but not image, vertex, or connectivity data, or user values.

Note —————————————————————————————————————

The fields of this structure may change in subsequent releases of IDL.

—————————————————————————————————————

Property Type	Structure		
Name String	*not displayed*		
Get: Yes	**Set:** No	**Init:** No	**Registered:** No

ALPHA_CHANNEL

Set this property to a floating-point value in the range [0.0, 1.0] to specify the opacity of the surface. The default value of 1.0 causes IDL to draw the surface completely opaque. If the value of this property is less than 1.0, then the pixels of the surface are blended with the pixels already on the screen. The color of the surface is multiplied by the alpha value and the pixels already on the screen are multiplied by 1.0-alpha.

Because an object can only be blended with objects already drawn on the screen, the drawing order of the objects must be considered carefully in order to obtain the desired results. This also applies to the individual facets of the surface that IDL generates to represent the surface geometry. Since you do not have control over the rendering order of the facets that form the surface, there is little you can do to change

the ordering so that the facets draw in a back-to-front order. Therefore, using this property to draw semi-transparent surfaces is not recommended unless the surface geometry and orientation is such that the surface can be viewed without self-overlapping areas.

This property has no effect on devices using indexed color mode.

When used with textures, the ALPHA_CHANNEL value controls the opacity of the polygon in the same manner as when not using a texture. If the texture contains alpha information, the effective alpha of each texel is the texel's alpha multiplied by the polygon's alpha value (ALPHA_CHANNEL property).

Note ———

For more detailed information on alpha channel support for IDL Object Graphics, see "Controlling Object Transparency" (Chapter 2, *Object Programming*).

Property Type	Float-point value		
Name String	*Transparency*		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** Yes

AMBIENT

Set this property to a three-element vector [*red*, *green*, *blue*] to specify the ambient reflective color of the object. The default is black or [0,0,0], which specifies that the value of the COLOR property determines the ambient reflective color of the object. Setting an ambient color other than black makes the object use that color for ambient reflectance. Ambient reflectance affects the overall color of the object and is most noticeable where the object is not directly lit by a light source. This property has no effect on devices using indexed color mode.

Property Type	COLOR		
Name String	*Ambient reflective color*		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** Yes

BOTTOM

A scalar or three-element vector [*red*, *green*, *blue*] specifying the color used to draw the bottom of the surface. Set this property to a scalar to draw the bottom with the same color as the top. If set to a scalar, IDL returns the default value of -1 if the

property is retrieved with GetProperty. Setting a bottom color is only supported when the destination device uses RGB color mode.

Property Type	COLOR		
Name String	Bottom color		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

CLIP_PLANES

A 4-by-*N* floating-point array that specifies the coefficients of the clipping planes to be applied to this object. The four coefficients for each clipping plane are of the form [A, B, C, D], where $Ax + By + Cz + D = 0$. Portions of this object that fall in the half space $Ax + By + Cz + D > 0$ will be clipped. By default, the value of this property is a scalar (-1) indicating that no clipping planes are to be applied.

Note

The clipping planes specified via this property are applied in addition to the near and far clipping planes associated with the IDLgrView in which this object appears.

Note

Clipping planes are applied in the data space of this object (prior to the application of any *x*, *y*, or *z* coordinate conversion).

Note

To determine the maximum number of clipping planes supported by the device, use the MAX_NUM_CLIP_PLANES property of the GetDeviceInfo method for the IDLgrBuffer, IDLgrClipboard, IDLgrWindow, and IDLgrVRML objects.

Property Type	Floating-point array		
Name String	*not displayed*		
Get: Yes	Set: Yes	Init: Yes	Registered: No

COLOR

The color to be used as the foreground color for this model. The color may be specified as a color lookup table index or as a three-element vector [*red*, *green*, *blue*]. The default is [0, 0, 0].

In a property sheet, this property appears as a color property.

Property Type	COLOR		
Name String	Color		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

DATA

An array of any type that specifies the surface data. The array format is based upon the following:

- If the DATAZ property (or Data argument) was set to an $M \times N$ array (via the ::Init or ::SetProperty methods), then the value returned via the DATA property is a $3 \times M \times N$ array, $[[[x,y,z],[x,y,z],...],[[x,y,z],[x,y,z],...],...]$.

- If the DATAZ keyword (or Data argument) was never set, then the value returned via the DATA property is an undefined variable.

The value of the DATA array represents the combination of the DATAX, DATAY, and DATAZ values defined using ::SetProperty. If DATAZ was set, and DATAX and DATAY were not, the DATA value returned includes the implied X and Y grid locations.

Property Type	Array of any type		
Name String	*not displayed*		
Get: Yes	Set: No	Init: No	Registered: No

DATAX

A floating-point vector or a two-dimensional array specifying the X coordinates of the surface grid. This property is stored as double precision floating point values if the property is of type DOUBLE or if the DOUBLE property is non-zero, otherwise it is stored as single precision floating point.

Specifying this property is the same as specifying the optional *X* argument to the IDLgrSurface::Init method.

Property Type	Floating-point vector or array		
Name String	*not displayed*		
Get: No	Set: Yes	Init: Yes	Registered: No

DATAY

A floating-point vector or a two-dimensional array specifying the Y coordinates of the surface grid. This property is stored as double precision floating point values if the property is of type DOUBLE or if the DOUBLE property is non-zero, otherwise it is stored as single precision floating point.

Specifying this property is the same as specifying the optional *Y* argument to the IDLgrSurface::Init method.

Property Type	Floating-point vector or array		
Name String	*not displayed*		
Get: No	**Set:** Yes	**Init:** Yes	**Registered:** No

DATAZ

A two-dimensional floating-point array to display as a surface. This property is stored as double precision floating point values if the property is of type DOUBLE or if the DOUBLE property is non-zero, otherwise it is stored as single precision floating point.

Specifying this property is the same as specifying the optional *Z* argument to the IDLgrSurface::Init method.

Property Type	Floating-point array		
Name String	*not displayed*		
Get: No	**Set:** Yes	**Init:** Yes	**Registered:** No

DEPTH_OFFSET

An integer value that specifies an offset in depth to be used when rendering filled primitives. This offset is applied along the viewing axis, with positive values moving the primitive away from the viewer.

The units are "Z-Buffer units," where a value of 1 is used to specify a distance that corresponds to a single step in the device's Z-Buffer.

Use DEPTH_OFFSET to always cause a filled primitive to be rendered slightly deeper than other primitives, independent of model transforms. This is useful for avoiding stitching artifacts caused by rendering lines or polygons on top of other polygons at the same depth.

Note ──

Use this feature to remove stitching artifacts and not as a means for "layering" complex scenes with multiple DEPTH_OFFSET values. It is safest to use only a DEPTH_OFFSET value of 0, the default, and one other non-zero value, such as 1. Many system-level graphics drivers are not consistent in their handling of DEPTH_OFFSET values, particularly when multiple non-zero values are used. This can lead to portability problems because a set of DEPTH_OFFSET values may produce better results on one machine than on another. Using IDL's software renderer will help improve the cross-platform consistency of scenes that use DEPTH_OFFSET.

──

Note ──

DEPTH_OFFEST has no effect unless the value of the STYLE property is 2 or 6 (Filled or LegoFilled).

──

Property Type	INTEGER		
Name String	Depth offset		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

DEPTH_TEST_DISABLE

An integer value that determines whether depth testing is disabled.

- Set this property to 0 (the default) to inherit the value set by the parent model or view. The parent view always enables depth testing. A model may also enable or disable depth testing.

- Set this property to 1 to explicitly disable depth buffer testing while drawing this object.

- Set this property to 2 to explicitly enable depth testing for this object.

Disabling depth testing allows an object to draw itself "on top" of other objects already on the screen, even if the object is located behind them.

Note ──

Disabling depth testing also disables depth buffer writing. When disabling depth testing, the DEPTH_TEST_FUNCTION and DEPTH_WRITE_DISABLE properties are effectively ignored.

──

This property is registered as an enumerated list, but it is hidden by default.

Property Type	ENUMLIST		
Name String	*not displayed*		
Get: Yes	Set: Yes	Init: Yes	Registered: No

DEPTH_TEST_FUNCTION

An integer value that determines the depth test function. Set this property to 0 (the default) to inherit the value set by the parent model or view. The parent view always sets a depth test function of LESS. A model may also set a depth test function value. The graphics device compares the object's depth at a particular pixel location with the depth stored in the depth buffer at that same pixel location. If the comparison test passes, the object's pixel is drawn at that location on the screen and the depth buffer is updated (if depth writing is enabled).

Set this property to any of the following values to use the desired function while rendering this object.

- 0 = INHERIT - use value from parent model or view.

- 1 = NEVER - never passes.

- 2 = LESS - passes if the object's depth is less than the depth buffer's value.

- 3 = EQUAL - passes if the object's depth is equal to the depth buffer's value.

- 4 = LESS OR EQUAL - passes if the object's depth is less than or equal to the depth buffer's value.

- 5 = GREATER - passes if the object's depth is greater than or equal to the depth buffer's value.

- 6 = NOT EQUAL - passes if the object's depth is not equal to the depth buffer's value.

- 7 = GREATER OR EQUAL - passes if the object's depth is greater than or equal to the depth buffer's value.

- 8 = ALWAYS - always passes

Less means closer to the viewer.

This property is registered as an enumerated list, but it is hidden by default.

Property Type	ENUMLIST		
Name String	*not displayed*		
Get: Yes	Set: Yes	Init: Yes	Registered: No

DEPTH_WRITE_DISABLE

An integer value that determines whether depth writing is disabled.

- Set this property to 0 (the default) to inherit the value set by the parent model or view. The parent view always enables depth writing. A model may also enable or disable depth writing.

- Set this property to 1 to explicitly disable depth buffer writing while rendering this object.

- Set this property to 2 to explicitly enable depth writing for this object.

Disabling depth writing allows an object to be overdrawn by other objects, even if the object is located in front of them.

Note

If depth testing (see DEPTH_TEST_DISABLE property) is disabled, depth writing is also automatically disabled.

This property is registered as an enumerated list, but it is hidden by default.

Property Type	ENUMLIST		
Name String	*not displayed*		
Get: Yes	Set: Yes	Init: Yes	Registered: No

DIFFUSE

Set this property to a three-element vector [*red*, *green*, *blue*] to specify the diffuse reflectance color of the object. The default is black or [0,0,0], which specifies that the value of the COLOR property determines the diffuse reflective color of the object. Setting a diffuse color other than black makes the object use that color for diffuse reflectance. Diffuse reflectance is an important factor in determining the color of the object and is affected by the color and angle of the light sources in a scene. This property has no effect on devices using indexed color mode.

Property Type	COLOR		
Name String	*Diffuse reflective color*		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** Yes

DOUBLE

A Boolean value that indicates whether data provided by any of the input arguments will be stored in this object as using double-precision floating-point format.

- Set this property equal to 1 to convert input data to double-precision floating-point format.

- Set this property equal to 0 to convert input data to single-precision floating-point format.

- If you do not specify a value for this property, no data type conversion will be performed, and the data will be stored with its original precision.

Setting this property may be desirable if the data consists of large integers that cannot be accurately represented in single-precision floating-point arithmetic. This property is also automatically set to 1 if any of the input arguments are stored using a variable of type DOUBLE.

Property Type	Boolean		
Name String	*not displayed*		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** No

EMISSION

Set this property to a three-element vector [*red*, *green*, *blue*] to specify the emissive color of the object. The default is black or [0,0,0], which specifies that the object contributes no additional color in an emissive sense. Setting an emission color other than black makes the object appear as if it were emitting that color. This property is used to simulate light sources or other objects that emit light in a scene. This property has no effect on devices using indexed color mode.

Property Type	COLOR		
Name String	*Emissive color*		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** Yes

EXTENDED_LEGO

A Boolean value that determines whether to force the IDLgrSurface object to display the last row and column of data when lego display styles are selected.

Property Type	Boolean		
Name String	Show last lego row/column		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** Yes

HIDDEN_LINES

A Boolean value that determines whether to draw point and wireframe surfaces using hidden line (point) removal. By default, hidden line removal is disabled.

Property Type	Boolean		
Name String	Remove hidden lines		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** Yes

HIDE

A Boolean value or an enumerated list item indicating whether this object should be drawn:

Value	Property Sheet Value	Description
0	True	Draw graphic (the default)
1	False	Do no draw graphic

Property Type	ENUMLIST		
Name String	Show		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** Yes

LINESTYLE

An integer value that indicates the line style to use to draw the surface lines. The value can be either an integer value specifying a pre-defined line style, or a two-element vector specifying a stippling pattern.

To use a pre-defined line style, set this property equal to one of the following integer values:

0	Solid line (the default)
1	Dotted
2	Dashed
3	Dash dot
4	Dash dot dot dot
5	Long dash
6	No line drawn

To define your own stippling pattern, specify a two-element vector [*repeat*, *bitmask*], where *repeat* indicates the number of times consecutive runs of 1's or 0's in the *bitmask* should be repeated. (That is, if three consecutive 0's appear in the *bitmask* and the value of *repeat* is 2, then the line that is drawn will have six consecutive bits turned off.) The value of *repeat* must be in the range $1 \le repeat \le 255$.

The *bitmask* indicates which pixels are drawn and which are not along the length of the line. *Bitmask* is most conveniently specified as a 16-bit hexadecimal value.

For example, LINESTYLE = [2, 'F0F0'X] describes a dashed line (8 bits on, 8 bits off, 8 bits on, 8 bits off).

In a property sheet, this property appears as follows:

Property Type	Linestyle		
Name String	Line style		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** Yes

MAX_VALUE

A double-precision floating-point value that determines the maximum value to be plotted. If this property is present, data values greater than the value of MAX_VALUE are treated as missing data and are not plotted. Note that the IEEE floating-point value NaN is also treated as missing data. IDL converts, maintains, and returns this data as double-precision floating-point.

Property Type	FLOAT		
Name String	Maximum value		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** Yes

MIN_VALUE

A double-precision floating-point value that determines the minimum value to be plotted. If this property is present, data values less than the value of MIN_VALUE are treated as missing data and are not plotted. Note that the IEEE floating-point value NaN is also treated as missing data. IDL converts, maintains, and returns this data as double-precision floating-point.

Property Type	FLOAT		
Name String	Minimum value		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** Yes

PALETTE

An object reference to a palette object (an instance of the IDLgrPalette object class) that defines the color palette of this object. This property is only used if the destination device is using the RGB color model. If so, and a color value for the object is specified as a color index value, the palette set by this property is used to translate the color to RGB space. If the PALETTE property on this object is not set, the destination object PALETTE property is used (which defaults to a grayscale ramp).

Note _____

Objects specified via this property are not automatically cleaned up when the IDLgrSurface object is destroyed.

_____

This property is registered as a user-defined property, but it is hidden by default.

Property Type	USERDEF		
Name String	Color palette		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

PARENT

An object reference to the object that contains this object.

Property Type	Object reference		
Name String	*not displayed*		
Get: Yes	Set: No	Init: No	Registered: No

REGISTER_PROPERTIES

A Boolean value that determines whether to register properties available for this object. If this property is set, all properties marked in this properties section as "Registered: Yes" will be registered for display in a property sheet. This property is useful mainly when creating iTools. By default, no properties are registered.

Property Type	Boolean		
Name String	*not displayed*		
Get: No	Set: No	Init: Yes	Registered: No

RESET_DATA

A Boolean value that determines whether to treat the data provided via one of the DATA[XYZ] properties as a new data set unique to this object, rather than overwriting data that is shared by other objects. There is no reason to use this property if the object on which the property is being set does not currently share data

with another object (that is, if the SHARE_DATA property is not in use). This
property has no effect if no new data is provided via a DATA[XYZ] property. .

Property Type	Boolean		
Name String	*not displayed*		
Get: No	**Set:** Yes	**Init:** Yes	**Registered:** No

SHADE_RANGE

A two-element integer array that specifies the range of pixel values (color indices) to
use for shading. The first element is the color index for the darkest pixel. The second
element is the color element for the brightest pixel. This value is ignored when the
polygons are drawn to a graphics destination that uses the RGB color model.

Property Type	Integer array		
Name String	*not displayed*		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** No

SHADER

An object reference to an IDLgrShader object (or an object containing IDLgrShader
as a superclass). When there is suitable graphics card hardware support, the surface is
rendered using the GLSL shader program (executed on the graphics card) instead of
using fixed OpenGL properties when initially drawn. (If a suitable graphics card is
not present, IDL ignores the shader object when the scene is drawn.) A single
IDLgrShader object may be associated with additional surface objects or other
graphic objects that have the SHADER property.

Property Type	Object reference		
Name String	*not displayed*		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** No

SHADING

An integer value or enumerated list item representing the type of shading to use if STYLE is set to 2 (Filled).

Value	Property Sheet Value	Description
0	Flat	The color has a constant intensity for each face of the surface, based on the normal vector (the default)
1	Gouraud	The colors are interpolated between vertices, and then along scanlines from each of the edge intensities

Gouraud shading may be slower than flat shading, but results in a smoother appearance.

Property Type	ENUMLIST		
Name String	Fill shading		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** Yes

SHARE_DATA

An object reference to an object whose data is to be shared by this surface. A surface may only share data with another surface. The SHARE_DATA property is intended for use when data values are not set via an argument to the object's Init method or by setting the object's DATA property.

Note

Objects specified via this property are not automatically cleaned up when the IDLgrSurface object is destroyed.

Property Type	Object reference		
Name String	*not displayed*		
Get: No	**Set:** Yes	**Init:** Yes	**Registered:** No

SHININESS

Set this property to a floating-point value between 0.0 and 128.0, inclusive. The default value is 25.0. Higher values of shininess concentrate specular highlights into smaller and brighter areas, while lower values will spread out specular highlights over a wider area and make them appear dimmer.

Property Type	FLOAT		
Name String	*Shininess*		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

SHOW_SKIRT

A Boolean value that determines whether to enable skirt drawing. The default is to disable skirt drawing. .

Property Type	Boolean		
Name String	Show skirt		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

SKIRT

A floating-point value that determines the *Z* value at which a skirt is to be defined around the array. The *Z* value is expressed in data units; the default is 0.0. If a skirt is defined, each point on the four edges of the surface is connected to a point on the skirt which has the given *Z* value, and the same *X* and *Y* values as the edge point. In addition, each point on the skirt is connected to its neighbor. The skirt value is ignored if skirt drawing is disabled (see SHOW_SKIRT above). IDL converts, maintains, and returns this data as double-precision floating-point.

Property Type	FLOAT		
Name String	Skirt bottom height		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

SPECULAR

Set this property to a three-element vector [*red*, *green*, *blue*] to specify the color of the specular highlights of an object. The default is white or [255,255,255]. This

property is used to simulate and control reflective highlights on an object. This property has no effect on devices using indexed color mode.

Property Type	COLOR		
Name String	*Specular highlight color*		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** Yes

STYLE

An integer value or an enumerated list item that indicates the style to be used to draw the surface. Valid values are:

Value	Property Sheet Value	Description
0	Points	Points
1	Wire mesh	Wire mesh (the default)
2	Filled	Filled
3	RuledXZ	RuledXZ
4	RuledYZ	RuledYZ
5	Lego	Lego
6	Lego filled	Lego filled for outline or shaded and stacked histogram-style plots

Note

Stitching effects may appear when combining an unfilled style (STYLE=0, 1, 3, 4, or 5) and hidden lines (HIDDEN_LINES=1). In such a case, missing lines may be caused by depth buffer resolution, limited depth offset support of the graphics card, or invisible parts of a surface occluding line visibility.

Property Type	ENUMLIST		
Name String	Surface style		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** Yes

TEXTURE_COORD

A 2-by-*n* floating-point array of texture map coordinate pairs that are internally mapped to surface vertex coordinates. The number of data points in the surface and the value of *n* in the 2-by-*n* array should be equal.

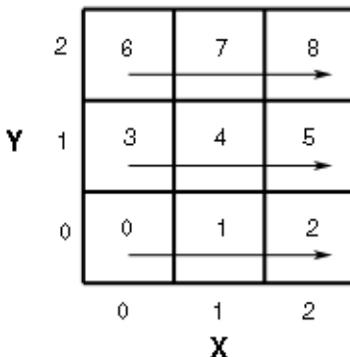
Each texture map coordinate pair is mapped to a surface vertex coordinate pair in array order. For example, with a 2-by-9 element array, texture map coordinates will be mapped to a 3-by-3 surface as follows:


Figure 32-10: Mapping Texture Coordinates

Use this property in conjunction with the TEXTURE_MAP property to warp images over the surface. To stretch (or shrink) the texture map to cover the surface mesh completely, set TEXTURE_COORD to a scalar. By default, IDL stretches (or shrinks) the texture map to cover the surface mesh completely, and sets TEXTURE_COORD to a scalar (-1).

Texture coordinates are normalized. This means that the *m* x *n* image object specified via the TEXTURE_MAP property is mapped into the range [0.0, 0.0] to [1.0, 1.0]. As the texture coordinates run from 0.0 to 1.0 across a texture, a texture coordinate of [0.5, 0.5] at a vertex specifies that the image pixel at the exact center of the image is mapped to the surface at that vertex. If texture coordinates outside the range [0.0, 0.0] to [1.0, 1.0] are specified, the image object is tiled into the larger range.

For example, suppose the image object specified via TEXTURE_MAP is a 256 x 256 array, and we want to map the image into a surface two units on each side. To completely fill the 2 x 2 surface with a single copy of the image:

```
TEXTURE_COORD = [[0,0], [1,0], [0,1], [1,1]]
```

To fill the 2 x 2 surface with four tiled copies of the image:

```
TEXTURE_COORD = [[0,0], [2,0], [0,2], [2,2]]
```

Because of the way in which high-resolution textures require modified texture coordinates, if the TEXTURE_COORD property is used, TEXTURE_HIGHRES will be disabled.

Property Type	Floating-point array		
Name String	*not displayed*		
Get: Yes	Set: Yes	Init: Yes	Registered: No

TEXTURE_HIGHRES

An integer value or enumerated list item that determines the type of texture tiling, if any, that will be used to maintain the full pixel resolution of the original texture image.

Value	Property Sheet Value	Description
0	No tiling	If the texture map is larger than the maximum resolution supported by the 3-D hardware, the texture is scaled down to this resolution (the default).
1	LOD tiling	If the texture map is larger than the maximum resolution supported by the hardware, texture tiling is used to ensure no loss of data. As a large image could easily consume all available video memory, this mode employs texture Level of Detail (LoD). Rather than loading the entire image into the texture tiles at the full resolution, the image tiles are downsampled based on the level of zoom. If the entire image is visible the texture tiles will contain highly downsampled data from the image to conserve video memory. As a portion of the image is zoomed in on, progressively higher resolution image data is loaded into the visible tiles, until the maximum resolution is reached. The tiles that are not visible during zooming are not loaded with high resolution data. **Note -** This mode is recommended if IDL is running on modern 3-D hardware and resolution loss due to downscaling becomes problematic when TEXTURE_HIGHRES=0.
2	Tiling	If the texture map is larger than the maximum resolution supported by the hardware, texture tiling is used to ensure no loss of data. However, the highest resolution data is loaded into all tiles. LoD tiling is disabled. This mode should only be used if the video memory is sufficient for the image size.

Note ———————————————————————————————
TEXTURE_HIGHRES is supported only when STYLE=2 (Filled).

Note ———————————————————————————————
Because of the way in which high-resolution textures require modified texture coordinates, if you specify the TEXTURE_COORD property, high resolution textures (TEXTURE_HIGHRES) will be disabled.

Property Type	ENUMLIST		
Name String	Texture hires		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** Yes

TEXTURE_INTERP

A Boolean value or enumerated list item that indicates whether bilinear sampling is to be used with texture mapping.

Value	Property Sheet Value	Description
0	Nearest neighbor	Surveys the value of the nearest pixel (the default)
1	Bilinear	Surveys the 4 closest pixels

Note ———————————————————————————————
See "Interpolation Methods" (Chapter 5, *Using IDL*) for details.

Property Type	ENUMLIST		
Name String	Texture interpolation		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** Yes

TEXTURE_MAP

An object reference to an instance of the IDLgrImage object class to be texture mapped onto the surface. If this property is omitted or set to a null object reference, no texture map is applied and the surface is filled with the color specified by the COLOR or VERT_COLORS property. If both TEXTURE_MAP and COLORS or

VERT_COLORS properties exist, the color of the texture is modulated by the base color of the object. (This means that for the clearest display of the texture image, the COLOR property should be set equal to [255,255,255].) By default, the texture map will be stretched (or shrunk) to cover the surface mesh completely.

Setting TEXTURE_MAP to the object reference of an IDLgrImage that contains an alpha channel allows you to create a transparent IDLgrSurface object. If an alpha channel is present in the IDLgrImage object, IDL blends the texture using the blend function src = alpha and dst = 1 - alpha, which corresponds to a BLEND_FUNCTION of (3,4) as described for the IDLgrImage object.

If a texture is provided without texture coordinates, IDLgrSurface generates its own texture mapping coordinates to map the texture onto the surface without resampling artifacts, even if the provided texture image does not have dimensions that are an exact power of two. If texture coordinates are provided, the image is resampled to the nearest larger dimensions that are exact powers of two.

Note
Texture mapping is disabled when rendering to a destination object that uses Indexed color mode.

Note
Texture mapping is applied to all styles that are set by the STYLE property except Lego and LegoFilled.

Note
Objects specified via this property are not automatically cleaned up when the IDLgrSurface object is destroyed.

This property is registered as a user-defined property, but it is hidden by default.

Property Type	USERDEF		
Name String	Texture map		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** Yes

THICK

A floating-point value between 1.0 and 10.0, specifying the line thickness to use to draw surface lines, in points. Out-of-range values are quietly clamped to the allowed range. The default is 1.0 points.

In a property sheet, this property appears as follows:

Property Type	Thickness		
Name String	Line thickness		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** Yes

USE_TRIANGLES

A Boolean value or an enumerated list item that determines whether to force the
IDLgrSurface object to use triangles instead of quads to draw the surface and skirt.

Value	Property Sheet Value	Description
0	Quads	Use quads to draw the surface and skirt (the default)
1	Triangles	Use triangles to draw the surface and skirt

Property Type	Boolean		
Name String	Draw method		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** Yes

VERT_COLORS

A vector of colors to be used to specify the color of a surface vertex. The vector may
be of the form [*n*] where each entry is a color index, or of the form [3,*n*] where each
3-element row is an RGB color, or of the form [4,*n*] where each 4-element row is an
RGBA color. To remove vertex colors after they have been set, set VERT_COLORS
to a scalar.

If VERT_COLORS is not specified, the entire surface is drawn in the single color
provided by the COLOR property, which is the default action.

If SHADING is set to 0 (Flat, the default) the color of a surface polygon is the color of the first vertex of that surface polygon. Color is interpolated between vertices if SHADING is set to 1 (Gouraud).

If there are more vertices than elements in VERT_COLORS, the elements of VERT_COLORS are cyclically repeated.

Note ————————————————————————————————
If the surface object is being rendered on a destination device that uses the Indexed color model, and the view that contains the surface also contains one or more light objects, the VERT_COLORS property is ignored and the SHADE_RANGE property is used instead.

——

This property is registered as a user-defined property, but it is hidden by default.

Property Type	USERDEF		
Name String	Vertex colors		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

XCOORD_CONV

A floating-point vector, $[s_0, s_1]$, of scaling factors used to convert *X* coordinates from data units to normalized units. The formula for the conversion is as follows:

$$\text{Normalized}X = s_0 + s_1 * \text{Data}X$$

Recommended values are:

$$[(-X_{min})/(X_{max}-X_{min}), \ 1/(X_{max}-X_{min})]$$

The default is [0.0, 1.0]. IDL converts, maintains, and returns this data as double-precision floating-point.

Property Type	Floating-point vector		
Name String	*not displayed*		
Get: Yes	Set: Yes	Init: Yes	Registered: No

XRANGE

A two-element floating-point vector of the form [*xmin*, *xmax*] that specifies the range of *x* data coordinates covered by the graphic object. IDL maintains and returns this property in double-precision floating-point.

Property Type	Floating-point vector		
Name String	*not displayed*		
Get: Yes	**Set:** No	**Init:** No	**Registered:** No

YCOORD_CONV

A floating-point vector, [s_0, s_1], of scaling factors used to convert *Y* coordinates from data units to normalized units. The formula for the conversion is as follows:

$$\text{Normalized}Y = s_0 + s_1 * \text{Data}Y$$

Recommended values are:

$$[(-Y_{min})/(Y_{max}-Y_{min}), 1/(Y_{max}-Y_{min})]$$

The default is [0.0, 1.0]. IDL converts, maintains, and returns this data as double-precision floating-point.

Property Type	Floating-point vector		
Name String	*not displayed*		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** No

YRANGE

A two-element floating-point vector of the form [*ymin*, *ymax*] that specifies the range of *y* data coordinates covered by the graphic object. IDL maintains and returns this property in double-precision floating-point.

Property Type	Floating-point vector		
Name String	*not displayed*		
Get: Yes	**Set:** No	**Init:** No	**Registered:** No

ZCOORD_CONV

A floating-point vector, $[s_0, s_1]$, of scaling factors used to convert Z coordinates from data units to normalized units. The formula for the conversion is as follows:

$$\text{Normalized}Z = s_0 + s_1 * \text{Data}Z$$

Recommended values are:

$$[(-Z_{min})/(Z_{max}-Z_{min}), 1/(Z_{max}-Z_{min})]$$

The default is [0.0, 1.0]. IDL converts, maintains, and returns this data as double-precision floating-point.

Property Type	Floating-point vector		
Name String	*not displayed*		
Get: Yes	Set: Yes	Init: Yes	Registered: No

ZERO_OPACITY_SKIP

A Boolean value that determines whether to gain finer control over the rendering of textured surface pixels (texels) by setting an opacity of 0 in the texture map. Texels with zero opacity do not affect the color of a screen pixel since they have no opacity. If this property is set to 1, any texels are "skipped" and not rendered at all. If this property is set to zero, the Z-buffer is updated for these pixels and the display image is not affected as noted above. By updating the Z-buffer without updating the display image, the surface can be used as a *clipping* surface for other graphics primitives drawn after the current graphics object. The default value for this property is 1.

Note

This property has no effect if no texture map is used or if the texture map in use does not contain an opacity channel.

Property Type	Boolean		
Name String	Skip zero opacity		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

ZRANGE

A two-element floating-point vector of the form [*zmin*, *zmax*] that specifies the range of *z* data coordinates covered by the graphic object. IDL maintains and returns this property in double-precision floating-point.

Property Type	Floating-point vector		
Name String	*not displayed*		
Get: Yes	Set: No	Init: No	Registered: No

IDLgrSurface::Cleanup

The IDLgrSurface::Cleanup procedure method performs all cleanup on the object.

Note ————————————————————————————————

Cleanup methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation and destruction. This means that in most cases, you cannot call the Cleanup method directly. There is one exception to this rule: if you write your own subclass of this class, you can call the Cleanup method from within the Init or Cleanup method of the subclass.

———

Syntax

OBJ_DESTROY, *Obj*

or

Obj->[IDLgrSurface::]Cleanup   *(In a lifecycle method only.)*

Arguments

None

Keywords

None

Version History

5.0	Introduced

IDLgrSurface::GetCTM

The IDLgrSurface::GetCTM function method returns the 4-by-4 double-precision floating-point graphics transform matrix from the current object upward through the graphics tree.

Syntax

Result = Obj->[IDLgrSurface::]GetCTM([, DESTINATION=*objref*]
   [, PATH=*objref(s)*] [, TOP=*objref to IDLgrModel object*])

Return Value

Returns the 4-by-4 double-precision floating-point graphics transform matrix from the current object upward through the graphics tree.

Arguments

None

Keywords

DESTINATION

Set this keyword to the object reference of a destination object to specify that the projection matrix for the View object in the current tree be included in the returned transformation matrix. The resulting matrix will transform a point in the data space of the object on which the GetCTM method is called into a normalized coordinate system (-1 to +1 in X, Y, and Z), relative to the View object that contains the surface object.

PATH

Set this keyword to a single object reference or a vector of object references. This keyword specifies the path in the graphics hierarchy to compute the transformation matrix. Each path object reference specified with this keyword must contain an alias. The transformation matrix is computed for the version of the object falling within that path. If this keyword is not set, the PARENT properties determine the path from the current object to the top of the graphics hierarchy and no alias paths are pursued. If IDLgrSurface::GetCTM is called from within a Draw method, with the DESTINATION keyword set and the PATH keyword not set, the alias path used to find the object during the draw is used, rather than the PARENT path.

Note ───

For more information on aliases, refer to the ALIAS keyword in IDLgrModel::Add.

───

TOP

Set this keyword equal to the object reference to an IDLgrModel object to specify that the returned matrix accumulate from the object on which the GetCTM method is called up to but not including the specified model object.

Version History

5.0	Introduced

IDLgrSurface::GetMultiTextureCoord

 The IDLgrSurface::GetMultiTextureCoord returns the texture coordinates associated with a given *Unit*. This method is useful when a shader program defined by an IDLgrShader object applies more than a single texture to an object. See Chapter 14, "Advanced Rendering Using Shader Objects" (*Object Programming*) for more information.

Syntax

Obj->[IDLgrSurface::]GetMultiTextureCoord, *Unit*, *TexCoord*

Arguments

Unit

This scalar numeric value specifies the texture unit. Texture units are used primarily with multi-texturing and allow OpenGL to handle multiple textures and multiple sets of texture coordinates and parameters. This value should be greater than or equal to zero and less than the MAX_VERTEX_TEXTURE_IMAGE_UNITS (for vertex shaders) or MAX_TEXTURE_IMAGE_UNITS (for fragment shaders). These values can be returned by IDLgrWindow::GetDeviceInfo.

Note ⎯⎯⎯⎯⎯⎯⎯⎯⎯⎯⎯⎯⎯⎯⎯⎯⎯⎯⎯⎯⎯⎯⎯

If the specified *Unit* value was never defined and stored in the surface object using IDLgrSurface::SetMultiTextureCoord, then the variable specified in the *TexCoord* parameter will be set to an undefined variable.

⎯⎯

TexCoord

Specifies a variable that contains the current texture coordinates associated with the specified *Unit*. Texture coordinates are stored in this parameter as single precision floating point numbers.

Keywords

None

Examples

See "Multi-texture Shaders" (Chapter 14, *Object Programming*)

Version History

6.4	Introduced

See Also

IDLgrSurface::SetMultiTextureCoord

IDLgrSurface::GetProperty

The IDLgrSurface::GetProperty procedure method retrieves the value of a property or group of properties for the surface.

Syntax

Obj->[IDLgrSurface::]GetProperty[, *PROPERTY=variable*]

Arguments

None

Keywords

Any property listed under "IDLgrSurface Properties" on page 4780 that contains the word "Yes" in the "Get" column of the properties table can be retrieved using this method. To retrieve the value of a property, specify the property name as a keyword set equal to a named variable that will contain the value of the property.

Any keyword not recognized is passed to this object's superclass.

Version History

5.0	Introduced

IDLgrSurface::GetVertexAttributeData

The IDLgrSurface::GetVertexAttributeData procedure method retrieves the data associated with a named attribute variable containing per-vertex attribute data. See "Attribute Variables" (Chapter 14, *Object Programming*). This method is useful when a shader program defined by an IDLgrShader object modifies the vertices of an object. See Chapter 14, "Advanced Rendering Using Shader Objects" (*Object Programming*) for more information.

Syntax

Obj->[IDLgrSurface::]GetVertexAttributeData, *Name, Value*

Arguments

Name

Specifies a case-sensitive string name of the attribute variable to retrieve.

Note ————————————————————————————————————

If the *Name* argument specifies an attribute variable that was never defined and stored in the surface object using SetVertexAttributeData, then the variable specified in the *Value* parameter will be set to an undefined variable.

———

Value

Specifies a variable that contains the current value of the vertex data attribute variable. The variable is stored in this parameter in exactly the same format as that used when it was defined using IDLgrSurface::SetVertexAttributeData.

Keywords

None

Examples

See "Vertex Shaders" (Chapter 14, *Object Programming*).

Version History

6.4	Introduced

See Also

IDLgrSurface::SetVertexAttributeData

IDLgrSurface::Init

The IDLgrSurface::Init function method initializes the surface object.

Note ───

Init methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation. This means that in most cases, you cannot call the Init method directly. There is one exception to this rule: if you write your own subclass of this class, you can call the Init method from within the Init method of the subclass.

───

Syntax

Obj = OBJ_NEW('IDLgrSurface' [, *Z* [, *X*, *Y*]] [, *PROPERTY=value*])

or

Result = Obj->[IDLgrSurface::]Init([*Z* [, *X*, *Y*]] [, *PROPERTY=value*])   *(In a lifecycle method only.)*

Return Value

When this method is called indirectly, as part of the call to the OBJ_NEW function, the return value is an object reference to the newly-created object.

When called directly within a subclass Init method, the return value is 1 if initialization was successful, or zero otherwise.

Arguments

X

A vector or two-dimensional array specifying the X coordinates of the grid. If this argument is a vector, each element of X specifies the X coordinates for a column of Z (e.g., X[0] specifies the X coordinate for Z[0, *]). If X is a two-dimensional array, each element of X specifies the X coordinate of the corresponding point in Z (X_{ij} specifies the X coordinate of Z_{ij}). This argument is stored as double precision floating point values if the argument variable is of type DOUBLE or if the DOUBLE property is non-zero, otherwise it is stored as single precision floating point.

Note

The value specified by the *X* argument is used to initialize the value of the DATAX property of the IDLgrSurface object.

Y

A vector or two-dimensional array specifying the Y coordinates of the grid. If this argument is a vector, each element of Y specifies the Y coordinates for a column of Z (e.g., Y[0] specifies the Y coordinate for Z[*, 0]). If Y is a two-dimensional array, each element of Y specifies the Y coordinate of the corresponding point in Z (Y_{ij} specifies the Y coordinate of Z_{ij}). This argument is stored as double precision floating point values if the argument variable is of type DOUBLE or if the DOUBLE property is non-zero, otherwise it is stored as single precision floating point.

Note

The value specified by the *Y* argument is used to initialize the value of the DATAY property of the IDLgrSurface object.

Z

The two-dimensional array to be displayed. If X and Y are provided, the surface is defined as a function of the (X, Y) locations specified by their contents. Otherwise, the surface is generated as a function of the array indices of each element of Z. This argument is stored as double precision floating point values if the argument variable is of type DOUBLE or if the DOUBLE property is non-zero, otherwise it is stored as single precision floating point.

Note

The value specified by the *Z* argument is used to initialize the value of the DATAZ property of the IDLgrSurface object.

Keywords

Any property listed under "IDLgrSurface Properties" on page 4780 that contains the word "Yes" in the "Init" column of the properties table can be initialized during object creation using this method. To initialize the value of a property, specify the property name as a keyword set equal to the appropriate property value.

All other keywords are passed to the superclass of this object.

Version History

5.0	Introduced

IDLgrSurface::SetProperty

The IDLgrSurface::SetProperty procedure method sets the value of a property or group of properties for the surface.

Syntax

Obj->[IDLgrSurface::]SetProperty[, *PROPERTY=value*]

Arguments

None

Keywords

Any property listed under "IDLgrSurface Properties" on page 4780 that contains the word "Yes" in the "Set" column of the properties table can be set using this method. To set the value of a property, specify the property name as a keyword set equal to the appropriate property value.

Version History

5.0	Introduced

IDLgrSurface::SetMultiTextureCoord

The IDLgrSurface::SetMultiTextureCoord procedure method passes texture coordinates to a shader program when the shader program applies more than one texture to an object. The shader program accesses these texture coordinates by using the GLSL predefined uniform variable gl_MultiTexCoord*n*, where *n* corresponds to the *Unit* parameter in this method. This method is useful when a shader program defined by an IDLgrShader object applies more than a single texture to an object. See Chapter 14, "Advanced Rendering Using Shader Objects" (*Object Programming*) for more information.

Syntax

Obj->[IDLgrSurface::]SetMultiTextureCoord, *Unit*, *TexCoord*

Arguments

Unit

This scalar numeric value specifies the texture unit. Texture units are used primarily with multi-texturing and allow OpenGL to handle multiple textures and multiple sets of texture coordinates and parameters. This value should be greater than or equal to zero and less than the MAX_VERTEX_TEXTURE_IMAGE_UNITS (for vertex shaders) or MAX_TEXTURE_IMAGE_UNITS (for fragment shaders). These values can be returned by IDLgrWindow::GetDeviceInfo. The behavior is undefined for any other setting.

Unit 0 is used by the TEXTURE_COORD property on IDLgrSurface. Using unit 0 in this method overrides any texture coordinates specified with the TEXTURE_COORD property. Therefore, the TEXTURE_COORD property can be used instead of this method if *Unit* is 0.

TexCoord

This data has exactly the same form as the TEXTURE_COORD property. IDL converts and maintains this data as single precision floating point. IDL displays an error message and does not draw the object if the number of texture coordinates provided in this parameter is not the same as the number of vertices in the surface.

IDL stores the texture coordinates in the instance of the graphic object when the application calls this method for the first time with a given *Unit* parameter. If the application calls this method again with a *Unit* number used in a previous call to this

method, IDL replaces the corresponding stored texture coordinates with the contents of the *TexCoord* parameter.

There is no way to remove texture coordinates from an instance of a graphics object. If texture coordinates are associated with a particular texture unit, and the shader program does not reference that unit, the texture coordinates are effectively ignored by the shader program.

Keywords

None

Examples

IDLgrSurface::GetMultiTextureCoord

IDLgrSurface::SetVertexAttributeData

The IDLgrSurface::SetVertexAttributeData procedure method passes a set of per-vertex attribute data to a vertex shader program. When an IDLgrShader object is associated with the surface via the SHADER property, this attribute data is made available, a vertex's worth at a time, to the vertex shader program as it processes each vertex in the surface. If there are more vertices in the surface than there are vertex attributes, the list of vertex attributes is reused until all the vertices are drawn. See "Attribute Variables" (Chapter 14, *Object Programming*) for a general introduction to attribute variables. Also see the chapter, "Advanced Rendering Using Shader Objects" (*Object Programming*) for additional shader program information and examples.

IDL stores the *Name* and *Value* of the vertex attribute data variable with this surface object the first time this method is called. When SetVertexAttributeData is called again using the same *Name* argument, the vertex attribute data variable is updated with the current contents of *Value*. Once a vertex attribute data variable is associated with this object, there is no way to remove the reference. The shader program ignores any vertex attribute data variable defined for this object but not declared in the shader program.

The attribute data may consist of 1 to 4 elements per vertex. The data is passed to the vertex shader program via a shader program variable with the attribute qualifier. The attribute variable may be of GLSL type float, vec2, vec3, vec4, mat2, mat3, or mat4. Internally, the mat2 type is treated as two vec2 attribute variables, mat3 as three vec3 attribute variables, and mat4 as four vec4 attribute variables.

If the attribute variable is larger than the data passed to it, the shader program pads the missing elements as follows. A missing second or third element is set to 0.0. A missing fourth element is set to 1.0.

For example, the IDL application has a set of vertex attribute data where there is an x-offset and a y-offset for each vertex. The vertex program defines an attribute variable using a vec4 type so that it can be used in 4x4 general transformations. The IDL program stores the x- and y-offset information in a [2, *n*] array and sets the value of the attribute variable to this array. As the shader program runs, for each vertex it assigns the two values from the corresponding row of the IDL array to the first two elements in the vec4 attribute variable. It also sets the third value to 0.0 and the fourth value to 1.0, thus expanding the 2-element data to a general 3-D point in homogenous coordinate space, suited for 4x4 general transforms.

Note

A minimum of 16 vertex attribute data variables can be passed to the shader vertex program (use IDLgrWindow::GetDeviceInfo to determine the exact number). IDL

uses one vertex attribute variable, leaving the remainder for user programs. For maximum shader program portability, define 15 or fewer attribute variables.

Syntax

Obj->[IDLgrSurface::]SetVertexAttributeData, *Name, Value*

Arguments

Name

Specifies a case-sensitive string name of the attribute variable.

Value

Specifies an IDL array of any numeric type. The array must be of the form [*n*], [*a*,*n*], or [*a*,*a*,*n*] where *a* is 1,2,3, or 4 and *n* is the number of vertex attribute elements. IDL will halt with an error if you assign IDL strings, structures, pointers, object references, and undefined variables to *Value*. IDL converts all numeric types to 32-bit float when submitting the data to the shader program.

Keywords

None

Examples

Suppose there is large set of point sample data, along with a set of initial velocity vectors for each point. You want to display an animation of these points as each point moves along its own velocity vector as a function of time. Without a shader program, you would normally have to recalculate the position of each point and replace all the vertices in an IDLgrPolygon (STYLE=0) object with the recomputed values for each animation frame, which would be inefficient with a large number of points.

However, with a vertex shader program and vertex attribute data, you can move the points around using the graphics card's GPU instead of recalculating and moving a lot of data around on the system CPU.

The interesting parts of the IDL code are:

```
; Define the original vertices at time=0.
oPolygon->SetProperty, DATA=vertices
```

```
; Set [3,n] array.
oPolygon->SetVertexAttributeData, 'velocity', velocities
FOR t=0.0, 100.0, 0.01 DO BEGIN  ;; time samples
   oShader->SetUniformVariable, 'time', t
   oWindow->Draw
ENDFOR
```

And the interesting parts of the vertex shader program are:

```
attribute vec3 velocity;
uniform float time;
void main () {
   vec4 vert;
   vert = gl_Vertex + vec4(velocity * time, 0.0);
   gl_Position = gl_ModelViewProjectMatrix * vert;
}
```

See "Vertex Shaders" (Chapter 14, *Object Programming*) for more information and examples.

IDLgrSurface::GetVertexAttributeData

IDLgrSymbol

A symbol object represents a graphical element that is plotted relative to a particular position.

Note

Seven predefined symbols are provided by IDL.

Superclasses

None

Creation

See "IDLgrSymbol::Init" on page 4834.

Properties

Objects of this class have the following properties. See "IDLgrSymbol Properties" on page 4827 for details on individual properties.

- ALL
- ALPHA_CHANNEL
- COLOR
- DATA
- NAME
- SIZE
- THICK
- UVALUE

Methods

This class has the following methods:

- IDLgrSymbol::Cleanup
- IDLgrSymbol::GetProperty
- IDLgrSymbol::Init

- IDLgrSymbol::SetProperty

In addition, this class inherits the methods of its superclasses (if any).

Version History

5.0	Introduced
6.1	Added ALPHA_CHANNEL property
6.2	Added NAME and UVALUE properties

IDLgrSymbol Properties

IDLgrSymbol objects have the following properties. Properties with the word "Yes" in the "Get" column of the property table can be retrieved via IDLgrSymbol::GetProperty. Properties with the word "Yes" in the "Init" column of the property table can be set via IDLgrSymbol::Init. Properties with the word "Yes" in the "Set" column in the property table can be set via IDLgrSymbol::SetProperty.

Note ───

For a discussion of the property description tables shown below, see "About Object Property Descriptions" on page 3135.

───

Objects of this class have the following properties.

- ALL
- ALPHA_CHANNEL
- COLOR
- DATA
- NAME
- SIZE
- THICK
- UVALUE

ALL

An anonymous structure containing the values of all of the properties associated with the *state* of this object. State information about the object includes things like color, range, tick direction, etc., but not image, vertex, or connectivity data, or user values.

Note ───

The fields of this structure may change in subsequent releases of IDL.

───

Property Type	Structure		
Name String	*not displayed*		
Get: Yes	**Set:** No	**Init:** No	**Registered:** No

ALPHA_CHANNEL

A floating-point value in the range [0.0, 1.0] to specify the opacity of the symbol. The default value of 1.0 causes IDL to draw the symbol completely opaque. If the value of this property is less than 1.0, then the pixels of the symbol are blended with the pixels already on the screen, where the color of the symbol is multiplied by the alpha value and the pixels already on the screen are multiplied by 1.0-alpha.

Because an object can only be blended with objects already drawn on the screen, the drawing order of the objects must be considered carefully in order to obtain the desired results.

This property has no effect on devices using indexed color mode.

Some of the objects that use symbols have properties that control the alpha value that is ultimately used to render the symbol. This ultimate alpha value might come from the parent object's ALPHA_CHANNEL property, an alpha value from a vertex color in the parent object, or the value of this property, depending on the settings of properties in the parent object. Refer to the reference guide for the parent properties for information on these controls.

Note

For more detailed information on alpha channel support for IDL Object Graphics, see "Controlling Object Transparency" (Chapter 2, *Object Programming*).

Property Type	Float-point value		
Name String	*Transparency*		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** No

COLOR

The color used to draw the symbol. The color may be specified as a color lookup table index or as a three-element vector [*red*, *green*, *blue*]. The default color is the color of the object for which this symbol is being used.

Property Type	Color		
Name String	*not displayed*		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** No

DATA

Either an integer value (from the following list), or an object reference to either an IDLgrModel object, or atomic graphic object.

Use one of the following scalar-represented internal default symbols:

- 0 = No symbol
- 1 = Plus sign, '+' (default)
- 2 = Asterisk
- 3 = Period (Dot)
- 4 = Diamond
- 5 = Triangle
- 6 = Square
- 7 = X
- 8 = "Greater-than" Arrow Head (>)
- 9 = "Less-than" Arrow Head (<)

If an instance of the IDLgrModel object class or an atomic graphic object is used, the object tree is used as the symbol. For best results, the object should fill the domain from -1 to +1 in all dimensions. The pre-defined symbols listed above are all defined in the domain -1 to +1.

Specifying this property is the same as specifying the optional *Data* argument to the IDLgrSymbol::Init method.

Note

Objects specified via this property are not automatically cleaned up when the IDLgrSymbol object is destroyed.

Property Type	Integer or object reference		
Name String	*not displayed*		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** No

NAME

A string giving the human-readable name of this object.

Property Type	STRING		
Name String	Name		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** No

SIZE

A one-, two-, or three-element floating-point vector describing the X, Y, and Z scaling factors to be applied to the symbol. The default is [1.0, 1.0, 1.0].

- If SIZE is specified as a scalar, then the X, Y, and Z scale factors are all equal to the scalar value.

- If SIZE is specified as a 2-element vector, then the X and Y scale factors are as specified by the vector, and the Z scale factor is 1.0.

- If SIZE is specified as a 3-element vector, then the X, Y, and Z scale factors are as specified by the vector.

IDL converts, maintains, and returns this data as double-precision floating-point.

Property Type	Floating-point vector		
Name String	*not displayed*		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** No

THICK

A floating-point value between 1.0 and 10.0, specifying the line thickness to used to draw any lines that make up the symbol, in points. Out-of-range values are quietly clamped to the allowed range. The default is 1.0 points.

Property Type	Floating-point		
Name String	*not displayed*		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** No

UVALUE

A value of any type containing any information you wish.

Note

Object references or pointers contained in the UVALUE property are *not* automatically cleaned up when the IDLgrSymbol object is destroyed.

Property Type	User Defined		
Name String	*not displayed*		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** No

IDLgrSymbol::Cleanup

The IDLgrSymbol::Cleanup procedure method performs all cleanup on the object.

Note ———————————————————————————————

Cleanup methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation and destruction. This means that in most cases, you cannot call the Cleanup method directly. There is one exception to this rule: if you write your own subclass of this class, you can call the Cleanup method from within the Init or Cleanup method of the subclass.

Syntax

OBJ_DESTROY, *Obj*

or

Obj->[IDLgrSymbol::]Cleanup   *(In a lifecycle method only.)*

Arguments

None

Keywords

None

Version History

5.0	Introduced

IDLgrSymbol::GetProperty

The IDLgrSymbol::GetProperty procedure method retrieves the value of a property or group of properties for the symbol.

Syntax

Obj->[IDLgrSymbol::]GetProperty[, *PROPERTY=variable*]

Arguments

None

Keywords

Any property listed under "IDLgrSymbol Properties" on page 4827 that contains the word "Yes" in the "Get" column of the properties table can be retrieved using this method. To retrieve the value of a property, specify the property name as a keyword set equal to a named variable that will contain the value of the property.

Version History

5.0	Introduced

IDLgrSymbol::Init

The IDLgrSymbol::Init function method initializes the plot symbol.

Note

Init methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation. This means that in most cases, you cannot call the Init method directly. There is one exception to this rule: if you write your own subclass of this class, you can call the Init method from within the Init method of the subclass.

Syntax

Obj = OBJ_NEW('IDLgrSymbol' [, *Data*] [, *PROPERTY=value*])

or

Result = Obj->[IDLgrSymbol::]Init([*Data*] [, *PROPERTY=value*])   *(In a lifecycle method only.)*

Return Value

When this method is called indirectly, as part of the call to the OBJ_NEW function, the return value is an object reference to the newly-created object.

When called directly within a subclass Init method, the return value is 1 if initialization was successful, or zero otherwise.

Arguments

Data

Either an integer value from the list shown below, or an object reference to either an IDLgrModel object or atomic graphic object.

Use one of the following scalar-represented internal default symbols:

- 0 = No symbol
- 1 = Plus sign, '+' (default)
- 2 = Asterisk
- 3 = Period (Dot)
- 4 = Diamond

- 5 = Triangle

- 6 = Square

- 7 = X

- 8 = "Greater-than" Arrow Head (>)

- 9 = "Less-than" Arrow Head (<)

If an instance of the IDLgrModel object class or an atomic graphic object is used, the object tree is used as the symbol. For best results, the object should fill the domain from -1 to +1 in all dimensions. The pre-defined symbols listed above are all defined in the domain -1 to +1.

Note —————————————————————————————

The value specified by the *Data* argument is used to initialize the value of the DATA property of the IDLgrSymbol object.

Keywords

Any property listed under "IDLgrSymbol Properties" on page 4827 that contains the word "Yes" in the "Init" column of the properties table can be initialized during object creation using this method. To initialize the value of a property, specify the property name as a keyword set equal to the appropriate property value.

Version History

5.0	Introduced
5.6	Added *Data* argument

IDLgrSymbol::SetProperty

The IDLgrSymbol::SetProperty procedure method sets the value of a property or group of properties for the symbol.

Syntax

Obj->[IDLgrSymbol::]SetProperty[, *PROPERTY=value*]

Arguments

None

Keywords

Any property listed under "IDLgrSymbol Properties" on page 4827 that contains the word "Yes" in the "Set" column of the properties table can be set using this method. To set the value of a property, specify the property name as a keyword set equal to the appropriate property value.

Version History

5.0	Introduced

IDLgrTessellator

A tessellator object decomposes a polygon description into a set of triangles. Use the tessellator object to convert complex and/or concave polygons into a form suitable for drawing with the IDLgrPolygon object. IDLgrPolygon can draw only convex polygons correctly.

The polygon contours may intersect each other and may be self-intersecting. The contours may be disjoint, overlapping, or contained within other contours. The contours may also be degenerate, may contain repeated points, and may or may not be closed. The order of the vertices may be either counter-clockwise or clockwise. Tesselation may produce unexpected results if the input polygon contours are not coplanar, or if a contour is not planar.

The tessellator object uses the "odd-winding rule" to determine if a point is in the interior of the polygon and therefore contained in a triangle output by the tessellator. With this rule, a point is in the interior if it is circled an odd number of times as we travel around each of the contours.

Note

The INTERIOR keyword for the AddPolygon method is no longer needed to inform the tessellator that the polygon defines an exterior or interior boundary. This keyword is ignored by the tessellator because it now performs the interior testing using the odd-winding rule.

Specify polygon contours with calls to the IDLgrTessellator::AddPolygon method. After adding all the contours, use the IDLgrTessellator::Tessellate method to perform the tessellation and retrieve the resulting list of vertices and connectivity array.

If the polygon contours contain intersecting or self-intersecting contours, the tessellator may return vertices that were not in the original set of vertices specified with the IDLgrTessellator::AddPolygon method. These vertices are created by the intersecting contours.

If your vertex data also includes other information, such as a color for each vertex, then you may wish for this extra information to be created for any new vertices generated by the tessellator. Use the AUXDATA keywords for IDLgrTessellator::AddPolygon and IDLgrTessellator::Tessellate to pass in and retrieve your per-vertex data. The tessellator object interpolates the per-vertex data from neighboring vertices to create new per-vertex data for the new vertices it generates.

In the following example of handling per-vertex data with generated vertices, the polygon is a simple self-intersecting "bow-tie" polygon. It is submitted to the tessellator with four vertices, but the tessellator returns a fifth at the point of self-intersection. Color data for the four original vertices is also supplied, and the tessellator returns a fifth color.

```
PRO tessaux
   oTess = OBJ_NEW('IDLgrTessellator')
   colors = [[0,255,0],[0,255,0],[0,64,0],[0,64,0]]
   oTess->AddPolygon, [0,1,0,1], [0,0,1,1], AUXDATA=colors
   result = oTess->Tessellate(v, c, AUXDATA=aux)
   PRINT, v[*,4]
   PRINT, aux[*,4]
   oPoly = OBJ_NEW('IDLgrPolygon', v, POLYGONS=c, $
      VERT_COLORS=aux, SHADING=1)
   XOBJVIEW, oPoly, /BLOCK
   OBJ_DESTROY, [oTess, oPoly]
END
```

The generated output will be:

```
0.500000      0.500000
   0      159        0
```

Superclasses

Version History

5.0	Introduced

IDLgrTessellator Properties

Objects of this class have no properties of their own.

IDLgrTessellator::AddPolygon

The IDLgrTessellator::AddPolygon procedure method adds a polygon to the tessellator object.

Syntax

Obj->[IDLgrTessellator::]AddPolygon, *X* [, *Y*[, *Z*]] [, AUXDATA=*array of auxiliary data*] [, /INTERIOR] [, POLYGON=*array of polygon descriptions*]

Arguments

X

A 1 x *n*, 2 x *n*, or 3 x *n* array of polygon vertices.

Y

A vector of Y values. If *X* and *Y* are both specified, they must be one-dimensional vectors of the same length.

Z

A vector of Z values. If *X*, *Y*, and *Z* are all specified, they must all three be one-dimensional vectors of the same length. If no *Z* values are specified, the *Z* value for the polygon is set to 0.

Keywords

AUXDATA

Set this keyword to an array of auxiliary per-vertex data. This array must have dimensions [*m,n*] where m is the number of auxiliary data items per vertex and *n* is the number of vertices specified in the *X*, *Y*, and *Z* arguments. If you specify AUXDATA in any invocation of the AddPolygon method, you must specify it on all invocations of the method for the polygons to be tessellated together with the Tessellate method. Further, the value of m in the dimensions must be the same for all polygons. That is, all polygons must have the same number of auxiliary data items for each vertex.

INTERIOR

Set this keyword to set a polygon to be an interior polygon, which is treated as a hole in the exterior polygons.

Note
The INTERIOR keyword for the AddPolygon method is no longer needed to inform the tessellator that the polygon defines an exterior or interior boundary. This keyword is ignored by the tessellator because it now performs the interior testing using the odd-winding rule.

POLYGON

Set this keyword to an array of polygon descriptions. A polygon description is an integer or long word array of the form: $[n, i_0, i_1, ..., i_{n-1}]$, where n is the number of vertices that define the polygon, and $i_0..i_{n-1}$ are indices into the *X*, *Y*, and *Z* arguments that represent the polygon vertices. To ignore an entry in the POLYGON array, set the vertex count, *n*, to 0. To end the drawing list, even if additional array space is available, set *n* to -1. If this keyword is not specified, a single polygon will be generated.

Note
The connectivity array described by POLYGONS allows you to add multiple polygons to the tessellator object with a single AddPolygon operation.

Version History

5.0	Introduced
5.6	Added AUXDATA keyword

IDLgrTessellator::Cleanup

The IDLgrTessellator::Cleanup procedure method performs all cleanup on the object.

Note ——————————————————————————————————————

Cleanup methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation and destruction. This means that in most cases, you cannot call the Cleanup method directly. There is one exception to this rule: if you write your own subclass of this class, you can call the Cleanup method from within the Init or Cleanup method of the subclass.

——

Syntax

OBJ_DESTROY, *Obj*

or

Obj->[IDLgrTessellator::]Cleanup   *(In a lifecycle method only.)*

Arguments

None

Keywords

None

Version History

5.0	Introduced

IDLgrTessellator::Init

The IDLgrTessellator::Init function method initializes the tessellator object.

Note

Init methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation. This means that in most cases, you cannot call the Init method directly. There is one exception to this rule: if you write your own subclass of this class, you can call the Init method from within the Init method of the subclass.

Syntax

Obj = OBJ_NEW('IDLgrTessellator')

or

Result = Obj->[IDLgrTessellator::]Init()   *(In a lifecycle method only.)*

Return Value

When this method is called indirectly, as part of the call to the OBJ_NEW function, the return value is an object reference to the newly-created object.

When called directly within a subclass Init method, the return value is 1 if initialization was successful, or zero otherwise.

Arguments

None

Keywords

None

Version History

5.0	Introduced

IDLgrTessellator::Reset

The IDLgrTessellator::Reset procedure method resets the object's internal state. All previously added polygons are removed from memory and the object is prepared for a new tessellation task.

Syntax

Obj->[IDLgrTessellator::]Reset

Arguments

None

Keywords

None

Version History

5.0	Introduced

IDLgrTessellator::Tessellate

The IDLgrTessellator::Tessellate function method performs the actual tessellation.

Syntax

Result = Obj->[IDLgrTessellator::]Tessellate(*Vertices*, *Poly* [, AUXDATA=*variable*]
　　[, /QUIET])

Return Value

Returns 1, and the contents of Vertices and Poly are set to the results of the tessellation. Returns 0 if tessellation fails.

Arguments

If the tessellation succeeds, IDLgrTessellator::Tessellate returns 1 and the contents of Vertices and Poly are set to the results of the tessellation. If the tessellation fails, the function returns 0.

Vertices

A 2 x *n* array if all the input polygons were 2-D. A 3 x *n* array if all the input polygons were 3-D.

Poly

An array of polygon descriptions. A polygon description is an integer or long word array of the form: [*n*, i_0, i_1, ..., i_{n-1}], where *n* is the number of vertices that define the polygon, and i_0..i_{n-1} are indices into the *X*, *Y*, and *Z* arguments that represent the polygon vertices.

Note

On output, the *Vertices* array can be used as the value of the DATA property, and the *Poly* array can be used as the value of the POLYGON property, of an IDLgrPolygon object.

Keywords

AUXDATA

Set this keyword to a named variable that receives the auxiliary data associated with each vertex returned in the Vertices argument. The data is an [*m*, *n*] array where m is the number of per-vertex auxiliary data items specified in the call(s) to the AddPolygon method, and n is the number of vertices returned in the Vertices argument. The type of the returned auxiliary data is the same as the type of the data supplied with the AUXDATA keyword in the last call to AddPolygon.

QUIET

Set this keyword to suppress warning and error message generation due to tessellation errors. !ERROR_STATE is not updated in the case of the return value being '0' when the QUIET keyword is specified.

Version History

5.0	Introduced
5.6	Added AUXDATA keyword

IDLgrText

A text object represents one or more text strings that share common rendering attributes. An IDLgrText object is an *atomic graphic object*; it is one of the basic drawable elements of the IDL Object Graphics system, and it is not a container for other objects.

Superclasses

IDLitComponent

Creation

- YCOORD_CONV
- ZCOORD_CONV

In addition, objects of this class inherit the properties of all superclasses of this class.

Methods

This class has the following methods:

- IDLgrText::Cleanup
- IDLgrText::GetCTM
- IDLgrText::GetProperty
- IDLgrText::Init
- IDLgrText::SetProperty

In addition, this class inherits the methods of its superclasses (if any).

Version History

5.0	Introduced
5.6	Added CLIP_PLANES property
6.4	Added SHADER property

IDLgrText Properties

IDLgrText objects have the following properties in addition to properties inherited from any superclasses. Properties with the word "Yes" in the "Get" column of the property table can be retrieved via IDLgrText::GetProperty. Properties with the word "Yes" in the "Init" column of the property table can be set via IDLgrText::Init. Properties with the word "Yes" in the "Set" column in the property table can be set via IDLgrText::SetProperty.

Note ──

For a discussion of the property description tables shown below, see "About Object Property Descriptions" on page 3135.

──

Objects of this class have the following properties:

- ALIGNMENT
- ALPHA_CHANNEL
- CHAR_DIMENSIONS
- COLOR
- DEPTH_TEST_FUNCTION
- ENABLE_FORMATTING
- FILL_COLOR
- HIDE
- LOCATIONS
- PALETTE
- RECOMPUTE_DIMENSIONS
- RENDER_METHOD
- STRINGS
- VERTICAL_ALIGNMENT
- XRANGE
- YRANGE
- ZRANGE

- ALL
- BASELINE
- CLIP_PLANES
- DEPTH_TEST_DISABLE
- DEPTH_WRITE_DISABLE
- FILL_BACKGROUND
- FONT
- KERNING
- ONGLASS
- PARENT
- REGISTER_PROPERTIES
- SHADER
- UPDIR
- XCOORD_CONV
- YCOORD_CONV
- ZCOORD_CONV

In addition, objects of this class inherit:

- IDLitComponent Properties

ALIGNMENT

A floating-point value between 0.0 and 1.0 to indicate the requested horizontal alignment of the text baseline. An alignment of 0.0 (the default) left-justifies the text at the given position; an alignment of 1.0 right-justifies the text, and an alignment of 0.5 centers the text over the given position.

Property Type	FLOAT		
Name String	Horizontal alignment		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** Yes

ALL

An anonymous structure containing the values of all of the properties associated with the *state* of this object. State information about the object includes things like color, range, tick direction, etc., but not image, vertex, or connectivity data, or user values.

Note ──
The fields of this structure may change in subsequent releases of IDL.
──

Property Type	Structure		
Name String	*not displayed*		
Get: Yes	**Set:** No	**Init:** No	**Registered:** No

ALPHA_CHANNEL

A floating-point value that determines the opacity of the text with respect to the background. Set this property to a value in the range [0.0, 1.0] (1.0 is the default) to draw the text foreground and background with the specified blending factor. A value of 1.0 draws the text opaquely without blending the text with objects already drawn on the destination. Edges of the glyphs are always blended. A value of 0.0 draws no text at all. A value in the middle of the range draws the text semi-transparently, which provides a way of creating labels that are visible while allowing features blocked by the labels to still be seen. This property is used only when the RENDER_METHOD in effect is 0 (Texture).

Note ───

For more detailed information on alpha channel support for IDL Object Graphics, see "Controlling Object Transparency" (Chapter 2, *Object Programming*).

───

Property Type	Float-point value		
Name String	*Transparency*		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** Yes

BASELINE

A two- or three-element floating-point vector describing the direction in which the baseline is to be oriented. Use this property in conjunction with the UPDIR property to specify the plane on which the text lies. The default BASELINE is [1.0,0,0] (i.e., parallel to the x-axis).

This property is registered as a user-defined property, but it is hidden by default.

Property Type	USERDEF		
Name String	Baseline direction		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** Yes

CHAR_DIMENSIONS

A two-element floating-point vector [*width*, *height*] indicating the dimensions (measured in data units) of a bounding box for each character, to be used when scaling text projected in three dimensions. If either *width* or *height* is zero, the text will be scaled such that if it were positioned halfway between the near and far clipping planes, it will appear at the point size associated with this text object's font. The default value is [0, 0]. IDL converts, maintains, and returns this data as double-precision floating-point.

Note ───

If you set the CHAR_DIMENSIONS property to [0,0] (using the SetProperty method), indicating that IDL should calculate the text size, the value (returned by the GetProperty method) will not be updated to reflect the calculated size until you call either the Draw method or the GetTextDimensions method.

───

For example, if the VIEWPLANE_RECT of the view the text object is being rendered in is set equal to [0,0,10,10] (that is, it spans ten data units in each of the X and Y directions), setting the CHAR_DIMENSIONS property equal to [2, 3] will scale the text such that each character fills 20% of the X range and 30% of the Y range.

This property has no effect if the ONGLASS property is set equal to one.

Property Type	Floating-point vector		
Name String	*not displayed*		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** No

CLIP_PLANES

A 4-by-*N* floating-point array that specifies the coefficients of the clipping planes to be applied to this object. The four coefficients for each clipping plane are of the form [A, B, C, D], where $Ax + By + Cz + D = 0$. Portions of this object that fall in the half space $Ax + By + Cz + D > 0$ will be clipped. By default, the value of this property is a scalar (-1) indicating that no clipping planes are to be applied.

Note
The clipping planes specified via this property are applied in addition to the near and far clipping planes associated with the IDLgrView in which this object appears.

Note
Clipping planes are applied in the data space of this object (prior to the application of any *x*, *y*, or *z* coordinate conversion).

Note
To determine the maximum number of clipping planes supported by the device, use the MAX_NUM_CLIP_PLANES property of the GetDeviceInfo method for the IDLgrBuffer, IDLgrClipboard, IDLgrWindow, and IDLgrVRML objects.

Property Type	Floating-point array		
Name String	*not displayed*		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** No

COLOR

The color to be used as the foreground color for the text. The color may be specified as a color lookup table index or as a three-element vector [*red*, *green*, *blue*]. The default is [0, 0, 0].

In a property sheet, this property appears as a color property.

Property Type	COLOR		
Name String	Color		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** Yes

DEPTH_TEST_DISABLE

An integer value that determines whether depth testing is disabled.

- Set this property to 0 (the default) to inherit the value set by the parent model or view. The parent view always enables depth testing. A model may also enable or disable depth testing.

- Set this property to 1 to explicitly disable depth buffer testing while drawing this object.

- Set this property to 2 to explicitly enable depth testing for this object.

Disabling depth testing allows an object to draw itself "on top" of other objects already on the screen, even if the object is located behind them.

Note

Disabling depth testing also disables depth buffer writing. When disabling depth testing, the DEPTH_TEST_FUNCTION and DEPTH_WRITE_DISABLE properties are effectively ignored.

This property is registered as an enumerated list, but it is hidden by default.

Property Type	ENUMLIST		
Name String	*not displayed*		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** No

DEPTH_TEST_FUNCTION

An integer value that determines the depth test function. Set this property to 0 (the default) to inherit the value set by the parent model or view. The parent view always sets a depth test function of LESS. A model may also set a depth test function value. The graphics device compares the object's depth at a particular pixel location with the depth stored in the depth buffer at that same pixel location. If the comparison test passes, the object's pixel is drawn at that location on the screen and the depth buffer is updated (if depth writing is enabled).

Set this property to any of the following values to use the desired function while rendering this object.

- 0 = INHERIT - use value from parent model or view.
- 1 = NEVER - never passes.
- 2 = LESS - passes if the object's depth is less than the depth buffer's value.
- 3 = EQUAL - passes if the object's depth is equal to the depth buffer's value.
- 4 = LESS OR EQUAL - passes if the object's depth is less than or equal to the depth buffer's value.
- 5 = GREATER - passes if the object's depth is greater than or equal to the depth buffer's value.
- 6 = NOT EQUAL - passes if the object's depth is not equal to the depth buffer's value.
- 7 = GREATER OR EQUAL - passes if the object's depth is greater than or equal to the depth buffer's value.
- 8 = ALWAYS - always passes

Less means closer to the viewer.

This property is registered as an enumerated list, but it is hidden by default.

Property Type	ENUMLIST		
Name String	*not displayed*		
Get: Yes	Set: Yes	Init: Yes	Registered: No

DEPTH_WRITE_DISABLE

An integer value that determines whether depth writing is disabled.

- Set this property to 0 (the default) to inherit the value set by the parent model or view. The parent view always enables depth writing. A model may also enable or disable depth writing.

- Set this property to 1 to explicitly disable depth buffer writing while rendering this object.

- Set this property to 2 to explicitly enable depth writing for this object.

Disabling depth writing allows an object to be overdrawn by other objects, even if the object is located in front of them.

Note
If depth testing (see DEPTH_TEST_DISABLE property) is disabled, depth writing is also automatically disabled.

This property is registered as an enumerated list, but it is hidden by default.

Property Type	ENUMLIST		
Name String	*not displayed*		
Get: Yes	Set: Yes	Init: Yes	Registered: No

ENABLE_FORMATTING

A Boolean value that determines whether the text object should honor embedded Hershey-style formatting codes within the strings. (Formatting codes are described in Appendix H, "Fonts".) The default is not to honor the formatting codes.

Property Type	Boolean		
Name String	*not displayed*		
Get: Yes	Set: Yes	Init: Yes	Registered: No

FILL_BACKGROUND

Set this property to zero (the default) to render the text with a transparent bitmap background, allowing graphics behind the text to show through between the glyphs. Set this property to non-zero to draw the text bitmap background with the color

specified by the FILL_COLOR property. This property can only be used when RENDER_METHOD is set to 0 (Texture).

Property Type	Boolean		
Name String	Fill background		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** Yes

FILL_COLOR

An integer vector that determines whether to use a text background color other than the view color. Set this property to -1 (the default) to specify that the text background should be drawn using the view color. Set this property to a three-element vector [*red*, *green*, *blue*] or color index value to specify that the text bitmap background should be drawn using the specified color. This property is used only when the FILL_BACKGROUND property has a non-zero value and the RENDER_METHOD in effect is 0 (Texture).

In a property sheet, this property appears as a color property

Property Type	COLOR		
Name String	Fill background		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** Yes

FONT

An object reference to an instance of an IDLgrFont object class to describe the font to use to draw this string. The default is 12 point Helvetica. See IDLgrFont for details.

Note ──

If the default font is in use, retrieving the value of the FONT property (using the GetProperty method) will return a null object.

──

Note ──

Objects specified via this property are not automatically cleaned up when the IDLgrText object is destroyed.

──

Property Type	Object reference		
Name String	*not displayed*		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** No

HIDE

A Boolean value or an enumerated list item indicating whether this object should be drawn:

Value	Property Sheet Value	Description
0	True	Draw graphic (the default)
1	False	Do not draw graphic

Property Type	ENUMLIST		
Name String	Show		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** Yes

KERNING

A Boolean value that determines whether to enable kerning while rendering characters. Kerning reduces the amount of space between glyphs if the shape of each glyph allows it, according to the font information stored in the font's file (e.g., AV). Set this property to a non-zero value (the default is zero) to enable kerning. Enabling kerning may not necessarily result in rendering glyphs more closely together because some fonts do not contain the required kerning information. This property is used only when the RENDER_METHOD in effect is 0 (Texture).

Property Type	Boolean		
Name String	Kerning		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** Yes

LOCATIONS

A floating-point array of one or more two- or three-element vectors specifying the coordinates (measured in data units) used to position the string(s). The default

location for each string is [0,0,0]. Each vector is of the form [*x*, *y*] or [*x*, *y*, *z*]; if *z* is not provided, it is assumed to be zero. Each location corresponds to a string in the *String* argument; the number of locations should be equal the number of strings. IDL converts, maintains, and returns this data as double-precision floating-point.

This property is registered as a user-defined property, but it is hidden by default.

Property Type	USERDEF		
Name String	Text locations		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

ONGLASS

A Boolean value that indicates whether the text should be displayed "on the glass". Text that is drawn "on the glass" always faces the viewer, regardless of the 3-D orientation of the objects "underneath" the glass. The default is projected 3-D text.

Property Type	Boolean		
Name String	On glass		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

PALETTE

An object reference to a palette object (an instance of the IDLgrPalette object class) that defines the color palette of this object. This property is only used if the destination device is using the RGB color model. If so, and a color value for the object is specified as a color index value, the palette set by this property is used to translate the color to RGB space. If the PALETTE property on this object is not set, the destination object PALETTE property is used (which defaults to a grayscale ramp).

Note ─────────────────────────────

Objects specified via this property are not automatically cleaned up when the IDLgrText object is destroyed.

───────────────────────────────────────

This property is registered as a user-defined property, but it is hidden by default.

Property Type	USERDEF		
Name String	Color palette		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

PARENT

An object reference to the object that contains this object.

Property Type	Object reference		
Name String	*not displayed*		
Get: Yes	Set: No	Init: No	Registered: No

RECOMPUTE_DIMENSIONS

An integer value that indicates when this text object's character dimensions (refer to the CHAR_DIMENSIONS property) are to be recomputed automatically:

0	The physical size of the text is affected by model and view transforms. The size of the text in terms of data units is obtained from CHAR_DIMENSIONS. Since the character dimensions are specified in data units, the text will maintain the data space size specified by CHAR_DIMENSIONS as the transforms change. In other words, the physical text size changes along with other primitives. If the value of this property is [0, 0], the text font's point size is used to compute the physical size of the text in terms of data units using the transforms in effect for the first draw. This setting is the default value for this property.
1	The physical size of the text is only affected by model transforms. The CHAR_DIMENSIONS property is ignored. The size of the text is computed from the font's point size the first time it is drawn, and IDL does not try to keep the size of the text constant with respect to changes in the model transforms.
2	The physical size of the text is held constant, even as the model and view change. The CHAR_DIMENSIONS property is ignored and the text is always drawn with a physical size equal to the text font's point size. IDL adjusts its internal text transforms to maintain the physical size of the text.

Property Type	ENUMLIST		
Name String	*not displayed*		
Get: Yes	Set: Yes	Init: Yes	Registered: No

REGISTER_PROPERTIES

A Boolean value that determines whether to register properties available for this object. If this property is set, all properties marked in this properties section as "Registered: Yes" will be registered for display in a property sheet. This property is useful mainly when creating iTools. By default, no properties are registered.

Property Type	Boolean		
Name String	*not displayed*		
Get: No	Set: No	Init: Yes	Registered: No

RENDER_METHOD

A Boolean value or enumerated list item that determines how the text object will be rendered. Set this property to one of the following values:

Value	Property Sheet Value	Description
0	Texture	IDL renders the text by placing a bitmap representation of a glyph into a texture map and then rendering a polygon with the texture map. The FILL_BACKGROUND, ALPHA_CHANNEL, and FILL_COLOR properties control the drawing of the background portions of the texture map and how the entire texture map is blended into the scene. Leaving these three properties set to their default values produces a result that closely approximates the TRIANGLES rendering method. One important difference is that the glyph bitmaps are generated by the FreeType font rendering library, producing glyphs that are more accurately rendered and anti-aliased than those drawn with the TRIANGLES method. The TEXTURE method cannot be used on indexed color destinations. The text is rendered with the TRIANGLES method if the destination color model is indexed.
1	Triangles	IDL renders the text by tessellating the glyph outline into a set of small triangles that are then drawn to produce the solid glyph. IDL also draws a blended line around the edge of the glyph to approximate anti-aliasing. This setting forces IDL to use the process it used as the default before IDL 6.0.

Property Type	ENUMLIST		
Name String	Render method		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** Yes

STRINGS

The string (or vector of strings) associated with the text object.

Specifying this property is the same as specifying the optional *String* argument to the IDLgrText::Init method.

If the number of strings matches the number of locations (as specified by the LOCATIONS property), the existing locations are used.

Note ——————————————————————————————————————

If the number of strings *does not* match the number of locations, the number of locations is modified to match the number of strings, and the location value for each string is reset to [0,0,0].

——

This property is registered as a user-defined property, but it is hidden by default.

Property Type	USERDEF		
Name String	Text strings		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** Yes

SHADER

An object reference to an IDLgrShader object (or an object containing IDLgrShader as a superclass). When there is suitable graphics card hardware support, the text is rendered using the GLSL shader program (executed on the graphics card) instead of using fixed OpenGL properties when initially drawn. (If a suitable graphics card is not present, IDL ignores the shader object when the scene is drawn.) A single IDLgrShader object may be associated with additional text objects or other graphic objects that have the SHADER property.

Property Type	Object reference		
Name String	*not displayed*		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** No

UPDIR

A two- (or three-) element floating-point vector describing the vertical direction for the string. The *upward direction* is the direction defined by a vector pointing from the origin to the point specified. Use this property in conjunction with the BASELINE property to specify the plane on which the text lies; the direction specified by UPDIR should be orthogonal to the direction specified by BASELINE. The default UPDIR is [0.0, 1.0, 0.0] (i.e., parallel to the *Y* axis).

This property is registered as a user-defined property, but it is hidden by default.

Property Type	USERDEF		
Name String	Up direction		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

VERTICAL_ALIGNMENT

A floating-point value between 0.0 and 1.0 to indicate the requested vertical alignment of the text. An alignment of 0.0 (the default) bottom-justifies the text at the given location; an alignment of 1.0 top-justifies the text at the given location.

Property Type	FLOAT		
Name String	Vertical alignment		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

XCOORD_CONV

A floating-point vector, $[s_0, s_1]$, of scaling factors used to convert X coordinates from data units to normalized units. The formula for the conversion is as follows:

$$\text{Normalized}X = s_0 + s_1 * \text{Data}X$$

Recommended values are:

$$[(-X_{min})/(X_{max}-X_{min}), 1/(X_{max}-X_{min})]$$

The default is [0.0, 1.0]. IDL converts, maintains, and returns this data as double-precision floating-point.

Property Type	Floating-point vector		
Name String	*not displayed*		
Get: Yes	Set: Yes	Init: Yes	Registered: No

XRANGE

A two-element floating-point vector of the form [*xmin*, *xmax*] that specifies the range of *x* data coordinates covered by the graphic object. IDL maintains and returns this property in double-precision floating-point.

Property Type	Floating-point vector		
Name String	*not displayed*		
Get: Yes	**Set:** No	**Init:** No	**Registered:** No

YCOORD_CONV

A floating-point vector, $[s_0, s_1]$, of scaling factors used to convert Y coordinates from data units to normalized units. The formula for the conversion is as follows:

$$\text{Normalized}Y = s_0 + s_1 * \text{Data}Y$$

Recommended values are:

$$[(-Y_{min})/(Y_{max}-Y_{min}), 1/(Y_{max}-Y_{min})]$$

The default is [0.0, 1.0]. IDL converts, maintains, and returns this data as double-precision floating-point.

Property Type	Floating-point vector		
Name String	*not displayed*		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** No

YRANGE

A two-element floating-point vector of the form [*ymin*, *ymax*] that specifies the range of *y* data coordinates covered by the graphic object. IDL maintains and returns this property in double-precision floating-point.

Property Type	Floating-point vector		
Name String	*not displayed*		
Get: Yes	**Set:** No	**Init:** No	**Registered:** No

ZCOORD_CONV

A floating-point vector, $[s_0, s_1]$, of scaling factors used to convert Z coordinates from data units to normalized units. The formula for the conversion is as follows:

$$Normalized Z = s_0 + s_1 * Data Z$$

Recommended values are:

$$[(-Z_{min})/(Z_{max}-Z_{min}), 1/(Z_{max}-Z_{min})]$$

The default is [0.0, 1.0]. IDL converts, maintains, and returns this data as double-precision floating-point.

Property Type	Floating-point vector		
Name String	*not displayed*		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** No

ZRANGE

A two-element floating-point vector of the form [*zmin*, *zmax*] that specifies the range of *z* data coordinates covered by the graphic object. IDL maintains and returns this property in double-precision floating-point.

Note
Until the text is drawn to the destination object, the [XYZ]RANGE properties will only report the locations of the text. Use the GetTextDimensions method of the destination object to get the data dimensions of the text prior to a draw operation.

Property Type	Floating-point vector		
Name String	*not displayed*		
Get: Yes	**Set:** No	**Init:** No	**Registered:** No

IDLgrText::Cleanup

The IDLgrText::Cleanup procedure method performs all cleanup on the object.

Note ——————————————————————————————

Cleanup methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation and destruction. This means that in most cases, you cannot call the Cleanup method directly. There is one exception to this rule: if you write your own subclass of this class, you can call the Cleanup method from within the Init or Cleanup method of the subclass.

Syntax

OBJ_DESTROY, *Obj*

or

Obj->[IDLgrText::]Cleanup   *(In a lifecycle method only.)*

Arguments

None

Keywords

None

Version History

5.0	Introduced

IDLgrText::GetCTM

The IDLgrText::GetCTM function method returns the 4-by-4 double-precision floating-point graphics transform matrix from the current object upward through the graphics tree.

Syntax

Result = Obj->[IDLgrText::]GetCTM([, DESTINATION=*objref*] [, PATH=*objref(s)*]
    [, TOP=*objref to IDLgrModel object*])

Return Value

Returns the 4-by-4 double-precision floating-point graphics transform matrix from the current object upward through the graphics tree.

Arguments

None

Keywords

DESTINATION

Set this keyword to the object reference of a destination object to specify that the projection matrix for the View object in the current tree be included in the returned transformation matrix. The resulting matrix will transform a point in the data space of the object on which the GetCTM method is called into a normalized coordinate system (-1 to +1 in X, Y, and Z), relative to the View object that contains the text object.

PATH

Set this keyword to a single object reference or a vector of object references. This keyword specifies the path in the graphics hierarchy to compute the transformation matrix. Each path object reference specified with this keyword must contain an alias. The transformation matrix is computed for the version of the object falling within that path. If this keyword is not set, the PARENT properties determine the path from the current object to the top of the graphics hierarchy and no alias paths are pursued. If IDLgrText::GetCTM is called from within a Draw method, with the DESTINATION keyword set and the PATH keyword not set, the alias path used to find the object during the draw is used, rather than the PARENT path.

Note ───────────────────

For more information on aliases, refer to the ALIAS keyword in IDLgrModel::Add.

───────────────────────────────

TOP

Set this keyword equal to the object reference to an IDLgrModel object to specify that the returned matrix accumulate from the object on which the GetCTM method is called up to but not including the specified model object.

Version History

5.0	Introduced

IDLgrText::GetProperty

The IDLgrText::GetProperty procedure method retrieves the value of a property or group of properties for the text.

Syntax

Obj->[IDLgrText::]GetProperty[, *PROPERTY=variable*]

Arguments

None

Keywords

Any property listed under "IDLgrText Properties" on page 4850 that contains the word "Yes" in the "Get" column of the properties table can be retrieved using this method. To retrieve the value of a property, specify the property name as a keyword set equal to a named variable that will contain the value of the property.

Any keyword not recognized is passed to this object's superclass.

Version History

5.0	Introduced

IDLgrText::Init

The IDLgrText::Init function method initializes the text object.

Note

Init methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation. This means that in most cases, you cannot call the Init method directly. There is one exception to this rule: if you write your own subclass of this class, you can call the Init method from within the Init method of the subclass.

Syntax

Obj = OBJ_NEW('IDLgrText' [, *String or vector of strings*] [, *PROPERTY=value*])

or

Result = Obj->[IDLgrText::]Init([*String or vector of strings*] [, *PROPERTY=value*])
     (In a lifecycle method only.)

Return Value

When this method is called indirectly, as part of the call to the OBJ_NEW function, the return value is an object reference to the newly-created object.

When called directly within a subclass Init method, the return value is 1 if initialization was successful, or zero otherwise.

Arguments

String

The string (or vector of strings) to be created. If this argument is not a string, it is converted prior to creation of the text object using the default formatting rules.

Note

Strings have a default location of [0,0,0]. Use the LOCATIONS property to provide a different location for each string.

Note

The value specified by the *String* argument is used to initialize the value of the STRINGS property of the IDLgrText object.

Keywords

Any property listed under "IDLgrText Properties" on page 4850 that contains the word "Yes" in the "Init" column of the properties table can be initialized during object creation using this method. To initialize the value of a property, specify the property name as a keyword set equal to the appropriate property value.

All other keywords are passed to the superclass of this object.

Version History

5.0	Introduced

IDLgrText::SetProperty

The IDLgrText::SetProperty procedure method sets the value of a property or group of properties for the text.

Syntax

Obj->[IDLgrText::]SetProperty[, *PROPERTY=value*]

Arguments

None

Keywords

Any property listed under "IDLgrText Properties" on page 4850 that contains the word "Yes" in the "Set" column of the properties table can be set using this method. To set the value of a property, specify the property name as a keyword set equal to the appropriate property value.

Version History

5.0	Introduced

IDLgrView

A view object represents a rectangular area in which graphics objects are drawn. It is a container for objects of the IDLgrModel class.

Note ──

See Chapter 3, "Positioning Objects in a View" (*Object Programming*) for more information on using the properties and methods of the view object.

───

Superclasses

IDL_Container

IDLitComponent

Creation

See "IDLgrView::Init" on page 4890.

Properties

Objects of this class have the following properties. See "IDLgrView Properties" on page 4876 for details on individual properties.

- ALL
- COLOR
- DEPTH_CUE
- DIMENSIONS
- DOUBLE
- EYE
- HIDE
- LOCATION
- PARENT
- PROJECTION
- REGISTER_PROPERTIES
- TRANSPARENT

- UNITS
- VIEWPLANE_RECT
- ZCLIP

In addition, objects of this class inherit the properties of all superclasses of this class.

Methods

This class has the following methods:

- IDLgrView::Add
- IDLgrView::Cleanup
- IDLgrView::GetByName
- IDLgrView::GetProperty
- IDLgrView::Init
- IDLgrView::SetProperty

In addition, this class inherits the methods of its superclasses (if any).

Version History

5.0	Introduced

IDLgrView Properties

IDLgrView objects have the following properties in addition to properties inherited from any superclasses. Properties with the word "Yes" in the "Get" column of the property table can be retrieved via IDLgrView::GetProperty. Properties with the word "Yes" in the "Init" column of the property table can be set via IDLgrView::Init. Properties with the word "Yes" in the "Set" column in the property table can be set via IDLgrView::SetProperty.

Note ───
For a discussion of the property description tables shown below, see "About Object Property Descriptions" on page 3135.
───

Objects of this class have the following properties.

- ALL
- COLOR
- DEPTH_CUE
- DIMENSIONS
- DOUBLE
- EYE
- HIDE
- LOCATION
- PARENT
- PROJECTION
- REGISTER_PROPERTIES
- TRANSPARENT
- UNITS
- VIEWPLANE_RECT
- ZCLIP

In addition, objects of this class inherit:

- IDL_Container
- IDLitComponent

ALL

An anonymous structure containing the values of all of the properties associated with the *state* of this object. State information about the object includes things like color, range, tick direction, etc., but not image, vertex, or connectivity data, or user values.

Note ————————————————————————

The fields of this structure may change in subsequent releases of IDL.

————————————————————————————————

Property Type	Structure		
Name String	*not displayed*		
Get: Yes	**Set:** No	**Init:** No	**Registered:** No

COLOR

The color for the view. This is the color to which the view area will be erased before its contents are drawn. The color may be specified as a color lookup table index or as a three-element vector [*red*, *green*, *blue*]. The default is [255, 255, 255] (white).

In a property sheet, this property appears as a color property.

Property Type	COLOR		
Name String	Color		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** Yes

DEPTH_CUE

A two-element floating-point array [*zbright*, *zdim*] specifying the near and far Z planes between which depth cueing is in effect. Depth cueing is only honored when drawing to a destination object that uses the RGB color model.

Depth cueing causes an object to appear to fade into the background color of the view object with changes in depth. If the depth of an object is further than *zdim* (that is, if the object's location in the Z direction is farther from the origin than the value specified by *zdim*), the object will be painted in the background color. Similarly, if the object is closer than the value of *zbright*, the object will appear in its "normal" color. Anywhere in-between, the object will be a blend of the background color and the object color. For example, if the DEPTH_CUE property is set to [-1,1], an object at the depth of 0.0 will appear as a 50% blend of the object color and the view color.

The relationship between Z_{bright} and Z_{dim} determines the result of the rendering:

- $Z_{bright} < Z_{dim}$: Rendering darkens with depth.
- $Z_{bright} > Z_{dim}$: Rendering brightens with depth.
- $Z_{bright} = Z_{dim}$: Disables depth cueing.

You can disable depth cueing by setting $z_{bright} = z_{dim}$. The default is [0.0, 0.0].

This property is registered as a user-defined property, but it is hidden by default.

Property Type	USERDEF		
Name String	Depth cue		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** Yes

DIMENSIONS

A two-element integer vector of the form [*width*, *height*] specifying the dimensions of the viewport (the rectangle in which models are displayed on a graphics destination). By default, the viewport dimensions are set to [0, 0], which indicates that it will match the dimensions of the graphics destination to which it is drawn. The dimensions are measured in the units specified by the UNITS property.

Property Type	Integer vector		
Name String	*not displayed*		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** No

Note

See "Location" (Chapter 3, *Object Programming*) for more information.

DOUBLE

A Boolean value that controls the precision used for rendering the entire contents of the view. If set, IDL calculates the transformations used for the modeling and view transforms using double-precision floating-point arithmetic. This allows the values specified for the VIEWPLANE_RECT, modeling transforms in IDLgrModel objects, and coordinate data in atomic graphic objects to be used as double-precision before mapping to device coordinates.

Note ———————————————————————————————————

If this property is set to 0, IDL uses single-precision floating-point arithmetic for these values, which can cause loss of significance and incorrect rendering of data. Setting this property to 1 may impact graphics performance and should only be used when handling data requiring double precision.

———————————————————————————————————————

The default value is 0.

Property Type	Boolean		
Name String	Double precision		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** Yes

EYE

A floating-point value that specifies the distance from the eyepoint to the viewplane (Z=0). The default is 4.0. The eyepoint is always centered within the viewplane rectangle. (That is, if the VIEWPLANE_RECT property is set equal to [0,0,1,1], the eyepoint will be at X=0.5, Y=0.5.) IDL converts, maintains, and returns this data as double-precision floating-point.

Property Type	FLOAT		
Name String	Eye distance		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** Yes

Note ———————————————————————————————————

See "Eye Position" (Chapter 3, *Object Programming*) for details.

———————————————————————————————————————

HIDE

A Boolean value or enumerated list item indicating whether this object should be drawn:

Value	Property Sheet Value	Description
0	True	Draw graphic (the default)
1	False	Do not draw graphic

Property Type	ENUMLIST		
Name String	Show		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** Yes

LOCATION

A two-element floating-point vector of the form [*x*, *y*] specifying the position of the lower left corner of the view. The default is [0, 0], and is measured in units specified by the UNITS property

This property is registered as a user-defined property, but it is hidden by default.

Property Type	USERDEF		
Name String	Viewport location		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** Yes

Note ───
See "Location" (Chapter 3, *Object Programming*) for more information.
──

PARENT

An object reference to the object that contains this object.

Property Type	Object reference		
Name String	*not displayed*		
Get: Yes	**Set:** No	**Init:** No	**Registered:** No

PROJECTION

An integer value or enumerated list item indicating the type of projection to use within this view. All models displayed within this view will be projected using this type of projection. Valid values are:

Value	Property Sheet Value	Description
0	None	Same result as setting Orthogonal or 1
1	Orthogonal	Models are projected along lines perpendicular to the view plane (the default)
2	Perspective	Models are projected toward the eye (located at the origin), which is the apex of the viewing frustum. With a perspective projection, models that are farther away from the eye will appear smaller in the view than models that are nearer to the eye.

Property Type	ENUMLIST		
Name String	Projection		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** Yes

Note

See "Projection" (Chapter 3, *Object Programming*) for details.

REGISTER_PROPERTIES

A Boolean value that determines whether to register properties available for this object. If this property is set, all properties marked in this properties section as "Registered: Yes" will be registered for display in a property sheet. This property is useful mainly when creating iTools. By default, no properties are registered.

Property Type	Boolean		
Name String	*not displayed*		
Get: No	**Set:** No	**Init:** Yes	**Registered:** No

TRANSPARENT

A Boolean value that determines whether to disable the viewport erase, making the viewport transparent. If this value is false, the viewport is erased and the depth buffer initialized. If this value is true, the viewport is not erased and the depth buffer is not initialized.

Property Type	Boolean		
Name String	Transparent		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

UNITS

An integer value or enumerated list item that specifies the units of measure for this view:

Value	Property Sheet Value	Description
0	Device	Device units are unit of measure (the default)
1	Inches	Inches are unit of measure
2	Centimeters	Centimeters are unit of measure
3	Normalization	Normalized units (relative to the graphics destination's *rect*) are unit of measure

Note

If you set the UNITS property (using the SetProperty method) of a view without also setting the LOCATION and DIMENSIONS properties, IDL will use the existing size and location values in the new units, *without conversion*. This means that if your view's location and dimensions were previously measured in centimeters, and you change the value of UNITS to 1 (measurement in inches), the actual size of the view object will change.

Property Type	ENUMLIST		
Name String	Units		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** Yes

VIEWPLANE_RECT

A four-element floating-point vector of the form [*x*, *y*, *width*, *height*] to describe the bounds in x and y of the view volume. Objects within the view volume are projected into the viewport. These values are measured in normalized space. The default is [-1.0, -1.0, 2.0, 2.0] IDL converts, maintains, and returns this data as double-precision floating-point.

Note ─────────
The z bounds of the view volume are set via the ZCLIP property. The viewplane rectangle is always located at Z=0.
────────────────

This property is registered as a user-defined property, but it is hidden by default.

Property Type	USERDEF		
Name String	Viewplane rectangle		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** Yes

Note ─────────
See "View Volume" (Chapter 3, *Object Programming*) for details.
────────────────

ZCLIP

A two element floating-point vector representing the near and far clipping planes to be applied to the objects in this view. The vector should take the form [*near*, *far*]. By default, these values are [1, -1]. IDL converts, maintains, and returns this data as double-precision floating-point.

This property is registered as a user-defined property, but it is hidden by default.

Property Type	USERDEF		
Name String	Z clipping		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** Yes

IDLgrView::Add

The IDLgrView::Add procedure method adds a child to this view.

Syntax

Obj->[IDLgrView::]Add, *Model* [, POSITION=*index*]

Arguments

Model

An instance of the IDLgrModel object class.

Keywords

POSITION

Set this keyword equal to the zero-based index of the position within the container at which the new object should be placed.

Version History

5.0	Introduced

IDLgrView::Cleanup

The IDLgrView::Cleanup procedure method performs all cleanup on the object.

Note —————————————————————————————————

Cleanup methods are special *lifecycle methods*, and as such cannot be called outside
the context of object creation and destruction. This means that in most cases, you
cannot call the Cleanup method directly. There is one exception to this rule: if you
write your own subclass of this class, you can call the Cleanup method from within
the Init or Cleanup method of the subclass.

Syntax

OBJ_DESTROY, *Obj*

or

Obj->[IDLgrView::]Cleanup   *(In a lifecycle method only.)*

Arguments

None

Keywords

None

Version History

5.0	Introduced

IDLgrView::GetByName

The IDLgrView::GetByName function method finds contained objects by name. If the named object is not found, the GetByName function returns a null object reference.

Note ────────────────────────────────

The GetByName function does *not* perform a recursive search through the object hierarchy. If a fully qualified object name is not specified, only the contents of the current container object are inspected for the named object.

───

Syntax

Result = Obj->[IDLgrView::]GetByName(*Name*)

Return Value

Returns contained objects by name. If the named object is not found, the GetByName function returns a null object reference.

Arguments

Name

A string containing the name of the object to be returned.

Object naming syntax is very much like the syntax of a UNIX filesystem. Objects contained by other objects can include the name of their parent object; this allows you to create a fully qualified name specification. For example, if object1 contains object2, which in turn contains object3, the string specifying the fully qualified object name of object3 would be 'object1/object2/object3'.

Object names are specified relative to the object on which the GetByName method is called. If used at the beginning of the name string, the / character represents the top of an object hierarchy. The string '..' represents the object one level "up" in the hierarchy.

Keywords

None

Version History

5.0	Introduced

IDLgrView::GetProperty

The IDLgrView::GetProperty procedure method retrieves the value of the property or group of properties for the view.

Syntax

Obj->[IDLgrView::]GetProperty[, *PROPERTY=variable*]

Arguments

None

Keywords

Any property listed under "IDLgrView Properties" on page 4876 that contains the word "Yes" in the "Get" column of the properties table can be retrieved using this method. To retrieve the value of a property, specify the property name as a keyword set equal to a named variable that will contain the value of the property.

Any keyword not recognized is passed to this object's superclass.

Version History

5.0	Introduced

IDLgrView::Init

The IDLgrView::Init function method initializes the view object.

Note ───

Init methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation. This means that in most cases, you cannot call the Init method directly. There is one exception to this rule: if you write your own subclass of this class, you can call the Init method from within the Init method of the subclass.

───

Syntax

Obj = OBJ_NEW('IDLgrView' [, *PROPERTY=value*])

or

Result = Obj->[IDLgrView::]Init([, *PROPERTY=value*])   *(In a lifecycle method only.)*

Return Value

When this method is called indirectly, as part of the call to the OBJ_NEW function, the return value is an object reference to the newly-created object.

When called directly within a subclass Init method, the return value is 1 if initialization was successful, or zero otherwise.

Arguments

None

Keywords

Any property listed under "IDLgrView Properties" on page 4876 that contains the word "Yes" in the "Init" column of the properties table can be initialized during object creation using this method. To initialize the value of a property, specify the property name as a keyword set equal to the appropriate property value.

All other keywords are passed to the superclass of this object.

Version History

5.0	Introduced

IDLgrView::SetProperty

The IDLgrView::SetProperty procedure method sets the value of the property or group of properties for the view.

Syntax

Obj->[IDLgrView::]SetProperty[, *PROPERTY=value*]

Arguments

None

Keywords

Any property listed under "IDLgrView Properties" on page 4876 that contains the word "Yes" in the "Set" column of the properties table can be set using this method. To set the value of a property, specify the property name as a keyword set equal to the appropriate property value.

Version History

5.0	Introduced

IDLgrViewgroup

The IDLgrViewgroup object is a simple container object, very similar to the IDLgrScene object. It contains one or more IDLgrView objects and an IDLgrScene can contain one or more of these objects. This object is special in that it can also contain objects which do not have a Draw method (e.g. IDLgrPattern and IDLgrFont). An IDLgrViewgroup object cannot be returned by a call to the IDLgrWindow::Select method or the IDLgrBuffer::Select method.

Superclasses

IDL_Container

IDLitComponent

Creation

See "IDLgrViewgroup::Init" on page 4902.

Properties

Objects of this class have the following properties. See "IDLgrViewgroup Properties" on page 4895 for details on individual properties.

- ALL
- HIDE
- PARENT
- REGISTER_PROPERTIES

In addition, objects of this class inherit the properties of all superclasses of this class.

Methods

This class has the following methods:

- IDLgrViewgroup::Add
- IDLgrViewgroup::Cleanup
- IDLgrViewgroup::GetByName
- IDLgrViewgroup::GetProperty

- IDLgrViewgroup::Init
- IDLgrViewgroup::SetProperty

In addition, this class inherits the methods of its superclasses (if any).

Version History

5.1	Introduced

IDLgrViewgroup Properties

IDLgrViewgroup objects have the following properties in addition to properties inherited from any superclasses. Properties with the word "Yes" in the "Get" column of the property table can be retrieved via IDLgrViewgroup::GetProperty. Properties with the word "Yes" in the "Init" column of the property table can be set via IDLgrViewgroup::Init. Properties with the word "Yes" in the "Set" column in the property table can be set via IDLgrViewgroup::SetProperty.

Note ───

For a discussion of the property description tables shown below, see "About Object Property Descriptions" on page 3135.

───

Objects of this class have the following properties.

- ALL
- HIDE
- PARENT
- REGISTER_PROPERTIES

In addition, objects of this class inherit:

- IDL_Container
- IDLitComponent

ALL

An anonymous structure containing the values of all of the retrievable properties associated with this object.

Property Type	Structure		
Name String	*not displayed*		
Get: Yes	**Set:** No	**Init:** No	**Registered:** No

HIDE

A Boolean value or enumerated list item that indicates whether this object should be drawn:

Value	Property Sheet Value	Description
0	True	Draw graphic (the default)
1	False	Do not draw graphic

Property Type	ENUMLIST		
Name String	Show		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** Yes

PARENT

An object reference to the object that contains this viewgroup.

Property Type	Object reference		
Name String	*not displayed*		
Get: Yes	**Set:** No	**Init:** No	**Registered:** No

REGISTER_PROPERTIES

A Boolean value that determines whether to register properties available for this object. If this property is set, all properties marked in this properties section as "Registered: Yes" will be registered for display in a property sheet. This property is useful mainly when creating iTools. By default, no properties are registered.

Property Type	Boolean		
Name String	*not displayed*		
Get: No	**Set:** No	**Init:** Yes	**Registered:** No

IDLgrViewgroup::Add

The IDLgrViewgroup::Add function method verifies that the added item is not an instance of the IDLgrScene or IDLgrViewgroup object. If it is not, IDLgrViewgroup:Add adds the object to the specified viewgroup.

Syntax

Obj->[IDLgrViewgroup::]Add, *Object* [, POSITION=*index*]

Arguments

Object

An instance of an object or a list of objects. Objects which subclass IDLgrScene or IDLgrViewgroup can not be added (avoiding circularity constraints). All other objects are allowed.

Keywords

POSITION

Set this keyword equal to the zero-based index of the position within the container at which the new object should be placed.

Version History

5.1	Introduced

IDLgrViewgroup::Cleanup

The IDLgrViewgroup::Cleanup procedure method performs all cleanup on the object.

Note —————————————————————————————————————

Cleanup methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation and destruction. This means that in most cases, you cannot call the Cleanup method directly. There is one exception to this rule: if you write your own subclass of this class, you can call the Cleanup method from within the Init or Cleanup method of the subclass.

Syntax

OBJ_DESTROY, *Obj*

or

Obj->[IDLgrViewgroup::]Cleanup   *(In a lifecycle method only.)*

Arguments

None

Keywords

None

Version History

5.1	Introduced

IDLgrViewgroup::GetByName

The IDLgrViewgroup::GetByName function method finds contained objects by name. If the named object is not found, the GetByName function returns a null object reference.

Note

The GetByName function does *not* perform a recursive search through the object hierarchy. If a fully qualified object name is not specified, only the contents of the current container object are inspected for the named object.

Syntax

Result = Obj->[IDLgrViewgroup::]GetByName(*Name*)

Return Value

Returns contained objects by name. If the named object is not found, the GetByName function returns a null object reference.

Arguments

Name

A string containing the name of the object to be returned.

Object naming syntax is very much like the syntax of a UNIX filesystem. Objects contained by other objects can include the name of their parent object; this allows you to create a fully qualified name specification. For example, if object1 contains object2, which in turn contains object3, the string specifying the fully qualified object name of object3 would be 'object1/object2/object3'.

Object names are specified relative to the object on which the GetByName method is called. If used at the beginning of the name string, the / character represents the top of an object hierarchy. The string '..' represents the object one level "up" in the hierarchy.

Keywords

None

Version History

5.1	Introduced

IDLgrViewgroup::GetProperty

The IDLgrViewgroup::GetProperty procedure method retrieves the value of a property or group of properties for the viewgroup object.

Syntax

Obj->[IDLgrViewgroup::]GetProperty[, *PROPERTY=variable*]

Arguments

None

Keywords

Any property listed under "IDLgrViewgroup Properties" on page 4895 that contains the word "Yes" in the "Get" column of the properties table can be retrieved using this method. To retrieve the value of a property, specify the property name as a keyword set equal to a named variable that will contain the value of the property.

Any keyword not recognized is passed to this object's superclass.

Version History

5.1	Introduced

IDLgrViewgroup::Init

The IDLgrViewgroup::Init function method initializes the viewgroup object.

Note ——————————————————————————

Init methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation. This means that in most cases, you cannot call the Init method directly. There is one exception to this rule: if you write your own subclass of this class, you can call the Init method from within the Init method of the subclass.

Syntax

Obj = OBJ_NEW('IDLgrViewgroup' [, *PROPERTY=value*])

or

Result = Obj->[IDLgrViewgroup::]Init([, *PROPERTY=value*])   *(In a lifecycle method only.)*

Return Value

When this method is called indirectly, as part of the call to the OBJ_NEW function, the return value is an object reference to the newly-created object.

When called directly within a subclass Init method, the return value is 1 if initialization was successful, or zero otherwise.

Arguments

None

Keywords

Any property listed under "IDLgrViewgroup Properties" on page 4895 that contains the word "Yes" in the "Init" column of the properties table can be initialized during object creation using this method. To initialize the value of a property, specify the property name as a keyword set equal to the appropriate property value.

All other keywords are passed to the superclass of this object.

Version History

5.1	Introduced

IDLgrViewgroup::SetProperty

The IDLgrViewgroup::SetProperty procedure method sets the value of a property or group of properties for the viewgroup.

Syntax

Obj->[IDLgrViewgroup::]SetProperty[, *PROPERTY=value*]

Arguments

None

Keywords

Any property listed under "IDLgrViewgroup Properties" on page 4895 that contains the word "Yes" in the "Set" column of the properties table can be set using this method. To set the value of a property, specify the property name as a keyword set equal to the appropriate property value.

Version History

5.1	Introduced

IDLgrVolume

A volume object represents a mapping from a three-dimensional array of data to a three-dimensional array of voxel colors, which, when drawn, are projected to two dimensions.

An IDLgrVolume object is an *atomic graphic object*; it is one of the basic drawable elements of the IDL Object Graphics system, and it is not a container for other objects.

Superclasses

IDLitComponent

Creation

See "IDLgrVolume::Init" on page 4931.

Properties

Objects of this class have the following properties. See "IDLgrVolume Properties" on page 4907 for details on individual properties.

- ALL
- AMBIENT
- CLIP_PLANES
- DATA0
- DATA2
- DEPTH_CUE
- HINTS
- LIGHTING_MODEL
- OPACITY_TABLE1
- REGISTER_PROPERTIES
- RGB_TABLE0
- SHADER

- ALPHA_CHANNEL
- BOUNDS
- COMPOSITE_FUNCTION
- DATA1
- DATA3
- HIDE
- INTERPOLATE
- OPACITY_TABLE0
- PARENT
- RENDER_STEP
- RGB_TABLE1
- TWO_SIDED

- VALID_DATA
- XCOORD_CONV
- YCOORD_CONV
- ZBUFFER
- ZERO_OPACITY_SKIP

- VOLUME_SELECT
- XRANGE
- YRANGE
- ZCOORD_CONV
- ZRANGE

In addition, objects of this class inherit the properties of all superclasses of this class.

Methods

This class has the following methods:

- IDLgrVolume::Cleanup
- IDLgrVolume::ComputeBounds
- IDLgrVolume::GetCTM
- IDLgrVolume::GetProperty
- IDLgrVolume::Init
- IDLgrVolume::PickVoxel
- IDLgrVolume::SetProperty

In addition, this class inherits the methods of its superclasses (if any).

Version History

5.0	Introduced
5.6	Added CLIP_PLANES keyword
6.0	Deprecated CUTTING_PLANES property
6.1	Added ALPHA_CHANNEL property
6.2	Removed NO_COPY property and documented as a keyword on IDLgrVolume::Init and IDLgrVolume::SetProperty
6.4	Added SHADER property

For more information on deprecated features, see Appendix I, "Obsolete Features".

IDLgrVolume Properties

IDLgrVolume objects have the following properties in addition to properties inherited from any superclasses. Properties with the word "Yes" in the "Get" column of the property table can be retrieved via IDLgrVolume::GetProperty. Properties with the word "Yes" in the "Init" column of the property table can be set via IDLgrVolume::Init. Properties with the word "Yes" in the "Set" column in the property table can be set via IDLgrVolume::SetProperty.

Note ————————————————————————————————

For a discussion of the property description tables shown below, see "About Object Property Descriptions" on page 3135.

————————————————————————————————

Objects of this class have the following properties.

- ALL
- AMBIENT
- CLIP_PLANES
- DATA0
- DATA2
- DEPTH_CUE
- HINTS
- LIGHTING_MODEL
- OPACITY_TABLE1
- REGISTER_PROPERTIES
- RGB_TABLE0

- HIDE
- INTERPOLATE
- OPACITY_TABLE0
- PARENT
- RENDER_STEP
- RGB_TABLE1
- TWO_SIDED
- VOLUME_SELECT
- XRANGE
- YRANGE
- ZCOORD_CONV
- ZRANGE

In addition, objects of this class inherit:

- IDLitComponent

ALL

An anonymous structure containing the values of all of the properties associated with the *state* of this object. State information about the object includes things like color, range, tick direction, etc., but not image, vertex, or connectivity data, or user values.

Note ———
The fields of this structure may change in subsequent releases of IDL.

Note ———
This structure returns COLOR, DEPTH_TEST_DISABLE, DEPTH_TEST_FUNCTION, and DEPTH_WRITE_DISABLE properties that are consistent with other graphic objects. However, these properties are not used by the IDLgrVolume object.

Property Type	Structure		
Name String	*not displayed*		
Get: Yes	Set: No	Init: No	Registered: No

ALPHA_CHANNEL

Apply to the volume only when the volume is rendered with a destination rendering quality setting of Low (0). In the case, the volume is rendered as a wireframe cube. Set this property to a floating-point value in the range [0.0, 1.0] to specify the opacity of the wireframe cube. The default value of 1.0 causes IDL to draw the wireframe cube completely opaque. If the value of this property is less than 1.0, then the pixels of the wireframe cube are blended with the pixels already on the screen, where the color of the wireframe cube is multiplied by the alpha value and the pixels already on the screen are multiplied by 1.0-alpha.

Because an object can only be blended with objects already drawn on the screen, the drawing order of the objects must be considered carefully in order to obtain the desired results.

This property has no effect on devices using indexed color mode.

Note ──

For more detailed information on alpha channel support for IDL Object Graphics, see "Controlling Object Transparency" (Chapter 2, *Object Programming*).

──

Property Type	Float-point value		
Name String	*Transparency*		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** Yes

AMBIENT

The color and intensity of the volume's base ambient lighting. Color is specified as a three-element vector [*red*, *green*, *blue*]. The default is [255, 255, 255]. AMBIENT is applicable only when LIGHTING_MODEL is set.

In a property sheet, this property appears as a color property.

Property Type	COLOR		
Name String	Ambient color		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** Yes

BOUNDS

A six-element floating-point vector of the form $[x_{min}, y_{min}, z_{min}, x_{max}, y_{max}, z_{max}]$, which represents the sub-volume to be rendered. .

This property is registered as a user-defined property, but it is hidden by default.

Property Type	USERDEF		
Name String	Subvolume bounds		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** Yes

CLIP_PLANES

A 4-by-*N* floating-point array that specifies the coefficients of the clipping planes to be applied to this object. The four coefficients for each clipping plane are of the form [A, B, C, D], where $Ax + By + Cz + D = 0$. Portions of this object that fall in the half space $Ax + By + Cz + D > 0$ will be clipped. By default, the value of this property is a scalar (-1) indicating that no clipping planes are to be applied.

Note ——————————————————————————————————
The clipping planes specified via this property are applied in addition to the near and far clipping planes associated with the IDLgrView in which this object appears.
——————————————————————————————————————

Note ——————————————————————————————————
Clipping planes are applied in the data space of this object (prior to the application of any *x*, *y*, or *z* coordinate conversion).
——————————————————————————————————————

Note ——————————————————————————————————
To determine the maximum number of clipping planes supported by the device, use the MAX_NUM_CLIP_PLANES property of the GetDeviceInfo method for the IDLgrBuffer, IDLgrClipboard, IDLgrWindow, and IDLgrVRML objects.
——————————————————————————————————————

Note ——————————————————————————————————
Clipping planes are equivalent to the obsolete cutting planes. If defined, CUTTING_PLANES will be applied first, then the CLIP_PLANES (until a maximum number of planes is reached).
——————————————————————————————————————

Property Type	Floating-point array		
Name String	*not displayed*		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** No

COMPOSITE_FUNCTION

An integer value or enumerated list item that determines the composite function to be used to measure the value of a pixel on the viewing plane by analyzing the voxels

falling along the corresponding ray. Specify one of the following compositing functions:

Value	Property Sheet Value	Description

0	Alpha blending	The recursive equation
		
		`dest' = src * srcalpha +`
		`    dest * (1 - srcalpha)`
		
		is used to compute the final pixel color (the default).

1	Maximum intensity projection	The color of each pixel on the viewing plane is determined by the voxel with the highest opacity value along the corresponding ray.

2	Alpha sum	The recursive equation
		
		`dest' = src + dest *`
		`    ( 1 - srcalpha)`
		
		is used to compute the final pixel color. This equation assumes that the color tables have been pre-multiplied by the opacity tables. The accumulated values can be no greater than 255.

3	Average intensity	The resulting image is the average of all voxels along the corresponding ray. Disables lighting and only works with grey scale palettes. Will not work with four-channel volumes.

Property Type	ENUMLIST		
Name String	Composite function		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** Yes

DATA0

A three-dimensional array of any type of the format (d_x, d_y, d_z), which specifies a data volume. If the data volume dimensions do not match those of any pre-existing data in DATA1, DATA2, or DATA3, all existing data is removed from the object.

Specifying this property is the same as specifying the optional vol_0 argument to the IDLgrVolume::Init method.

Note ───

IDL converts and stores volume data in a BYTE array. Thus, all incoming volume data is converted to BYTE type. This could alter the volume data values if the incoming data cannot accurately be stored as BYTE data.

───

Property Type	Array of any type		
Name String	*not displayed*		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** No

DATA1

A three-dimensional array of any type of the format (d_x, d_y, d_z), which specifies a data volume. If the data volume dimensions do not match those of any pre-existing data in DATA0, DATA2, or DATA3, all existing data is removed from the object.

Specifying this property is the same as specifying the optional vol_1 argument to the IDLgrVolume::Init method.

Note ───

IDL converts and stores volume data in a BYTE array. Thus, all incoming volume data is converted to BYTE type. This could alter the volume data values if the incoming data cannot accurately be stored as BYTE data.

───

Property Type	Array of any type		
Name String	*not displayed*		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** No

DATA2

A three-dimensional array of any type of the format (d_x, d_y, d_z), which specifies a data volume. If the data volume dimensions do not match those of any pre-existing data in DATA0, DATA1, or DATA3, all existing data is removed from the object.

Specifying this property is the same as specifying the optional vol_2 argument to the IDLgrVolume::Init method.

Note

IDL converts and stores volume data in a BYTE array. Thus, all incoming volume data is converted to BYTE type. This could alter the volume data values if the incoming data cannot accurately be stored as BYTE data.

Property Type	Array of any type		
Name String	*not displayed*		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** No

DATA3

A three-dimensional array of any type of the format (d_x, d_y, d_z), which specifies a data volume. If the data volume dimensions do not match those of any pre-existing data in DATA0, DATA1, or DATA2, all existing data is removed from the object.

Specifying this property is the same as specifying the optional *vol$_3$* argument to the IDLgrVolume::Init method.

Note

DATA0, DATA1, DATA2, and DATA3 sizes are dynamic.

Note

IDL converts and stores volume data in a BYTE array. Thus, all incoming volume data is converted to BYTE type. This could alter the volume data values if the incoming data cannot accurately be stored as BYTE data.

Property Type	Array of any type		
Name String	*not displayed*		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** No

DEPTH_CUE

A two-element floating-point array [*zbright*, *zdim*] specifying the near and far Z planes between which depth cueing is in effect. Depth cueing is only honored when drawing to a destination object that uses the RGB color model.

Depth cueing causes an object to appear to fade into the background color of the view object with changes in depth. If the depth of an object is further than *zdim* (that is, if

the object's location in the Z direction is farther from the origin than the value specified by *zdim*), the object will be painted in the background color.

Similarly, if the object is closer than the value of *zbright*, the object will appear in its "normal" color. Anywhere in-between, the object will be a blend of the background color and the object color. For example, if the DEPTH_CUE property is set to [-1,1], an object at the depth of 0.0 will appear as a 50% blend of the object color and the view color.

The relationship between Z_{bright} and Z_{dim} determines the result of the rendering:

- $Z_{bright} < Z_{dim}$: Rendering darkens with depth.

- $Z_{bright} > Z_{dim}$: Rendering brightens with depth.

- $Z_{bright} = Z_{dim}$: Disables depth cueing.

You can disable depth cueing by setting $z_{bright} = z_{dim}$. The default is [0.0, 0.0].

This property is registered as a user-defined property, but it is hidden by default.

Property Type	USERDEF		
Name String	Depth cue range		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

HIDE

A Boolean value or enumerated list item indicating whether this object should be drawn:

Value	Property Sheet Value	Description
0	True	Draw graphic (the default)
1	False	Do not draw graphic

Property Type	ENUMLIST		
Name String	Show		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

HINTS

An integer value or enumerated list item that specifies one of the following acceleration hints:

Value	Property Sheet Value	Description
0	Disable	Disables all acceleration hints (the default).
1	Euclidean distance map (EDM)	Enables Euclidean distance map (EDM) acceleration. This option generates a volume map containing the distance from any voxel to the nearest non-zero opacity voxel. The map is used to speed ray casting by allowing the ray to jump over open spaces. It is most useful with sparse volumes. After setting the EDM hint, the draw operation generates the volume map; this process can take some time. Subsequent draw operations will reuse the generated map and may be much faster, depending on the volume's sparseness. A new map is not automatically generated to match changes in opacity tables or volume data (for performance reasons). The user may force recomputation of the EDM map by setting the HINTS property to 1 again.
2	Multiple CPU	Enables the use of multiple CPUs for volume rendering if the platforms used support such use. If HINTS is set to 2, IDL will use all the available (up to 8) CPUs to render portions of the volume in parallel.
3	EDM and Multiple CPU	Selects the two acceleration options described above

Property Type	ENUMLIST		
Name String	Acceleration hints		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** Yes

INTERPOLATE

A Boolean value or enumerated list item that determines whether the interpolation method.

Value	Property Sheet Value	Description
0	Nearest neighbor	Values between the voxels are estimated using nearest neighbor sampling (the default).
1	Trilinear	Values for each step on a ray are computed from the eight nearest values. Setting this property improves quality at the cost of more computing time, especially when the volume has low resolution with respect to the size of the viewing plane.

Note —————————————————————————————

See "Interpolation Methods" (Chapter 5, *Using IDL*) for details.

—————————————————————————————————————

Property Type	ENUMLIST		
Name String	Interpolation		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** Yes

LIGHTING_MODEL

A Boolean value that determines whether to use the current lighting model during rendering in conjunction with a local gradient evaluation.

Note —————————————————————————————

Only DIRECTIONAL light sources are honored by the volume object. Because normals must be computed for all voxels in a lighted view, enabling light sources increases the rendering time.

—————————————————————————————————————

Property Type	Boolean		
Name String	Use lighting		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** Yes

OPACITY_TABLE0

A 256-element byte array that specifies the opacity table for DATA0. The default table is the linear ramp.

Property Type	Byte array		
Name String	*not displayed*		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** No

OPACITY_TABLE1

A 256-element byte array that specifies the opacity table for DATA1. The default table is the linear ramp. This table is used only when VOLUME_SELECT is set equal to 1.

Property Type	Byte array		
Name String	*not displayed*		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** No

PARENT

An object reference to the object that contains this object.

Property Type	Object reference		
Name String	*not displayed*		
Get: Yes	**Set:** No	**Init:** No	**Registered:** No

REGISTER_PROPERTIES

A Boolean value that determines whether to register properties available for this object. If this property is set, all properties marked in this properties section as

"Registered: Yes" will be registered for display in a property sheet. This property is useful mainly when creating iTools. By default, no properties are registered.

Property Type	Boolean		
Name String	*not displayed*		
Get: No	Set: No	Init: Yes	Registered: No

RENDER_STEP

A three-element floating-point vector of the form [*x*, *y*, *z*] that specifies the stepping factor through the voxel matrix.

This property is registered as a user-defined property, but it is hidden by default.

Property Type	USERDEF		
Name String	XYZ render step		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

RGB_TABLE0

A 256 x 3-element byte array that specifies the RGB color table for DATA0. The default table is the linear ramp. .

Property Type	Byte array		
Name String	*not displayed*		
Get: Yes	Set: Yes	Init: Yes	Registered: No

RGB_TABLE1

A 256 x 3-element byte array that specifies the RGB color table for DATA1. The default table is the linear ramp. This table is used only when VOLUME_SELECT is set equal to 1.

Property Type	Byte array		
Name String	*not displayed*		
Get: Yes	Set: Yes	Init: Yes	Registered: No

SHADER

An object reference to an IDLgrShader object (or an object containing IDLgrShader as a superclass). When there is suitable graphics card hardware support, the volume is rendered using the GLSL shader program (executed on the graphics card) instead of using fixed OpenGL properties when initially drawn. (If a suitable graphics card is not present, IDL ignores the shader object when the scene is drawn.) A single IDLgrShader object may be associated with additional volume objects or other graphic objects that have the SHADER property.

Property Type	Object reference		
Name String	*not displayed*		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** No

TWO_SIDED

A Boolean value or an enumerated list item that determines whether the lighting model uses a two-sided voxel gradient.

Value	**Property Sheet Value**	**Description**
0	One-sided	The default.
1	Two-sided	Differs from one-sided in that this method uses the absolute value of the inner product of the light direction and the surface gradient instead of clamping to 0.0 for negative values.

Property Type	ENUMLIST		
Name String	Voxel gradient		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** Yes

VALID_DATA

An integer array (one per volume, DATA0, DATA1, etc.) which have the value 1 if volume data has been loaded for that volume and 0 if that volume data is currently undefined.

Property Type	Integer array		
Name String	*not displayed*		
Get: Yes	**Set:** No	**Init:** No	**Registered:** No

VOLUME_SELECT

An integer value that selects how the volume data (DATA0, DATA1, DATA2, DATA3) is combined to form the src and srcalpha parameters described in the COMPOSITE_FUNCTION function property.

The volume data is always stored and treated as 8-bit indices into the RGB and opacity tables.

Set the RGB and/or opacity tables to linear ramps to use the volume data as direct color or opacity values. Accepted values are:

0	Render single volume from DATA0. This is the default. The value at voxel [i,j,k] would be computed as:
	
	 ```srcRed[i,j,k] = RGB_TABLE0[DATA0[i,j,k],0]```
	 ```srcGreen[i,j,k] = RGB_TABLE0[DATA0[i,j,k],1]```
	 ```srcBlue[i,j,k] = RGB_TABLE0[DATA0[i,j,k],2]```
	 ```srcAlpha[i,j,k] = OPACITY_TABLE0[DATA0[i,j,k]]```

1	Render dual volume from DATA0 and DATA1. The value at voxel [i,j,k] is modulated between the two data sets as follows:
	
	``
	srcRed[i,j,k] = (RGB_TABLE0[DATA0[i,j,k],0] *
	                  RGB_TABLE1[DATA1[i,j,k],0]) / 255
	srcGreen[i,j,k] = (RGB_TABLE0[DATA0[i,j,k],1] *
	                    RGB_TABLE1[DATA1[i,j,k],1]) / 255
	srcBlue[i,j,k] = (RGB_TABLE0[DATA0[i,j,k],2] *
	                   RGB_TABLE1[DATA1[i,j,k],2]) / 255
	srcAlpha[i,j,k] = (OPACITY_TABLE0[DATA0[i,j,k]] *
	                    OPACITY_TABLE1[DATA1[i,j,k]]) / 255
	``

2	Render RGBA volume from DATA0 (red), DATA1 (green), DATA2 (blue), and DATA3 (alpha). The value at voxel [i,j,k] would be computed as: ``` srcRed[i,j,k] = RGB_TABLE0[DATA0[i,j,k],0] srcGreen[i,j,k] = RGB_TABLE0[DATA1[i,j,k],1] srcBlue[i,j,k] = RGB_TABLE0[DATA2[i,j,k],2] srcAlpha[i,j,k] = OPACITY_TABLE0[DATA3[i,j,k]] ```

Property Type	Integer		
Name String	*not displayed*		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** No

XCOORD_CONV

A floating-point vector, $[s_0, s_1]$, of scaling factors used to convert X coordinates from data units to normalized units. The formula for the conversion is as follows:

Normalized$X = s_0 + s_1 *$ Data$X$

Recommended values are:

$[(-X_{min})/(X_{max}-X_{min}), 1/(X_{max}-X_{min})]$

The default is [0.0, 1.0]. IDL converts, maintains, and returns this data as double-precision floating-point.

Property Type	Floating-point vector		
Name String	*not displayed*		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** No

XRANGE

A two-element double-precision floating-point vector of the form [*xmin*, *xmax*] that specifies the range of *x* data coordinates covered by the graphic object.

Property Type	Floating-point vector		
Name String	*not displayed*		
Get: Yes	Set: No	Init: No	Registered: No

YCOORD_CONV

A floating-point vector, [s_0, s_1], of scaling factors used to convert Y coordinates from data units to normalized units. The formula for the conversion is as follows:

$$Normalized Y = s_0 + s_1 * Data Y$$

Recommended values are:

$$[(-Y_{min})/(Y_{max}-Y_{min}), 1/(Y_{max}-Y_{min})]$$

The default is [0.0, 1.0]. IDL converts, maintains, and returns this data as double-precision floating-point.

Property Type	Floating-point vector		
Name String	*not displayed*		
Get: Yes	Set: Yes	Init: Yes	Registered: No

YRANGE

A two-element double-precision floating-point vector of the form [*ymin*, *ymax*] that specifies the range of *y* data coordinates covered by the graphic object.

Property Type	Floating-point vector		
Name String	*not displayed*		
Get: Yes	Set: No	Init: No	Registered: No

ZBUFFER

A Boolean value that determines whether to clip the rendering to the current Z-buffer and then update the buffer. The default is to not modify the current Z-buffer.

Property Type	Boolean		
Name String	Update Z buffer		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** Yes

ZCOORD_CONV

A floating-point vector, [s_0, s_1], of scaling factors used to convert Z coordinates from data units to normalized units. The formula for the conversion is as follows:

$$Normalized Z = s_0 + s_1 * Data Z$$

Recommended values are:

$$[(-Z_{min})/(Z_{max}-Z_{min}), 1/(Z_{max}-Z_{min})]$$

The default is [0.0, 1.0]IDL converts, maintains, and returns this data as double-precision floating-point.

Property Type	Floating-point vector		
Name String	*not displayed*		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** No

ZERO_OPACITY_SKIP

A Boolean value that determines whether to skip voxels with an opacity of 0. This property can increase the output contrast of MIP (MAXIMUM_INTENSITY) projections by allowing the background to show through. If this property is set, voxels with an opacity of zero will not modify the Z-buffer. The default (not setting the property) continues to render voxels with an opacity of zero.

Property Type	Boolean		
Name String	Skip zero opacity		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** Yes

ZRANGE

A two-element double-precision floating-point vector of the form [*zmin*, *zmax*] that specifies the range of *z* data coordinates covered by the graphic object.

Property Type	Floating-point vector		
Name String	*not displayed*		
Get: Yes	Set: No	Init: No	Registered: No

IDLgrVolume::Cleanup

The IDLgrVolume::Cleanup procedure method performs all cleanup on the object.

Note

Cleanup methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation and destruction. This means that in most cases, you cannot call the Cleanup method directly. There is one exception to this rule: if you write your own subclass of this class, you can call the Cleanup method from within the Init or Cleanup method of the subclass.

Syntax

OBJ_DESTROY, *Obj*

or

Obj->[IDLgrVolume::]Cleanup   *(In a lifecycle method only.)*

Arguments

None

Keywords

None

Version History

5.0	Introduced

IDLgrVolume::ComputeBounds

The IDLgrVolume::ComputeBounds procedure method computes the smallest bounding box that contains all voxels whose opacity lookup is greater than a given opacity value. The BOUNDS property is updated to the computed bounding box.

Syntax

Obj->[IDLgrVolume::]ComputeBounds [, OPACITY=*value*] [, /RESET]
    [, VOLUMES=*int array*]

Arguments

None

Keywords

OPACITY

Set this keyword to the opacity value to be used to determine which voxels are included within the bounding box. All voxels whose opacity lookup is greater than this value will be included. The default value is zero.

RESET

Set this keyword to cause the BOUNDS keyword of IDLgrVolume::Init to be reset to contain the entire volume.

VOLUMES

Set this keyword to an array of integers which select which volumes to consider when computing the bounding box. A non-zero value selects a volume to be searched. The default is to search all loaded volumes. For example: VOLUMES=[0,1] will cause ComputeBounds to search only the volume loaded in DATA1.

Version History

5.0	Introduced

IDLgrVolume::GetCTM

The IDLgrVolume::GetCTM function method returns the 4-by-4 double-precision floating-point graphics transform matrix from the current object upward through the graphics tree.

Syntax

Result = Obj->[IDLgrVolume::]GetCTM([, DESTINATION=*objref*]
   [, PATH=*objref(s)*] [, TOP=*objref to IDLgrModel object*])

Return Value

Returns the 4-by-4 double-precision floating-point graphics transform matrix from the current object upward through the graphics tree.

Arguments

None

Keywords

DESTINATION

Set this keyword to the object reference of a destination object to specify that the projection matrix for the View object in the current tree be included in the returned transformation matrix. The resulting matrix will transform a point in the data space of the object on which the GetCTM method is called into a normalized coordinate system (-1 to +1 in X, Y, and Z), relative to the View object that contains the volume object.

PATH

Set this keyword to a single object reference or a vector of object references. This keyword specifies the path in the graphics hierarchy to compute the transformation matrix. Each path object reference specified with this keyword must contain an alias. The transformation matrix is computed for the version of the object falling within that path. If this keyword is not set, the PARENT properties determine the path from the current object to the top of the graphics hierarchy and no alias paths are pursued. If IDLgrVolume::GetCTM is called from within a Draw method, with the DESTINATION keyword set and the PATH keyword not set, the alias path used to find the object during the draw is used, rather than the PARENT path.

Note ———
For more information on aliases, refer to the ALIAS keyword in IDLgrModel::Add.
———

TOP

Set this keyword equal to the object reference to an IDLgrModel object to specify
that the returned matrix accumulate from the object on which the GetCTM method is
called up to but not including the specified model object.

Version History

5.0	Introduced

IDLgrVolume::GetProperty

The IDLgrVolume::GetProperty procedure method retrieves the value of a property or group of properties for the volume.

Syntax

Obj->[IDLgrVolume::]GetProperty[, *PROPERTY=variable*] [, /NO_COPY]

Arguments

None

Keywords

Any property listed under "IDLgrVolume Properties" on page 4907 that contains the word "Yes" in the "Get" column of the properties table can be retrieved using this method. To retrieve the value of a property, specify the property name as a keyword set equal to a named variable that will contain the value of the property.

Any keyword not recognized is passed to this object's superclass.

NO_COPY

If this keyword is set to a non-zero value, and the DATA0, DATA1, DATA2, or DATA3 property is specified in the same invocation, the data is relocated from the volume object into the destination variable, removing the data from the object.

```
vol = BYTARR(30,30,30, /NOZERO)
oVol = OBJ_NEW('IDLgrVolume')
oVol->SetProperty, DATA0=vol

oVol->GetProperty, DATA0=vol, /NO_COPY
HELP, vol
; IDL prints VOL BYTE = Array[30, 30, 30]

; Verify that the data has been removed from the object by
; repeating the call.
oVol->GetProperty, DATA0=vol2, /NO_COPY
HELP, vol2
; IDL prints VOL2 UNDEFINED = <Undefined>
```

There can be 1, 2, 3, or 4 volumes stored in an IDLgrVolume. Calling Get with NO_COPY is a good way to remove the data associated with one of the volumes without destroying the object.

Version History

5.0	Introduced
6.1	Added NO_COPY keyword

IDLgrVolume::Init

The IDLgrVolume::Init function method initializes the volume object. At least one volume must be specified, via arguments or keywords.

Note ———————————————————————————————

Init methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation. This means that in most cases, you cannot call the Init method directly. There is one exception to this rule: if you write your own subclass of this class, you can call the Init method from within the Init method of the subclass.

———————————————————————————————

Note ———————————————————————————————

IDL converts and stores volume data in a BYTE array. Thus, all incoming volume data is converted to BYTE type. This could alter the volume data values if the incoming data cannot accurately be stored as BYTE data.

———————————————————————————————

Syntax

Obj = OBJ_NEW('IDLgrVolume' [, *vol$_0$* [, *vol$_1$* [, *vol$_2$* [, *vol$_3$*]]]]
   [, *PROPERTY=value*] [, /NO_COPY])

or

Result = *Obj*->[IDLgrVolume::]Init([*vol$_0$* [, *vol$_1$* [, *vol$_2$* [, *vol$_3$*]]]]
   [, *PROPERTY=value*] [, /NO_COPY])   *(In a lifecycle method only.)*

Return Value

When this method is called indirectly, as part of the call to the OBJ_NEW function, the return value is an object reference to the newly-created object.

When called directly within a subclass Init method, the return value is 1 if initialization was successful, or zero otherwise.

Arguments

Note ———————————————————————————————

The values specified by the *vol$_0$*, *vol$_1$*, *vol$_2$*, and *vol$_3$* arguments are used to initialize the values of the DATA0, DATA1, DATA2, and DATA3 properties of the IDLgrVolume object, respectively.

———————————————————————————————

vol$_0$

A three-dimensional array (d_x, d_y, d_z) which specifies a data volume.

vol$_1$

A three-dimensional array (d_x, d_y, d_z) which specifies a data volume.

vol$_2$

A three-dimensional array (d_x, d_y, d_z) which specifies a data volume.

vol$_3$

A three-dimensional array (d_x, d_y, d_z) which specifies a data volume.

Note

If two or more of the above arguments are specified, they must have matching dimensions.

Keywords

Any property listed under "IDLgrVolume Properties" on page 4907 that contains the word "Yes" in the "Init" column of the properties table can be initialized during object creation using this method. To initialize the value of a property, specify the property name as a keyword set equal to the appropriate property value.

All other keywords are passed to the superclass of this object.

NO_COPY

If this keyword is set to a non-zero value, it relocates the volume data from the input variable to the volume object, leaving the input variable (*vol$_0$*, *vol$_1$*, *vol$_2$*, *vol$_3$*, or DATA0, DATA1, DATA2, or DATA3) undefined. Only these data-related arguments and properties are affected by the NO_COPY keyword.

```
vol = BYTARR(30,30,30, /NOZERO)
oVol = OBJ_NEW('IDLgrVolume', vol, /NO_COPY)

; Verify the data no longer exists in the input variable.
HELP, vol
; IDL prints VOL UNDEFINED = <Undefined>
```

If this keyword is omitted, the input volume data will be duplicated and a copy will be stored in the object.

Version History

5.0	Introduced
6.2	Added NO_COPY keyword

IDLgrVolume::PickVoxel

The IDLgrVolume::PickVoxel function method computes the coordinates of the voxel projected to a location specified by the 2-D device coordinates point, [x_i, y_i], and the current Z-buffer. The function returns the volume indices as a a vector of three long integers. If the selected point is not within the volume, this function returns [-1,-1,-1].

Syntax

Result = Obj->[IDLgrVolume::]PickVoxel (*Win*, *View*, *Point* [, PATH=*objref(s)*])

Return Value

Returns the volume indices as a a vector of three long integers. If the selected point is not within the volume, this function returns [-1,-1,-1].

Arguments

Win

The IDLgrWindow object from which the Z-buffer is to be used.

View

The IDLgrView object that contains the volume.

Point

The [*x*, *y*] viewport coordinates of the point chosen.

Keywords

PATH

Set this keyword to a single object reference or a vector of object references. This keyword specifies the path in the graphics hierarchy to map the device position to a voxel coordinate. Each path object reference specified with this keyword must contain an alias. The voxel coordinate is computed for the version of the object falling within the specified path. If this keyword is not set, the PARENT properties determine the path from the current object to the top of the graphics hierarchy and no alias paths are pursued.

Note ————

For more information on aliases, refer to the ALIAS keyword in IDLgrModel::Add.

————

Version History

5.0	Introduced

IDLgrVolume::SetProperty

The IDLgrVolume::SetProperty procedure method sets the value of a property or group of properties for the volume.

Syntax

Obj->[IDLgrVolume::]SetProperty[, *PROPERTY=value*] [/NO_COPY]

Arguments

None

Keywords

Any property listed under "IDLgrVolume Properties" on page 4907 that contains the word "Yes" in the "Set" column of the properties table can be set using this method. To set the value of a property, specify the property name as a keyword set equal to the appropriate property value.

NO_COPY

If this keyword is set to a non-zero value, it relocates the volume data from the input variable to the volume object, leaving the input variable (DATA0, DATA1, DATA2, or DATA3) undefined. Only these data-related arguments and properties are affected by the NO_COPY keyword.

```
vol = BYTARR(30,30,30, /NOZERO)
oVol = OBJ_NEW('IDLgrVolume')
oVol->SetProperty, Data0=vol, /NO_COPY

; Verify that the data has been removed from the variable.
HELP, vol
; IDL prints VOL UNDEFINED = <Undefined>
```

If this keyword is omitted, the input volume data will be duplicated and a copy will be stored in the object.

Version History

5.0	Introduced
6.2	Added NO_COPY keyword

IDLgrVRML

The IDLgrVRML object allows you to save the contents of an Object Graphics hierarchy into a VRML 2.0 format file. The graphics tree can only contain a single view due to limitations in the VRML specification. The resulting VRML file is interactive and allows you to explore the geometry interactively using a VRML browser.

Note
Objects or subclasses of this type can not be saved or restored.

Note
Tiled images are not supported on IDLgrVRML.

Aspect ratios are difficult to duplicate as they can be browser dependent. The object is limited to the primitives supported by VRML. Texture maps (and images) will be inlined into the output file. While this will generate large VRML files, the files are fully self-contained.

Several entities cannot be translated perfectly. These include:

IDLgrImage Objects

Rotation and Z buffer behavior are not completely supported. Image objects will be converted into texture mapped polygons. BLEND_FUNCTION is not completely supported (only binary srcAlpha,1-srcAlpha) This function is applied automatically if an alpha channel is present. It is also very browser dependent. Channel masks are not supported.

IDLgrPolygon and IDLgrSurface Objects

Hidden line/hidden point display, color and vertex color blending with texture colors, and bottom color are not supported. Shading may be browser dependent. Front face culling is not supported and back face culling is only supported at the browser's discretion.

Note
The AMBIENT material property is not supported.

IDLgrLight Objects

Lighting scope and intensity may be browser dependent.

IDLgrText Objects

Text using the ONGLASS property is only supported for the initial view.

IDLgrViewgroup, IDLgrScene, IDLgrVolume Objects

These objects are not supported.

IDLgrPalette Objects

Palette objects are simulated using an RGB color model.

IDLgrPattern Objects

Only solid or clear patterns are supported.

IDLgrFont, IDLgrSymbol Objects

The THICK property is not supported.

IDLgrPolyline, IDLgrSymbol, IDLgrSurface, IDLgrPolygon and IDLgrPlot Objects

Line attributes (thickness, linestyle) are not supported.

IDLgrView Objects

Z-clipping control, aspect ratio preservation, the LOCATION property, and orthographic projections are not supported.

Destination Objects

The COLOR_MODEL property is not fully supported in Indexed Color mode, when using a SHADER_RANGE (an RGB model will be substituted instead). The QUALITY property is not supported.

Superclasses

IDLitComponent

Creation

See "IDLgrVRML::Init" on page 4957.

Properties

Objects of this class have the following properties. See "IDLgrVRML Properties" on page 4942 for details on individual properties.

- ALL
- COLOR_MODEL
- DIMENSIONS
- FILENAME
- GRAPHICS_TREE
- N_COLORS
- PALETTE
- QUALITY
- REGISTER_PROPERTIES
- RESOLUTION
- SCREEN_DIMENSIONS
- UNITS
- WORLDINFO
- WORLDTITLE

In addition, objects of this class inherit the properties of all superclasses of this class.

Methods

This class has the following methods:

- IDLgrVRML::Cleanup
- IDLgrVRML::Draw
- IDLgrVRML::GetDeviceInfo
- IDLgrVRML::GetFontnames
- IDLgrVRML::GetProperty
- IDLgrVRML::GetTextDimensions
- IDLgrVRML::Init

- IDLgrVRML::SetProperty

In addition, this class inherits the methods of its superclasses (if any).

Version History

5.1	Introduced

IDLgrVRML Properties

IDLgrVRML objects have the following properties in addition to properties inherited from any superclasses. Properties with the word "Yes" in the "Get" column of the property table can be retrieved via IDLgrVRML::GetProperty. Properties with the word "Yes" in the "Init" column of the property table can be set via IDLgrVRML::Init. Properties with the word "Yes" in the "Set" column in the property table can be set via IDLgrVRML::SetProperty.

Note ————————————————————————————————

For a discussion of the property description tables shown below, see "About Object Property Descriptions" on page 3135.

——

Objects of this class have the following properties.

- ALL
- COLOR_MODEL
- DIMENSIONS
- FILENAME
- GRAPHICS_TREE
- N_COLORS
- PALETTE
- QUALITY
- REGISTER_PROPERTIES
- RESOLUTION
- SCREEN_DIMENSIONS
- UNITS
- WORLDINFO
- WORLDTITLE

In addition, objects of this class inherit:

- IDLitComponent

ALL

An anonymous structure containing the values of all of the retrievable properties associated with this object.

Property Type	Structure		
Name String	*not displayed*		
Get: Yes	**Set:** No	**Init:** No	**Registered:** No

COLOR_MODEL

An integer value or enumerated list item that determines the color model for the buffer:

Value	Property Sheet Value	Description
0	RGB	RGB (default)
1	Indexed	Color indexed

Property Type	ENUMLIST		
Name String	Color model		
Get: Yes	**Set:** No	**Init:** Yes	**Registered:** Yes

DIMENSIONS

A two-element integer vector of the form [*width*, *height*] to specify the dimensions of the window in units specified by the UNITS property. The default is [640,480].

Note

The only use of this property is to support the use of normalized coordinates for the dimensions of the IDLgrView object passed to the IDLgrVRML::Draw method.

Property Type	Integer vector		
Name String	*not displayed*		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** No

FILENAME

A string that specifies the name of a file into which the vector data will be saved. The default is `idl.wrl`.

Property Type	String		
Name String	*not displayed*		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** No

GRAPHICS_TREE

An object reference of type IDLgrView. If this property is set to a valid object reference, calling the Draw method on the destination object with no arguments will cause the object reference associated with this property to be drawn. If this object is valid and the destination object is destroyed, this object reference will be destroyed as well. By default the GRAPHICS_TREE property is set equal to the null-object. .

Property Type	Object reference		
Name String	*not displayed*		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** No

N_COLORS

An integer that specifies the number of colors (between 2 and 256) to be used if COLOR_MODEL is set to indexed.

Property Type	Integer		
Name String	Number of colors		
Get: Yes	**Set:** No	**Init:** Yes	**Registered:** Yes

PALETTE

An object reference to a palette object (an instance of the IDLgrPalette object class) that specifies the red, green, and blue values that are to be loaded into the buffer's color lookup table.

Note ———

Objects specified via this property are not automatically cleaned up when the IDLgrVRML object is destroyed.

This property is registered as a user-defined property, but it is hidden by default.

Property Type	USERDEF		
Name String	Color palette		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** Yes

QUALITY

An integer value or enumerated list item indicating the rendering quality at which graphics are to be drawn to the buffer:

Value	Property Sheet Value	Description
0	Low	Low quality
1	Medium	Medium quality
2	High	High quality (the default)

Property Type	ENUMLIST		
Name String	Quality		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** Yes

REGISTER_PROPERTIES

A Boolean value that determines whether to register properties available for this object. If this property is set, all properties marked in this properties section as "Registered: Yes" will be registered for display in a property sheet. This property is useful mainly when creating iTools. By default, no properties are registered.

Property Type	Boolean		
Name String	*not displayed*		
Get: No	**Set:** No	**Init:** Yes	**Registered:** No

RESOLUTION

A two-element floating-point vector of the form [*xres*, *yres*] specifying the device resolution in centimeters per pixel.

Note ———————————————————————————————————

This property is used for text scaling and partial aspect ratio preservation only. The default value is [0.0352778, 0.0352778] (72 DPI).

——

This property is registered as a user-defined property, but it is hidden by default.

Property Type	USERDEF		
Name String	Resolution		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** Yes

SCREEN_DIMENSIONS

A two-element integer vector of the form [*width*, *height*] specifying the dimensions of the overall screen dimensions for the screen with which this object associated. The screen dimensions are measured in device units.

Property Type	Integer vector		
Name String	*not displayed*		
Get: Yes	**Set:** No	**Init:** No	**Registered:** No

UNITS

An integer that indicates the units of measure for the DIMENSIONS property. Valid values are:

- 0 = Device (the default)
- 1 = Inches
- 2 = Centimeters
- 3 = Normalized (relative to 1600 x 1200)

.

Property Type	Integer		
Name String	*not displayed*		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** No

WORLDINFO

A list of strings for the info field of the VRML WorldInfo node. The default is the null string, ''.

Property Type	String		
Name String	*not displayed*		
Get: No	**Set:** No	**Init:** Yes	**Registered:** No

WORLDTITLE

A string containing the title for the VRML WorldInfo node, TITLE field. The default is `'IDL VRML file'`.

Property Type	String		
Name String	*not displayed*		
Get: No	**Set:** No	**Init:** Yes	**Registered:** No

IDLgrVRML::Cleanup

The IDLgrVRML::Cleanup procedure method performs all cleanup on the object.

Note

Cleanup methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation and destruction. This means that in most cases, you cannot call the Cleanup method directly. There is one exception to this rule: if you write your own subclass of this class, you can call the Cleanup method from within the Init or Cleanup method of the subclass.

Syntax

OBJ_DESTROY, *Obj*

or

Obj->[IDLgrVRML::]Cleanup   *(In a lifecycle method only.)*

Arguments

None

Keywords

None

Version History

5.1	Introduced

IDLgrVRML::Draw

The IDLgrVRML::Draw procedure method draws the given picture to this graphics destination.

Syntax

Obj->[IDLgrVRML::]Draw [, *Picture*]

Arguments

Picture

The view (an instance of an IDLgrView object) to be drawn. If the view has a LOCATION property, it is ignored.

Keywords

None

Version History

5.1	Introduced

IDLgrVRML::GetDeviceInfo

The IDLgrVRML::GetDeviceInfo procedure method returns information which allows IDL applications to intelligently make decisions for optimal performance. For example, it allows an application to determine if RENDERER=1 is actually implemented in hardware. It also allows applications to make optimal quality decisions when dynamically building texture maps.

Syntax

Obj->[IDLgrVRML::]GetDeviceInfo [, ALL=*variable*]
   [, MAX_NUM_CLIP_PLANES=*variable*]
   [, MAX_TEXTURE_DIMENSIONS=*variable*]
   [, MAX_VIEWPORT_DIMENSIONS=*variable*] [, NAME=*variable*]
   [, NUM_CPUS=*variable*] [, VENDOR=*variable*] [, VERSION=*variable*]

Arguments

None

Keywords

ALL

Set this keyword to a named variable which, upon return, contains a structure with the values of all the device information keywords as fields.

MAX_NUM_CLIP_PLANES

Set this keyword to a named variable that upon return will contain an integer that specifies the maximum number of user-defined clipping planes supported by the device.

MAX_TEXTURE_DIMENSIONS

Set this keyword equal to a named variable. Upon return, *MAX_TEXTURE_DIMENSIONS* contains a two element integer array that specifies the maximum texture size supported by the device.

MAX_VIEWPORT_DIMENSIONS

Set this keyword equal to a named variable. Upon return, *MAX_VIEWPORT_DIMENSIONS* contains a two element integer array that specifies the maximum size of a graphics display supported by the device.

NAME

Set this keyword equal to a named variable. Upon return, *NAME* contains the name of the rendering device as a string.

NUM_CPUS

Set this keyword equal to a named variable. Upon return, *NUM_CPUS* contains an integer that specifies the number of CPUs that are known to, and available to IDL.

Note
The NUM_CPUS keyword accurately returns the number of CPUs for the SUN and Microsoft Windows platforms. For platforms other than these, the number returned may not reflect the actual number of CPUs available to IDL in the current system.

VENDOR

Set this keyword equal to a named variable. Upon return, *VENDOR* contains the name of the rendering device creator as a string.

VERSION

Set this keyword equal to a named variable. Upon return, *VERSION* contains the version of the rendering device driver as a string.

Version History

5.1	Introduced
5.6	Added MAX_NUM_CLIP_PLANES keyword

IDLgrVRML::GetFontnames

The IDLgrVRML::GetFontnames function method returns the list of available fonts that can be used in IDLgrFont objects. This method will only return the names of the available TrueType fonts. Hershey fonts will not be returned; see Appendix H, "Fonts" for more information.

Syntax

Result = *Obj*->[IDLgrVRML::]GetFontnames(*FamilyName* [, IDL_FONTS={0 | 1 | 2}] [, STYLES=*string*])

Return Value

Returns the list of available fonts that can be used in IDLgrFont objects.

Arguments

FamilyName

A string representing the name of the font family to which all of the returned fonts must belong. The string may be a fully specified family name, such as "Helvetica". You can use both "*" and "?" as wildcard characters, matching any number of characters or one character respectively. To return all available family names, use "*".

Keywords

IDL_FONTS

Set this keyword to specify where to search for fonts that IDL may use. Set IDL_FONT to 1 to select only fonts installed by IDL and to 2 to select only fonts detected in the host operating system. The default value is 0, specifying that both IDL and operating system fonts should be returned.

STYLES

Set this keyword to a string specifying the styles that are to be matched by the returned font names. You can set STYLES to a fully specified style string, such as "Bold Italic". If you set STYLES to the null string, ' ', only fontnames without style modifiers will be returned. You can use both "*" and "?" as wildcard characters, matching any number of characters or one character respectively. The default value is

the string, "*", which returns all fontnames containing the *FamilyName* argument, with or without style modifiers.

Version History

5.1	Introduced

IDLgrVRML::GetProperty

The IDLgrVRML::GetProperty procedure method retrieves the value of a property or group of properties for the VRML object.

Syntax

Obj->[IDLgrVRML::]GetProperty[, *PROPERTY=variable*]

Arguments

None

Keywords

Any property listed under "IDLgrVRML Properties" on page 4942 that contains the word "Yes" in the "Get" column of the properties table can be retrieved using this method. To retrieve the value of a property, specify the property name as a keyword set equal to a named variable that will contain the value of the property.

Any keyword not recognized is passed to this object's superclass.

Version History

5.1	Introduced

IDLgrVRML::GetTextDimensions

The IDLgrVRML::GetTextDimensions function method retrieves the dimensions of a text or axis object that will be rendered in a window. In order to compute the effective text dimensions, the object must be inserted into an object graphics hierarchy prior to using this method. The result is a 3-element double-precision floating-point vector [*xDim*, *yDim*, *zDim*] representing the dimensions of the text or axis object, measured in data units. If the object specified is an axis object, the result encompasses the tick labels and the title of the axis (if any).

Note

The returned results take into account the setting of the IDLgrText RECOMPUTE_DIMENSIONS property.

Syntax

Result = Obj->[IDLgrVRML::]GetTextDimensions(*TextObj* [, DESCENT=*variable*] [, PATH=*objref(s)*])

Return Value

Returns a 3-element double-precision floating-point vector [*xDim*, *yDim*, *zDim*] representing the dimensions of the text or axis object, measured in data units.

Arguments

TextObj

The object reference to a text or axis object for which the text dimensions are requested.

Keywords

DESCENT

Set this keyword equal to a named variable that will contain an array of double-precision floating-point values (one for each string in the IDLgrText object). The values represent the distance to travel (parallel to the UPDIR vector) from the text baseline to reach the bottom of the lowest descender in the string. All values will be negative numbers, or zero. This keyword is valid only if *TextObj* is an IDLgrText object.

PATH

Set this keyword to a single object reference or a vector of object references. This keyword specifies the path in the graphics hierarchy to compute the text dimensions. Each path object reference specified with this keyword must contain an alias. The text dimensions are computed for the version of the object falling within that path. If this keyword is not set, the PARENT properties determine the path from the current object to the top of the graphics hierarchy and no alias paths are pursued. If IDLgrVRML::GetTextDimensions is called from within a Draw method and the PATH keyword is not set, the alias path used to find the object during the draw is used, rather than the PARENT path.

Note ───

For more information on aliases, refer to the ALIAS keyword in IDLgrModel::Add.

───

Version History

5.1	Introduced

IDLgrVRML::Init

The IDLgrVRML::Init function method initializes the VRML object. This creates an object that will convert object hierarchies rendered to it into VRML format files.

Note

Init methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation. This means that in most cases, you cannot call the Init method directly. There is one exception to this rule: if you write your own subclass of this class, you can call the Init method from within the Init method of the subclass.

Syntax

Obj = OBJ_NEW('IDLgrVRML' [, *PROPERTY=value*])

or

Result = Obj->[IDLgrVRML::]Init([, *PROPERTY=value*])   *(In a lifecycle method only.)*

Return Value

When this method is called indirectly, as part of the call to the OBJ_NEW function, the return value is an object reference to the newly-created object.

When called directly within a subclass Init method, the return value is 1 if initialization was successful, or zero otherwise.

Arguments

None

Keywords

Any property listed under "IDLgrVRML Properties" on page 4942 that contains the word "Yes" in the "Init" column of the properties table can be initialized during object creation using this method. To initialize the value of a property, specify the property name as a keyword set equal to the appropriate property value.

All other keywords are passed to the superclass of this object.

Version History

5.1	Introduced

IDLgrVRML::SetProperty

The IDLgrVRML::SetProperty procedure method sets the value of a property or group of properties for the VRML world.

Syntax

Obj->[IDLgrVRML::]SetProperty[, *PROPERTY=value*]

Arguments

None

Keywords

Any property listed under "IDLgrVRML Properties" on page 4942 that contains the word "Yes" in the "Set" column of the properties table can be set using this method. To set the value of a property, specify the property name as a keyword set equal to the appropriate property value.

Version History

5.1	Introduced

IDLgrWindow

A window object is a representation of an on-screen area on a display device that serves as a graphics destination.

Note ───
Objects or subclasses of this type can not be saved or restored.

───

Note on Window Size Limits

The OpenGL libraries IDL uses impose limits on the maximum size of a drawable area. The limits are device-dependent — they depend both on your graphics hardware and the setting of the RENDERER property. Currently, the smallest maximum drawable area on any IDL platform is 1280 x 1024 pixels; the limit on your system may be larger.

Superclasses

IDLitComponent

Creation

See "IDLgrWindow::Init" on page 4994.

Properties

Objects of this class have the following properties. See "IDLgrWindow Properties" on page 4963 for details on individual properties.

- ALL
- CURRENT_ZOOM
- DISPLAY_NAME (X Only)
- IMAGE_DATA
- MINIMUM_VIRTUAL_DIMENSIONS
- PALETTE
- REGISTER_PROPERTIES
- RESOLUTION

- COLOR_MODEL
- DIMENSIONS
- GRAPHICS_TREE
- LOCATION
- N_COLORS
- QUALITY
- RENDERER
- RETAIN

- SCREEN_DIMENSIONS
- UNITS
- VIRTUAL_DIMENSIONS
- ZBUFFER_DATA
- ZOOM_NSTEP

- TITLE
- VIEWPORT_DIMENSIONS
- VISIBLE_LOCATION
- ZOOM_BASE

In addition, objects of this class inherit the properties of all superclasses of this class.

Methods

This class has the following methods:

- IDLgrWindow::Cleanup
- IDLgrWindow::Draw
- IDLgrWindow::Erase
- IDLgrWindow::GetContiguousPixels
- IDLgrWindow::GetDeviceInfo
- IDLgrWindow::GetDimensions
- IDLgrWindow::GetFontnames
- IDLgrWindow::GetProperty
- IDLgrWindow::GetTextDimensions
- IDLgrWindow::Iconify
- IDLgrWindow::Init
- IDLgrWindow::OnEnter
- IDLgrWindow::OnExit
- IDLgrWindow::OnExpose
- IDLgrWindow::OnKeyboard
- IDLgrWindow::OnMouseDown
- IDLgrWindow::OnMouseMotion
- IDLgrWindow::OnMouseUp
- IDLgrWindow::OnResize

- IDLgrWindow::OnWheel
- IDLgrWindow::PickData
- IDLgrWindow::QueryRequiredTiles
- IDLgrWindow::Read
- IDLgrWindow::Select
- IDLgrWindow::SetCurrentCursor
- IDLgrWindow::SetCurrentZoom
- IDLgrWindow::SetProperty
- IDLgrWindow::Show
- IDLgrWindow::ZoomIn
- IDLgrWindow::ZoomOut

In addition, this class inherits the methods of its superclasses (if any).

Version History

5.0	Introduced.
6.1	Added MINIMUM_VIRTUAL_DIMENSIONS, ZOOM_BASE, and ZOOM_NSTEP properties.
6.2	Added QueryRequiredTiles method. Added VIEWPORT_DIMENSIONS property.
6.3	Added OnEnter, OnExit, OnExpose, OnKeyboard, OnMouseDown, OnMouseMotion, OnMouseUp, and OnResize methods.
6.4	Added OnWheel method.

IDLgrWindow Properties

IDLgrWindow objects have the following properties in addition to properties inherited from any superclasses. Properties with the word "Yes" in the "Get" column of the property table can be retrieved via IDLgrWindow::GetProperty. Properties with the word "Yes" in the "Init" column of the property table can be set via IDLgrWindow::Init. Properties with the word "Yes" in the "Set" column in the property table can be set via IDLgrWindow::SetProperty.

Note ───
For a discussion of the property description tables shown below, see "About Object Property Descriptions" on page 3135.
──

Objects of this class have the following properties.

- ALL
- CURRENT_ZOOM
- DISPLAY_NAME (X Only)
- IMAGE_DATA
- MINIMUM_VIRTUAL_DIMENSIONS
- PALETTE
- REGISTER_PROPERTIES
- RESOLUTION
- SCREEN_DIMENSIONS
- UNITS
- VIRTUAL_DIMENSIONS
- ZBUFFER_DATA
- ZOOM_NSTEP

- COLOR_MODEL
- DIMENSIONS
- GRAPHICS_TREE
- LOCATION
- N_COLORS
- QUALITY
- RENDERER
- RETAIN
- TITLE
- VIEWPORT_DIMENSIONS
- VISIBLE_LOCATION
- ZOOM_BASE

In addition, objects of this class inherit:

- IDLitComponent

ALL

An anonymous structure containing the values of all of the properties associated with the *state* of this object. State information about the object includes things like color, range, tick direction, etc., but not image, vertex, or connectivity data, or user values.

Note ───
The fields of this structure may change in subsequent releases of IDL.
───

Property Type	Structure		
Name String	*not displayed*		
Get: Yes	**Set:** No	**Init:** No	**Registered:** No

COLOR_MODEL

An integer value or enumerated list item that determines the color model for the window:

Value	Property Sheet Value	Description
0	RGB	RGB (default)
1	Indexed	Color indexed

Note ───
For some X11 display situations, IDL may not be able to support a color index model destination object in object graphics. We do, however, guarantee that an RGB color model destination will be available for all display situations.
───

Property Type	ENUMLIST		
Name String	Color model		
Get: Yes	**Set:** No	**Init:** Yes	**Registered:** Yes

CURRENT_ZOOM

A floating-point value that represents the current zoom factor associated with this window.

Property Type	FLOAT		
Name String	Zoom factor		
Get: Yes	**Set:** No	**Init:** No	**Registered:** Yes

DIMENSIONS

A two-element integer vector of the form [*width*, *height*] to specify the dimensions of the window in units specified by the UNITS property. By default, if no value is specified for DIMENSIONS, IDL uses the values of the IDL_GR_WIN_HEIGHT and IDL_GR_WIN_WIDTH preferences (under Microsoft Windows) or the values of the IDL_GR_X_HEIGHT and IDL_GR_X_WIDTH preferences (under UNIX). There are limits on the maximum size of an IDLgrWindow object; see "Note on Window Size Limits" on page 4960 for details.

Note ───
Changing the DIMENSIONS property is merely a request to the windowing system and may be ignored.
──

This property is registered as a user-defined property, but it is hidden by default.

Property Type	USERDEF		
Name String	Dimensions		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** Yes

DISPLAY_NAME (X Only)

A string that specifies the name of the X Windows display on which the window is to appear.

Property Type	STRING		
Name String	Display name		
Get: Yes	**Set:** Yes	**Init:** No	**Registered:** Yes

GRAPHICS_TREE

An object reference of type IDLgrScene, IDLgrViewgroup, or IDLgrView describing the graphics tree of this window object. If this property is set to a valid object reference, calling the Draw method on the destination object with no arguments will cause the object reference associated with this property to be drawn. If this object is valid and the destination object is destroyed, this object reference will be destroyed as well. By default the GRAPHICS_TREE property is set equal to the null-object.

Property Type	Object reference		
Name String	*not displayed*		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** No

IMAGE_DATA

A byte array representing the image that is currently displayed in the window. If the window object uses an RGB color model, the returned array will have dimensions (3, *winXSize*, *winYSize*), or (4, *winXSize*, *winYSize*) if an alpha channel is included. If the window object uses an Indexed color model, the returned array will have dimensions (*winXSize*, *winYSize*). See "IDLgrWindow::Read" on page 5019 for more information.

Property Type	Byte array		
Name String	*not displayed*		
Get: Yes	**Set:** No	**Init:** No	**Registered:** No

LOCATION

A two-element floating-point vector of the form [*x*, *y*] to specify the location of the upper lefthand corner of the window relative to the display screen, in units specified by the UNITS property. The default value for the LOCATION property is [0,0].

About Multi-Monitor Configurations and LOCATION

If explicit window dimensions are not specified and the IDL_GR_WIN_QSCREEN or IDL_GR_X_QSCREEN preference is set to true, IDL will use the size of the monitor on which the window will be created to calculate the dimensions of a window 1/4 the screen size. In multi-monitor configurations, if a window's LOCATION property does not specify a value that is on any monitor, IDL uses the size of the monitor containing the location [0,0] for the 1/4 screen calculation.

Additionally, some window managers and desktop systems may override application-specified window locations. Therefore, a window may not always be positioned at the location specified by the LOCATION property.

This property is registered as a user-defined property, but it is hidden by default.

Property Type	USERDEF		
Name String	Location		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** Yes

MINIMUM_VIRTUAL_DIMENSIONS

A two-element vector, [*width*, *height*], specifying the minimum dimensions allowed for the virtual canvas of this window. The unit of measure is specified by the UNITS property. In a scrolling window, the virtual canvas represents the full canvas, of which only a smaller visible portion is displayed at any given time. The default value of this property is [0, 0], a value indicating that the minimum virtual dimensions should match the current virtual dimensions.

Property Type	Vector		
Name String	*not displayed*		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** No

N_COLORS

An integer value that specifies the number of colors (between 2 and 256) to be used if COLOR_MODEL is set to Indexed (1). This property is ignored if COLOR_MODEL is set to RGB (0).

Note

If COLOR_MODEL is set to Color Index (1), setting N_COLORS is treated as a request to your operating system. You should always check the actual number of available colors for any Color Indexed destination with the IDLgrWindow::GetProperty method. The actual number of available colors depends on your system and also on how you have used IDL.

Property Type	Integer		
Name String	Number of colors		
Get: Yes	**Set:** No	**Init:** Yes	**Registered:** Yes

PALETTE

An object reference to a palette object (an instance of the IDLgrPalette object class) to specify the red, green, and blue values that are to be loaded into the graphics destination's color lookup table, applicable if the Indexed color model is used.

Note ───

Objects specified via this property are not automatically cleaned up when the IDLgrWindow object is destroyed.

───

This property is registered as a user-defined property, but it is hidden by default.

Property Type	USERDEF		
Name String	Color palette		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** Yes

QUALITY

An integer value or enumerated list item indicating the rendering quality with which graphics are to be drawn to this destination. Valid values are:

Value	**Property Sheet Value**	**Description**
0	Low	Low quality
1	Medium	Medium quality
2	High	High quality (the default)

Property Type	ENUMLIST		
Name String	Draw quality		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** Yes

REGISTER_PROPERTIES

A Boolean value that determines whether to register properties available for this object. If this property is set, all properties marked in this properties section as "Registered: Yes" will be registered for display in a property sheet. This property is useful mainly when creating iTools. By default, no properties are registered.

Property Type	Boolean		
Name String	*not displayed*		
Get: No	**Set:** No	**Init:** Yes	**Registered:** No

RENDERER

An integer value or enumerated list item indicating which graphics renderer to use when drawing objects within the window. Valid values are:

Value	Property Sheet Value	Description
0	OpenGL	Uses platform native OpenGL
1	Software	Uses IDL's software implementation

By default, IDL uses the renderer specified by the IDL_GR_WIN_RENDERER (Windows) or IDL_GR_X_RENDERER (UNIX) preference. If your platform does not have a native OpenGL implementation, IDL uses its own software implementation regardless of the value of this property. See "Hardware vs. Software Rendering" (Chapter 2, *Object Programming*) for details. Your choice of renderer may also affect the maximum size of an IDLgrWindow object; see "Note on Window Size Limits" on page 4960 for details.

Property Type	ENUMLIST		
Name String	Renderer		
Get: Yes	**Set:** No	**Init:** Yes	**Registered:** Yes

RESOLUTION

A floating-point vector of the form [*xres*, *yres*] reporting the pixel resolution, measured in centimeters per pixel. This value is stored in double precision.

Property Type	FLOAT		
Name String	Resolution		
Get: Yes	**Set:** No	**Init:** No	**Registered:** Yes

RETAIN

An integer value that specifies how backing store should be handled for the window. By default, if no value is specified for RETAIN, IDL uses the value of the "Backing Store" preference set in the IDL Workbench's **Preferences** dialog. If there is no preference file for the Workbench (that is, if you always use IDL in plain tty mode), the RETAIN property is set equal to 0 by default.

Value	Property Sheet Value	Description
0	No backing	No backing store.
1	Server/Window	The server or window system is requested to provide the backing store. **Note -** Requesting backing store from the server is only a request; backing store may not be provided in all situations
2	IDL	Requests that IDL provide the backing store directly. In some situations, IDL can not provide this backing store in Object Graphics. To see if IDL provided backing store, query the RETAIN property of IDLgrWindow::GetProperty. IDL may also alter the RENDERER property while attempting to provide backing store.

In IDL Object Graphics, it is almost always best to disable backing store (that is, set the RETAIN property equal to zero). This is because drawing to an off-screen

pixmap (which is what happens when backing store is enabled) almost always bypasses any hardware graphics acceleration that may be available, causing all rendering to be done in software. To ensure that windows are redrawn properly, enable the generation of expose events on the WIDGET_DRAW window and redraw the window explicitly when an expose event is received.

Note ————————————————————————————————————
On Macintosh and Microsoft Windows systems, if you are using software rendering (that is, the RENDERER property is set equal to one), IDL will refresh the window automatically regardless of the setting of the RETAIN property.

————————————————————————————————————

Property Type	ENUMLIST		
Name String	Retain		
Get: Yes	**Set:** No	**Init:** Yes	**Registered:** Yes

SCREEN_DIMENSIONS

A two-element floating-point vector of the form [*width*, *height*] specifying the dimensions of the overall screen dimensions for the screen with which this window is associated. The screen dimensions are measured in device units.

Note ————————————————————————————————————
The maximum screen dimension size depends on the graphics device.

————————————————————————————————————

On multi-monitor configurations, this SCREEN_DIMENSIONS returns information for the primary monitor only. For information about other monitors, use the IDLsysMonitorInfo object.

Property Type	Floating-point vector		
Name String	*not displayed*		
Get: Yes	**Set:** No	**Init:** No	**Registered:** No

TITLE

A string that represents the title of the window.

Property Type	STRING		
Name String	Title		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** Yes

UNITS

An integer value or enumerated list item that specifies the units of measure for the LOCATION and DIMENSIONS properties. Valid values are:

Value	Property Sheet Value	Description
0	Device	Device units (the default)
1	Inches	Inches
2	Centimeters	Centimeters
3	Normalization	Normalized units (relative to the dimensions of the primary monitor/screen, as stored in the SCREEN_DIMENSIONS property)

Note ———————————————————————————————————

If you set the value of the UNITS property (using the SetProperty method) without also setting the value of the LOCATION and DIMENSIONS properties, IDL will convert the current size and location values into the new units.

———

Property Type	ENUMLIST		
Name String	Units		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** Yes

VIEWPORT_DIMENSIONS

A two-element floating-point vector of the form [*width*, *height*] specifying the dimensions of the *viewport* of the draw widget that contains this window. If the window is not within a draw widget, this property is equivalent to the DIMENSIONS property.

Property Type	Floating-point vector		
Name String	*not displayed*		
Get: Yes	Set: No	Init: No	Registered: No

VIRTUAL_DIMENSIONS

A two-element integer vector, [*width*, *height*], specifying the dimensions of the *virtual canvas* for this window. In a scrolling window, the virtual canvas represents the full canvas, of which only a smaller visible portion is displayed at any given time. The default is [0,0], indicating that the virtual canvas dimensions should match the visible dimensions (as specified via the DIMENSIONS property).

Note

When a drawable window is created using the WIDGET_DRAW function with the GRAPHICS_LEVEL keyword set equal to 2, the *width* and *height* values are initialized using the values of the X_SCROLL_SIZE and Y_SCROLL_SIZE keywords to WIDGET_DRAW.

This property is registered as a user-defined property, but it is hidden by default.

Property Type	USERDEF		
Name String	Virtual dimensions		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

VISIBLE_LOCATION

A two-element integer vector, [x,y], specifying the lower left location of the visible portion of the canvas (relative to the virtual canvas). In a scrolling window, the virtual canvas represents the full canvas, of which only a smaller visible portion is displayed at any given time.

This property is registered as a user-defined property, but it is hidden by default.

Property Type	USERDEF		
Name String	Visible location		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

ZBUFFER_DATA

A floating-point array representing the zbuffer that is currently within the buffer. The returned array will have dimensions (*xdim*, *ydim*).

Property Type	Floating-point array		
Name String	*not displayed*		
Get: Yes	Set: No	Init: No	Registered: No

ZOOM_BASE

A floating point value representing the base value by which the window's current zoom factor will be multiplied or divided for zooming in or zooming out. Allowable values are those greater than 1.0. The default is 2.0.

Property Type	Float		
Name String	*not displayed*		
Get: Yes	Set: Yes	Init: Yes	Registered: No

ZOOM_NSTEP

A named variable that, upon return, will contain an integer that indicates the number of times this window's ZOOM_BASE property has been applied to achieve the current zoom factor. A positive value indicates that the current zoom factor represents the result of zooming in ZOOM_NSTEP times. A negative value indicates that the current zoom factor represents the result of zooming out ZOOM_NSTEP times.

Property Type	Integer		
Name String	*not displayed*		
Get: Yes	Set: No	Init: No	Registered: No

IDLgrWindow::Cleanup

The IDLgrWindow::Cleanup procedure method performs all cleanup on the object.

Note

Cleanup methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation and destruction. This means that in most cases, you cannot call the Cleanup method directly. There is one exception to this rule: if you write your own subclass of this class, you can call the Cleanup method from within the Init or Cleanup method of the subclass.

Syntax

OBJ_DESTROY, *Obj*

or

Obj->[IDLgrWindow::]Cleanup   *(In a lifecycle method only.)*

Arguments

None

Keywords

None

Version History

5.0	Introduced

IDLgrWindow::Draw

The IDLgrWindow::Draw procedure method draws the specified scene or view object to this graphics destination.

Note ———————————————————————————————

Objects are drawn to the destination device in the order that they are added to the model, view, viewgroup, or scene object that contains them.

_____

Syntax

Obj->[IDLgrWindow::]Draw [, *Picture*] [, CREATE_INSTANCE={1 | 2}]
[, DRAW_INSTANCE={1 | 2}]

Arguments

Picture

The view (an instance of an IDLgrView object), viewgroup (an instance of an IDLgrViewgroup object), or scene (an instance of an IDLgrScene object) to be drawn. If *Picture* is not supplied, the graphics hierarchy specified by the GRAPHICS_TREE property of the IDLgrWindow object will be drawn, if it exists. If neither the *Picture* argument or the GRAPHICS_TREE property are specified, nothing is drawn.

Keywords

CREATE_INSTANCE

Set this keyword equal to one to specify that this scene or view is the unchanging part of a drawing. Some destinations can make an instance from the current window contents without having to perform a complete redraw. If the view or scene to be drawn is identical to the previously drawn view or scene, this keyword can be set equal to 2 to hint the destination to create the instance from the current window contents if it can.

DRAW_INSTANCE

Set this keyword to specify that the instance, or unchanging part of the drawing, is drawn to the device first. IDL then draws the changing part of the drawing, indicated by the scene, view or viewgroup specified by the Picture argument.

If the value of this keyword is 1, IDL copies both the instance image (color buffer) and the instance depth buffer to the device.

If the value of this keyword is 2, IDL copies only the instance image to the device.

Note ———
Set the TRANSPARENT property of any IDLgrView objects associated with the *Picture* argument to a non-zero value before calling the Draw method with the DRAW_INSTANCE keyword set. This prevents the drawn instance (the unchanging part of the scene) from being erased when drawing the changing portion of the scene contained in the *Picture* argument.

Version History

5.0	Introduced

IDLgrWindow::Erase

The IDLgrWindow::Erase procedure method erases the entire contents of the window and initializes the depth buffer.

Syntax

Obj->[IDLgrWindow::]Erase [, COLOR=*index or RGB vector*]

Arguments

None

Keywords

COLOR

Set this keyword to the color to be used for the erase. The color may be specified as a color lookup table index or as a three-element vector [*red*, *green*, *blue*]. The default erase color is white.

Version History

5.0	Introduced

IDLgrWindow::GetContiguousPixels

The IDLgrWindow::GetContiguousPixels function method returns an array of long integers whose length is equal to the number of colors available in the index color mode (that is, the value of the N_COLORS property).

The returned array marks contiguous pixels with the ranking of the range's size. This means that within the array, the elements in the largest available range are set to zero, the elements in the second-largest range are set to one, etc. Use this range to set an appropriate colormap for use with the SHADE_RANGE property of the IDLgrSurface and IDLgrPolygon object classes.

To get the largest contiguous range, you could use the following IDL command:

```
result = obj->GetContiguousPixels()
Range0 = WHERE(result EQ 0)
```

A contiguous region in the colormap can be increasing or decreasing in values. The following would be considered contiguous:

```
[0,1,2,3,4]
[4,3,2,1,0]
```

Syntax

Result = Obj->[IDLgrWindow::]GetContiguousPixels()

Return Value

Returns an array of long integers whose length is equal to the number of colors available in the index color mode.

Arguments

None

Keywords

None

Version History

5.0	Introduced

IDLgrWindow::GetDeviceInfo

The IDLgrWindow::GetDeviceInfo procedure method returns information which allows IDL applications to intelligently make decisions for optimal performance. For example, it allows an application to determine if RENDERER=0 is actually implemented in hardware. It also allows applications to make optimal quality decisions when dynamically building texture maps.

Syntax

Obj->[IDLgrWindow::]GetDeviceInfo [, ALL=*variable*]
    [, FRAMEBUFFER_OBJECT_EXTENSION=*variable*]
    [, MAX_FRAGMENT_UNIFORM_COMPONENTS=*variable*]
    [, MAX_NUM_CLIP_PLANES=*variable*]
    [, MAX_TEXTURE_DIMENSIONS=*variable*]
    [, MAX_TILE_DIMENSIONS=*variable*]
    [, MAX_TEXTURE_IMAGE_UNITS=*variable*]
    [, MAX_VERTEX_ATTRIBUTES=*variable*]
    [, MAX_VERTEX_TEXTURE_IMAGE_UNITS=*variable*]
    [, MAX_VERTEX_UNIFORM_COMPONENTS=*variable*]
    [, MAX_VIEWPORT_DIMENSIONS=*variable*] [, NAME=*variable*]
    [, NUM_CPUS=*variable*] [, SHADING_LANGUAGE_VERSION=*variable*]
    [, VENDOR=*variable*] [, VERSION=*variable*]

Arguments

None

Keywords

ALL

Set this keyword to a named variable which, upon return, contains a structure with the values of all the device information keywords as fields.

FRAMEBUFFER_OBJECT_EXTENSION

Set this keyword to a named variable that will indicate whether the graphics card and OpenGL driver support the GLSL `framebuffer_object_extension`, which is

required for IDLgrFilterChain object support and image caching (using
IDLgrShader's CACHE_RESULT property):

0	No support for chaining shaders or caching
1	Support for chaining shaders and caching

MAX_FRAGMENT_UNIFORM_COMPONENTS

Set this keyword to a named variable that will contain the maximum number of
components, or storage units, declared by active uniform variables in a fragment
shader program. For example, a uniform variable of GLSL vector variable type vec2
uses 2 components. This value is zero for devices that do not support shader
programs, implemented using the IDLgrShader object.

MAX_NUM_CLIP_PLANES

Set this keyword to a named variable that upon return will contain an integer that
specifies the maximum number of user-defined clipping planes supported by the
device.

MAX_TEXTURE_DIMENSIONS

Set this keyword equal to a named variable. Upon return,
MAX_TEXTURE_DIMENSIONS contains a two element integer array that
specifies the maximum texture size supported by the device.

MAX_TEXTURE_IMAGE_UNITS

Set this keyword to a named variable that will contain the number of texture units
available to the fragment shader program. This value is zero for devices that do not
support shader programs, implemented using the IDLgrShader object.

MAX_TILE_DIMENSIONS

Set this keyword equal to a named variable. Upon return,
MAX_TILE_DIMENSIONS contains a two element integer array that specifies the
maximum tile size supported by the device.

MAX_VERTEX_ATTRIBUTES

Set this keyword to a named variable that will contain the maximum number of
positions available for GLSL vertex attribute variables associated with a shader
program. Each shader program attribute variable occupies one position, except for

GLSL matrix attribute variables of type `mat2`, `mat3`, and `mat4`, which occupy 2, 3, and 4 attribute variable positions, respectively. This value is zero for devices that do not support shader programs, implemented using the IDLgrShader object.

Note ────────────────────────────────────

IDL always uses one vertex attribute variable. The value reported by the MAX_VERTEX_ATTRIBUTES property is the number of positions that remain after deducting the variable used by IDL. Thus, if the graphics hardware provides 16 slots for vertex attribute variables, this property will report 15 available slots.

──

MAX_VERTEX_TEXTURE_IMAGE_UNITS

Set this keyword to a named variable that will contain the maximum number of texture units available to the vertex shader program. This value is zero for devices that do not support vertex shader texture units.

MAX_VERTEX_UNIFORM_COMPONENTS

Set this keyword to a named variable that will contain the maximum number of components, or storage units, declared by active uniform variables in a vertex shader program. For example, a uniform variable of GLSL vector type `vec2` uses 2 components. This value is zero for devices that do not support shader programs, implemented using the IDLgrShader object.

MAX_VIEWPORT_DIMENSIONS

Set this keyword equal to a named variable. Upon return, MAX_VIEWPORT_DIMENSIONS contains a two element integer array that specifies the maximum size of a graphics display supported by the device.

NAME

Set this keyword equal to a named variable. Upon return, NAME contains the name of the rendering device as a string.

NUM_CPUS

Set this keyword equal to a named variable. Upon return, NUM_CPUS contains an integer that specifies the number of CPUs that are known to, and available to IDL.

Note

The NUM_CPUS keyword accurately returns the number of CPUs for the SUN and Microsoft Windows platforms. For platforms other than these, the number returned may not reflect the actual number of CPUs available to IDL in the current system.

SHADING_LANGUAGE_VERSION

Set this keyword to a named variable that will contain a string indicating the version of OpenGL Shading Language (GLSL) supported by the system's graphic card. The string is of the form:

```
<version number><space><vendor-specific information>
```

where the version number is defined as

```
majorVersionNumber.minorVersionNumber
```

or

```
majorVersionNumber.minorVersionNumber.releaseNumber
```

This value is the empty string for devices that do not support shader programs, implemented using IDLgrShader. For information on the level of support needed by the IDLgrShader object, see "Hardware Requirements for Shaders" (Chapter 14, *Object Programming*).

VENDOR

Set this keyword equal to a named variable. Upon return, VENDOR contains the name of the rendering device creator as a string.

VERSION

Set this keyword equal to a named variable. Upon return, VERSION contains the version of the rendering device driver as a string.

Version History

5.0	Introduced
5.6	Added MAX_NUM_CLIP_PLANES keyword

6.2	Added MAX_TILE_DIMENSIONS keyword
6.4	Added FRAMEBUFFER_OBJECT_EXTENSION, MAX_FRAGMENT_UNIFORM_COMPONENTS, MAX_TEXTURE_IMAGE_UNITS, MAX_VERTEX_ATTRIBUTES, MAX_VERTEX_TEXTURE_IMAGE_UNITS, MAX_VERTEX_UNIFORM_COMPONENTS, and SHADING_LANGUAGE_VERSION keywords

IDLgrWindow::GetDimensions

The IDLgrWindow::GetDimensions function method returns a two-element vector, [*width*, *height*], representing the visible dimensions (in pixel units) of this window.

Syntax

Result = *Obj* -> [IDLgrWindow::]GetDimensions
    ([, MINIMUM_VIRTUAL_DIMENSIONS=*variable*]
    [, ORIGINAL_VIRTUAL_DIMENSIONS=*variable*]
    [, VIRTUAL_DIMENSIONS=*variable*] [, VISIBLE_LOCATION=*variable*])

Return Value

Returns the visible dimensions of the window (in pixel units) in a two-element vector [*width*, *height*].

Arguments

None

Keywords

MINIMUM_VIRTUAL_DIMENSIONS

Set this keyword to a named variable that will contain a two-element vector, [*width*, *height*], representing the minimum allowed virtual dimensions for this window.

Note ──

Returning MINIMUM_VIRTUAL_DIMENSIONS using GetDimensions provides the width and height of the window in pixel units. The property, "MINIMUM_VIRTUAL_DIMENSIONS" on page 4967, returns the dimensions of the window in units specified by the UNITS property.

──

ORIGINAL_VIRTUAL_DIMENSIONS

Set this keyword to a named variable that will contain a two-element vector, [*width*, *height*], representing the virtual dimensions in pixels for this window if the current zoom factor was 1.0.

VIRTUAL_DIMENSIONS

Set this keyword to a named variable that will contain a two-element vector, [*width*, *height*], representing the dimensions in pixels of the virtual canvas for this window.

VISIBLE_LOCATION

Set this keyword to a named variable that will contain a two-element vector, [*x*, *y*], representing the lower-left location of the visible portion of the window (relative to its virtual canvas).

Version History

6.1	Introduced

IDLgrWindow::GetFontnames

The IDLgrWindow::GetFontnames function method returns the list of available fonts that can be used in IDLgrFont objects. This method will only return the names of the available TrueType fonts. Hershey fonts will not be returned; see Appendix H, "Fonts" for more information.

Syntax

Result = Obj->[IDLgrWindow::]GetFontnames(*FamilyName* [, IDL_FONTS={0 | 1 | 2}] [, STYLES=*string*])

Return Value

Returns the list of available fonts that can be used in IDLgrFont objects.

Arguments

FamilyName

A string representing the name of the font family to which all of the returned fonts must belong. The string may be a fully specified family name—such as "Helvetica". You can use both "*" and "?" as wildcard characters, matching any number of characters or one character respectively. To return all available family names, use "*".

Keywords

IDL_FONTS

Set this keyword to specify where to search for fonts that IDL may use. Set IDL_FONT to 1 to select only fonts installed by IDL and to 2 to select only fonts detected in the host operating system. The default value is 0, specifying that both IDL and operating system fonts should be returned.

STYLES

Set this keyword to a string specifying the styles that are to be matched by the returned font names. You can set STYLES to a fully specified style string, such as "Bold Italic". If you set STYLES to the null string, ' ', only fontnames without style modifiers will be returned. You can use both "*" and "?" as wildcard characters, matching any number of characters or one character respectively. The default value is

the string, "*", which returns all fontnames containing the *FamilyName* argument, with or without style modifiers.

Version History

5.0	Introduced

IDLgrWindow::GetProperty

The IDLgrWindow::GetProperty procedure method retrieves the value of a property or group of properties for the window.

Syntax

Obj->[IDLgrWindow::]GetProperty[, *PROPERTY=variable*]

Arguments

None

Keywords

Any property listed under "IDLgrWindow Properties" on page 4963 that contains the word "Yes" in the "Get" column of the properties table can be retrieved using this method. To retrieve the value of a property, specify the property name as a keyword set equal to a named variable that will contain the value of the property.

Any keyword not recognized is passed to this object's superclass.

Version History

5.0	Introduced

IDLgrWindow::GetTextDimensions

The IDLgrWindow::GetTextDimensions function method retrieves the dimensions of a text or axis object that will be rendered in a window. In order to compute the effective text dimensions, the object must be inserted into an object graphics hierarchy prior to using this method. The result is a 3-element double-precision floating-point vector [*xDim*, *yDim*, *zDim*] representing the dimensions of the text or axis object, measured in data units. If the object specified is an axis object, the result encompasses the tick labels and the title of the axis (if any).

Note

The returned results take into account the setting of the IDLgrText RECOMPUTE_DIMENSIONS property.

Syntax

Result = Obj->[IDLgrWindow::]GetTextDimensions(*TextObj*
   [, DESCENT=*variable*] [, PATH=*objref(s)*])

Return Value

Returns a 3-element double-precision floating-point vector [*xDim*, *yDim*, *zDim*] representing the dimensions of the text or axis object, measured in data units.

Arguments

TextObj

The object reference to a text or axis object for which the text dimensions are requested.

Keywords

DESCENT

Set this keyword equal to a named variable that will contain an array of double-precision floating-point values (one for each string in the IDLgrText object). The values are the distance to travel (parallel to the UPDIR direction) from the baseline to reach the bottom of all the descenders for the string; the values will be negative or 0. This keyword is only valid if *TextObj* is of the class IDLgrText.

PATH

Set this keyword to a single object reference or a vector of object references. This keyword specifies the path in the graphics hierarchy to compute the text dimensions. Each path object reference specified with this keyword must contain an alias. The text dimensions are computed for the version of the object falling within that path. If this keyword is not set, the PARENT properties determine the path from the current object to the top of the graphics hierarchy and no alias paths are pursued. If IDLgrWindow::GetTextDimensions is called from within a Draw method and the PATH keyword is not set, the alias path used to find the object during the draw is used, rather than the PARENT path.

Note

For more information on aliases, refer to the ALIAS keyword in IDLgrModel::Add.

Version History

5.0	Introduced

IDLgrWindow::Iconify

The IDLgrWindow::Iconify procedure method iconifies or de-iconifies the window.

Note

Iconification under window systems is solely handled by the window manager; client applications, such as IDL, do not have the capability to manage icons. The Iconify method provides a hint to the window manager, which applies the information as it sees fit.

Syntax

Obj->[IDLgrWindow::]Iconify, *IconFlag*

Arguments

IconFlag

Set *IconFlag* to 1 (one) to iconify the window or to 0 (zero) to restore the window. If the window is already restored, it is brought to the front of the window stack.

Keywords

None

Version History

5.0	Introduced

IDLgrWindow::Init

The IDLgrWindow::Init function method initializes the window object.

Note ───

Init methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation. This means that in most cases, you cannot call the Init method directly. There is one exception to this rule: if you write your own subclass of this class, you can call the Init method from within the Init method of the subclass.

───

Warning ──

When an IDLgrWindow object is created, its pixel values and depth buffer values are in an indeterminate state. This normally does not create a problem because most windows are completely covered by a non-transparent IDLgrView object, which causes the entire window to be painted with the view's background color and causes the depth buffer to be cleared before drawing the graphics.

However, if any area of the window is left uncovered by an IDLgrView, that area may contain random pixels after the window is drawn. In addition, if a transparent view covers an area of the window not also covered by a non-transparent view, there may be unwanted random pixels in the transparent view as well as random depth buffer values, which may cause some graphic primitives to not appear in the view at all.

Calling the IDLgrWindow::Erase method is useful for initializing the areas of a window not covered by a view (or which are "under" transparent views) to the desired color and for initializing the depth buffer for subsequent drawing in transparent views.

───

Syntax

Obj = OBJ_NEW('IDLgrWindow' [, *PROPERTY=value*])

or

Result = Obj->[IDLgrWindow::]Init([, *PROPERTY=value*])   *(In a lifecycle method only.)*

Return Value

When this method is called indirectly, as part of the call to the OBJ_NEW function, the return value is an object reference to the newly-created object.

When called directly within a subclass Init method, the return value is 1 if initialization was successful, or zero otherwise.

Arguments

None

Keywords

Any property listed under "IDLgrWindow Properties" on page 4963 that contains the word "Yes" in the "Init" column of the properties table can be initialized during object creation using this method. To initialize the value of a property, specify the property name as a keyword set equal to the appropriate property value.

All other keywords are passed to the superclass of this object.

Version History

5.0	Introduced

IDLgrWindow::OnEnter

The IDLgrWindow::OnEnter procedure method handles notification from the window that a mouse enter event has occurred.

Note ───

This method is only useful in conjunction with the Export Bridge. The method is only a stub and provides no functionality. In your subclass of IDLgrWindow, you should override this method to provide your own functionality. Your method will be automatically called by the Export Bridge. For more information, see "Exporting Drawable Objects" (Chapter 11, *IDL Connectivity Bridges*).

───

Syntax

Obj->[IDLgrWindow::]OnEnter

Arguments

None

Keywords

None

Version History

6.3	Introduced

IDLgrWindow::OnExit

The IDLgrWindow::OnExit procedure method handles notification from the window that a mouse exit event has occurred.

Note ————————————————————————————

This method is only useful in conjunction with the Export Bridge. The method is only a stub, and provides no functionality. In your subclass of IDLgrWindow, you should override this method to provide your own functionality. Your method will be automatically called by the Export Bridge. For more information, see "Exporting Drawable Objects" (Chapter 11, *IDL Connectivity Bridges*).

Syntax

Obj->[IDLgrWindow::]OnExit

Arguments

None

Keywords

None

Version History

6.3	Introduced

IDLgrWindow::OnExpose

The IDLgrWindow::OnExpose procedure method handles notification from the window that an expose event has occurred.

Note

This method is only useful in conjunction with the Export Bridge. By default, the OnExpose method will automatically redraw the graphics hierarchy specified by the GRAPHICS_TREE property. If you are using a subclass of IDLgrWindow and require additional functionality, you should override this method. Your method will be automatically called by the Export Bridge. For more information, see "Exporting Drawable Objects" (Chapter 11, *IDL Connectivity Bridges*).

Syntax

Obj->[IDLgrWindow::]OnExpose, *X*, *Y*, *Width*, *Height*

Arguments

X

A floating-point value representing the *x*-coordinate of the lower left corner of the newly exposed portion of the canvas (in device coordinates).

Y

A floating-point value representing the *y*-coordinate of the lower left corner of the newly exposed portion of the canvas (in device coordinates).

Width

A floating-point value representing the width of the newly exposed portion of the canvas (in device coordinates).

Height

A floating-point value representing the height of the newly exposed portion of the canvas (in device coordinates).

Keywords

None

Version History

6.3	Introduced

IDLgrWindow::OnKeyboard

The IDLgrWindow::OnKeyboard procedure method handles notification from the window that a keyboard event has occurred.

Note ───

This method is only useful in conjunction with the Export Bridge. The method is only a stub and provides no functionality. In your subclass of IDLgrWindow, you should override this method to provide your own functionality. Your method will be automatically called by the Export Bridge. For more information, see "Exporting Drawable Objects" (Chapter 11, *IDL Connectivity Bridges*).

───

Syntax

Obj->[IDLgrWindow::]OnKeyboard, *IsASCII*, *Character*, *KeySymbol*, *X*, *Y*, *Press*, *Release*, *Modifiers*

Arguments

IsASCII

A scalar byte value that indicates whether the keyboard event corresponds to a character in the ASCII character set. If *IsASCII* is non-zero, the *Character* argument will be set to a byte value corresponding to the character of the pressed key. If *IsASCII* is zero, the *KeySymbol* argument will be set to a numeric value indicating the key that was pressed.

Character

If *IsASCII* is non-zero, this argument is set to a byte value corresponding to the ASCII character of the key that was pressed. Otherwise, this argument is set to zero.
