Returns the correlation coefficient.

Arguments

X

An *n*-element integer, single-, or double-precision floating-point vector that specifies the independent variable data.

Y

An *n*-element integer, single-, or double-precision floating-point vector that specifies the dependent variable data.

C

An integer, single-, or double-precision floating-point array that specifies the independent variable data whose effects are to be removed. *C* may either be an *n*-element vector containing the independent variable, or a *p*-by-*n* two-dimensional array in which each column corresponds to a separate independent variable.

Keywords

DOUBLE

Set this keyword to force the computation to be done in double-precision arithmetic.

Examples

```
; Define three sample populations:
X0 = [64, 71, 53, 67, 55, 58, 77, 57, 56, 51, 76, 68]
X1 = [57, 59, 49, 62, 51, 50, 55, 48, 52, 42, 61, 57]
X2 = [ 8, 10, 6, 11, 8, 7, 10, 9, 10, 6, 12, 9]

; Compute the partial correlation of X0 and X1 with the effects
; of X2 removed.
result = P_CORRELATE(X0, X1, X2)

PRINT, result
```

IDL prints:

```
0.533469
```

PARSE_URL

The PARSE_URL function breaks a URL string into substrings that correspond to the URL_* properties of IDLnet* objects.

Note ───

This is not an object method and does not set any object properties.

───

Note ───

If a port number is not found in the URL string parameter, the default port value is 80.

───

PARSE_URL is a pure string-processing routine. Validation of the values is left to the user. The returned value is a structure created by applying the following rules to the input URL string:

URL Index	URL Section	Example	Rule
0	Scheme	"http", "https", or "ftp"	From beginning of URL string up to (but not including) "://"
1	Username	anonymous	If '@' is present before the first single '/', everything from "://" to either ':' or '@' if ':' is not present
2	Password	make-something-up	If both '@' and ':' are present before the first single '/', everything from ':' to '@'
3	Host	somehost.com	Everything from "://" or '@' to ':' or first single '/'
4	Port	80	If ':' follows the host name, everything between ':' and the first single '/'
5	Path	`directory/subdirectory/index.html`	Everything between the first single '/' and '?' or end of string
6	Query	`parm1=value1&parm2=value2`	Everything from '?' to the end of the string

URL string components are illustrated in the following example:

```
http://uname:passwd@somehost.com:80/path/page.pl?p1=v1&p2=v2
| 0 | | 1 | | 2 | |    3   ||4|   5     | |   6   |
```

This routine is written in the IDL language. Its source code can be found in the file `parse_url.pro` in the `lib` subdirectory of the IDL distribution.

Syntax

Result = PARSE_URL(*URL*)

Return Value

PARSE_URL returns an anonymous structure containing the disassembled segments of the URL. The fields in the structure are:

```
SCHEME
USERNAME
PASSWORD
HOST
PORT
PATH
QUERY
```

All fields contain string values.

To see the structure tag names, enter the following code in the IDL command line:

```
help, Result, /struct
```

Arguments

URL

A URL in string form.

Keywords

None.

Examples

The following example strips a known URL to its component strings.

```
PRO ParseUrlExample
```

```
; Start with a hypothetical URL string
urlString = 'http://someserver.com/path/to/firstfile.dat'
PRINT, 'Original URL string = '+urlString

; Split the URL into its component substrings
urlComponents = PARSE_URL(urlString)

; Populate an IDLnetURL object with the URL information
urlObj =OBJ_NEW('IDLnetURL')
urlObj->SetProperty, URL_SCHEME = urlComponents.scheme, $
   URL_HOST = urlComponents.host, $
   URL_PATH = urlComponents.path

; Get the object's URL property values, and print them
urlObj->GetProperty, URL_SCHEME = urlScheme
urlObj->GetProperty, URL_HOST = urlHost
urlObj->GetProperty, URL_PATH = urlPath

PRINT, 'URL scheme = '+urlScheme
PRINT, 'URL host = '+ urlHost
PRINT, 'URL path = '+urlPath

END
```

PARTICLE_TRACE

The PARTICLE_TRACE procedure traces the path of a massless particle through a vector field. The function allows the user to specify a set of starting points and a vector field. The input seed points can come from any vertex-producing process. The points are tracked by treating the vector field as a velocity field and integrating. Each path is tracked until the path leaves the input volume or a maximum number of steps is reached. The vertices generated along the paths are returned packed into a single array along with a polyline connectivity array. The polyline connectivity array organizes the vertices into separate paths (one per seed). Each path has an orientation. The initial orientation may be set using the SEED_NORMAL keyword. As a path is tracked, the change in the normal is also computed and may be returned to the user as an optional argument. Path output can be passed directly to an IDLgrPolyline object or passed to the STREAMLINE procedure for generation of orientated ribbons. Control over aspects of the integration (e.g. method or stepsize) is also provided.

Syntax

PARTICLE_TRACE, *Data*, *Seeds*, *Verts*, *Conn* [, *Normals*]
　　[, MAX_ITERATIONS=*value*] [, ANISOTROPY=*array*]
　　[, INTEGRATION={0 | 1}] [, SEED_NORMAL=*vector*]
　　[, TOLERANCE=*value*] [, MAX_STEPSIZE=*value*] [, /UNIFORM]

Arguments

Data

Input data array. This array can be of dimensions [2, *dx*, *dy*] for two-dimensional vector fields or [3, *dx*, *dy*, *dz*] for three-dimensional vector fields.

Seeds

Input array of seed points ([3, *n*] or [2, *n*]).

Verts

Array of output path vertices ([3, *n*] or [2, *n*] array of floats).

Conn

Output path connectivity array in IDLgrPolyline POLYLINES keyword format. There is one set of line segments in this array for each input seed point.

Normals

Output normal estimate at each output vertex ([3, *n*] array of floats).

Keywords

ANISOTROPY

Set this input keyword to a two- or three- element array describing the distance between grid points in each dimension. The default value is [1.0, 1.0, 1.0] for three-dimensional data and [1.0, 1.0] for two-dimensional data.

INTEGRATION

Set this keyword to one of the following values to select the integration method:

- 0 = 2nd order Runge-Kutta (the default)

- 1 = 4th order Runge-Kutta

SEED_NORMAL

Set this keyword to a three-element vector which selects the initial normal for the paths. The default value is [0.0, 0.0, 1.0]. This keyword is ignored for 2-D data.

TOLERANCE

This keyword is used with adaptive step-size control in the 4th order Runge-Kutta integration scheme. It is ignored if the UNIFORM keyword is set or the 2nd order Runge-Kutta scheme is selected.

MAX_ITERATIONS

This keyword specifies the maximum number of line segments to return for each path. The default value is 200.

MAX_STEPSIZE

This keyword specifies the maximum path step size. The default value is 1.0.

UNIFORM

If this keyword is set, the step size will be set to a fixed value, set via the MAX_STEPSIZE keyword. If this keyword is not specified, and TOLERANCE is either unspecified or inapplicable, then the step size is computed based on the velocity at the current point on the path according to the formula:

stepsize = MIN(MaxStepSize, MaxStepSize/MAX(ABS(U), ABS(V), ABS(W)))

where (U,V,W) is the local velocity vector.

PATH_CACHE

The PATH_CACHE procedure is used to control IDL's use of the *path cache*. By default, as IDL searches directories included in the !PATH system variable for `.pro` or `.sav` files to compile, it creates an in-memory list of *all* `.pro` and `.sav` files contained in each directory. When IDL later searches for a `.pro` or `.sav` file, before attempting to open the file in a given directory, IDL checks the path cache to determine whether the directory has already been cached. If the directory is included in the cache, IDL uses the cached information to determine whether the file will be found in that directory, and will only attempt to open the file there if the cache tells it that the file exists. By eliminating unnecessary attempts to open files, the path cache speeds the path searching process.

The path cache is enabled by default, and in almost all cases its operation is transparent to the IDL user, save for the boost in path searching speed it provides. Because the cache automatically adjusts to changes made to IDL's path, use of PATH_CACHE should not be necessary in typical IDL operation. It is provided to allow complete control over the details of how and when the caching operation is performed.

- For information on when the path cache is *not* used, see "Situations in which IDL will not use the Path Cache" on page 1781.

- For information on disabling the path cache, see "Disabling the Path Cache" on page 1782.

Note ───
Prior to IDL 6.0, IDL did not use a path cache. Aside from the improvement in performance, the behavior of IDL with the path cache is identical to that without in almost all cases. The rare cases in which it differs, and options for disabling its use, are discussed in "Options for Avoiding Use of the Path Cache" on page 1783.
───

About the Path Cache

The first time an IDL session attempts to call a function or procedure written in the IDL language, it must locate and compile the file containing the code for that routine. The file containing the routine must have the same name as the routine, with either a `.pro` or a `.sav` extension. After trying to open the file in the user's current working directory, IDL will attempt to open the file in each of the directories listed in the !PATH system variable, in the order specified by !PATH. The search stops when a file with the desired name is found or no directories remain in !PATH.

By default, IDL maintains an in-memory cache of the locations of .pro and .sav files stored in directories included in the !PATH system variable. The path cache is built automatically during normal operation, as IDL searches the directories specified by !PATH. Once a directory is cached, IDL knows whether or not it contains a given file, without the need to actually attempt to open that file. This information allows IDL to bypass directories that do not contain the desired file, providing a significant boost in the speed of path searching. The path cache can significantly improve the startup speed of large, object-oriented applications, because method resolution requires extensive path searching.

The path cache operates on a per-directory basis; if IDL searches a directory for a .pro or .sav file, the locations of *all* .pro and .sav files in that directory are added to the cache, and the directory is not searched again until the cache is cleared and rebuilt.

Note

The current contents of the path cache can be viewed using the PATH_CACHE keyword to the HELP procedure.

Syntax

PATH_CACHE[, /CLEAR] [, /ENABLE] [, /REBUILD]

Arguments

None.

Keywords

CLEAR

Set this keyword to clear the entire contents of the path cache, leaving it completely empty. If path caching is enabled, IDL will begin rebuilding the cache the next time it needs to locate a .pro or .sav file. If you wish to prevent the rebuilding of the cache, set the ENABLE keyword equal to zero as well.

Note

The .RESET_SESSION executive command clears the entire path cache as part of resetting the IDL session.

ENABLE

Set this keyword to a non-zero value to specify that IDL should use the path cache when searching for files and also add new directories to the cache as they are opened. Set this keyword to zero to disable use of the cache when searching for files, and to discontinue adding new directories.

Note ────────────────────────────────────

Disabling the cache does not cause the current contents of the cache to be discarded. To discard the cache information, specify the CLEAR keyword.

──

REBUILD

Set this keyword to discard the current contents of the path cache (as if the CLEAR keyword had been specified), and then immediately rebuild the cache by searching the directories specified by the current value of the !PATH system variable for .pro and .sav files.

Note ────────────────────────────────────

If !PATH contains many directories, or if access to those directories is slow, rebuilding the cache using this method may also be slow. In many cases, the CLEAR keyword is sufficient, since IDL will rebuild the empty cache as program execution requires it to search for .pro and .sav files.

──

Situations in which IDL will not use the Path Cache

By default, IDL uses the path cache whenever it tries to locate .pro or .sav files. However, IDL will never use the path cache in the following situations:

Current Working Directory

The path cache is neither checked nor added to if the file being searched for exists in the current working directory. Before IDL searches !PATH for a file to compile, it always looks in the current working directory without checking the cache.

Relative Paths

The path cache does not cache directories specified relative to the current directory, even though relative paths are allowed in the specification of !PATH.

An absolute (or *fully qualified*) path is a path that completely specifies the location of a file. Under UNIX, an absolute path is specified relative to the root of the filesystem, and therefore starts with a slash (/) character. Under Microsoft Windows, an absolute

path starts with a drive letter (C:, for example) or a double backslash (\\) (if the file is specified using the Universal Naming Convention format). In contrast, a relative path is incomplete, and must be interpreted relative to the current working directory of the IDL process. IDL only caches absolute paths.

Executive Commands

The path cache is neither checked nor added to when a .COMPILE or .RUN executive command is issued. In such cases, IDL performs a standard directory-by-directory search of the directories included in !PATH.

IDL_NOCACHE File Present

IDL will not cache the contents of any directory that contains a file named IDL_NOCACHE. See "Marking Specific Directories as Uncacheable" on page 1783 for additional information on this feature.

Path Cache Disabled

IDL will neither check nor add files to the path cache if it has been disabled. See "Disabling the Path Cache", below, for additional information.

Disabling the Path Cache

By default, IDL caches the locations of .pro and .sav files in all directories specified by the !PATH system variable. Use of the path cache can be fully disabled in the following ways:

1. By issuing the PATH_CACHE command with the ENABLE keyword set equal to zero. This will disable the path cache until you manually re-enable it, or for the duration of the current IDL session. See the description of the ENABLE keyword, above, for details.

2. By unchecking the "Enable Path Caching" checkbox on the Path tab of the workbench Preferences dialog.

3. By defining setting the IDL_PATH_CACHE_DISABLE preference to true. See Appendix E, "IDL System Preferences" for details.

In addition, you can selectively disable use of the path cache for specific directories by creating a file named IDL_NOCACHE in the directory. See "Marking Specific Directories as Uncacheable" for details.

Marking Specific Directories as Uncacheable

You can mark specific directories as being uncacheable even though the directory is included in !PATH. To do so, create a file named IDL_NOCACHE in that directory.

Note —————————————————————————————

IDL does not inspect the contents of an IDL_NOCACHE file; it can contain anything you wish, or nothing at all. Under Unix operating systems, the IDL_NOCACHE file must be named exactly as shown, using all uppercase characters in the name. Under Microsoft Windows, the characters can have any case, but use upper case for consistency.

———————————————————————————————————————

When IDL encounters a directory containing an IDL_NOCACHE file during normal path searching, it makes a special entry in the path cache telling it that the directory must not be cached. Once this is done, all future attempts to locate files in that directory will be done without using cached information.

Note —————————————————————————————

If the directory to which you add an IDL_NOCACHE file has already been added to the path cache for the current IDL session, you must clear the existing cache (using the CLEAR keyword to the PATH_CACHE procedure) before the no-cache setting will take effect.

———————————————————————————————————————

To re-enable path caching for a directory that has been marked as uncacheable, remove the IDL_NOCACHE file, and then reset IDL's path cache in one of the following ways:

- Specify the CLEAR keyword to the PATH_CACHE procedure.
- Issue the .RESET_SESSION executive command.
- Exit and restart the IDL session.

Options for Avoiding Use of the Path Cache

In most cases, the files contained in directories included in !PATH do not change during an IDL session. In such cases the path cache is completely transparent to the IDL user, and serves only to speed compilation of IDL routines. As a result, there is rarely a reason to globally disable the path cache.

If files are created or deleted in a directory included in !PATH during an IDL session, the path cache can become confused and provide bad information to IDL about the contents of that directory. There are several ways to handle this situation. The

following list of alternatives is given in rough order of preference, with the easiest and lowest-impact options given first:

1. Leave the path cache enabled, and change your current working directory to the directory in which files are created or deleted. Since IDL checks the current working directory before checking the directories in !PATH, use of the path cache does not affect IDL's ability to find these files.

2. If the addition or deletion of files in a directory included in !PATH is a rare occurrence, leave the path cache enabled and clear it in one of the following ways after the contents of the directory have changed:

   • Specify the CLEAR keyword to the PATH_CACHE procedure.

   • Issue the .RESET_SESSION executive command.

   • Exit and restart the IDL session.

3. Leave the path cache enabled and use the .COMPILE or .RUN executive commands to force the compilation of any file, regardless of the contents of the path cache.

4. If you have a directory (other than your current working directory) in which files are regularly added or deleted during the execution of IDL sessions, you can leave path caching enabled but explicitly disable caching of that specific directory by creating an IDL_NOCACHE file, as described in "Marking Specific Directories as Uncacheable" on page 1783. This approach works for all IDL sessions that access the directory, and is therefore convenient in long-term or multi-user situations.

5. You can completely disable operation of the path cache using one of the methods described under "Disabling the Path Cache" on page 1782. This is not recommended, because most directories are not dynamic, and completely disabling path caching sacrifices the performance advantages of caching directories whose contents *are* static.

Note on Behavior at Startup

Depending on the value of your !PATH system variable, you may notice that some directories are being cached immediately when IDL starts up. This will occur if your path definition string includes the <IDL_DEFAULT> token, or if one or more entries include the "+" symbol. In these cases, in order for IDL to build the !PATH system variable, it must inspect subdirectories of the specified directories for the presence of .pro and .sav files, with the side effect of adding these directories to the path cache. See EXPAND_PATH for a discussion of IDL's path expansion behavior.

Examples

The following statement disables path caching for the current session:

```
PATH_CACHE, ENABLE = 0
```

The following statement disables path caching for the current session and throws away the current contents of the cache:

```
PATH_CACHE, ENABLE = 0, /CLEAR
```

Suppose you want to remove a directory included in !PATH from the cache without resetting your IDL session. The following statements cause the specified directory not to be included in future caching by creating a file named IDL_NOCACHE in that directory:

```
OPENW, UNIT = u, '/home/idluser/idl_dev_dir/IDL_NOCACHE', /GET_LUN
FREE_LUN, u
```

The OPENW and FREE_LUN statements create an empty file with the desired name in the target directory. Executing the following statement clears the cache so as to reflect the change in the current IDL session:

```
PATH_CACHE, /CLEAR
```

The next time IDL encounters this directory in a path search, it will see the presence of the IDL_NOCACHE and make a note in the path cache that the directory is not cacheable.

Note ───

You can also create the IDL_NOCACHE file outside IDL using any convenient command (text editor, Unix `touch` command, *etc.*). If the file is created outside IDL, only the PATH_CACHE, /CLEAR statement is necessary.

.FULL_RESET_SESSION, .RESET_SESSION, "!PATH" in Appendix D, "Environment Variables Used by IDL" (Chapter 1, *Using IDL*)

PATH_SEP

The PATH_SEP function returns the proper file path segment separator character for the current operating system. This is the character used by the host operating system for delimiting subdirectory names in a path specification. Use this function instead of hard-coding separators to make code more portable.

This routine is written in the IDL language. Its source code can be found in the file `path_sep.pro` in the `lib` subdirectory of the IDL distribution.

Syntax

Result = PATH_SEP([, /PARENT_DIRECTORY] [, /SEARCH_PATH])

Return Value

Returns a string containing the specified separator character.

Arguments

None.

Keywords

Specify at most one of the following keywords:

PARENT_DIRECTORY

If set, PATH_SEP returns the standard directory notation used by the host operating system to indicate the parent of a directory.

SEARCH_PATH

If set, PATH_SEP returns the character used to separate entries in a search path.

FILE_BASENAME, FILE_DIRNAME, FILE_SEARCH, FILEPATH

PCOMP

The PCOMP function computes the principal components of an *m*-column, *n*-row array, where *m* is the number of variables and *n* is the number of observations or samples. The principal components of a multivariate data set may be used to restate the data in terms of derived variables or may be used to reduce the dimensionality of the data by reducing the number of variables (columns).

This routine is written in the IDL language. Its source code can be found in the file pcomp.pro in the lib subdirectory of the IDL distribution.

Syntax

Result = PCOMP(*A* [, COEFFICIENTS=*variable*] [, /COVARIANCE] [, /DOUBLE]
   [, EIGENVALUES=*variable*] [, NVARIABLES=*value*] [, /STANDARDIZE]
   [, VARIANCES=*variable*])

Return Value

The result is an *nvariables*-column (*nvariables* ≤ *m*), *n*-row array of derived variables.

Arguments

A

An *m*-column, *n*-row, single- or double-precision floating-point array.

Keywords

COEFFICIENTS

Use this keyword to specify a named variable that will contain the principal components used to compute the derived variables. The principal components are the coefficients of the derived variables and are returned in an *m*-column, *m*-row array. The rows of this array correspond to the coefficients of the derived variables. The coefficients are scaled so that the sums of their squares are equal to the eigenvalue from which they are computed.

COVARIANCE

Set this keyword to compute the principal components using the covariances of the original data. The default is to use the correlations of the original data to compute the principal components.

DOUBLE

Set this keyword to use double-precision for computations and to return a double-precision result. Set DOUBLE=0 to use single-precision for computations and to return a single-precision result. The default is /DOUBLE if *Array* is double precision, otherwise the default is DOUBLE=0.

EIGENVALUES

Use this keyword to specify a named variable that will contain a one-column, *m*-row array of eigenvalues that correspond to the principal components. The eigenvalues are listed in descending order.

NVARIABLES

Use this keyword to specify the number of derived variables. A value of zero, negative values, and values in excess of the input array's column dimension result in a complete set (*m*-columns and *n*-rows) of derived variables.

STANDARDIZE

Set this keyword to convert the variables (the columns) of the input array to standardized variables (variables with a mean of zero and variance of one).

VARIANCES

Use this keyword to specify a named variable that will contain a one-column, *m*-row array of variances. The variances correspond to the percentage of the total variance for each derived variable.

Examples

```
PRO ex_pcomp

   ;Define an array with 4 variables and 20 observations.
   array = [[19.5, 43.1, 29.1, 11.9], $
            [24.7, 49.8, 28.2, 22.8], $
            [30.7, 51.9, 37.0, 18.7], $
            [29.8, 54.3, 31.1, 20.1], $
```

```
             [19.1, 42.2, 30.9, 12.9], $
             [25.6, 53.9, 23.7, 21.7], $
             [31.4, 58.5, 27.6, 27.1], $
             [27.9, 52.1, 30.6, 25.4], $
             [22.1, 49.9, 23.2, 21.3], $
             [25.5, 53.5, 24.8, 19.3], $
             [31.1, 56.6, 30.0, 25.4], $
             [30.4, 56.7, 28.3, 27.2], $
             [18.7, 46.5, 23.0, 11.7], $
             [19.7, 44.2, 28.6, 17.8], $
             [14.6, 42.7, 21.3, 12.8], $
             [29.5, 54.4, 30.1, 23.9], $
             [27.7, 55.3, 25.7, 22.6], $
             [30.2, 58.6, 24.6, 25.4], $
             [22.7, 48.2, 27.1, 14.8], $
             [25.2, 51.0, 27.5, 21.1]]

;Remove the mean from each variable.
m = 4    ; number of variables
n = 20   ; number of observations
means = TOTAL(array, 2)/n
array = array - REBIN(means, m, n)

;Compute derived variables based upon the principal components.
result = PCOMP(array, COEFFICIENTS = coefficients, $

PLOT

The PLOT procedure draws graphs of vector arguments. If one parameter is used, the vector parameter is plotted on the ordinate versus the point number on the abscissa. To plot one vector as a function of another, use two parameters. PLOT can also be used to create polar plots by setting the POLAR keyword.

Syntax

PLOT, [*X*,] *Y* [, /ISOTROPIC] [, MAX_VALUE=*value*] [, MIN_VALUE=*value*]
   [, NSUM=*value*] [, /POLAR] [, THICK=*value*] [, /XLOG] [, /YLOG]
   [, /YNOZERO]

Graphics Keywords: [, BACKGROUND=*color_index*] [, CHARSIZE=*value*]
   [, CHARTHICK=*integer*] [, CLIP=*[X$_0$, Y$_0$, X$_1$, Y$_1$]*] [, COLOR=*value*] [, /DATA |
   , /DEVICE | , /NORMAL] [, FONT=*integer*] [, LINESTYLE={0 | 1 | 2 | 3 | 4 | 5}]
   [, /NOCLIP] [, /NODATA] [, /NOERASE] [, POSITION=*[X$_0$, Y$_0$, X$_1$, Y$_1$]*]
   [, PSYM=*integer*{0 to 10}] [, SUBTITLE=*string*] [, SYMSIZE=*value*] [, /T3D]
   [, THICK=*value*] [, TICKLEN=*value*] [, TITLE=*string*]
   [, {X | Y | Z}CHARSIZE=*value*]
   [, {X | Y | Z}GRIDSTYLE=*integer*{0 to 5}]
   [, {X | Y | Z}MARGIN=*[left*, *right]*]
   [, {X | Y | Z}MINOR=*integer*]
   [, {X | Y | Z}RANGE=*[min*, *max]*]
   [, {X | Y | Z}STYLE=*value*]
   [, {X | Y | Z}THICK=*value*]
   [, {X | Y | Z}TICK_GET=*variable*]
   [, {X | Y | Z}TICKFORMAT=*string*]
   [, {X | Y | Z}TICKINTERVAL= *value*]
   [, {X | Y | Z}TICKLAYOUT=*scalar*]
   [, {X | Y | Z}TICKLEN=*value*]
   [, {X | Y | Z}TICKNAME=*string_array*]
   [, {X | Y | Z}TICKS=*integer*]
   [, {X | Y | Z}TICKUNITS=*string*]
   [, {X | Y | Z}TICKV=*array*]
   [, {X | Y | Z}TITLE=*string*]
   [, ZVALUE=*value*{0 to 1}]

Arguments

X

A vector representing the abscissa values to be plotted. If X is not specified, *Y* is plotted as a function of point number (starting at zero). If both arguments are provided, *Y* is plotted as a function of *X*.

This argument is converted to double precision floating-point before plotting. Plots created with PLOT are limited to the range and precision of double-precision floating-point values.

Y

The ordinate data to be plotted. This argument is converted to double-precision floating-point before plotting.

Keywords

ISOTROPIC

Set this keyword to force the scaling of the X and Y axes to be equal.

Note

The X and Y axes will be scaled isotropically and then fit within the rectangle defined by the POSITION keyword; one of the axes may be shortened. See "POSITION" on page 5470 for more information.

MAX_VALUE

The maximum value to be plotted. If this keyword is present, data values greater than the value of MAX_VALUE are treated as missing and are not plotted. Note that the IEEE floating-point value NaN is also treated as missing data. (See "Special Floating-Point Values" (Chapter 8, *Application Programming*) for more information on IEEE floating-point values.)

MIN_VALUE

The minimum value to be plotted. If this keyword is present, data values less than the value of MIN_VALUE are treated as missing and are not plotted. Note that the IEEE floating-point value NaN is also treated as missing data. (See "Special Floating-Point Values" (Chapter 8, *Application Programming*) for more information on IEEE floating-point values.)

NSUM

The presence of this keyword indicates the number of data points to average when plotting. If NSUM is larger than 1, every group of NSUM points is averaged to produce one plotted point. If there are *m* data points, then *m*/NSUM points are displayed. On logarithmic axes a geometric average is performed.

It is convenient to use NSUM when there is an extremely large number of data points to plot because it plots fewer points, the graph is less cluttered, and it is quicker.

POLAR

Set this keyword to produce polar plots. The *X* and *Y* vector parameters, both of which must be present, are first converted from polar to Cartesian coordinates. The first parameter is the radius, and the second is the angle (expressed in radians). For example, to make a polar plot, you would use a command such as:

```
PLOT, /POLAR, R, THETA
```

Note
See "Using AXIS with Polar Plots" on page 133 for an example that adds axes to a polar plot.

THICK

Controls the thickness of the lines connecting the points. A thickness of 1.0 is normal, 2 is double wide, etc.

XLOG

Set this keyword to specify a logarithmic X axis, producing a log-linear plot. Set both XLOG and YLOG to produce a log-log plot. Note that logarithmic axes that have ranges of less than a decade are not labeled.

YLOG

Set this keyword to specify a logarithmic Y axis, producing a linear-log plot. Set both XLOG and YLOG to produce a log-log plot. Note that logarithmic axes that have ranges of less than a decade are not labeled.

YNOZERO

Set this keyword to inhibit setting the minimum Y axis value to zero when the *Y* data are all positive and nonzero, and no explicit minimum Y value is specified (using YRANGE, or !Y.RANGE). By default, the Y axis spans the range of 0 to the

maximum value of *Y*, in the case of positive Y data. Set bit 4 in !Y.STYLE to make this option the default.

Graphics Keywords Accepted

See Appendix B, "Graphics Keywords" for the description of the following graphics and plotting keywords:

BACKGROUND, CHARSIZE, CHARTHICK, CLIP, COLOR, DATA, DEVICE, FONT, LINESTYLE, NOCLIP, NODATA, NOERASE, NORMAL, POSITION, PSYM, SUBTITLE, SYMSIZE, T3D, THICK, TICKLEN, TITLE, [XYZ]CHARSIZE, [XYZ]GRIDSTYLE, [XYZ]MARGIN, [XYZ]MINOR, [XYZ]RANGE, [XYZ]STYLE, [XYZ]THICK, [XYZ]TICKFORMAT, [XYZ]TICKINTERVAL, [XYZ]TICKLAYOUT, [XYZ]TICKLEN, [XYZ]TICKNAME, [XYZ]TICKS, [XYZ]TICKUNITS, [XYZ]TICKV, [XYZ]TICK_GET, [XYZ]TITLE, ZVALUE

Note

Many of the graphic keyword parameters correspond directly to fields in the system variables !P, !X, !Y, or !Z. When specifying a keyword parameter name and value in a call that value affects only the current call, the corresponding system-variable field is not changed. Changing the value of a system-variable field changes the default for that particular parameter and remains in effect until explicitly changed. The system variables involving graphics and their corresponding keywords are detailed in "!P" in Appendix D.

Examples

This section includes the following examples:

Note ──

Several of the following examples use batch files. See if IDL does not find the batch file.

───

Simple Plot

The PLOT procedure has many keywords that allow you to create a vast variety of plots. Here are a few simple examples using the PLOT command.

```
; Create a simple dataset:
D = FINDGEN(100)

; Create a simple plot with the title "Simple Plot":
PLOT, D, TITLE = 'Simple Plot'

; Plot one argument versus another:
PLOT, SIN(D/3), COS(D/6)

; Create a polar plot:
PLOT, D, D, /POLAR, TITLE = 'Polar Plot'

; Use plotting symbols instead of connecting lines by including the
; PSYM keyword. Label the X and Y axes with XTITLE and YTITLE:
PLOT, SIN(D/10), PSYM=4, XTITLE='X Axis', YTITLE='Y Axis'
```

X Versus Y Plots

This section illustrates the use of the basic *x* versus *y* plotting routines, PLOT and OPLOT. PLOT produces linear-linear plots by default, and can produce linear-log, log-linear, or log-log plots with the addition of the XLOG and YLOG keywords.

Data used in these examples are from a fictitious study of Pacific Northwest Salmon fisheries. In the example, we suppose that data were collected in the years 1967, 1970, and from 1975 to 1983. The following IDL statements create and initialize the variables SOCKEYE, COHO, CHINOOK, and HUMPBACK, which contain fictitious fish population counts, in thousands, for the 11 observations:

```
SOCKEYE=[463, 459, 437, 433, 431, 433, 431, 428, 430, 431, 430]
COHO=[468, 461, 431, 430, 427, 425, 423, 420, 418, 421, 420]
CHINOOK=[514, 509, 495, 497, 497, 494, 493, 491, 492, 493, 493]
HUMPBACK=[467, 465, 449, 446, 445, 444, 443, 443, 443, 443, 445]
; Construct a vector in which each element contains
; the year of the sample:
YEAR = [1967, 1970, INDGEN(9) + 1975]
```

Example Code

If you prefer not to enter the data by hand, run the batch file `plot01`, located in the `examples/doc/plot` subdirectory of the IDL installation directory with the following command at the IDL prompt:

`@plot01`

The following IDL commands create a plot of the population of Sockeye salmon, by year:

```
PLOT, YEAR, SOCKEYE, $
   TITLE='Sockeye Population', XTITLE='Year', $
   YTITLE='Fish (thousands)'
```

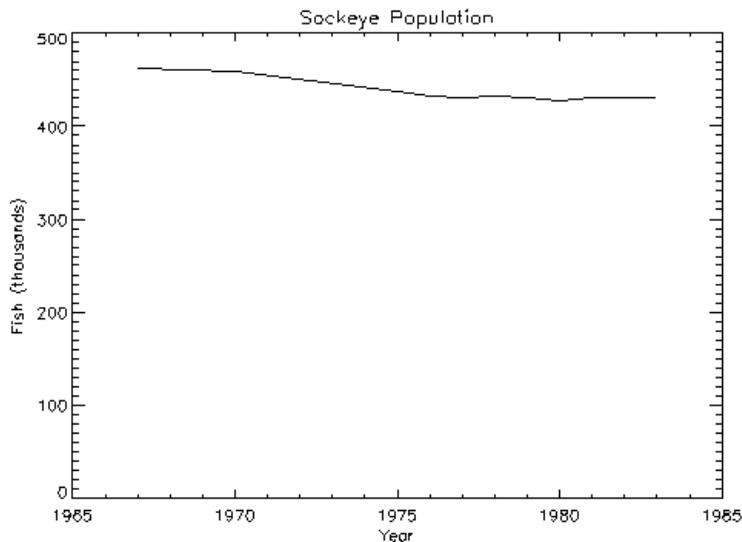
The PLOT procedure, which produces an *x* versus *y* plot on a new set of axes, requires one or two parameters: a vector of *y* values or a vector of *x* values followed by a vector of *y* values. The first attempt at making a plot produces the figure shown below. Note that the three titles, defined by the keywords TITLE, XTITLE, and YTITLE, are optional.


Figure 18-1: Initial Population Plot

Axis Scaling

The fluctuations in the data are hard to see because the scores range from 428 to 463, and the plot's *y*-axis is scaled from 0 to 500. Two factors cause this effect. By default, IDL sets the minimum *y*-axis value of linear plots to zero if the *y* data are all positive. The maximum axis value is automatically set by IDL from the maximum *y* data value. In addition, IDL attempts to produce from three to six tick-mark intervals that are in increments of an integer power of 10 times 2, 2.5, 5, or 10. In this example, this rounding effect causes the maximum axis value to be 500, rather than 463.

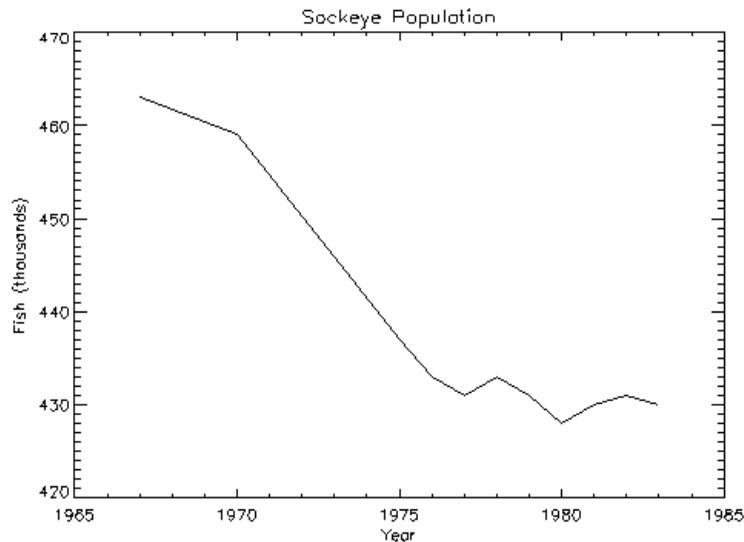
The YNOZERO keyword parameter inhibits setting the *y*-axis minimum to zero when given positive, nonzero data. The figure below illustrates the data plotted using this keyword. The *y*-axis now ranges from 420 to 470, and IDL creates tick-mark intervals of 10.


Figure 18-2: Properly Scaled Plot

```
; Define variables:
@plot01
PLOT, YEAR, SOCKEYE, /YNOZERO, $
   TITLE='Sockeye Population', XTITLE='Year', $
   YTITLE='Fish (thousands)'
```

Multiline Titles

The graph-text positioning command !C, starts a new line of text output. Titles containing more than one line of text are easily produced by separating each line with this positioning command.

In the above example, the main title could have been displayed on two centered lines by changing the keyword parameter TITLE to the following statement:

```
TITLE = 'Sockeye!CPopulation'
```

Note ──

When using multiple line titles you may find that the default margins are inadequate, causing the titles to run off the page. In this case, set the [XY]MARGIN keywords or increase the values of !X.MARGIN or !Y.MARGIN.

───

Range Keyword

The range of the *x*, *y*, or *z* axes can be explicitly specified with the [XYZ] RANGE keyword parameter. The argument of the keyword parameter is a two-element vector containing the minimum and maximum axis values.

As explained above, IDL attempts to produce even tick intervals, and the axis range selected by IDL may be slightly larger than that given with the RANGE keyword. To obtain the exact specified interval, set the axis style parameter to one (YSTYLE = 1).

The effect of the YNOZERO keyword is identical to that obtained by including the keyword parameter YRANGE = [MIN(Y), MAX(Y)] in the call to PLOT. You can make /YNOZERO the default in subsequent plots by setting bit 4 of !Y.STYLE to one (!Y.STYLE = 16).

See "STYLE" on page 5524 for details on the STYLE field of the axis system variables !X, !Y, and !Z. Briefly: Other bits in the STYLE field extend the axes by providing a margin around the data, suppress the axis and its notation, and suppress the box-style axes by drawing only left and bottom axes.

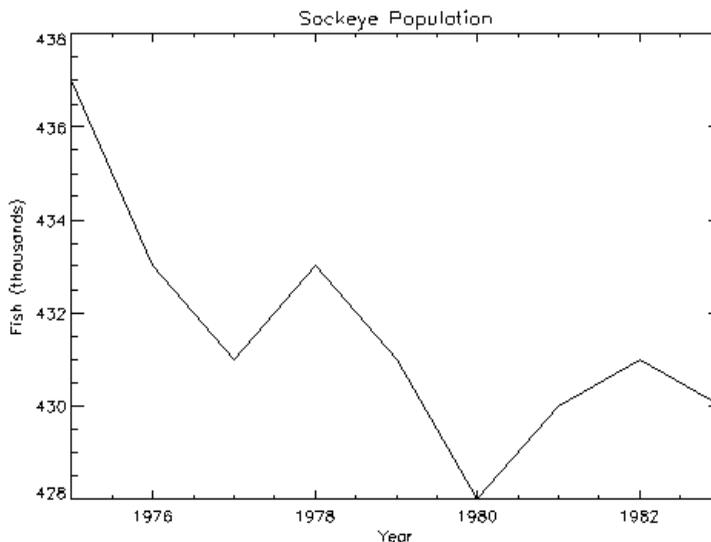
For example, to constrain the x-axis to the years 1975 to 1983, the keyword parameter XRANGE = [1975, 1983] is included in the call to PLOT. The following figure illustrates the result.


Figure 18-3: Plot with X-Axis Range of 1975 to 1983

Note that the *x*-axis actually extends from 1974 to 1984, as IDL elected to make five tick-mark intervals, each spanning two years. If, as explained above, the *x*-axis style is set to one, the plot will exactly span the given range. The call combining all these options is as follows:

```
; Define variables:
@plot01
PLOT, YEAR, SOCKEYE, /YNOZERO, $
   TITLE='Sockeye Population', XTITLE = 'Year', $
   YTITLE = 'Fish (thousands)', XRANGE = [1975, 1983], /XSTYLE
```

Note ──

The keyword parameter syntax /XSTYLE is synonymous with the expression XSTYLE = 1. Setting a keyword parameter to 1 is often referred to as simply setting the keyword.

──

Plotting Symbols

Each data point can be marked with a symbol and/or connected with lines. The value of the keyword parameter PSYM selects the marker symbol, as described in "PSYM" on page 5471. For example, a value of 1 marks each data point with the plus sign (+), 2 is an asterisk (*), etc. Setting PSYM to minus the symbol number marks the points with a symbol and connects them with lines. A value of –1 marks points with a plus sign (+) and connects them with lines. Note also that setting PSYM to a value of 10 produces histogram style plots in which a horizontal line is drawn across each *x* bin.

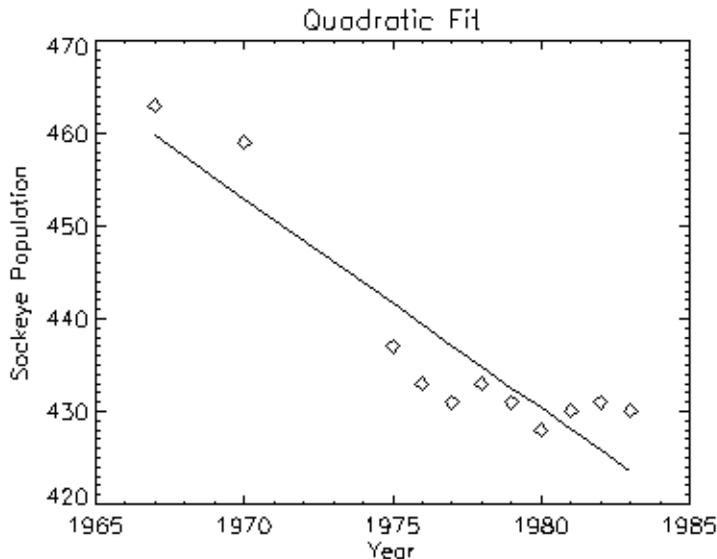
Frequently, when data points are plotted against the results of a fit or model, symbols are used to mark the data points while the model is plotted using a line. The figure below illustrates this, fitting the Sockeye population values to a quadratic function of the year. The IDL function POLY_FIT is used to calculate the quadratic.


Figure 18-4: Plotting with Predefined Marker Symbols

The statements used to construct the above plot are as follows:

```
; Define variables.
@plot01
; Use the LINFIT function to fit the data to a line:
coeff = LINFIT(YEAR, SOCKEYE)
;YFIT is the fitted line:
YFIT = coeff[0] + coeff[1]*YEAR
```

```
; Plot the original data points with PSYM = 4, for diamonds:
PLOT, YEAR, SOCKEYE, /YNOZERO, PSYM = 4, $
   TITLE = 'Quadratic Fit', XTITLE = 'Year', $
   YTITLE = 'Sockeye Population'
; Overplot the smooth curve using a plain line:
OPLOT, YEAR, YFIT
```

Example Code

Alternatively, you can run the `plot03` batch file to create the plot by entering:
@plot03

Bar Charts

Bar (or box) charts are used in business-style graphics and are useful in comparing a small number of measurements within a few discrete data sets. Although not designed as a tool for business graphics, IDL can produce many business-style plots with little effort.

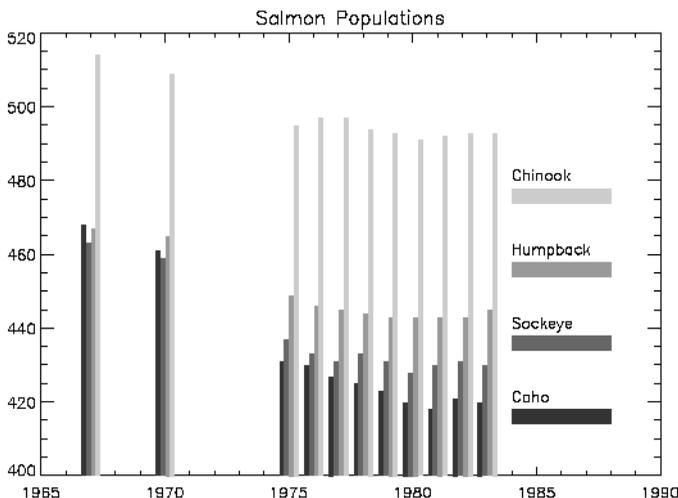
The following example produces a box-style chart showing the four salmon populations as boxes of differing colors or shading. The commands used to draw the next figure are shown below with annotation.


Figure 18-5: Bar Chart Drawn with POLYFILL

Example Code

You do not need to type these commands in yourself; they are collected in the files plot05.pro, which contains the two procedures, and the batch file, plot06, which creates the plot. These files are located in the examples/doc/plot subdirectory of the IDL distribution. Run the example procedure by entering plot05 at the IDL command prompt or view the file in an IDL Editor window by entering .EDIT plot05.pro.

First, we define a procedure called EX_BOX, which draws a box given the coordinates of two diagonal corners:

```
; Define a procedure that draws a box, using POLYFILL,
; whose corners are (X0, Y0) and (X1, Y1):
PRO EX_BOX, X0, Y0, X1, Y1, color
   ; Call POLYFILL:
   POLYFILL, [X0, X0, X1, X1], [Y0, Y1, Y1, Y0], COL = color
END
```

Next, create a procedure to draw the bar graph:

```
PRO EX_BARGRAPH, minval
   ; Define variables:
   @plot01
   ; Width of bars in data units:
   del = 1./5.
   ; The number of colors used in the bar graph is
   ; defined by the number of colors available on your system:
   ncol=!D.N_COLORS/5
   ; Create a vector of color indices to be used in this procedure:
   colors = ncol*INDGEN(4)+ncol
   ; Loop for each sample:
   FOR iscore = 0, 3 DO BEGIN
   ; The y value of annotation. Vertical separation is 20 data
   ; units:
   yannot = minval + 20 *(iscore+1)
   ; Label for each bar:
   XYOUTS, 1984, yannot, names[iscore]
   ; Bar for annotation:
   EX_BOX, 1984, yannot - 6, 1988, yannot - 2, colors[iscore]
   ; The x offset of vertical bar for each sample:
   xoff = iscore * del - 2 * del
   ; Draw vertical box for each year's sample:
   FOR iyr=0, N_ELEMENTS(year)-1 DO $
      EX_BOX, year[iyr] + xoff, minval, $
      year[iyr] + xoff + del, $
      allpts[iyr, iscore], $
      colors[iscore]
   ENDFOR
```

```
        END
```

Enter the following at the IDL prompt to compile these two procedures from the IDL distribution:

```
.run plot05.pro
```

To create the bar graph on your screen, enter the following commands.

```
; Load a color table:
LOADCT, 39
```

As in the previous example, the PLOT procedure is used to draw the axes and to establish the scaling using the NODATA keyword.

```
PLOT, year, CHINOOK, YRANGE = [MIN(allpts),MAX(allpts)], $
   TITLE = 'Salmon Populations', /NODATA, $
   XRANGE = [year[0], 1990]
; Get the y value of the bottom x-axis:
minval = !Y.CRANGE[0]
; Create the bar chart:
EX_BARGRAPH, minval
```

Specifying Tick Marks

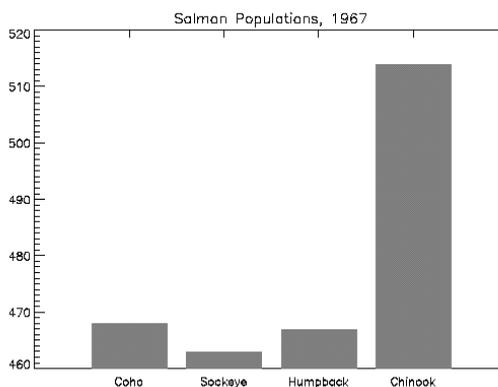
The following figure shows a box chart illustrating the direct specification of the *x*-axis tick values, number of ticks, and tick names. Building upon the previous program, this program shows each of the four scores for the year 1967, the first year in our data. It uses the EX_BOX procedure from the previous example to draw a rectangle for each sample.


Figure 18-6: Controlling Tick Marks and Their Annotation

Enter the following command at the IDL prompt to compile the EX_BOX and EX_BARGRAPH procedures (discussed in the previous example) from the IDL distribution:

```
.run plot05.pro
```

Enter the following commands to create the box chart:

```
; Define variables:
@plot01
; Tick x values, 0.2, 0.4, 0.6, 0.8:
XVAL = FINDGEN(4)/5. + .2
; Make a vector of scores from first year, corresponding to
; the name vector from above:
YVAL = [COHO[0], SOCKEYE[0], HUMPBACK[0], CHINOOK[0]]
; Make the axes with no data. Force x range to [0, 1],
; centering xval, which also contains the tick values.
; Force three tick intervals making four tick marks.
; Specify the tick names from the names vector:
PLOT, XVAL, YVAL, /YNOZERO/, XRANGE = [0,1], XTICKV = XVAL, $
   XTICKS = 3, XTICKNAME = NAMES, /NODATA, $
   TITLE = 'Salmon Populations, 1967'
; Draw the boxes, centered over the tick marks.
; !Y.CRANGE[0] is the y value of the bottom x-axis.
FOR I = 0, 3 DO EX_BOX, XVAL[I] - .08, !Y.CRANGE[0], $
   XVAL[I] + 0.08, YVAL[I], 128
```

Example Code ————————————————

Alternatively, you can enter @plot07 at the IDL command prompt to run the plot07 batch file and create the plot.

———————————————————————————————————————

Note ————————————————

You can display date/time data on plots, contours, and surfaces through the tick settings of the date/time axis. Date/time data can be displayed on any axis (x, y or z). The date/time data is stored as Julian dates, but the LABEL_DATE routine and axis keywords allow you to display this data as calendar dates. See LABEL_DATE for examples.

———————————————————————————————————————

Logarithmic Scaling

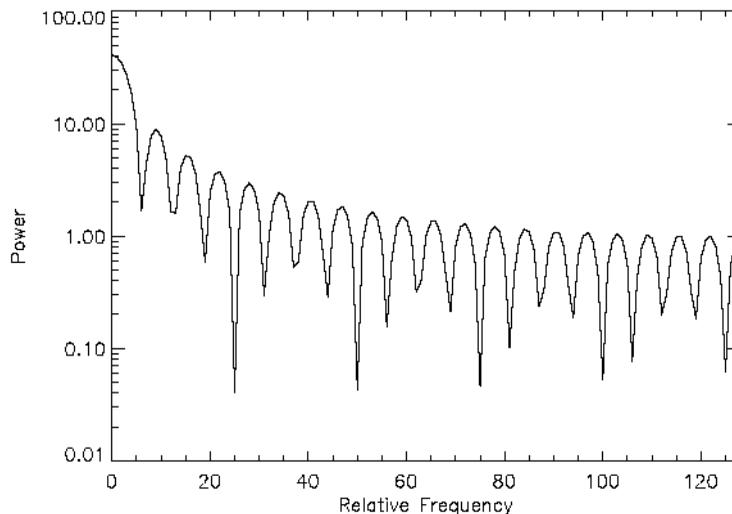
The XLOG, YLOG, and ZLOG keywords can be used with the PLOT routine to get any combination of linear and logarithmic axes. The OPLOT procedure uses the same scaling and transformation as did the most recent plot.


Figure 18-7: Example of Logarithmic Scaling

The figure illustrates using PLOT to make a linear-log plot. It was produced with the following statements:

```
; Create data array:
X = FLTARR(256)
; Make a step function. Array elements 80 through 120 are set to 1:
X[80:120] = 1
; Make a filter:
FREQ = FINDGEN(256)
; Make the filter symmetrical about the value x = 128:
FREQ = FREQ < (256-FREQ)
; Second order Butterworth, cutoff frequency = 20.
FIL = 1./(1+(FREQ/20)^2)
; Plot with a logarithmic x-axis. Use exact axis range:
PLOT, /YLOG, FREQ, ABS(FFT(X,1)), $
    XTITLE = 'Relative Frequency', YTITLE = 'Power', $
    XSTYLE = 1
; Plot graph:
OPLOT, FREQ, FIL
```

Example Code ——————————————————————

Alternatively, you can run the `plot08` batch file to create the plot:

```
@plot08
```

Multiple Plots on a Page

Plots can be grouped on the display or page in the horizontal and/or vertical directions using the system variable field !P.MULTI. IDL sets the plot window to produce the given number of plots on each page and moves the window to a new sector at the beginning of each plot. If the page is full, it is first erased. If more than two rows or columns of plots are produced, IDL decreases the character size by a factor of 2.

!P.MULTI controls the output of multiple plots. Set !P.MULTI equal to an integer vector in which:

- The first element of the vector contains the number of empty sectors remaining on the page. The display is erased if this field is zero when a new plot is begun.

- The second element of the vector contains the number of plots per page in the horizontal direction.

- The third element contains the number of plots per page in the vertical direction.

- The fourth element contains the number of plots stacked in the Z dimension.

- The fifth element controls the order in which plots are drawn. Set the fifth element equal to zero to make plots from left to right (column major), and top to bottom. Set the fifth element equal to one to make plots from top to bottom, left to right (row major).

Omitting any of the five elements from the vector is the same as setting that element equal to zero.

For example, to set up IDL to stack two plots vertically on each page, use the following statement:

```
!P.MULTI = [0, 1, 2]
```

Note that the first element, !P.MULTI (0), is set to zero to cause the next plot to begin a new page. To make four plots per page with two columns and two rows, use the following statement:

```
!P.MULTI = [0, 2, 2]
```

To reset to the default of one plot per page, set the value of !P.MULTI to 0, as shown
in the following statement:

```
!P.MULTI = 0
```

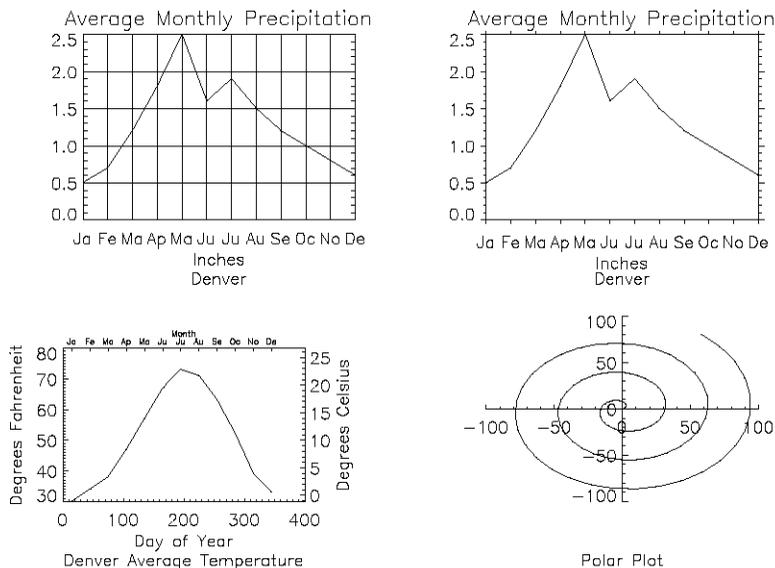

Figure 18-8: Multiple Plots Per Page, Various Tick Marks, and Multiple Axes

This figure shows four plots in a single window.

Example Code

For details, inspect the batch file `plot09` in the `examples/doc/plot`
subdirectory of the IDL distribution or type `@plot09` at the IDL command prompt
to run the example.

Note the following features of the plots in the figure:

1. The plot in the upper left has grid-style tick marks. This is accomplished by
   setting the TICKLEN keyword equal to 1.0

2. The plot in the upper right has outward-facing tick marks. This is
   accomplished by setting the TICKLEN keyword to a negative value.

3. The plot in the lower left corner has different axes on left and right, top and bottom. This is accomplished by drawing the top and right axes separately, using the AXIS procedure.

4. The plot in the lower right uses no default axes at all. The centered axes are drawn with calls to the AXIS procedure.

Specifying the Location of the Plot

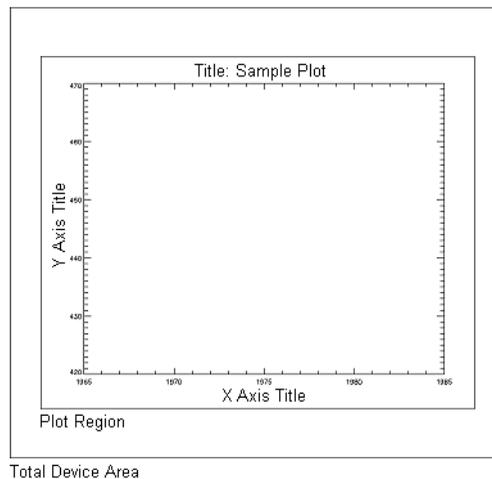
The plot-data window is the region of the page or screen enclosed by the axes. The plot region is the box enclosing the plot-data window and the titles and tick annotation.


Figure 18-9: The Plot-Data Window, Plot Region, and Device Area Relationship

The figure illustrates the relationship of the plot-data window, plot region, and the entire device area. These areas are determined by the following system variables and keyword parameters, in order of decreasing precedence:

> POSITION
>
> !P.POSITION
>
> !P.REGION
>
> !P.MULTI

[XYZ]MARGIN

![XYZ].MARGIN

Plotting Missing Data

The MAX_VALUE and MIN_VALUE keywords to PLOT can be used to create missing data plots wherein bad data values are not plotted. Data values greater than the value of the MAX_VALUE keyword or less than the value of the MIN_VALUE keyword are treated as missing and are not plotted. The following code creates a dataset with bad data values and plots it with and without these keywords:

```
; Make a 100-element array where each element is
; set equal to its index:
A = FINDGEN(100)
; Set 20 random point in the array equal to 400.
; This simulates "bad" data values above the range
; of the "real" data.
A(RANDOMU(SEED, 20)*100)=400
; Set 20 random point in the array equal to -10.
; This simulates "bad" data values below the range
; of the "real" data.
A(RANDOMU(SEED, 20)*100)=-10
; Plot the dataset with the bad values. Looks pretty bad!
PLOT, A
; Plot the dataset, but don't plot any value over 101.
; The resulting plot looks better, but still shows spurious values:
PLOT, A, MAX_VALUE=101
; This time leave out both high and low spurious values.
; The resulting plot more accurately reflects the "real" data:
PLOT, A, MAX_VALUE=101, MIN_VALUE=0
```

The following plotting routines allow you to set maximum and minimum values in this manner: CONTOUR, PLOT, SHADE_SURF, SURFACE.

In addition to the maximum and minimum values specified with the MAX_VALUE and MIN_VALUE keywords, these plotting routines treat the IEEE floating-point value NaN (Not A Number) as missing data automatically. (For more information on NaN, see "Special Floating-Point Values" (Chapter 8, *Application Programming*).)

PLOT_3DBOX

The PLOT_3DBOX procedure plots a function of two variables (e.g., *Z=f(X, Y)*) inside a 3-D box. Optionally, the data can be projected onto the "walls" surrounding the plot area.

This routine is written in the IDL language. Its source code can be found in the file plot_3dbox.pro in the lib subdirectory of the IDL distribution.

Syntax

PLOT_3DBOX, *X*, *Y*, *Z* [, AX=*degrees*] [, AZ=*degrees*] [, GRIDSTYLE={0 | 1 | 2 | 3 | 4 | 5}] [, PSYM=*integer*{1 to 10}] [, /SOLID_WALLS] [, /XY_PLANE] [, XYSTYLE={0 | 1 | 2 | 3 | 4 | 5}] [, /XZ_PLANE] [, XZSTYLE={0 | 1 | 2 | 3 | 4 | 5}] [, /YZ_PLANE] [, YZSTYLE={0 | 1 | 2 | 3 | 4 | 5}] [, ZAXIS={1 | 2 | 3 | 4}]

Graphics Keywords: Accepts all graphics keywords accepted by PLOT except for: FONT, PSYM, SYMSIZE, {XYZ}TICK_GET, and ZVALUE.

Arguments

X

A vector (i.e., a one-dimensional array) of X coordinates.

Y

A vector of Y coordinates.

Z

A vector of Z coordinates. *Z[i]* is a function of *X[i]* and *Y[i]*.

Keywords

AX

This keyword specifies the angle of rotation, about the X axis, in degrees towards the viewer. This keyword is effective only if !P.T3D is not set. If !P.T3D is set, the three-dimensional to two-dimensional transformation used by PLOT_3DBOX is taken from the 4 by 4 array !P.T.

The surface represented by the two-dimensional array is first rotated, AZ (see below) degrees about the Z axis, then by AX degrees about the X axis, tilting the surface towards the viewer (AX > 0), or away from the viewer.

The AX and AZ keyword parameters default to +30 degrees if omitted and !P.T3D is 0.

The three-dimensional to two-dimensional transformation represented by AX and AZ, can be saved in !P.T by including the SAVE keyword.

AZ

This keyword specifies the counterclockwise angle of rotation about the Z axis. This keyword is effective only if !P.T3D is not set. The order of rotation is AZ first, then AX.

GRIDSTYLE

Set this keyword to the linestyle index for the type of line to be used when drawing the gridlines. Linestyles are described in the following table:

Index	Linestyle
0	Solid
1	Dotted
2	Dashed
3	Dash Dot
4	Dash Dot Dot
5	Long Dashes

Table 18-1: IDL Linestyles

PSYM

Set this keyword to a plotting symbol index to be used in plotting the data. For more information, see "PSYM" on page 5471.

SOLID_WALLS

Set this keyword to cause the boundary "walls" of the plot to be filled with the color index specified by the COLOR keyword.

XY_PLANE

Set this keyword to plot the *X* and *Y* values on the Z=0 axis plane.

XYSTYLE

Set this keyword to the linestyle used to draw the XY plane plot. See the table above for a list of linestyles.

XZ_PLANE

Set this keyword to plot the *Y* and *Z* values on the Y=MAX(*Y*) axis plane.

XZSTYLE

Set this keyword to the linestyle used to draw the XZ plane plot. See the table above for a list of linestyles.

YZ_PLANE

Set this keyword to plot the *Y* and *Z* values on the X=MAX(*X*) axis plane.

YZSTYLE

Set this keyword to the linestyle used to draw the YZ plane plot. See the table above for a list of linestyles.

ZAXIS

This keyword specifies the placement of the Z axis for the PLOT_3DBOX plot.

By default, PLOT_3DBOX draws the Z axis at the upper left corner of the axis box. To suppress the Z axis, use ZAXIS=-1 in the call. The position of the Z axis is determined from the value of ZAXIS as follows: 1 = lower right, 2 = lower left, 3 = upper left, and 4 = upper right.

Graphics Keywords Accepted

See Appendix B, "Graphics Keywords" for the description of the following graphics and plotting keywords:

BACKGROUND, CHARSIZE, CHARTHICK, CLIP, COLOR, DATA, DEVICE, LINESTYLE, NOCLIP, NOERASE, NORMAL, POSITION, SUBTITLE, T3D, THICK, TICKLEN, TITLE, [XYZ]CHARSIZE, [XYZ]GRIDSTYLE, [XYZ]MARGIN, [XYZ]MINOR, [XYZ]RANGE, [XYZ]STYLE, [XYZ]THICK,

[XYZ]TICKFORMAT, [XYZ]TICKLEN, [XYZ]TICKNAME, [XYZ]TICKS, [XYZ]TICKV, [XYZ]TITLE

Examples

```
; Create some data to be plotted:
X = REPLICATE(5., 10.)
X1 = COS(FINDGEN(36)*10.*!DTOR)*2.+5.
X = [X, X1, X]
Y = FINDGEN(56)
Z = REPLICATE(5., 10)
Z1 = SIN(FINDGEN(36)*10.*!DTOR)*2.+5.
Z = [Z, Z1, Z]

; Create the box plot with data projected on all of the walls. The
; PSYM value of -4 plots the data as diamonds connected by lines:
PLOT_3DBOX, X, Y, Z, /XY_PLANE, /YZ_PLANE, /XZ_PLANE, $
    /SOLID_WALLS, GRIDSTYLE=1, XYSTYLE=3, XZSTYLE=4, $
    YZSTYLE=5, AZ=40, TITLE='Example Plot Box', $
    XTITLE='X Coordinate', YTITLE='Y Coodinate', $
    ZTITLE='Z Coordinate', SUBTITLE='Sub Title', $
    /YSTYLE, ZRANGE=[0,10], XRANGE=[0,10], $
    PSYM=-4, CHARSIZE=1.6
```

PLOT_FIELD

The PLOT_FIELD procedure plots a 2-D field. *N* random points are picked, and from each point a path is traced along the field. The length of the path is proportional to the field vector magnitude.

This routine is written in the IDL language. Its source code can be found in the file plot_field.pro in the lib subdirectory of the IDL distribution.

Syntax

PLOT_FIELD, *U*, *V* [, ASPECT=*ratio*] [, LENGTH=*value*] [, N=*num_arrows*]
   [, TITLE=*string*]

Arguments

U

A 2-D array giving the field vector at each point in the U(X) direction.

V

A 2-D array giving the field vector at each point in the V(Y) direction.

Keywords

ASPECT

Set this keyword to the aspect ratio of the plot (i.e., the ratio of the X size to Y size). The default is 1.0.

LENGTH

Set this keyword to the length of the longest field vector expressed as a fraction of the plotting area. The default is 0.1.

N

Set this keyword to the number of arrows to draw. The default is 200.

TITLE

Set this keyword to the title of plot. The default is ''Velocity Field''.

Examples

```
; Create array X:
X = FINDGEN(20, 20)

; Create array Y:
Y = FINDGEN(20, 20)*3

; Plot X vs. Y:
PLOT_FIELD, X, Y
```

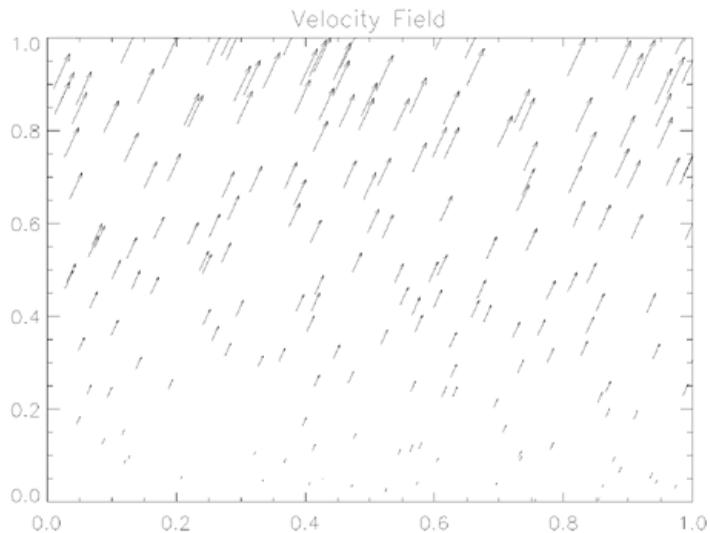
The above commands produce the following plot:


Figure 18-10: PLOT_FIELD Example

FLOW3, VEL, VELOVECT

PLOTERR

The PLOTERR procedure plots individual data points with error bars.

This routine is written in the IDL language. Its source code can be found in the file ploterr.pro in the lib subdirectory of the IDL distribution.

Syntax

PLOTERR, [*X* ,] *Y* , *Err* [, TYPE={1 | 2 | 3 | 4}] [, PSYM=*integer*{1 to 10}]

Arguments

X

An optional array of X values. The procedure checks the number of arguments passed to decide if X was passed. If X is not passed, INDGEN(Y) is assumed for X values.

Y

The array of Y values. *Y* cannot be of type string.

Err

The array of error-bar values.

Keywords

TYPE

The type of plot to be produced. The possible types are:

- 1 = X Linear - Y Linear (default)
- 2 = X Linear - Y Log
- 3 = X Log - Y Linear
- 4 = X Log - Y Log

PSYM

The plotting symbol to use. The default is +7.

Version History

ERRPLOT, IPLOT, OPLOTERR, PLOT

PLOTS

The PLOTS procedure plots vectors or points on the current graphics device in either two or three dimensions. The coordinates can be given in data, device, or normalized form using the DATA (the default), DEVICE, or NORMAL keywords.

The COLOR keyword can be set to a scalar or vector value. If it is set to a vector value, the line segment connecting (X_i, Y_i) to (X_{i+1}, Y_{i+1}) is drawn with a color index of $COLOR_{i+1}$. In this case, COLOR must have the same number of elements as *X* and *Y*.

Syntax

PLOTS, *X* [, *Y* [, *Z*]] [, /CONTINUE]

Graphics Keywords: [, CLIP=*[X$_0$, Y$_0$, X$_1$, Y$_1$]*] [, COLOR=*value*] [, /DATA | , /DEVICE | , /NORMAL] [, LINESTYLE={0 | 1 | 2 | 3 | 4 | 5}] [, /NOCLIP] [, PSYM=*integer*{0 to 10}] [, SYMSIZE=*value*] [, /T3D] [, THICK=*value*] [, Z=*value*]

Arguments

X

A vector or scalar argument providing the X components of the points to be connected. If only one argument is specified, *X* must be an array of either two or three vectors (i.e., (2,*) or (3,*)). In this special case, X[0,*] are taken as the X values, X[1,*] are taken as the Y values, and X[2,*] are taken as the Z values.

Y

An optional argument providing the Y coordinate(s) of the points to be connected.

Z

An optional argument providing the Z coordinates of the points to be connected. If *Z* is not provided, X and Y are used to draw lines in two dimensions.

Z has no effect if the keyword T3D is not specified and the system variable !P.T3D= 0.

Keywords

CONTINUE

Set this keyword to continue drawing a line from the last point of the most recent call to PLOTS.

For example:

```
; Draw X and Y axes
AXIS, XAXIS=0 & AXIS, YAXIS=0

; Position at (0,0):
PLOTS, 0, 0

; Draws vector from (0,0) to (3,3):
PLOTS, 3, 3, /CONTINUE

; Draws two vectors from (3,3) to (5,3) to (2,7):
PLOTS, [5,2], [3,7], /CONTINUE
```

Graphics Keywords Accepted

See Appendix B, "Graphics Keywords" for the description of the following graphics and plotting keywords:

CLIP, COLOR, DATA, DEVICE, LINESTYLE, NOCLIP, NORMAL, PSYM, SYMSIZE, T3D, THICK, Z

Examples

Draw a line from (100, 200) to (600, 700), in device coordinates:

```
PLOTS, [100,600], [200,700], /DEVICE
```

Draw a polyline where the line color is proportional to the ordinate that ends each line segment.

```
; Set IDL to use decomposed color mode and load a good
; colortable to better show the result:
DEVICE, DECOMPOSED=0
LOADCT, 13

; Create datasets X and Y:
X = SIN(FINDGEN(100)) & Y = COS(FINDGEN(100))

; Now plot X and Y in normalized coordinates with colors as
; described above:
```

```
PLOTS, X, Y, COLOR = BYTSCL(Y, TOP=!D.N_COLORS-1), /NORMAL
```

Draw 3-D vectors over an established SURFACE plot. The SAVE keyword tells IDL to save the 3-D transformation established by SURFACE.

```
; Load the standard grayscale color table:
LOADCT, 0

; Draw a surface plot:
SURFACE, DIST(5), /SAVE

; Draw a line between (0,0,0) and (3,3,3). The T3D keyword makes
; PLOTS use the previously established 3-D transformation:
PLOTS, [0,3], [0,3], [0,3], /T3D

; Draw a line between (3,0,0) and (3,3,3):
PLOTS, [3,3], [0,3], [0,3], /T3D

; Draw a line between (0,3,0) and (3,3,3):
PLOTS, [0,3], [3,3], [0,3], /T3D
```

PNT_LINE

The PNT_LINE function computes the perpendicular distance between a point *P0* and a line between points *L0* and *L1*. This function is limited by the machine accuracy of single precision floating point.

This routine is written in the IDL language. Its source code can be found in the file pnt_line.pro in the lib subdirectory of the IDL distribution.

Syntax

Result = PNT_LINE(*P0*, *L0*, *L1* [, *Pl*] [, /INTERVAL])

Return Value

Returns the perpendicular distance.

Arguments

P0

The location of the point. *P0* may have 2 to *n* elements, for *n* dimensions.

L0

One end-point of the line. *L0* must have same number of elements as *P0*.

L1

The other end-point of the line. *L1* must have the same number of elements as *L0*.

PI

A named variable that will contain the location of the point on the line between *L0* and *L1* that is closest to *P0*. *Pl* is not necessarily in the interval (*L0, L1*).

Keywords

INTERVAL

If set, and if the point on the line between *L0* and *L1* that is closest to *P0* is not within the interval (*L0, L1*), PNT_LINE will return the distance from *P0* to the closer of the two endpoints *L0* and *L1*.

Examples

To print the distance between the point (2,3) and the line from (-3,3) to (5,12), and also the location of the point on the line closest to (2,3), enter the following command:

```
PRINT, PNT_LINE([2,3], [-3,3], [5,12], Pl), Pl
```

IDL prints:

```
3.73705    -0.793104      5.48276
```

POINT_LUN

The POINT_LUN procedure sets or obtains the current position of the file pointer for the specified file.

Note ——

POINT_LUN cannot be used with files opened with the RAWIO keyword to the OPEN routines. Depending upon the device in question, the IOCTL function might be used instead for files of this type.

——

Use Of POINT_LUN On Compressed Files

In general, it is not possible to arbitrarily move the file pointer within a compressed file (files opened with the COMPRESS keyword to OPEN) because the file compression code needs to maintain a compression state for the file that includes all the data that has already been passed in the stream. This limitation results in the following constraints on the use of POINT_LUN with compressed files:

- POINT_LUN is not allowed on compressed files open for output, except to positions beyond the current file position. The compression code emulates such motion by outputting enough zero bytes to move the pointer to the new position.

- POINT_LUN is allowed to arbitrary positions on compressed files opened for input. However, this feature is emulated by positioning the file to the beginning of the file and then reading and discarding enough data to move the file pointer to the desired position. This can be extremely slow.

For these reasons, use of POINT_LUN on compressed files, although possible under some circumstances, is best avoided.

Syntax

POINT_LUN, *Unit*, *Position*

Arguments

Unit

The file unit for the file in question. If *Unit* is positive, POINT_LUN sets the file position to the position given by *Position*. If negative, POINT_LUN gets the current

file position and assigns it to the variable given by *Position*. Note that POINT_LUN cannot be used with the 3 standard file units (0, -1, and -2).

Position

If *Unit* is positive, *Position* gives the byte offset into the file at which the file pointer should be set. For example, to rewind the file to the beginning, specify 0.

If *Unit* is negative, *Position* must be a named variable into which the current file position will be stored. The returned type will be a longword signed integer if the position is small enough to fit, and a 64-bit longword integer otherwise.

Keywords

None.

Examples

To move the file pointer 2048 bytes into the file associated with file unit number 1, enter:

```
POINT_LUN, 1, 2048
```

To return the file pointer for file unit number 2, enter:

```
POINT_LUN, -2, pos
```

GET_LUN, OPENR/OPENU/OPENW, TRUNCATE_LUN

POLAR_CONTOUR

The POLAR_CONTOUR procedure draws a contour plot from data in polar coordinates. Data can be regularly- or irregularly-gridded. All of the keyword options supported by CONTOUR are available to POLAR_CONTOUR.

This routine is written in the IDL language. Its source code can be found in the file `polar_contour.pro` in the `lib` subdirectory of the IDL distribution.

Syntax

POLAR_CONTOUR, *Z*, *Theta*, *R* [, C_ANNOTATION=*vector_of_strings*]
    [, C_CHARSIZE=*value*] [, C_CHARTHICK=*integer*] [, C_COLORS=*vector*]
    [, C_LINESTYLE=*vector*] [, /FILL | , CELL_FILL
    [, C_ORIENTATION=*degrees*] [, C_SPACING=*value*]] [, C_THICK=*vector*]
    [, /CLOSED] [, /IRREGULAR] [, /ISOTROPIC] [, LEVELS=*vector* /
    NLEVELS=*integer*{1 to 29}] [, MAX_VALUE=*value*] [, MIN_VALUE=*value*]
    [, /OVERPLOT] [, TRIANGULATION=*variable*] [, /XLOG] [, /YLOG]
    [, /ZAXIS] [, SHOW_TRIANGULATION=*color_index*]

Graphics Keywords: Accepts all graphics keywords accepted by PLOT except for: LINESTYLE, PSYM, SYMSIZE. See "Graphics Keywords Accepted" on page 1834.

Arguments

Z

The data values to be contoured. If the data is regularly gridded, *Z* must have the dimensions (N_ELEMENTS(*Theta*), N_ELEMENTS(*R*)). Note that the ordering of the elements in the array *Z* is opposite that used by the POLAR_SURFACE routine.

Theta

A vector of angles in radians. For regularly-gridded data, *Theta* must have the same number of elements as the first dimension of *Z*. For a scattered grid, *Theta* must have the same number of elements as *Z*.

R

A vector of radius values. For regularly-gridded data, *R* must have the same number of elements as the second dimension of *Z*. For a scattered grid, *R* must have the same number of elements as *Z*.

Keywords

C_ANNOTATION

The label to be drawn on each contour. Usually, contours are labeled with their value. This parameter, a vector of strings, allows any text to be specified. The first label is used for the first contour drawn, and so forth. If the LEVELS keyword is specified, the elements of C_ANNOTATION correspond directly to the levels specified, otherwise, they correspond to the default levels chosen by the POLAR_CONTOUR procedure. If there are more contour levels than elements in C_ANNOTATION, the remaining levels are labeled with their values.

Note

This keyword has no effect if the FILL or CELL_FILL keyword is set (i.e., if the contours are drawn with solid-filled or line-filled polygons).

C_CHARSIZE

The size of the characters used to annotate contour labels. Normally, contour labels are drawn at 3/4 of the size used for the axis labels (specified by the CHARSIZE keyword or !P.CHARSIZE system variable. This keyword allows the contour label size to be specified directly. Use of this keyword implies use of the FOLLOW keyword.

C_CHARTHICK

The thickness of the characters used to annotate contour labels. Set this keyword equal to an integer value specifying the line thickness of the vector drawn font characters. This keyword has no effect when used with the hardware drawn fonts. The default value is 1.

C_COLORS

The color index used to draw each contour. This parameter is a vector, converted to integer type if necessary. If there are more contour levels than elements in C_COLORS, the elements of the color vector are cyclically repeated.

C_LINESTYLE

The line style used to draw each contour. As with C_COLORS, C_LINESTYLE is a vector of line style indices. If there are more contour levels than line styles, the line styles are cyclically repeated. See "LINESTYLE" on page 5468 for a list of available styles.

C_ORIENTATION

If the FILL keyword is set, this keyword can be set to the angle, in degrees counterclockwise from the horizontal, of the lines used to fill contours. If neither C_ORIENTATION nor C_SPACING are specified, the contours are solid filled.

C_SPACING

If the FILL keyword is set, this keyword can be used to control the distance, in centimeters, between the lines used to fill the contours.

C_THICK

The line used to draw each contour level. As with C_COLORS, C_THICK is a vector of line thickness values, although the values are floating point. If there are more contours than thickness elements, elements are repeated. If omitted, the overall line thickness specified by the THICK keyword parameter or !P.THICK is used for all contours.

CELL_FILL

Set this keyword to produce a filled contour plot using a "cell filling" algorithm. Use this keyword instead of FILL when you are drawing filled contours over a map, when you have missing data, or when contours that extend off the edges of the contour plot. CELL_FILL is less efficient than FILL because it makes one or more polygons for each data cell. It also gives poor results when used with patterned (line) fills, because each cell is assigned its own pattern. Otherwise, this keyword operates identically to the FILL keyword, described below.

Tip ————————————————————————————————

In order for POLAR_CONTOUR to fill the contours properly when using a map projection, the X and Y arrays (if supplied) must be arranged in increasing order. This ensures that the polygons generated will be in counterclockwise order, as required by the mapping graphics pipeline.

——

Warning ————————————————————————————————

Do not draw filled contours over the poles on Cylindrical map projections. In this case, the polar points map to lines on the map, and the interpolation becomes ambiguous, causing errors in filling. One possible work-around is to limit the latitudes to the range of -89.9 degrees to + 89.9 degrees, avoiding the poles.

——

CLOSED

Set this keyword to a nonzero value to close contours that intersect the plot boundaries. After a contour hits a boundary, it follows the plot boundary until it connects with its other boundary intersection.

FILL

Set this keyword to produce a filled contour plot. The contours are filled with solid or line-filled polygons. For solid polygons, use the C_COLOR keyword to specify the color index of the polygons for each contour level. For line fills, use C_ORIENTATION, C_SPACING, C_COLOR, C_LINESTYLE, and/or C_THICK to specify attributes for the lines.

If the current device is not a pen plotter, each polygon is erased to the background color before the fill lines are drawn, to avoid superimposing one pattern over another.

Contours that are not closed cannot be filled because their interior and exterior are undefined. Contours created from data sets with missing data may not be closed; many map projections can also produce contours that are not closed. You should not use filled contours in these cases.

You should not use this keyword when you are drawing filled contours over a map, when you have missing data, or when contours extend off the edges of the contour plot. In these cases, you should use CELL_FILL instead.

Note ——————

If the current graphics device is the Z-buffer, the algorithm used when the FILL keyword is specified will not work when a Z value is also specified with the graphics keyword ZVALUE. In this situation, use the CELL_FILL keyword instead of the FILL keyword.

IRREGULAR

Set this keyword to indicate that the input data is irregularly gridded. Setting IRREGULAR is the same as performing an explicit triangulation.

ISOTROPIC

Set this keyword to force the scaling of the X and Y axes to be equal.

Note

    The X and Y axes will be scaled isotropically and then fit within the rectangle
defined by the POSITION keyword; one of the axes may be shortened. See
"POSITION" on page 5470 for more information.

LEVELS

Specifies a vector containing the contour levels drawn by the POLAR_CONTOUR
procedure. A contour is drawn at each level in LEVELS.

MAX_VALUE

Data points with values above this value are ignored (i.e., treated as missing data)
when contouring. Cells containing one or more corners with values above
MAX_VALUE will have no contours drawn through them. Note that the IEEE
floating-point value NaN is also treated as missing data. (See "Special Floating-Point
Values" (Chapter 8, *Application Programming*) for more information on IEEE
floating-point values.)

MIN_VALUE

Data points with values less than this value are ignored (i.e., treated as missing data)
when contouring. Cells containing one or more corners with values below
MIN_VALUE will have no contours drawn through them. Note that the IEEE
floating-point value NaN is also treated as missing data. (See "Special Floating-Point
Values" (Chapter 8, *Application Programming*) for more information on IEEE
floating-point values.)

NLEVELS

The number of equally spaced contour levels that are produced by
POLAR_CONTOUR. If the LEVELS parameter, which explicitly specifies the value
of the contour levels, is present, this keyword has no effect. If neither parameter is
present, approximately six levels are drawn. NLEVELS should be a positive integer.

OVERPLOT

Set this keyword to make POLAR_CONTOUR "overplot". That is, the current
graphics screen is not erased, no axes are drawn and the previously established
scaling remains in effect. You must explicitly specify either the values of the contour
levels or the number of levels (via the NLEVELS keyword) when using this option,
unless geographic mapping coordinates are in effect.

Note ───

When specifying overplot levels with the NLEVELS keyword, keep in mind that the levels are calculated according to the range set by the original POLAR_CONTOUR call. If the overplot dataset has a different range, you might want to set your levels more explicitly with the NLEVELS keyword.

──

SHOW_TRIANGULATION

Set this keyword to a color index to be used in overplotting the triangulation between datapoints.

TRIANGULATION

Set this keyword to a variable that contains an array of triangles returned from the TRIANGULATE procedure. Providing triangulation data allows you to contour irregularly gridded data directly, without gridding.

XLOG

Set this keyword to specify a logarithmic X axis.

YLOG

Set this keyword to specify a logarithmic Y axis.

ZAXIS

Set this keyword to an integer value to draw a Z axis for the POLAR_CONTOUR plot. POLAR_CONTOUR draws no Z axis by default. This keyword is of use only if a three-dimensional transformation is established. Possible values are:

- 0 - No Z axis is drawn (the default).
- 1 - Draws Z axis from the lower right-hand corner of the plot
- 2 - Draws Z axis from the lower left-hand corner of the plot
- 3 - Draws Z axis from the upper left-hand corner of the plot
- 4 - Draws Z axis from the upper right-hand corner of the plot

Graphics Keywords Accepted

See Appendix B, "Graphics Keywords" for the description of the following graphics and plotting keywords:

BACKGROUND, CHARSIZE, CHARTHICK, CLIP, COLOR, DATA, DEVICE, FONT, NOCLIP, NODATA, NOERASE, NORMAL, POSITION, SUBTITLE, T3D, THICK, TICKLEN, TITLE, [XYZ]CHARSIZE, [XYZ]GRIDSTYLE, [XYZ]MARGIN, [XYZ]MINOR, [XYZ]RANGE, [XYZ]STYLE, [XYZ]THICK, [XYZ]TICKFORMAT, [XYZ]TICKINTERVAL, [XYZ]TICKLAYOUT, [XYZ]TICKLEN, [XYZ]TICKNAME, [XYZ]TICKS, [XYZ]TICKUNITS, [XYZ]TICKV, [XYZ]TICK_GET, [XYZ]TITLE, ZVALUE

Examples

This example uses POLAR_CONTOUR with regularly-gridded data:

```
;Handle TrueColor displays:
DEVICE, DECOMPOSED=0

;Load color table
TEK_COLOR

nr = 12 ; number of radii
nt = 18 ; number of Thetas

; Create a vector of radii:
r = FINDGEN(nr)/(nr-1)

; Create a vector of Thetas:
theta = 2*!PI * FINDGEN(nt)/(nt-1)

; Create some data values to be contoured:
z = COS(theta*3) # (r-0.5)^2

; Create the polar contour plot:
POLAR_CONTOUR, z, theta, r, /FILL, c_color=[2, 3, 4, 5]
```

CONTOUR

POLAR_SURFACE

The POLAR_SURFACE function interpolates a surface from polar coordinates (R, Theta, Z) to rectangular coordinates (X, Y, Z).

This routine is written in the IDL language. Its source code can be found in the file `polar_surface.pro` in the `lib` subdirectory of the IDL distribution.

Syntax

Result = POLAR_SURFACE(*Z*, *R*, *Theta* [, /GRID] [, SPACING=*[xspacing,*
   yspacing]] [, BOUNDS=*[x$_0$, y$_0$, x$_1$, y$_1$]*] [, /QUINTIC] [, MISSING=*value*])

Return Value

The function returns a two-dimensional array of the same type as Z.

Arguments

Z

An array containing the surface value at each point. If the data are regularly gridded in *R* and *Theta*, *Z* is a two dimensional array, where *Z$_{i,j}$* has a radius of *R$_i$* and an azimuth of *Theta$_j$*. If the data are irregularly-gridded, *R$_i$* and *Theta$_i$* contain the radius and azimuth of each *Z$_i$*. Note that the ordering of the elements in the array *Z* is opposite that used by the POLAR_CONTOUR routine.

R

The radius. If the data are regularly gridded in *R* and *Theta*, *Z$_{i,j}$* has a radius of *R$_i$*. If the data are irregularly-gridded, *R* must have the same number of elements as *Z*, and contains the radius of each point.

Theta

The azimuth, in radians. If the data are regularly gridded in *R* and *Theta*, *Z$_{i,j}$* has an azimuth of *Theta$_j$*. If the data are irregularly-gridded, *Theta* must have the same number of elements as *Z*, and contains the azimuth of each point.

Keywords

GRID

Set this keyword to indicate that *Z* is regularly gridded in *R* and *Theta*.

SPACING

A two element vector containing the desired grid spacing of the resulting array in *x* and *y*. If omitted, the grid will be approximately 51 by 51.

BOUNDS

A four element vector, $[x_0, y_0, x_1, y_1]$, containing the limits of the *xy* grid of the resulting array. If omitted, the extent of input data sets the limits of the grid.

QUINTIC

Set this keyword to use quintic interpolation, which is slower but smoother than the default linear interpolation.

MISSING

Use this keyword to specify a value to use for areas within the grid but not within the convex hull of the data points. The default is 0.0.

Examples

```
; Define radius and Theta:
R = FINDGEN(50) / 50.0
THETA = FINDGEN(50) * (2 * !PI / 50.0)

; Make a function (tilted circle):
Z = R # SIN(THETA)

; Show it:
SURFACE, POLAR_SURFACE(Z, R, THETA, /GRID)
```

POLAR keyword to PLOT

POLY

The POLY function evaluates a polynomial function of a variable.

This routine is written in the IDL language. Its source code can be found in the file poly.pro in the lib subdirectory of the IDL distribution.

Syntax

Result = POLY(*X*, *C*)

Return Value

The result is equal to:

$$C_0 + C_1 x + C_2 x^2 + ...$$

Arguments

X

The variable. This value can be a scalar, vector or array.

C

The vector of polynomial coefficients. The degree of the polynomial is N_ELEMENTS(*C*) - 1.

Keywords

None.

FZ_ROOTS

POLY_2D

The POLY_2D function performs polynomial warping of images. This function performs a geometrical transformation in which the resulting array is defined by:

$$g\ [x,\ y] = f\ [x',\ y'] = f\ [a\ [x,\ y],\ b\ [x,\ y]]$$

where $g[x, y]$ represents the pixel in the output image at coordinate (x, y), and $f\ [x', y']$ is the pixel at (x', y') in the input image that is used to derive $g[x, y]$. The functions $a\ (x, y)$ and $b\ (x, y)$ are polynomials in x and y of degree N, whose coefficients are given by P and Q, and specify the spatial transformation:

$$x' = a(x, y) = \sum_{i=0}^{N} \sum_{j=0}^{N} P_{i,j} x^j y^i$$

$$y' = b(x, y) = \sum_{i=0}^{N} \sum_{j=0}^{N} Q_{i,j} x^j y^i$$

Either the nearest neighbor or bilinear interpolation methods can be selected.

Syntax

Result = POLY_2D(*Array, P, Q* [, *Interp* [, *Dim_x, Dim_y*]] [, CUBIC={-1 to 0}]
　　[, MISSING=*value*])

Arguments

Array

A two-dimensional array of any basic type except string. The result has the same type as *Array.*

P and Q

P and *Q* are arrays containing the polynomial coefficients. Each array must contain $(N+1)^2$ elements (where *N* is the degree of the polynomial). For example, for a linear transformation, *P* and *Q* contain four elements and can be a 2 x 2 array or a 4-element vector. $P_{i,j}$ contains the coefficient used to determine *x'*, and is the weight of the term $x^j y^i$. The POLYWARP procedure can be used to fit *(x', y')* as a function of *(x, y)* and determines the coefficient arrays *P* and *Q*.

Interp

Set this argument to 1 to perform bilinear interpolation. Set this argument to 2 to perform cubic convolution interpolation (as described under the CUBIC keyword, below). Otherwise, the nearest neighbor method is used. For the linear case, (N=1), bilinear interpolation requires approximately twice as much time as does the nearest neighbor method.

Dim$_x$

If present, Dim_x specifies the number of columns in the output. If omitted, the output has the same number of columns as *Array*.

Dim$_y$

If present, Dim_y specifies the number of rows in the output. If omitted, the output has the same number of rows as *Array*.

Keywords

CUBIC

Set this keyword to a value between -1 and 0 to use the cubic convolution interpolation method with the specified value as the interpolation parameter. Setting this keyword equal to a value greater than zero specifies a value of -1 for the interpolation parameter. Park and Schowengerdt (see reference below) suggest that a value of -0.5 significantly improves the reconstruction properties of this algorithm. Note that cubic convolution interpolation works only with one- and two-dimensional arrays.

Cubic convolution is an interpolation method that closely approximates the theoretically optimum sinc interpolation function using cubic polynomials. According to sampling theory, details of which are beyond the scope of this document, if the original signal, *f*, is a band-limited signal, with no frequency component larger than ω_0, and *f* is sampled with spacing less than or equal to $1/2\omega_0$, then *f* can be reconstructed by convolving with a sinc function: sinc $(x) = \sin(\pi x) / (\pi x)$.

In the one-dimensional case, four neighboring points are used, while in the two-dimensional case 16 points are used. Note that cubic convolution interpolation is significantly slower than bilinear interpolation.

For further details see:

Rifman, S.S. and McKinnon, D.M., "Evaluation of Digital Correction Techniques for ERTS Images; Final Report", Report 20634-6003-TU-00, TRW Systems, Redondo Beach, CA, July 1974.

S. Park and R. Schowengerdt, 1983 "Image Reconstruction by Parametric Cubic Convolution", Computer Vision, Graphics & Image Processing 23, 256.

MISSING

Specifies the output value for points whose *x', y'* is outside the bounds of *Array.* If MISSING is not specified, the resulting output value is extrapolated from the nearest pixel of *Array.*

Thread Pool Keywords

This routine is written to make use of IDL's *thread pool*, which can increase execution speed on systems with multiple CPUs. The values stored in the !CPU system variable control whether IDL uses the thread pool for a given computation. In addition, you can use the thread pool keywords TPOOL_MAX_ELTS, TPOOL_MIN_ELTS, and TPOOL_NOTHREAD to override the defaults established by !CPU for a single invocation of this routine. See Appendix C, "Thread Pool Keywords" for details.

Examples

Some simple linear (degree one) transformations are:

$P_{0,0}$	$P_{1,0}$	$P_{0,1}$	$P_{1,1}$	$Q_{0,0}$	$Q_{1,0}$	$Q_{0,1}$	$Q_{1,1}$	Effect
0	0	1	0	0	1	0	0	Identity
0	0	0.5	0	0	1	0	0	Stretch X by a factor of 2
0	0	1	0	0	2.0	0	0	Shrink Y by a factor of 2
z	0	1	0	0	1	0	0	Shift left by z pixels
0	1	0	0	0	0	1	0	Transpose

Table 18-2: Simple Transformations for Use with POLY_2D

POLY_2D is often used in conjunction with the POLYWARP procedure to warp images.

```
; Create and display a simple image:
A = BYTSCL(SIN(DIST(250)), TOP=!D.TABLE_SIZE) & TV, A

; Set up the arrays of original points to be warped:
XO = [61, 62, 143, 133]
YO = [89, 34, 38, 105]

; Set up the arrays of points to be fit:
XI = [24, 35, 102, 92]
YI = [81, 24, 25, 92]

; Use POLYWARP to generate the P and Q inputs to POLY_2D:
POLYWARP, XI, YI, XO, YO, 1, P, Q

; Perform an image warping based on P and Q:
B = POLY_2D(A, P, Q)

; Display the new image:
TV, B, 250, 250
```

Images can also be warped over irregularly gridded control points using the WARP_TRI procedure.

Note

Also see "Warping Images Using Direct Graphics" (Chapter 5, *Image Processing in IDL*).

POLYWARP

POLY_AREA

The POLY_AREA function returns the area of a polygon given the coordinates of its vertices.

It is assumed that the polygon has *n* vertices with *n* sides and the edges connect the vertices in the order:

   [(x1,y1), (x2,y2), ... , (x*n*,y*n*), (x1,y1)]

such that the last vertex is connected to the first vertex.

This routine is written in the IDL language. Its source code can be found in the file poly_area.pro in the lib subdirectory of the IDL distribution.

Syntax

Result = POLY_AREA(*X*, *Y* [, /DOUBLE] [, /SIGNED])

Return Value

If either of the input arguments is double-precision or if the DOUBLE keyword is set, the result is a double-precision value, otherwise, the result is single-precision.

Arguments

X

An *n*-element vector of X coordinate locations for the vertices.

Y

An *n*-element vector of Y coordinate locations for the vertices.

Keywords

DOUBLE

Set this keyword to use double-precision for computations and to return a double-precision result. Explicitly set DOUBLE=0 to use single-precision for computations and to return a single-precision result. By default, if either of the arguments to POLY_AREA is double-precision, computations are done in double-precision; if both arguments are single-precision, computations are done in single-precision.

SIGNED

If set, returns a signed area. Polygons with edges traversed in counterclockwise order have a positive area; polygons traversed in the clockwise order have a negative area.

DEFROI, POLYFILLV

POLY_FIT

The POLY_FIT function performs a least-square polynomial fit with optional weighting and returns a vector of coefficients.

The POLY_FIT routine uses matrix inversion to determine the coefficients. A different version of this routine, SVDFIT, uses singular value decomposition (SVD). The SVD technique is more flexible and robust, but may be slower.

This routine is written in the IDL language. Its source code can be found in the file poly_fit.pro in the lib subdirectory of the IDL distribution.

Syntax

Result = POLY_FIT(*X*, *Y*, *Degree* [, CHISQ=*variable*] [, COVAR=*variable*]
  [, /DOUBLE] [, MEASURE_ERRORS=*vector*] [, SIGMA=*variable*]
  [, STATUS=*variable*] [, YBAND=*variable*] [, YERROR=*variable*]
  [, YFIT=*variable*])

Return Value

POLY_FIT returns a vector of coefficients of length *Degree*+1. If the DOUBLE keyword is set, or if *X* or *Y* are double precision, then the result will be double precision, otherwise the result will be single precision.

Arguments

X

An *n*-element vector of independent variables.

Y

A vector of dependent variables, the same length as *X*.

Degree

The degree of the polynomial to fit.

Keywords

CHISQ

Set this keyword to a named variable that will contain the value of the unreduced chi-square goodness-of-fit statistic.

COVAR

Set this keyword to a named variable that will contain the Covariance matrix of the coefficients.

Note

The COVAR matrix depends only upon the independent variable X and (optionally) the MEASURE_ERRORS. The values do not depend upon Y. See section 15.4 of *Numerical Recipes in C* (Second Edition) for details.

DOUBLE

Set this keyword to force computations to be done in double-precision arithmetic. All computations are performed using double-precision arithmetic.

MEASURE_ERRORS

Set this keyword to a vector containing standard measurement errors for each point *Y*[*i*]. This vector must be the same length as *X* and *Y.*

Note

For Gaussian errors (e.g., instrumental uncertainties), MEASURE_ERRORS should be set to the standard deviations of each point in *Y.* For Poisson or statistical weighting, MEASURE_ERRORS should be set to SQRT(*Y*).

SIGMA

Set this keyword to a named variable that will contain the 1-sigma uncertainty estimates for the returned parameters.

Note ──

If MEASURE_ERRORS is omitted, then you are assuming that a polynomial is the correct model for your data, and therefore, no independent goodness-of-fit test is possible. In this case, the values returned in SIGMA are multiplied by SQRT(CHISQ/(N–M)), where N is the number of points in X, and M is the number of coefficients. See section 15.2 of *Numerical Recipes in C* (Second Edition) for details.

──

STATUS

Set this keyword to a named variable to receive the status of the operation. Possible status values are:

- 0 = Successful completion.

- 1 = Singular array (which indicates that the inversion is invalid). *Result* is NaN.

- 2 = Warning that a small pivot element was used and that significant accuracy was probably lost.

- 3 = Undefined (NaN) error estimate was encountered.

Note ──

If STATUS is not specified, any error messages will be output to the screen.

──

Tip ───

Status values of 2 or 3 can often be resolved by setting the DOUBLE keyword.

──

YBAND

Set this keyword to a named variable that will contain the 1 standard deviation error estimate for each point.

YERROR

Set this keyword to a named variable that will contain the standard error between YFIT and Y.

YFIT

Set this keyword to a named variable that will contain the vector of calculated *Y* values. These values have an error of + or – YBAND.

Examples

In this example, we use X and Y data corresponding to the known polynomial $f(x) = 0.25 - x + x^2$. Using POLY_FIT to compute a second degree polynomial fit returns the exact coefficients (to within machine accuracy).

```
; Define an 11-element vector of independent variable data:
X = [0.0, 0.1, 0.2, 0.3, 0.4, 0.5, 0.6, 0.7, 0.8, 0.9, 1.0]

; Define an 11-element vector of dependent variable data:
Y = [0.25, 0.16, 0.09, 0.04, 0.01, 0.00, 0.01, 0.04, 0.09, $
   0.16, 0.25]

; Define a vector of measurement errors:
measure_errors = REPLICATE(0.01, 11)

; Compute the second degree polynomial fit to the data:
result = POLY_FIT(X, Y, 2, MEASURE_ERRORS=measure_errors, $
   SIGMA=sigma)

; Print the coefficients:
PRINT, 'Coefficients: ', result
PRINT, 'Standard errors: ', sigma
```

IDL prints:

```
Coefficients:    0.250000    -1.00000    1.00000
Standard errors:    0.00761853    0.0354459    0.0341395
```

POLYFILL

The POLYFILL procedure fills the interior of a region of the display enclosed by an arbitrary two or three-dimensional polygon. The available filling methods are: solid fill, parallel lines, or a pattern contained in an array. Not all methods are available on every hardware output device. See "Fill Methods" below.

Note ───

POLYFILL uses the current graphics device's own polygon filling methodology when possible. For some devices, polygon filling is designed to avoid filling a given pixel more than once when neighboring polygons (that is, polygons with shared edges) are drawn. If the resulting pixel fill from POLYFILL is unsatisfactory, consider using DRAW_ROI instead.

───

The polygon is defined by a list of connected vertices stored in X, Y, and Z. The coordinates can be given in data, device, or normalized form using the DATA, DEVICE, or NORMAL keywords.

Fill Methods

Line-fill method: Filling using parallel lines is device-independent and works on all devices that can draw lines. Crosshatching can be simulated by performing multiple fills with different orientations. The spacing, linestyle, orientation, and thickness of the filling lines can be specified using the corresponding keyword parameters. The LINE_FILL keyword selects this filling style, but is not required if either the ORIENTATION or SPACING parameters are present.

Solid fill method: By default, POLYFILL fills the polygon with a solid color. For devices that do not directly support filling with a solid color, the solid fill is automatically emulated using the line-fill method.

Patterned fill: Some output devices support filling with a pattern. For these devices, the fill pattern array can be explicitly specified with the PATTERN keyword. Refer to the description of that keyword for a list of devices that support patterned fill.

Syntax

POLYFILL, *X* [, *Y* [, *Z*]] [, IMAGE_COORD=*array*] [, /IMAGE_INTERP]
    [, /LINE_FILL] [, PATTERN=*array*] [, SPACING=*centimeters*]
    [, TRANSPARENT=*value*]

Graphics Keywords: [, CLIP=*[X$_0$, Y$_0$, X$_1$, Y$_1$]*] [, COLOR=*value*] [, /DATA | ,
    /DEVICE | , /NORMAL] [, LINESTYLE={0 | 1 | 2 | 3 | 4 | 5}] [, /NOCLIP]

[, ORIENTATION=*ccw_degrees_from_horiz*] [, /T3D] [, THICK=*value*]
[, Z=*value*]

Arguments

X

A vector argument providing the X coordinates of the points to be connected. The
vector must contain at least three elements. If only one argument is specified, *X* must
be an array of either two or three vectors (i.e., (2,*) or (3,*)). In this special case,
the vector X[0,*] specifies the X values, X[1,*] specifies Y, and X[2,*] contain
the Z values.

Y

A vector argument providing the Y coordinates of the points to be connected. *Y* must
contain at least three elements.

Z

An optional vector argument providing the Z coordinates of the points to be
connected. If Z is not provided, X and Y are used to draw lines in two dimensions. Z
must contain at least three elements. Z has no effect if the keyword T3D is not
specified and the system variable !P.T3D= 0.

Keywords

IMAGE_COORD

This keyword is only available when creating output in the Z-Buffer.

A 2 x *n* array containing the fill pattern array subscripts of each of the *n* polygon
vertices. Use this keyword in conjunction with the PATTERN keyword to warp
images over 2-D and 3-D polygons.

IMAGE_INTERP

This keyword is only available when creating output in the Z-Buffer.

Specifies the method of sampling the PATTERN array when the IMAGE_COORD
keyword is present. The default method is to use nearest-neighbor sampling. Bilinear
interpolation sampling is performed if IMAGE_INTERP is set.

LINE_FILL

Set this keyword to indicate that polygons are to be filled with parallel lines, rather than using solid or patterned filling methods.When using the line-drawing method of filling, the thickness, linestyle, orientation, and spacing of the lines may be specified with keywords.

PATTERN

Set this keyword to a rectangular array of pixels giving the fill pattern. If this keyword parameter is omitted, POLYFILL fills the area with a solid color. The pattern array may be of any size; if it is smaller than the filled area the pattern array is cyclically repeated.

Note ──

This keyword is supported for the following devices:

METAFILE, PRINTER, PS, WIN, X, and Z.

For the PostScript device, fill patterns are only supported with language level 2. Use the LANGUAGE_LEVEL keyword to DEVICE to set the PostScript language level to 2 if filled patterns are to be used.

For the Z device, the pattern can either an [*m* x *n*] array (a single-channel image), or as an [3 x *m* x *n*] array (a three-channel image) to be "warped" between the vertices of the polygons. See "Polyfill Procedure" on page 5455 in the description of "The Z-Buffer Device" in Appendix A.

──

For example, to fill the current plot window with a grid of dots, enter the following commands:

```
; Define pattern array as 10 by 10:
PAT = BYTARR(10,10, /NOZERO)

; Set center pixel to bright:
PAT[5,5] = 255

winsize=300
WINDOW, /FREE, XSIZE=winsize, YSIZE=winsize
; Fill the rectangle defined by the window with a 10% margin:
POLYFILL, [.1,.9,.9,.1]*winsize, $
          [.1,.1,.9,.9]*winsize, /DEVICE, PATTERN = PAT
```

SPACING

The spacing, in centimeters, between the parallel lines used to fill polygons.

TRANSPARENT

This keyword is only available when creating output in the Z-Buffer.

Specifies the minimum pixel value to draw in conjunction with the PATTERN and IMAGE_COORD keywords. Pixels less than this value are not drawn and the Z-buffer is not updated.

Graphics Keywords Accepted

See Appendix B, "Graphics Keywords" for the description of the following graphics and plotting keywords:

CLIP, COLOR, DATA, DEVICE, LINESTYLE, NOCLIP, NORMAL, ORIENTATION, T3D, THICK, Z

Z-Buffer-Specific Keywords

Certain keyword parameters are only active when the Z-buffer is the currently selected graphics device: IMAGE_COORD, IMAGE_INTERP, TRANSPARENT and COLOR. These parameters allow images to be warped over 2-D or 3-D polygons, and the output of shaded polygons. See "Polyfill Procedure" on page 5455 in the description of "The Z-Buffer Device" in Appendix A.

For shaded polygons, the COLOR keyword can specify an array that contains the color index at each vertex. Color indices are linearly interpolated between vertices. If COLOR contains a scalar, the entire polygon is drawn with the given color index, just as with the other graphics output devices.

Images can be warped over polygons by passing in the image with the PATTERN parameter, and a (2, *n*) array containing the image space coordinates that correspond to each of the N vertices with the IMAGE_COORD keyword.

The IMAGE_INTERP keyword indicates that bilinear interpolation is to be used, rather than the default nearest-neighbor sampling. Pixels less than the value of TRANSPARENT are not drawn, simulating transparency.

Examples

Fill a rectangular polygon that has the vertices (30,30), (100, 30), (100, 100), and (30, 100) in device coordinates:

```
; Create the vectors of X and Y values:
X = [30, 100, 100, 30] & Y = [30, 30, 100, 100]

; Fill the polygon with color index 175:
POLYFILL, X, Y, COLOR = 175, /DEVICE
```

Many scientific graphs use region filling to highlight the difference between two or more curves, to illustrate boundaries, etc. The IDL POLYFILL procedure fills the interior of arbitrary polygons given a list of vertices. The interior of the polygon can be filled with a solid color or with some devices, a user-defined fill pattern contained in a rectangular array.

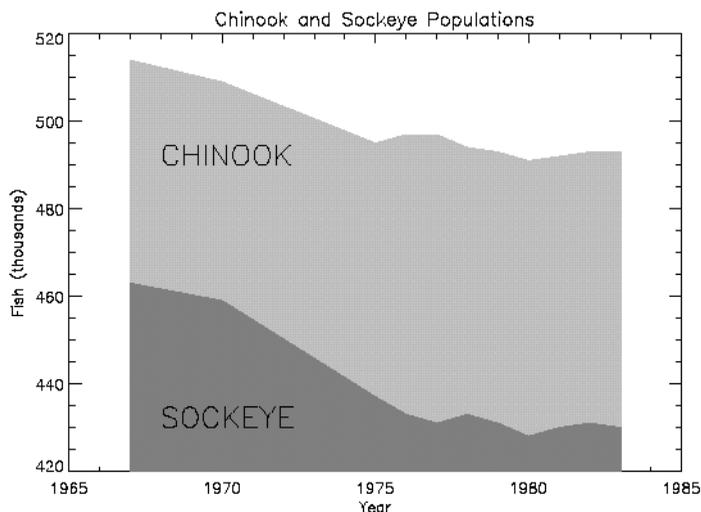
The figure below illustrates a simple example of polygon filling by filling the region under the Chinook population graph with a color index of 25 percent the maximum, then filling the region under the Sockeye population graph with 50 percent of the maximum index. Because the Chinook populations are always higher than the Sockeye populations, the graph appears as two distinct regions.


Figure 18-11: Filling Regions Using POLYFILL

The program that produced this figure is shown below. It first draws a plot axis with no data, using the NODATA keyword. The minimum and maximum *y* values are directly specified with the YRANGE keyword. Because the *y*-axis range does not always exactly include the specified interval (see "X Versus Y Plots" on page 1797), the variable MINVAL, is set to the current *y*-axis minimum, !Y.CRANGE[0]. Next,

the upper Chinook population region is shaded with a polygon that contains the vertices of the Chinook samples, preceded and followed by points on the *x*-axis, (YEAR[0], MINVAL), and (YEAR[n-1], MINVAL). The polygon for the Sockeye samples is drawn using the same method with a different color. Finally, the XYOUTS procedure is used to annotate the two regions.

Enter the following IDL commands to create the plot:

```
; Define variables:
@plot01
; Draw axes, no data, set the range:
PLOT, YEAR, CHINOOK, YRANGE = [MIN(SOCKEYE), MAX(CHINOOK)], $
   /NODATA, TITLE='Sockeye and Chinook Populations', $
   XTITLE='Year', YTITLE='Fish (thousands)'
; Make a vector of x values for the polygon by duplicating
; the first and last points:
PXVAL = [YEAR[0], YEAR, YEAR[N1]]
; Get y value along bottom x-axis:
MINVAL = !Y.CRANGE[0]
; Make a polygon by extending the edges down to the x-axis:
POLYFILL, PXVAL, [MINVAL, CHINOOK, MINVAL], $
   COL = 0.75 * !D.N_COLORS
; Same with second polygon.
POLYFILL, PXVAL, [MINVAL, SOCKEYE, MINVAL], $
   COL = 0.50 * !D.N_COLORS
; Label the polygons:
XYOUTS, 1968, 430, 'SOCKEYE', SIZE=2
XYOUTS, 1968, 490, 'CHINOOK', SIZE=2
```

Example Code

Alternatively, you can run the plot04 batch file to create the plot:
```
@plot04
```

Note

If IDL does not find the batch file, the required directory may not be in your IDL search path. All of the files mentioned are located in the examples/doc/plot subdirectory of the IDL distribution. By default, this directory is part of IDL's path; if you have not changed your path, you will be able to run the examples as described here. See !PATH for information on modifying IDL's path.

POLYFILLV

POLYFILLV

The POLYFILLV function returns a vector containing the subscripts of the array elements contained inside a polygon defined by vectors.

The *X* and *Y* parameters are vectors that contain the subscripts of the vertices that define the polygon in the coordinate system of the two-dimensional S_x by S_y array. The S_x and S_y parameters define the number of columns and rows in the array enclosing the polygon. At least three points must be specified, and all points should lie within the limits: $0 \leq X_i < S_x$ and $0 \leq Y_i < S_y$ for all *i*.

As with the POLYFILL procedure, the polygon is defined by connecting each point with its successor and the last point with the first. This function is useful for defining, analyzing, and displaying regions of interest within a two-dimensional array.

The scan line coordinate system defined by Rogers in *Procedural Elements for Computer Graphics*, McGraw-Hill, 1985, page 71, is used. In this system, the scan lines are considered to pass through the center of each row of pixels. Pixels are activated if the center of the pixel is to the right of the intersection of the scan line and the polygon edge within the interval.

Syntax

Result = POLYFILLV(*X*, *Y*, S_x, S_y [, *Run_Length*])

Return Value

Returns a vector containing the one-dimensional subscripts of the array elements contained inside a polygon defined by vectors *X* and *Y*. These subscripts will be LONG64 values if the dimensions of the input array ($S_x * S_y$) warrant that size for proper addressing. If no points are contained within the polygon, a -1 is returned, and an informational message is printed.

Arguments

X

A vector containing the X subscripts of the vertices that define the polygon.

Y

A vector containing the Y subscripts of the vertices that define the polygon.

S$_x$

The number of columns in the array surrounding the polygon.

S$_y$

The number of rows in the array surrounding the polygon.

Run_Length

Set this optional parameter to a nonzero value to make POLYFILLV return a vector of run lengths, rather than subscripts. For large polygons, a considerable savings in space results. When run-length encoded, each element with an even subscript result contains the length of the run, and the following element contains the starting index of the run.

Examples

To determine the mean and standard deviation of the elements within a triangular region defined by the vertices at pixel coordinates (100, 100), (200, 300), and (300, 100), inside a 512 x 512 array called DATA, enter the commands:

```
; Get the subscripts of the elements inside the triangle:
P = DATA[POLYFILLV([100,200,300], [100,300,100], 512, 512)]

; Use the STDEV function to obtain the mean and standard deviation
; of the selected elements:
STD = STDEV(P,MEAN)
```

POLYFILL

POLYSHADE

The POLYSHADE function creates a shaded-surface representation of one or more solids described by a set of polygons. This function accepts, as arguments, an array of three-dimensional vertices and a list of the indices of the vertices that describe each polygon.

Shading values are determined from one of three sources: a light source model, a user-specified array containing vertex shade values, or a user-specified array containing polygon shade values.

The shaded surface is constructed using the scan line algorithm. The default shading model is a combination of diffuse reflection and depth cueing. With this shading model, polygons are shaded using either constant shading, in which each polygon is given a constant intensity, or with Gouraud shading where the intensity is computed at each vertex and then interpolated over the polygon. Use the SET_SHADING procedure to control the direction of the light source and other shading parameters.

User-specified shading arrays allow "4-dimensional" displays that consist of a surface defined by a set of polygons, shaded with values from another variable.

Syntax

Result = POLYSHADE(*Vertices*, *Polygons*)

or

Result = POLYSHADE(*X*, *Y*, *Z*, *Polygons*)

Keywords: [, /DATA | , /NORMAL] [, POLY_SHADES=*array*] [, SHADES=*array*] [, /T3D] [, TOP=*value*] [, XSIZE=*columns*] [, YSIZE=*rows*]

Return Value

Returns a shaded-surface representation. Output is a two-dimensional byte array containing the shaded image unless the current graphics output device is the Z-buffer. If the current output device is the Z-buffer, the results are merged with the Z-buffer's contents and the function result contains a dummy value.

Arguments

Vertices

A (3, *n*) array containing the X, Y, and Z coordinates of each vertex. Coordinates can be in either data or normalized coordinates, depending on which keywords are present.

X, Y, Z

The X, Y, and Z coordinates of each vertex can, alternatively, be specified as three array expressions of the same dimensions.

Polygons

An integer or longword array containing the indices of the vertices for each polygon. The vertices of each polygon should be listed in counterclockwise order when observed from outside the surface. The vertex description of each polygon is a vector of the form: $[n, i_0, i_1, ..., i_{n-1}]$ and the array *Polygons* is the concatenation of the lists of each polygon. For example, to render a pyramid consisting of four triangles, *Polygons* would contain 16 elements, made by concatenating four, four-element vectors of the form $[3, V_0, V_1, V_2]$. V_0, V_1, and V_2 are the indices of the vertices describing each triangle.

Keywords

DATA

Set this keyword to indicate that the vertex coordinates are in data units, the default coordinate system.

NORMAL

Set this keyword to indicate that coordinates are in normalized units, within the three dimensional (0,1) cube.

POLY_SHADES

An array expression, with the same number of elements as there are polygons defined in the *Polygons* array, containing the color index used to render each polygon. No interpolation is performed if all pixels within a given polygon have the same shade value. For most displays, this parameter should be scaled into the range of bytes.

SHADES

An array expression, with the same number of elements as *Vertices*, containing the color index at each vertex. The shading of each pixel is interpolated from the surrounding SHADE values. For most displays, this parameter should be scaled into the range of bytes.

Warning

When using the SHADES keyword on TrueColor devices, we recommend that decomposed color support be turned off by setting DECOMPOSED=0 for DEVICE.

T3D

Set this keyword to use the three-dimensional to two-dimensional transformation contained in the homogeneous 4 by 4 matrix !P.T. Note that if T3D is set, !P.T must contain a valid transformation matrix. The SURFACE, SCALE3, and T3D procedures (and others) can all be used to set up transformations.

TOP

The maximum shading value when light source shading is in effect. The default value is one less than the number of colors available in the currently selected graphics device.

XSIZE

The number of columns in the output image array. If this parameter is omitted, the number of columns is equal to the X size of the currently selected display device.

Warning: The size parameters should be explicitly specified when the current graphics device is PostScript or any other high-resolution device. Making the output image the default full device size is likely to cause an insufficient memory error.

YSIZE

The number of rows in the output image array. If this parameter is omitted, the number of rows is equal to the Y resolution of the currently selected display device.

Examples

POLYSHADE is often used in conjunction with SHADE_VOLUME for volume visualization. The following example creates a spherical volume dataset and renders an isosurface from that dataset:

```
; Create an empty, 3-D array:
SPHERE = FLTARR(20, 20, 20)

; Create the spherical dataset:
FOR X=0,19 DO FOR Y=0,19 DO FOR Z=0,19 DO $
   SPHERE(X, Y, Z) = SQRT((X-10)^2 + (Y-10)^2 + (Z-10)^2)

; Find the vertices and polygons for a density level of 8:
SHADE_VOLUME, SPHERE, 8, V, P

; Set up an appropriate 3-D transformation so we can see the
; sphere. This step is very important:
SCALE3, XRANGE=[0,20], YRANGE=[0,20], ZRANGE=[0,20]

; Render the image. Note that the T3D keyword has been set so that
; the previously-established 3-D transformation is used:
image = POLYSHADE(V, P, /T3D)

; Display the image:
TV, image
```

POLYWARP

The POLYWARP procedure performs polynomial spatial warping.

Using least squares estimation, POLYWARP determines the coefficients $Kx_{i,j}$ and $Ky_{(i,j)}$ of the polynomial functions:

$$X_i = \sum_{i,\, j} Kx_{i,\, j} \cdot Xo^j \cdot Yo^i$$

$$Y_i = \sum_{i,\, j} Ky_{i,\, j} \cdot Xo^j \cdot Yo^i$$

Kx and *Ky* can be used as inputs P and Q to the built-in function POLY_2D. This coordinate transformation may be then used to map from *Xo, Yo* coordinates into *Xi, Yi* coordinates.

This routine is written in the IDL language. Its source code can be found in the file polywarp.pro in the lib subdirectory of the IDL distribution.

Syntax

POLYWARP, *Xi*, *Yi*, *Xo*, *Yo*, *Degree*, *Kx*, *Ky* [, /DOUBLE] [, STATUS=*variable*]

Arguments

Xi, Yi

Vectors of X and Y coordinates to be fit as a function of Xo and Yo.

Xo, Yo

Vectors of X and Y independent coordinates. These vectors must have the same number of elements as *Xi* and *Yi*.

Degree

The degree of the fit. The number of coordinate pairs must be greater than or equal to $(Degree+1)^2$.

Kx

A named variable that will contain the array of coefficients for *Xi* as a function of (*Xo, Y*o). This parameter is returned as a (*Degree*+1) by (*Degree*+1) element array.

Ky

A named variable that will contain the array of coefficients for *Yi*. This parameter is returned as a (*Degree*+1) by (*Degree*+1) element array.

Keywords

DOUBLE

Set this keyword to use double-precision for computations and to return a double-precision result. Explicitly set DOUBLE=0 to ensure the use of single-precision for computations and to return a single-precision result. By default, POLYWARP performs computations in double precision and returns a double-precision result if any of the inputs are double-precision; computations are performed in single precision and the result returned as single-precision if all of the inputs are single-precision.

STATUS

Set this keyword to a named variable to receive the status of the operation. Possible status values are:

Value	Description
0	Successful completion.
1	Singular array (which indicates that the inversion is invalid).
2	Warning that a small pivot element was used and that significant accuracy was probably lost.

Table 18-3: STATUS Keyword Values

Note
If STATUS is not specified, any warning messages will be output to the screen.

Examples

The following example shows how to display an image and warp it using the POLYWARP and POLY_2D routines.

```
; Create and display the original image:
A = BYTSCL(SIN(DIST(250)))
TVSCL, A

; Now set up the Xi's and Yi's:
XI = [24, 35, 102, 92]
YI = [81, 24, 25, 92]

; Enter the Xo's and Yo's:
XO = [61, 62, 143, 133]
YO = [89, 34, 38, 105]

; Run POLYWARP to obtain a Kx and Ky:
POLYWARP, XI, YI, XO, YO, 1, KX, KY

; Create a warped image based on Kx and Ky with POLY_2D:
B = POLY_2D(A, KX, KY)

; Display the new image:
TV, B
```

Note ──

POLY_2D, WARP_TRI

POPD

The POPD procedure changes the current working directory to the directory saved on the top of the directory stack maintained by the PUSHD and POPD procedures. This top entry is then removed from the stack.

Attempting to pop a directory when the stack is empty causes a warning message to be printed. The current directory is not changed in this case. The common block DIR_STACK is used to store the directory stack.

This routine is written in the IDL language. Its source code can be found in the file popd.pro in the lib subdirectory of the IDL distribution.

Syntax

POPD

Arguments

None.

Keywords

None.

Version History

Pre-4.0	Introduced

CD, PRINTD, PUSHD

POWELL

The POWELL procedure minimizes a user-written function *Func* of two or more independent variables using the Powell method. POWELL does not require a user-supplied analytic gradient.

POWELL is based on the routine `powell` described in section 10.5 of *Numerical Recipes in C: The Art of Scientific Computing* (Second Edition), published by Cambridge University Press, and is used by permission.

Syntax

POWELL, *P*, *Xi*, *Ftol*, *Fmin*, *Func* [, /DOUBLE] [, ITER=*variable*]
   [, ITMAX=*value*]

Arguments

P

On input, *P* is an *n*-element vector specifying the starting point. On output, it is replaced with the location of the minimum.

Note —————————————————————————————————
  If POWELL is complex then only the real part is used for the computation.
——

Xi

On input, *Xi* is an initial *n* by *n* element array whose columns contain the initial set of directions (usually the *n* unit vectors). On output, it is replaced with the then-current directions.

Ftol

An input value specifying the fractional tolerance in the function value. Failure to decrease by more than *Ftol* in one iteration signals completeness. For single-precision computations, a value of 1.0×10^{-4} is recommended; for double-precision computations, a value of 1.0×10^{-8} is recommended.

Fmin

On output, *Fmin* contains the value at the minimum-point *P* of the user-supplied function specified by *Func*.

Func

A scalar string specifying the name of a user-supplied IDL function of two or more independent variables to be minimized. This function must accept a vector argument *X* and return a scalar result.

For example, suppose we wish to minimize the function

$$f(x, y) = (x + 2y)e^{-x^2 - y^2}$$

To evaluate this expression, we define an IDL function named POWFUNC:

```
FUNCTION powfunc, X
   RETURN, (X[0] + 2.0*X[1]) * EXP(-X[0]^2 -X[1]^2)
END
```

Keywords

DOUBLE

Set this keyword to force the computation to be done in double-precision arithmetic.

ITER

Use this keyword to specify an output variable that will be set to the number of iterations performed.

ITMAX

Use this keyword to specify the maximum allowed number of iterations. The default is 200.

Warning
POWELL halts once the value specified with ITMAX has been reached.

Examples

We can use POWELL to minimize the function POWFUNC given above.

```
PRO TEST_POWELL

   ; Define the fractional tolerance:
   ftol = 1.0e-4
```

```
; Define the starting point:
P = [.5d, -.25d]

; Define the starting directional vectors in column format:
xi = TRANSPOSE([[1.0, 0.0],[0.0, 1.0]])

; Minimize the function:
POWELL, P, xi, ftol, fmin, 'powfunc'

; Print the solution point:
PRINT, 'Solution point: ', P

; Print the value at the solution point:
PRINT, 'Value at solution point: ', fmin

END

FUNCTION powfunc, X
   RETURN, (X[0] + 2.0*X[1]) * EXP(-X[0]^2 -X[1]^2)
END
```

IDL prints:

```
Solution point:    -0.31622777    -0.63245552
Value at solution point:    -0.95900918
```

The exact solution point is [-0.31622777, -0.63245553].

The exact minimum function value is -0.95900918.

PREF_COMMIT

The PREF_SET procedure is used to set new values for IDL preferences. However, a preference value set in this way does not immediately take effect. Rather, it is put into a pending state, in which IDL remembers the change, but does not use it. To make a pending preference value take effect, IDL must commit it. To commit a preference, IDL takes the following steps:

1. Writes a new user preference file that merges the new changes with the previously specified preference values.

2. Updates its internal state to make the pending values current.

3. Notifies the various parts of IDL that depend on the altered preference so that they can adapt to the change.

There are two ways to commit a preference:

- **PREF_COMMIT** — used to commit preferences already in the pending state

- **COMMIT keyword to PREF_SET** — used to set and commit a specific preference in a single operation

The pending state is useful for applications that let a user manipulate preferences. In such an application, the user can make changes, but those changes can be discarded without taking effect if the user clicks the **Cancel** button. PREF_SET can be used to make the user's changes. If the user clicks **Done** to confirm the changes, PREF_COMMIT is used to make them permanent. Otherwise, they are discarded by using the RESET keyword. The pending state lifts the burden of tracking user changes from the high-level application and greatly simplifies its implementation.

Note ───
Authors of IDL applications should not use this routine in their code to make preference changes. See "Using Preference Etiquette" on page 5537 for more information.
───

Syntax

PREF_COMMIT [, *PreferenceName*] [, /RESET] [, /RESIGNAL]

Arguments

PreferenceName

A string scalar or array that supplies the names of the preferences to commit. If no arguments are supplied, all preferences currently in the pending state are committed. Any specified preferences that are not in the pending state are quietly ignored.

Keywords

RESET

Set this keyword to have PREF_COMMIT discard the pending values, if any, for the specified preferences. The preferences leave the pending state and retain their previous value.

RESIGNAL

Set this keyword to have PREF_COMMIT not check or alter the pending state of the specified preferences. Instead, the procedure behaves as if the current value of the preference had just been committed and signals the part of IDL that uses that preference to reset itself.

Examples

To commit all preferences with pending values:

```
PREF_COMMIT
```

To commit only the IDL_PATH preference (which supplies the value of the !PATH system variable), while leaving all other preferences in their current state:

```
PREF_COMMIT, 'IDL_PATH'
```

To discard the currently pending value for IDL_PATH:

```
PREF_COMMIT, /RESET, 'IDL_PATH'
```

To restore the !PATH system variable to the value given by the IDL_PATH preference (without discarding the pending value, if any):

```
PREF_COMMIT, /RESIGNAL, 'IDL_PATH'
```

PREF_GET, PREF_MIGRATE, PREF_SET

PREF_GET

The PREF_GET function returns information about IDL preferences. It can return any of the following information:

- The current effective value for a given preference (specified by *PrefName)*

- The names of all the preferences (specified by /NAMES_ALL)

- The number of pending preferences (specified by /NUM_PENDING); that is, the ones that have had a value set (PREF_SET), but not committed (PREF_COMMIT)

- Detailed information for a given preference (specified by *PrefName* and /STRUCTURE), including:

    - A string giving a description of the preference's purpose

    - The current effective value and its source

    - Whether the value is read-only

    - Any minimum or maximum values within which the preference must fit

    - Whether or not the preference accepts a fixed (discrete) set of values, and any mnemonic names allowed for each value

Syntax

Result = PREF_GET([*PrefName*] [, /NAMES_ALL | /NUM_PENDING | /STRUCTURE])

Return Value

The default return value is a scalar returning the current effective value for the named preference (specified by *PrefName*).

If the NAMES_ALL keyword is set, the return value is a string array containing the names of all the preferences.

If the NUM_PENDING keyword is set, the return value is an integer count of the number of preferences that currently have a value that was set (by PREF_SET) and not committed.

If the STRUCTURE keyword is set, the return value is a structure providing full details on the preference specified by *PrefName*. For more information, see "Information Returned by STRUCTURE Keyword" below.

Arguments

PrefName

The name of the preference for which information is desired.

Keywords

NAMES_ALL

If this keyword is set, PREF_GET returns a string array containing the names of all the preferences.

NUM_PENDING

If this keyword is set, PREF_GET returns the number of preferences within IDL that currently have a value that was set (by PREF_SET) and not yet committed.

STRUCTURE

Set this keyword to cause PREF_GET to return a structure giving detailed information about the preference specified by *PrefName*. For more information, see "Information Returned by STRUCTURE Keyword" below.

Information Returned by STRUCTURE Keyword

If the STRUCTURE keyword is set, PREF_GET returns a structure giving detailed information about the preference. The type and number of fields present in the returned structure depends on the preference in question. Every such result will contain the same set of initial fields. Based on the information provided by these initial fields, there may be additional fields that supply extra information.

The fields contained in the returned structure are:

- **NAME** — a string giving the name of the preference.

- **DESCRIPTION** — a string giving a one line description of the preference.

- **CURRENT_SOURCE** — a string that reports the source of the current effective value. The following values for this field are possible (listed in ascending order of the source's priority):

DEFAULT	IDL's built in default value for this preference
USERFILE	User preference file

DISTFILE	Preference file from the `resource/pref` directory of the IDL distribution.
ENV	Environment variable
CMDLINE	Command line option

- **COMMIT_SEEN** — a string that describes when IDL will begin to use the new value of the preference once it has been committed. The following values are possible:

IMMEDIATE	Value will take effect immediately after commit
RESET	Value will take effect after the next `.reset_session` or `.full_reset_session`, or in subsequent IDL sessions
RESTART	Value will not take effect in this IDL session, but will be used in subsequent IDL sessions

- **READONLY** — true (1) if the preference is read-only and false (0) otherwise. A preference is read-only if its value is currently being set by a source with a higher precedence than that of the user's preference file. See CURRENT_SOURCE above for the hierarchy of source priority.

- **HAS_MIN, VALUE_MIN** — HAS_MIN is true (1) if the preference value is required to be greater than or equal to a minimum value. It is false (0) if there is no minimum value. If HAS_MIN is true, the returned structure also contains a field named VALUE_MIN that contains the minimum value. If HAS_MIN is false, VALUE_MIN is not present.

- **HAS_MAX, VALUE_MAX** — HAS_MAX is true (1) if the preference value is required to be less than or equal to a maximum value. It is false (0) if there is no maximum value. If HAS_MAX is true, the returned structure will also contain a field named VALUE_MAX that contains the maximum value. If HAS_MAX is false, VALUE_MAX is not present.

- **HAS_DISCRETE_VALUES, NUM_VALUES, VALUES, NUM_ALIAS, ALIAS_VALUES** — HAS_DISCRETE_VALUES is true (1) if the preference value must come from a predefined list of possible values. It is false (0) otherwise. Although preferences with discrete values are always numeric, IDL lets the values be referenced by mnemonic names called aliases. If HAS_DISCRETE_VALUES is true, the returned structure also contains fields that supply additional information about the values. If HAS_DISCRETE_VALUES is false (0), these extra fields are not present (listed in the order in which they appear in the structure):

NUM_VALUES	The number of discrete values.
VALUES	An array of NUM_VALUES elements. Each element contains one of the allowed values for this preference.
NUM_ALIAS	An array of NUM_VALUES elements. Each element reports the number of alias names that exist for the corresponding value in VALUES.
ALIAS_VALUES	An array of size [MAX(NUM_ALIAS), NUM_VALUES]. Each row of ALIAS_VALUES gives the alias names that are allowed for the corresponding element of VALUES. For example, the aliases allowed for the first value (VALUES[0]) is ALIAS_VALUES[0:NUM_ALIAS[0], 0].

- **HAS_PENDING** — true (1) if the preference has a currently pending value. A pending value is a value that has been set (by PREF_SET) but not yet committed. If HAS_PENDING is true, the VALUE_PENDING field contains the pending value.

- **VALUE_EFFECTIVE** — the current effective value for the preference.

- **VALUE_DEFAULT** — IDL's built in default value for the preference. This is the value IDL uses if no other source is present.

- **VALUE_PENDING** — if HAS_PENDING is true (1), this field contains the pending value. Otherwise, it will contain 0 (numeric) or a NULL string, depending on the type of the preference.

PREF_COMMIT, PREF_MIGRATE, PREF_SET

PREF_MIGRATE

The PREF_MIGRATE procedure is used to import IDL user preferences from other versions of IDL for use by the currently running version. Under Microsoft Windows, it is also used to import workbench macros.

IDL user preferences are maintained on a per-release basis, meaning that a different user preference file exists for each version of IDL you use on your system. When you first use a new version of IDL, it is common to want to carry over the preference settings you were using with the previous version of IDL. The PREF_MIGRATE procedure exists to help you with this migration. You can run it at any time. In addition, each new version of IDL runs it once the first time you run that version if you have migratable preferences from other versions of IDL on your system.

Note

Beginning with IDL 7.0, PREF_MIGRATE is no longer called automatically the first time IDL is run. You can still use PREF_MIGRATE to manually migrate IDL system preferences. IDL Workbench preferences an managed separately, by the workbench itself. For more on the difference between system and workbench preferences, see "About IDL System Preferences" on page 5530.

This routine is written in the IDL language. Its source code can be found in the file `pref_migrate.pro` in the `lib` subdirectory of the IDL distribution.

Syntax

PREF_MIGRATE [, /MACRO] [, /PREFERENCE] [, /STARTUP]

Arguments

None

Keywords

MACRO

If this keyword is set, the migration process migrates only workbench macros. This option is allowed only under Microsoft Windows because it has no meaning to the Motif (UNIX) version of the workbench.

PREFERENCE

If this keyword is set, the migration process migrates only workbench preferences and not macros. This option has meaning only under Microsoft Windows. It is quietly ignored on other platforms.

STARTUP

At startup, if IDL determines that the user does not have a user preference file, it runs PREF_MIGRATE with the STARTUP keyword set prior to running the startup file (if any) or prompting the user for input. STARTUP mode differs from a regular call in a few ways:

- A dialog is used to explain what is happening and to ask for the user's permission to continue, before moving into the main application.

- It runs in a blocking mode so that any changes it makes will be in effect before the startup file (if any) runs and the user is able to enter commands at the IDL prompt.

Version History

6.2	Introduced

See Also

PREF_COMMIT, PREF_GET, PREF_SET

PREF_SET

The PREF_SET procedure is used to set new values for IDL preferences. Once committed, these values are written to the user's IDL preference file and persist between IDL sessions. For more information on committing preference values, see the discussion of the COMMIT keyword below, as well as the documentation for PREF_COMMIT.

Note ───
A preference is considered to be read-only if its value is currently being set by a source with a higher precedence than that of the user's preference file (command line, environment variable, or IDL distribution preference file). You cannot use PREF_SET to change the value of such a preference. You must instead change the preference's value at its source and then restart IDL.
───

Note ───
Authors of IDL applications should not use this routine in their code to make preference changes. See "Using Preference Etiquette" on page 5537 for more information.
───

Syntax

PREF_SET, *PrefName$_1$*, *Value$_1$* [, ... *PrefName$_n$*, *Value$_n$*] [, /COMMIT]

or

PREF_SET, *PrefName$_1$* [, ... *PrefName$_n$*] , /DEFAULT, [, /COMMIT]

or

PREF_SET, FILENAME=*file* [, /COMMIT]

The first syntax uses a preference-value pair to set the value for each preference named. The second syntax uses the default value for each preference named. The third syntax imports values from the named preference file.

Arguments

PrefNames$_i$

A string containing the name of the preference being set.

Value_i

The value of the preference being set.

Keywords

COMMIT

Set this keyword to immediately commit all of the preferences made by this call. Normally, PREF_SET puts new preference values into a pending state in which IDL remembers the change, but does not use it. In order to make a pending preference value take effect, it must first be committed. Alternatively, you can use the PREF_COMMIT procedure after this call.

DEFAULT

If this keyword is set, each specified preference is set to IDL's default value for it. You can see the default value for each preference by issuing the following command:

```
HELP, /PREFERENCES, /FULL
```

Note

If DEFAULT is set, you must use the *PrefName* argument to specify a preference (or more than one preference with *PrefName*$_1$ ... *PrefName*$_n$).

FILENAME

Set this keyword to supply the path to an existing IDL preference file. PREF_SET reads the file and sets all preferences referenced within to the specified values. FILENAME is used to migrate preferences from other IDL versions. It is, for example, the method by which the PREF_MIGRATE procedure works.

Note

If FILENAME is set, you cannot use the *PrefName* and *Value* arguments.

Examples

Under UNIX, issue the following command to set the default value of the !PATH system variable to use a locally installed library of IDL programs in /usr/local/idllib, followed by the default IDL libraries, and to immediately commit the change:

```
PREF_SET, 'IDL_PATH', '+/usr/local/idllib:<IDL_DEFAULT>', /COMMIT
```

Under Microsoft Windows, issue the following commands to set the default value of the !PATH system variable to use a locally installed library of IDL programs in C:\local_idllib, followed by the default IDL libraries, but defer the commit step to a later call to IDL_COMMIT:

```
PREF_SET, 'IDL_PATH', '+C:\local_idllib;<IDL_DEFAULT>'
...
PREF_COMMIT
```

To revert to using IDL's default for the initial value of !PATH:

```
PREF_SET, 'IDL_PATH', /DEFAULT
```

Version History

6.2	Introduced

PREF_COMMIT, PREF_GET, PREF_MIGRATE

PREWITT

The PREWITT function returns an approximation to the Prewitt edge enhancement operator for images,

$$G_{jk} = \sqrt{(G_x \cdot G_x + G_y \cdot G_y)}$$

$$G_Y = F_{j-1, k-1} + F_{j, k-1} + F_{j+1, k-1} - (F_{j-1, k+1} + F_{j, k+1} + F_{j+1, k+1})$$

$$G_X = F_{j+1, k+1} + F_{j+1, k} + F_{j+1, k-1} - (F_{j-1, k+1} + F_{j-1, k} + F_{j-1, k-1})$$

where (j, k) are the coordinates of each pixel F_{jk} in the *Image*. This is equivalent to a convolution using the masks,

$$\text{X mask} = \begin{bmatrix} -1 & 0 & 1 \\ -1 & 0 & 1 \\ -1 & 0 & 1 \end{bmatrix} \qquad \text{Y mask} = \begin{bmatrix} 1 & 1 & 1 \\ 0 & 0 & 0 \\ -1 & -1 & -1 \end{bmatrix}$$

All of the edge points in the result are set to zero.

Syntax

Result = PREWITT(*Image*)

Return Value

PREWITT returns a two-dimensional array of the same size as *Image*. If *Image* is of type byte or integer then the result is of integer type, otherwise the result is of the same type as *Image*.

Note ———

To avoid overflow for integer types, the computation is done using the next larger signed type and the result is transformed back to the correct type. Values larger than the maximum for that integer type are truncated. For example, for integers the function is computed using type long, and on output, values larger than 32767 are set equal to 32767. The calculation $SQRT(G_x \times G_x + G_y \times G_y)$ is accomplished in double precision floating point.

Arguments

Image

The two-dimensional array containing the image to which edge enhancement is applied.

Keywords

None.

Examples

If the variable `myimage` contains a two-dimensional image array, a Prewitt sharpened version of `myimage` can be displayed with the command:

```
TVSCL, PREWITT(myimage)
```

Note ———

Also see "Detecting Edges" (Chapter 8, *Image Processing in IDL*).

PRIMES

The PRIMES function computes the first *K* prime numbers.

This routine is written in the IDL language. Its source code can be found in the file `primes.pro` in the `lib` subdirectory of the IDL distribution.

Syntax

Result = PRIMES(*K*)

Return Value

The result is a *K*-element long integer vector.

Arguments

K

An integer or long integer scalar that specifies the number of primes to be computed.

Examples

To compute the first 25 prime numbers:

```
PRINT, PRIMES(25)
```

IDL prints:

```
    2       3       5       7      11      13
   17      19      23      29      31      37
   41      43      47      53      59      61
   67      71      73      79      83      89
   97
```

4.0	Introduced

PRINT/PRINTF

The two PRINT procedures perform formatted output. PRINT performs output to the standard output stream (IDL file unit -1), while PRINTF requires a file unit to be explicitly specified.

Note ——————————————————————————————————————

IDL uses the standard I/O function `sprintf` to do its formatting. Different platforms implement this function in different ways, which may lead to slight inconsistencies in the appearance of the output. In most cases, specifying an explicit output format via the FORMAT keyword allows better control over the appearance than simply using the default formatting.

Format Compatibility

If the FORMAT keyword is not present and PRINT is called with more than one argument, and the first argument is a scalar string starting with the characters "$(", this initial argument is taken to be the format specification, just as if it had been specified via the FORMAT keyword. This feature is maintained for compatibility with version 1 of VMS IDL.

Syntax

PRINT [, *Expr$_1$*, ..., *Expr$_n$*]

PRINTF [, *Unit*, *Expr$_1$*, ..., *Expr$_n$*]

Keywords: [, AM_PM=*[string, string]*] [, DAYS_OF_WEEK=*string_array*{7 names}] [, FORMAT=*value*] [, MONTHS=*string_array*{12 names}] [, /STDIO_NON_FINITE]

Arguments

Unit

For PRINTF, *Unit* specifies the file unit to which the output is sent.

Expr*$_i$*

The expressions to be output.

Keywords

AM_PM

Supplies a string array of 2 names to be used for the names of the AM and PM string when processing explicitly formatted dates (CAPA, CApA, and CapA format codes) with the FORMAT keyword.

DAYS_OF_WEEK

Supplies a string array of 7 names to be used for the names of the days of the week when processing explicitly formatted dates (CDWA, CDwA, and CdwA format codes) with the FORMAT keyword.

FORMAT

If FORMAT is not specified, IDL uses its default rules for formatting the output. FORMAT allows the format of the output to be specified in precise detail, using a FORTRAN-style specification. See "Using Explicitly Formatted Input/Output" (Chapter 18, *Application Programming*).

MONTHS

Supplies a string array of 12 names to be used for the names of the months when processing explicitly formatted dates (CMOA, CMoA, and CmoA format codes) with the FORMAT keyword.

STDIO_NON_FINITE

Set this keyword to allow the writing of data files readable by C or FORTRAN programs on a given platform; it is otherwise unnecessary.The various systems supported by IDL differ widely in the representation used for non-finite floating point values (i.e., NaN and Infinity). Consider that the following are all possible representations for NaN on at least one IDL platform:

    NaN, NanQ, ?.0000, nan0x2, nan0x7, 1.#QNAN, -1.#IND0.

And the following are considered to be Infinity:

    Inf, Infinity, ++.0000, ----.0000, 1.#INF

On input, IDL can recognize any of these, but on output, it uses the same standard representation on all platforms. This promotes cross-platform consistency. To cause IDL to use the system C library sprintf() function to format such values, yielding the native representation for that platform, set the STDIO_NON_FINITE keyword.

Examples

To print the string "IDL is fun." enter the command:

```
PRINT, 'IDL is fun.'
```

To print the same message to the open file associated with file unit number 2, use the command:

```
PRINTF, 2, 'IDL is fun.'
```

Version History

Original	Introduced
Pre-6.2	Deprecated REWRITE keyword

For information on obsolete keywords, see Appendix I, "Obsolete Features".

ANNOTATE, MESSAGE, STRING, WRITEU, XYOUTS

PRINTD

The PRINTD procedure prints the contents of the directory stack maintained by the PUSHD and POPD procedures. The contents of the directory stack are listed on the default output device. The common block DIR_STACK is used to store the directory stack.

This routine is written in the IDL language. Its source code can be found in the file printd.pro in the lib subdirectory of the IDL distribution.

Syntax

PRINTD

Arguments

None.

Keywords

None.

Version History

Pre-4.0	Introduced

CD, POPD, PUSHD

PRO

The PRO statement defines an IDL procedure.

Note ───
For information on using the PRO statement, see Chapter 2, "Creating and Running Programs in IDL" and Chapter 5, "Creating Procedures and Functions" (*Application Programming*).
───

Syntax

PRO *Procedure_Name*, *argument$_1$*, ..., *argument$_n$*

. . .

END

Arguments

argument$_n$

A parameter that is passed to the procedure.

Keywords

None.

Examples

The following example demonstrates the use of arguments in a PRO statement:

```
PRO MYPROCEDURE
   X = 5
   ; Call the ADD procedure:
   ADD, 3, X
END

PRO ADD, A, B
   PRINT, 'A = ', A
   PRINT, 'B = ', B
   A = A + B
   PRINT, 'A = ', A
END
```

After you run `myprocedure.pro`, IDL returns:

```
A =    3
B =    5
A =    8
```

Version History

Original	Introduced

PRODUCT

The PRODUCT function returns the product of elements within an array. The product of the array elements over a given dimension is returned if the *Dimension* argument is present. Because the product can easily overflow, the product is computed using double-precision arithmetic and the *Result* is double precision.

Tip

If your array has a mix of very large and very small values, the product may underflow or overflow during the computation, even though the final result would be within double-precision limits. In this case, you should not use PRODUCT, but instead compute the product by taking the logarithm, using the TOTAL function, and then taking the exponential: *Result* = EXP(TOTAL(ALOG(*Array*))).

Syntax

Result = PRODUCT(*Array* [, *Dimension*] [, /CUMULATIVE] [, /INTEGER]
    [, /NAN] [, /PRESERVE_TYPE])

Return Value

Returns the product of the elements of *Array*.

Arguments

Array

The array for which to compute the product. This array can be of any basic type except string.

Dimension

An optional argument specifying the dimension over which to compute the product, starting at one. If this argument is not present or zero, the product of all the array elements is returned. If this argument is present, the result is an array with one less dimension than *Array*.

For example, if the dimensions of *Array* are N1, N2, N3, and *Dimension* is 2, the dimensions of the result are (N1, N3), and element (*i,j*) of the result contains the product:

$$R_{i,j} = \prod_{k=0}^{N_2-1} A_{i,k,j}$$

Keywords

CUMULATIVE

If this keyword is set, the result is an array of the same size as the input, with each element, *i*, containing the product of the input array elements 0 to *i*. This keyword also works with the *Dimension* parameter, in which case the cumulative product is performed over the given dimension.

Tip

If the input array is a temporary variable or an expression, and the result type matches the input type (for example by using the PRESERVE_TYPE keyword), then PRODUCT will perform the cumulative product in place and no additional memory will be used.

INTEGER

Set this keyword to perform the PRODUCT using integer arithmetic, and to return an integer result. If *Array* is of type ULONG64 then unsigned 64-bit integers are used for the computation and the Result is of type ULONG64, otherwise signed 64-bit integers are used and the Result is of type LONG64. If *Array* is complex and INTEGER is set, then only the real part of each value is used for the computation.

Note

If *Array* has a large number of values or the values themselves are large, then the PRODUCT with the INTEGER keyword may easily overflow the largest 64-bit integer and return an incorrect result. In this case you may want to avoid using the INTEGER keyword.

NAN

Set this keyword to cause the routine to check for occurrences of the IEEE floating-point values *NaN* or *Infinity* in the input data. Elements with the value *NaN* or *Infinity* are treated as missing data with the value 1. (See "Special Floating-Point Values" (Chapter 8, *Application Programming*) for more information on IEEE floating-point values.)

PRESERVE_TYPE

Set this keyword to perform the PRODUCT using the input type, and to return a result of the same type. The INTEGER keyword is ignored if PRESERVE_TYPE is set.

Note ———————————————————————————————

For byte or integer data the PRODUCT with PRESERVE_TYPE may easily overflow the largest value for that type. In these cases you may want to use the INTEGER keyword instead.

Thread Pool Keywords

This routine is written to make use of IDL's thread pool, which can increase execution speed on systems with multiple CPUs. The values stored in the !CPU system variable control whether IDL uses the thread pool for a given computation. In addition, you can use the thread pool keywords TPOOL_MAX_ELTS, TPOOL_MIN_ELTS, and TPOOL_NOTHREAD to override the defaults established by !CPU for a single invocation of this routine. See Appendix C, "Thread Pool Keywords".

Examples

To find the product of all elements in a one-dimensional array:

```
; Define a one-dimensional array:
array = [20, 10, 5, 5, 3]

; Find the product of the array elements:
prod = PRODUCT(array)

; Print the results:
PRINT, 'Product of Array = ', prod
```

IDL prints:

```
Product of Array =       15000.000
```

Now find the product of elements in a two-dimensional array:

```
; Define a two-dimensional array:
array = FINDGEN(4,4) + 1

; Find the product of all array elements:
prodAll = PRODUCT(array)

; Find the product along the first dimension:
prod1 = PRODUCT(array, 1)

; Find the product along the second dimension:
prod2 = PRODUCT(array, 2)

; Print the results:
PRINT, 'Product of all elements = ', prodAll
PRINT, 'Product along first dimension: '
PRINT, prod1
PRINT, 'Product along second dimension: '
PRINT, prod2
```

IDL prints:

```
Product of all elements   2.0922790e+013
Product along first dimension:
 24.000000      1680.0000      11880.000      43680.000
Product along second dimension:
 585.00000      1680.0000      3465.0000      6144.0000
```

FACTORIAL, TOTAL

PROFILE

The PROFILE function extracts a profile from an image and returns the values of the image along the profile line marked by the user.

This routine is written in the IDL language. Its source code can be found in the file profile.pro in the lib subdirectory of the IDL distribution.

Using PROFILE

To mark a profile line after calling PROFILE, click in the image with the left mouse button to mark the beginning and ending points. The pixel coordinates of the selected points are displayed in the IDL command log.

Syntax

Result = PROFILE(*Image* [, *XX*, *YY*] [, /NOMARK] [, XSTART=*value*]
   [, YSTART=*value*])

Return Value

Returns a floating-point vector containing the values along the profile line.

Arguments

Image

The data array representing the image. This array can be of any type except complex.

XX

A named variable that will contain the X coordinates of the points along the selected profile.

YY

A named variable that will contain the Y coordinates of the points along the selected profile.

Keywords

NOMARK

Set this keyword to inhibit marking the image with the profile line.

XSTART

The starting X location of the lower-left corner of *Image*. If this keyword is not specified, 0 is assumed.

YSTART

The starting Y location of the lower-left corner of *Image*. If this keyword is not specified, 0 is assumed.

Examples

This example displays an image, selects a profile, and plots that profile in a new window:

```
; Create an image:
A = BYTSCL(DIST(256))

; Display the image:
TV, A

; Extract a profile from the image:
R = PROFILE(A)
```

Mark two points on the image with the mouse.

```
; Create a new plotting window:
WINDOW, /FREE

; Plot the profile:
PLOT, R
```

Note

The PROFILES procedure is an interactive version of this routine.

PROFILES

PROFILER

The PROFILER procedure allows you to access the IDL Code Profiler. The IDL Code Profiler helps you analyze the performance of your applications. You can easily monitor the calling frequency and execution time for procedures and functions.

Syntax

PROFILER [, *Module*] [, /CLEAR] [, DATA=*variable*] [, FILENAME=*path*]
   [, OUTPUT=*variable*] [, /REPORT] [, /RESET] [, /SYSTEM]

Arguments

Module

The program to which changes in profiling will be applied. If *Module* is not specified, profiling changes will be applied to all currently-compiled programs.

Note

The *Module* is often named with respect to the file in which it is stored. For example, the file build_it.pro may contain the module, build_it. If you specify the file name, you will incur a syntax error.

Keywords

CLEAR

Set this keyword to disable profiling of *Module* or of all compiled modules if *Module* is not specified. If the *Module* is a system routine then the SYSTEM keyword must also be set.

DATA

If the REPORT keyword is set, then set this keyword to a specified variable containing output of the report as an unnamed structure with the following tags and data types:

```
{NAME:char, COUNT:long, ONLY_TIME:double, TIME:double,
SYSTEM:byte}
```

FILENAME

If the REPORT keyword is set, then set this keyword to the name of a file in which to write the profile results.

OUTPUT

If the REPORT keyword is set, then set this keyword to a specified variable in which to store the results of the REPORT keyword.

REPORT

Set this keyword to report the results of profiling. If DATA or OUTPUT are present then the results are returned in the specified variables. Otherwise the results are output to the IDL output log.

RESET

Set this keyword to reset the results of profiling. If this keyword is present then all other arguments and keywords are ignored.

SYSTEM

Set this keyword to apply profiling changes to IDL system procedures and functions. By default, changes are only applied to user-written or library files.

Examples

```
; First ensure that the routine you want to profile is compiled.
void = DIST(500)

; Now include both user routines and system routines.
PROFILER
PROFILER, /SYSTEM

; Now perform the actual commands to profile.
a = DIST(500)
TV, a

; Retrieve the profiling results.
PROFILER, /REPORT
```

IDL prints:

```
Module     Type  Count    Only(s)   Avg.(s)    Time(s)   Avg.(s)
DIST       (U)      1    0.004473  0.004473   0.014675  0.014675
FINDGEN    (S)      1    0.000015  0.000015   0.000015  0.000015
```

```
        FLTARR       (S)        1     0.000036   0.000036      0.000036   0.000036
        N_ELEMENTS   (S)        1     0.000004   0.000004      0.000004   0.000004
        ON_ERROR     (S)        1     0.000003   0.000003      0.000003   0.000003
        SQRT         (S)      251     0.010144   0.000040      0.010144   0.000040
        TV           (S)        1     0.089689   0.089689      0.089689   0.089689
```

Version History

5.1	Introduced
7.0	Added FILENAME keyword

Chapter 8, "Debugging and Error-Handling" (*Application Programming*).

PROFILES

The PROFILES procedure interactively draws row or column profiles of an image in a separate window. A new window is created and the mouse location in the original window is used to plot profiles in the new window.

This routine is written in the IDL language. Its source code can be found in the file profiles.pro in the lib subdirectory of the IDL distribution.

Using PROFILES

Moving the mouse within the original image interactively creates profile plots in the newly-created profile window. Pressing the left mouse button toggles between row and column profiles. The right mouse button exits.

Syntax

PROFILES, *Image* [, /ORDER] [, SX=*value*] [, SY=*value*] [, WSIZE=*value*]

Arguments

Image

The variable that represents the image displayed in the current window. This data need not be scaled into bytes. The profile graphs are made from this array, even if it is not currently displayed.

Keywords

ORDER

Set this keyword to 1 for images written top down or 0 for bottom up. Default is the current value of !ORDER.

SX

Starting X position of the image in the window. If this keyword is omitted, 0 is assumed.

SY

Starting Y position of the image in the window. If this keyword is omitted, 0 is assumed.

WSIZE

The size of the PROFILES window as a fraction or multiple of 640 by 512.

Examples

Create and display an image and use the PROFILES routine on it.

```
; Create an image:
A = BYTSCL(DIST(256))

; Display the image:
TV, A

; Run the PROFILES routine:
PROFILES, A, WSIZE = .5
```

A 320 x 256 pixel PROFILES window should appear. Move the cursor over the original image to see the profile at the cursor position. Press the left mouse button to toggle between row and column profiles. Press the right mouse button (with the cursor over the original image) to exit the routine.

PROFILE

PROJECT_VOL

The PROJECT_VOL function returns a two-dimensional image that is the projection of a 3-D volume of data onto a plane (similar to an X-ray). The returned image is a translucent rendering of the volume (the highest data values within the volume show up as the brightest regions in the returned image). Depth queuing and opacity may be used to affect the image. The volume is projected using a 4x4 matrix, so any type of projection may be used including perspective. Typically the system viewing matrix (!P.T) is used as the 4x4 matrix.

Note ──

The VOXEL_PROJ procedure performs many of the same functions as this routine, and is faster.

──

This routine is written in the IDL language. Its source code can be found in the file project_vol.pro in the lib subdirectory of the IDL distribution.

Syntax

Result = PROJECT_VOL(*Vol*, *X_Sample*, *Y_Sample*, *Z_Sample*
    [, /AVG_INTENSITY] [, /CUBIC] [, DEPTH_Q=*value*] [, OPAQUE=*3D_array*]
    [, TRANS=*array*] [, XSIZE=*longword integer*] [, YSIZE=*longword integer*]
    [, /Z_BUFFER])

Return Value

Returns a projection of the volumetric data.

Arguments

Vol

A 3-D array of any type except string or structure containing the three-dimensional volume of data to project.

X_Sample

A long integer specifying the number of rays to project along the X dimension of the image. The returned image will have the dimensions *X_sample* by *Y_sample*.

Y_Sample

A long integer specifying the number of rays to project along the Y dimension of the image. To preserve the correct aspect ratio of the data, *Y_sample* should equal *X_sample*.

Z_Sample

A long integer specifying the number of samples to take along each ray. Higher values for *X_sample*, *Y_sample*, and *Z_sample* increase the image resolution as well as execution time.

Keywords

AVG_INTENSITY

If this keyword is set, the average intensity method of projection is used. The default is a maximum intensity projection. This keyword is ignored if the Z_BUFFER keyword is set.

CUBIC

If this keyword is set, the cubic method of interpolation is used. The default is bilinear interpolation.

DEPTH_Q

Set this keyword to indicate that the image should be created using depth queuing. The depth queuing should be a single floating-point value between 0.0 and 1.0. This value specifies the brightness of the farthest regions of the volume relative to the closest regions of the volume. A value of 0.0 will cause the back side of the volume to be completely blacked out, while a value of 1.0 indicates that the back side will show up just as bright as the front side. The default is 1.0 (indicating no depth queuing).

OPAQUE

A 3-D array of any type except string or structure, with the same size and dimensions as *Vol*. This array specifies the opacity of each cell in the volume. OPAQUE values of 0 allow all light to pass through. OPAQUE values are cumulative. For example, if a ray emanates from a data value of 50, and then passes through 10 opaque cells (each with a data value of 0 and an opacity value of 5) then that ray would be completely blocked out (the cell with the data value of 50 would be invisible on the returned image). The default is no opacity.

TRANS

A 4x4 floating-point array to use as the transformation matrix when projecting the volume. The default is to use the system viewing matrix (!P.T).

XSIZE

The *x* size of the returned image to return. CONGRID is used to resize the final image to be XSIZE by YSIZE. The default is the *x* size of the current window (or the *x* size of the Z-buffer). If no current window exists, then the default is *X_sample*.

YSIZE

The *y* size of the returned image. CONGRID is used to resize the final image to be XSIZE by YSIZE. The default is the *y* size of the current window (or the *y* size of the Z-buffer). If no current window exists, then the default is *Y_sample*.

Z_BUFFER

If this keyword is set, the projection is combined with the contents of the Z-buffer. The default is to not use the Z-buffer contents.

Examples

Use the T3D routine to set up a viewing projection and render a volume of data using PROJECT_VOL.

```
; First, create some data:
vol = RANDOMU(S, 40, 40, 40)
FOR I=0, 10 DO vol = SMOOTH(vol, 3)
vol = BYTSCL(vol(3:37, 3:37, 3:37))
opaque = RANDOMU(S, 40, 40, 40)
FOR I=0, 10 DO opaque = SMOOTH(opaque, 3)
opaque = BYTSCL(opaque(3:37, 3:37, 3:37), TOP=25B)

; Set up the view:
xmin = 0 & ymin = 0 & zmin = 0
xmax = 34 & ymax = 34 & zmax = 34
!X.S = [-xmin, 1.0] / (xmax - xmin)
!Y.S = [-ymin, 1.0] / (ymax - ymin)
!Z.S = [-zmin, 1.0] / (zmax - zmin)
T3D, /RESET
T3D, TRANSLATE=[-0.5, -0.5, -0.5]
T3D, SCALE=[0.7, 0.7, 0.7]
T3D, ROTATE=[30, -30, 60]
T3D, TRANSLATE=[0.5, 0.5, 0.5]
WINDOW, 0, XSIZE=512, YSIZE=512
```

```
; Generate and display the image:
img = PROJECT_VOL(vol, 64, 64, 64, DEPTH_Q=0.7, $
  OPAQUE=opaque, TRANS=(!P.T))
TVSCL, img
```

POLYSHADE, VOXEL_PROJ

PS_SHOW_FONTS

The PS_SHOW_FONTS procedure displays all the PostScript fonts that IDL knows about, with both the StandardAdobe and ISOLatin1 encodings. Each display takes a separate page, and each character in each font is shown with its character index.

A PostScript file is produced, one page per font/mapping combination. The output file contains almost 70 pages of output. A PostScript previewer is recommended rather than sending it to a printer.

This routine is written in the IDL language. Its source code can be found in the file `ps_show_fonts.pro` in the `lib` subdirectory of the IDL distribution.

Syntax

PS_SHOW_FONTS [, /NOLATIN]

Arguments

None.

Keywords

NOLATIN

Set this keyword to prevent output of ISOLatin1 encodings.

Version History

Pre-4.0	Introduced

See Also

PSAFM

PSAFM

The PSAFM procedure takes an Adobe Font Metrics file as input and generates a new AFM file in the format that IDL likes. This new file differs from the original in the following ways:

- Information not used by IDL is removed.
- AFM files with the AdobeStandardEncoding are supplemented with an ISOLatin1Encoding.

This routine is written in the IDL language. Its source code can be found in the file `psafm.pro` in the `lib` subdirectory of the IDL distribution.

Syntax

PSAFM, *Input_Filename*, *Output_Filename*

Arguments

Input_Filename

A string that contains the name of existing AFM file from Adobe.

Output_Filename

A string that specifies the name of new IDL-format AFM file to be created.

Keywords

None.

Version History

Pre-4.0	Introduced

PS_SHOW_FONTS

PSEUDO

The PSEUDO procedure creates a pseudo-color table based on the LHB (Lightness, Hue, and Brightness) system and loads it.

The pseudo-color mapping used is generated by first translating from the LHB coordinate system to the LAB coordinate system, finding *N* colors spread out along a helix that spans this LAB space (supposedly a near maximal entropy mapping for the eye, given a particular *N*) and remapping back into the RGB (Red, Green, and Blue) colorspace. The result is loaded as the current colortable.

This routine is written in the IDL language. Its source code can be found in the file pseudo.pro in the lib subdirectory of the IDL distribution.

Syntax

PSEUDO, *Litlo*, *Lithi*, *Satlo*, *Sathi*, *Hue*, *Loops* [, *Colr*]

Arguments

Litlo

Starting lightness, from 0 to 100%.

Lithi

Ending lightness, from 0 to 100%.

Satlo

Starting saturation, from 0 to 100%.

Sathi

Ending saturation, from 0 to 100%.

Hue

Starting hue, in degrees, from 0 to 360.

Loops

The number of loops of hue to make in the color helix. This value can range from 0 to around 3 to 5 and need not be an integer.

Colr

An optional (256,3) integer array in which the new R, G, and B values are returned. Red = *Colr*[*,0], green = *Colr*[*,1], blue = *Colr*[*,2].

Keywords

None.

Version History

Original	Introduced

COLOR_QUAN, COLOR_QUAN

PTR_FREE

The PTR_FREE procedure destroys the heap variables pointed at by its pointer arguments. Any memory used by the heap variable is released, and the variable ceases to exist. No change is made to the arguments themselves and all pointers to the destroyed variables continue to exist. Such pointers are known as *dangling references.* PTR_FREE is the only way that pointer heap variables can be destroyed. If PTR_FREE is not called on a heap variable, it continues to exist until the IDL session ends, even if no pointers remain that can be used to reference it.

Note ───

PTR_FREE is not recursive. That is, if the heap variable pointed at by `pointer1` contains `pointer2`, destroying `pointer1` will *not* destroy the heap variable pointed at by `pointer2`. Take care not to lose the only pointer to a heap variable by destroying a pointer to a heap variable that contains that pointer.

Syntax

PTR_FREE, P_1, ... …, P_n

Arguments

P*i*

Scalar or array arguments of pointer type. If the NULL pointer is passed, PTR_FREE ignores it quietly.

Keywords

None.

Version History

5.0	Introduced

PTR_NEW

The PTR_NEW function provides the primary mechanism for creating heap variables.

Syntax

Result = PTR_NEW([*InitExpr*] [, /ALLOCATE_HEAP] [, /NO_COPY])

Return Value

It returns a pointer to the created variable.

Arguments

InitExpr

If *InitExpr* is provided, PTR_NEW uses it to initialize the newly created heap variable. Note that the new heap variable does not point at the *InitExpr* variable in any sense—the new heap variable simply contains a copy of its value.

If *InitExpr* is not provided, PTR_NEW does not create a new heap variable, and returns the *Null Pointer,* a special pointer with a fixed known value that can never point at a heap variable. The null pointer is useful as a terminator in dynamic data structures, or as a placeholder in structure definitions.

Keywords

ALLOCATE_HEAP

Set this keyword to cause PTR_NEW to allocate an undefined heap variable rather than return a null pointer when *InitExpr* is not specified.

NO_COPY

Usually, when the *InitExpr* argument is provided, PTR_NEW allocates additional memory to make a copy. If the NO_COPY keyword is set, the value data is taken away from the *InitExpr* variable and attached directly to the heap variable. This feature can be used to move data very efficiently. However, it has the side effect of causing the *InitExpr* variable to become undefined.

Using the NO_COPY keyword is completely equivalent to the statement:

```
Result = PTR_NEW(TEMPORARY(InitExpr))
```

and is provided as a syntactic convenience.

Version History

5.0	Introduced

PTR_VALID

The PTR_VALID function verifies the validity of its pointer arguments, or alternatively returns a vector of pointers to all the existing valid pointer heap variables.

Syntax

Result = PTR_VALID([*Arg*] [, /CAST] [, COUNT=*variable*])

Return Value

If called with an pointer or array of pointers as its argument, PTR_VALID returns a byte array of the same size as the argument. Each element of the result is set to True (1) if the corresponding pointer in the argument refers to an existing valid heap variable, or to False (0) otherwise.

If called with an integer or array of integers as its argument and the CAST keyword is set, PTR_VALID returns an array of pointers. Each element of the result is a pointer to the heap variable indexed by the integer value. Integers used to index heap variables are shown in the output of the HELP and PRINT commands. This is useful primarily in programming/debugging when you have lost a reference but see it with HELP and need to get a reference to it interactively in order to determine what it is and take steps to fix the code. See the "Examples" section below for an example.

If no argument is specified, PTR_VALID returns a vector of pointers to all existing valid pointer heap variables—*even if there are currently no pointers to the heap variable*. This usage allows you to "reclaim" pointer heap variables to which all pointers have been lost. If no valid pointer heap variables exist, a scalar null pointer is returned.

Arguments

Arg

Arg can be one of the following:

1. A scalar or array argument of pointer type.

2. If the CAST keyword is set, an integer index or array of integer indices to heap variables. Integers used to index heap variables are shown in the output of the HELP and PRINT commands.

Keywords

CAST

Set this keyword to create a new pointer to each heap variable index specified in *Arg*.

COUNT

Set this keyword equal to a named variable that will contain the number of currently valid heap variables. This value is returned as a longword integer.

Examples

To determine if a given pointer refers to a valid heap variable:

```
IF (PTR_VALID(p)) THEN …
```

To destroy all existing pointer heap variables:

```
PTR_FREE, PTR_VALID()
```

You can use the CAST keyword to "reclaim" lost heap variables. For example:

```
A = PTR_NEW(10)
PRINT, A
```

IDL prints:

```
<PtrHeapVar2>
```

In this case, the integer index to the heap variable is 2. If we reassign the variable A, we will "lose" the pointer, but the heap variable will still exist:

```
A=0
PRINT, A, PTR_VALID()
```

IDL prints:

```
0 <PtrHeapVar2>
```

We can reclaim the lost heap variable using the CAST keyword:

```
A = PTR_VALID(2, /CAST)
PRINT, A
```

IDL prints:

```
<PtrHeapVar2>
```

PTRARR

The PTRARR function returns a pointer vector or array. The individual elements of the array are set to the Null Pointer.

Syntax

Result = PTRARR(D_1, ... …, D_8 [, /ALLOCATE_HEAP | , /NOZERO])

Return Value

Returns a vector or array of the specified dimensions.

Arguments

D*ᵢ*

Either an array or a series of scalar expressions specifying the dimensions of the result. If a single argument is specified, it can be either a scalar expression or an array of up to eight elements. If multiple arguments are specified, they must all be scalar expressions. Up to eight dimensions can be specified.

Keywords

ALLOCATE_HEAP

Normally, PTRARR sets every element of the result to the null pointer. It you wish IDL to allocate heap variables for every element of the array instead, set the ALLOCATE_HEAP keyword. In this case, every element of the array will be initialized to point at an undefined heap variable.

NOZERO

If ALLOCATE_HEAP is not specified, PTRARR sets every element of the result to the null pointer. If NOZERO is nonzero, this initialization is not performed and PTRARR executes faster. NOZERO is ignored if ALLOCATE_HEAP is specified.

Warning —————————————————————————————————

If you specify NOZERO, the resulting array will have whatever value happens to exist at the system memory location that the array is allocated from. You should be careful to initialize such an array to valid pointer values.

———

Example

Create P, a 3 element by 3 element pointer array with each element containing the Null Pointer by entering:

```
P = PTRARR(3, 3)
```

PUSHD

The PUSHD procedure pushes a directory onto the top of the directory stack maintained by the PUSHD and POPD procedures. The name of the current directory is pushed onto the directory stack. This directory becomes the next directory used by POPD. IDL changes directories to the one specified by the *Dir* argument. The common block DIR_STACK is used to store the directory stack.

This routine is written in the IDL language. Its source code can be found in the file pushd.pro in the lib subdirectory of the IDL distribution.

Syntax

PUSHD, *Dir*

Arguments

Dir

A string containing the name of the directory to change to. The current directory is pushed onto the top of the directory stack.

Keywords

None.

Routines: Q

QGRID3

The QGRID3 function linearly interpolates the dependent variable values to points in a regularly sampled volume. Its inputs are a triangulation of scattered data points in three dimensions, and the value of a dependent variable for each point.

Note ──

QGRID3 accepts complex input but only utilizes the real part of any complex number.

──

Syntax

Result = QGRID3(*XYZ*, *F*, *Tetrahedra* [, DELTA=*vector*] [, DIMENSION=*vector*] [, MISSING=*value*] [, START=*vector*])

or

Result = QGRID3(*X*, *Y*, *Z*, *F*, *Tetrahedra* [, DELTA=*array*] [, DIMENSION=*array*] [, MISSING=*value*] [, START=*array*])

Return Value

Result is a 3-dimensional array of either single or double precision floating type, of the specified dimensions.

Arguments

XYZ

This is a 3-by-*n* array containing the scattered points.

X, Y, Z

One-dimensional vectors containing the *X*, *Y*, and *Z* point coordinates.

F

The function value at each location in the form of an *n*-element vector.

Tetrahedra

A longword array containing the point indices of each tetrahedron, as created by QHULL.

Keywords

Note ───

Any of the keywords may be set to a scalar if all elements are the same.

───

DELTA

A scalar or three element array specifying the grid spacing in *X*, *Y*, and *Z*. If this keyword is not specified, it is set to create a grid of DIMENSION cells, enclosing the volume from START to [max(*x*), max(*y*), max(*z*)].

DIMENSION

A three-element array specifying the grid dimensions in *X*, *Y*, and *Z*. If only one or two elements are supplied, the first element is used for the missing elements. The dimensions must be greater than or equal to 2. If an element is less than 2, the default value of 25 is used for that dimension.

MISSING

The value to be used for grid points that lie outside the convex hull of the scattered points. The default is 0.

START

A three element array specifying the start of the grid in *X*, *Y*, and *Z*. Default value is [min(*x*), min(*y*), min(*z*)].

Examples

Example 1

This example interpolates a data set measured on an irregular grid.

```
; Create a dataset of N points.
n = 200
x = RANDOMU(seed, n)
y = RANDOMU(seed, n)
z = RANDOMU(seed, n)

; Create dependent variable.
f = x^2 - x*y + z^2 + 1

; Obtain a tetrahedra using the QHULL procedure.
QHULL, x, y, z, tet, /DELAUNAY
```

```
; Create a volume with dimensions [51, 51, 51]
; over the unit cube.
volume = QGRID3(x, y, z, f, tet, START=0, DIMENSION=51, $
   DELTA=0.02)

; Display the volume.
XVOLUME, BYTSCL(volume)
```

Example 2

This example is similar to the previous one, however in this example we use a [3, *n*] array of points.

```
; Create a dataset of N points.
n = 200
p = RANDOMU(seed, 3, n)

; Create dependent variable.
f = p[0,*]^2 - p[0,*]*p[1,*] + p[2,*]^2 + 1

; Obtain a tetrahedra.
QHULL, p, tet, /DELAUNAY

; Create a volume with dimensions [51, 51, 51] over the unit cube.
volume = QGRID3(p, f, tet, START=0, DIMENSION=51, DELTA=0.02)

; Display the volume.
XVOLUME, BYTSCL(volume)
```

Example 3

The following example uses the data from the `irreg_grid2.txt` ASCII file. This file contains scattered three-dimensional data. This file contains bore hole data for a square mile of land. The QHULL procedure is used to triangulate the three-dimensional locations. The QGRID3 function uses the results from QHULL to grid the data into a volume. The scattered data is displayed as symbol polyline objects in the XOBJVIEW utility. The resulting gridded volume is displayed in the XVOLUME utility:

```
; Import the Data:

; Determine the path to the file. This file contains bore hole
; data for a square mile of land.  The bore hole samples were
; roughly taken diagonally from the upper left corner of the
; square to the lower right corner.
file = FILEPATH('irreg_grid2.txt', $
   SUBDIRECTORY = ['examples', 'data'])
```

```
; Import the data from the file into a structure.
dataStructure = READ_ASCII(file)

; Get the imported array from the first field of
; the structure.
dataArray = TRANSPOSE(dataStructure.field1)

; Initialize the variables of this example from
; the imported array.
x = dataArray[*, 0]
y = dataArray[*, 1]
z = dataArray[*, 2]
data = dataArray[*, 3]

; Determine number of data points.
nPoints = N_ELEMENTS(data)

; Triangulate the Data with QHULL:

; Construct the convex hulls of the volume.
QHULL, x, y, z, tetrahedra, /DELAUNAY

; Grid the Data and Display the Results:

; Initialize volume parameters.
cubeSize = [51, 51, 51]
; Grid the data into a volume.
volume = QGRID3(x, y, z, data, tetrahedra, START = 0, $
   DIMENSION = cubeSize, DELTA = 0.02)
; Scale the volume to be able to view the full data value range
; with the color tables provided in the XVOLUME utility.
scaledVolume = BYTSCL(volume)

; Display the results in the XVOLUME utility.
XVOLUME, scaledVolume

; Derive the isosurface for mineral deposits with the data value
; of 2.5.
ISOSURFACE, volume, 2.5, vertices, connectivity

; Initialize a model to contain the isosurface.
oModel = OBJ_NEW('IDLgrModel')

; Initialize the polygon object of the isosurface.
oPolygon = OBJ_NEW('IDLgrPolygon', vertices, $
   POLYGONS = connectivity, COLOR = [0, 0, 255])

; Determine the range in each direction.
```

```
        xRange = [0, cubeSize[0]]
        yRange = [0, cubeSize[1]]
        zRange = [0, cubeSize[2]]

        ; Initialize an axis for each direction.
        oAxes = OBJARR(3)
        oAxes[0] = OBJ_NEW('IDLgrAxis', 0, RANGE = xRange, $
           LOCATION = [xRange[0], yRange[0], zRange[0]], /EXACT, $
           TICKLEN = (0.02*(yRange[1] - yRange[0])))
        oAxes[1] = OBJ_NEW('IDLgrAxis', 1, RANGE = yRange, $
           LOCATION = [xRange[0], yRange[0], zRange[0]], /EXACT, $
           TICKLEN = (0.02*(xRange[1] - xRange[0])))
        oAxes[2] = OBJ_NEW('IDLgrAxis', 2, RANGE = zRange, $
           LOCATION = [xRange[0], yRange[1], zRange[0]], /EXACT, $
           TICKLEN = (0.02*(xRange[1] - xRange[0])))

        ; Add the polygon and axes object to the model.
        oModel->Add, oPolygon
        oModel->Add, oAxes

        ; Rotate the model for a better perspective.
        oModel->Rotate, [0, 0, 1], 30.
        oModel->Rotate, [1, 0, 0], -45.

        ; Display the model, which contains the isosurface.
        XOBJVIEW, oModel, /BLOCK, SCALE = 0.75, $
           TITLE = 'Isosurface at the Value of 2.5'

        ; Cleanup object references.
        OBJ_DESTROY, [oModel]
```

QHULL

QHULL

The QHULL procedure constructs convex hulls, Delaunay triangulations, and Voronoi diagrams of a set of points of 2-dimensions or higher. It uses and is based on the program QHULL, which is described in Barber, Dobkin and Huhdanpaa, "The Quickhull Algorithm for Convex Hulls," *ACM Transactions on Mathematical Software*, Vol. 22, No 4, December 1996, Pages 469-483.

Note ─────────────────────────────────────

QHULL accepts complex input but only utilizes the real part of any complex number.

──

For more information about QHULL see http://www.geom.umn.edu/software/qhull/.

Syntax

QHULL, *V*, *Tr*

or,

QHULL, *V0* , *V1*, [, *V2 ...* [, *V6*]] , *Tr*

Keywords: [, BOUNDS=*variable*] [, CONNECTIVITY=*variable*]
[, /DELAUNAY] [, SPHERE=*variable*] [, VDIAGRAM=*array*]
[, VNORMALS=*array*] [, VVERTICES=*array*]

Arguments

V

An input argument providing an *nd*-by-*np* array containing the locations of *np* points, in *nd* dimensions. The number of dimensions, *nd*, must be greater than or equal to 2.

V0, V1, V2, ..., V(N−1)

Input vectors of dimension *np*-by-1 elements each containing the *i*-th coordinate of *np* points in *nd* dimensions. A maximum of seven input vectors may be specified.

Tr

An *nd1*-by-*nt* array containing the indices of either the convex hull (*nd1* is equal to *nd*), or the Delaunay triangulation (*nd1* is equal to *nd*+1) of the input points.

Keywords

BOUNDS

Set this keyword equal to a named variable that will contain the indices of the vertices of the convex hull.

Note ———————————————————————————————————————

The order of the vertices returned in this variable is unspecified.

———

CONNECTIVITY

Set this keyword to a named variable in which the adjacency list for each of the *np* nodes is returned. The list has the following form:

Each element *i*, $0 \leq i < np$, contains the starting index of the connectivity list (*list*) for node *i* within the list array. To obtain the adjacency list for node *i*, extract the list elements from *list*[*i*] to *list*[*i*+1] – 1. The adjacency list is not ordered. To obtain the connectivity list, either the DELAUNAY or SPHERE keywords must also be specified.

For example, to perform a spherical triangulation, use the following procedure call:

```
QHULL, lon, lat, CONNECTIVITY = list, SHPERE = sphere
```

which returns the adjacency list in the variable list. The subscripts of the nodes adjacent to *lon*[*i*] and *lat*[*i*] are contained in the array: *list*[*list*[*i*] :*list*[*i*+1] – 1].

DELAUNAY

Performs a Delaunay triangulation and returns the vertex indices of the resulting polyhedra; otherwise, the convex hull of the data are returned.

SPHERE

Computes the Delaunay triangulation of the points which lie on the surface of a sphere. The *V0* argument contains the longitude, in degrees, and *V1* contains the latitude, in degrees, of each point.

VDIAGRAM

When specified, this keyword returns the connectivity of the Voronoi diagram.

For two-dimensional arrays, VDIAGRAM is a 4-by-*nv* integer array. For each Voronoi ridge, *i*, VDIAGRAM[0:1, *i*] contains the index of the two input points the ridge bisects. VDIAGRAM [2:3, *i*] contains the indices within VVERTICES of the

Voronoi vertices. In the case of an unbounded half-space, VDIAGRAM[2, *i*] is set to a negative index, *j*, indicating that the corresponding Voronoi ridge is unbounded, and that the equation for the ridge is contained in VNORMAL[*, –*j*-1], and starts at Voronoi vertex [3, *i*].

For three-dimensional or higher dimensional arrays, VDIAGRAM is returned as a connectivity vector. This vector has the form [*n*, v0, v1, i0, i1, ..., in-3], where n is the number of points needed to describe that particular Voronoi ridge, v0 and v1 contain the indices for the two input points that the ridge bisects, and i0...in -3 contain the indices within VVERTICES of the Voronoi vertices. In the case of an unbounded half-space, VDIAGRAM[*i*] is set to a negative index, *j*, indicating that the corresponding Voronoi ridge is unbounded, and that the equation for the ridge is contained in VNORMAL[*, –*j*-1].

VNORMALS

When specified, this keyword returns the normals of each Voronoi ridge that is unbounded. The normals consist of a (*nd*+1)-by-*nu* array, where *nd* is the number of dimensions and *nu* is the number of unbounded vertices. Each row contains the equation for the unbounded ridge in the form:

$$V_0 X_0 + V_1 X_1 + V_2 X_2 + \ldots + V_{nd} X_{nd} + V_{nd+1} = 0$$

where V_* are the elements of the row within VNORMALS, and X_* are the multidimensional coordinates. See the preceding description of VDIAGRAM for details.

VVERTICES

When specified, this keyword returns the Voronoi vertices.

Examples

```
PRO ex_qhull

   ; Create a collection of random points.
   n = 20
   seed = 15
   x = RANDOMU(seed, n)
   y = RANDOMU(seed, n)

   ; Construct the Delaunay triangulation
   ; and the Voronoi diagram.
   QHULL, x, y, triangle, /DELAUNAY, $
      VDIAGRAM=vdiagram, VVERTICES=vvert, VNORM=vnorm
```

```
         ; Plot our input points.
         PLOT, [-0.1, 1.1], [-0.1, 1.1], /NODATA, $
            XSTYLE=4, YSTYLE=4
         PLOTS, x, y, PSYM=4

         ; Plot the Voronoi diagram.
         FOR i=0,N_ELEMENTS(vdiagram[2,*])-1 DO BEGIN
            vdiag = vdiagram[*, i]
            j = vdiag[2] + 1
            ; Bounded or unbounded?
            IF (j gt 0) THEN BEGIN   ; Bounded.
               PLOTS, vvert[*, vdiag[2:3]], PSYM=-5
               CONTINUE
            ENDIF

            ; Unbounded, retrieve starting vertex.
            xystart = vvert[*, vdiag[3]]
            ; Determine the line equation.
            ; Vnorm[0]*x + Vnorm[1]*y + Vnorm[2] = 0
            slope = -vnorm[0,-j]/vnorm[1,-j]
            intercept = -vnorm[2,-j]/vnorm[1,-j]

            ; Need to determine the line direction.
            ; Pick a point on one side along the line.
            xunbound = xystart[0] + 5
            yunbound = slope*xunbound + intercept

            ; Find the closest original vertex.
            void = MIN( (x-xunbound)^2 + (y-yunbound)^2, idx)
            ; By definition of Voronoi diagram, the line should
            ; be closest to one of the bisected points. If not,
            ; our line went in the wrong direction.
            IF (idx ne vdiag[0] && idx ne vdiag[1]) THEN BEGIN
               xunbound = xystart[0] - 5
               yunbound = slope*xunbound + intercept
            ENDIF

            PLOTS, [[xystart], [xunbound, yunbound]]

         ENDFOR

      END
```

For some other examples using the QHULL procedure, see the QGRID3 function.

QGRID3

QROMB

The QROMB function evaluates the integral of a function over the closed interval [*A, B*] using Romberg integration.

QROMB is based on the routine `qromb` described in section 4.3 of *Numerical Recipes in C: The Art of Scientific Computing* (Second Edition), published by Cambridge University Press, and is used by permission.

Syntax

Result = QROMB(*Func*, *A*, *B* [, /DOUBLE] [, EPS=*value*] [, JMAX=*value*]
   [, K=*value*])

Return Value

The result will have the same structure as the smaller of *A* and *B*, and the resulting type will be single- or double-precision floating, depending on the input types.

Arguments

Func

A scalar string specifying the name of a user-supplied IDL function to be integrated. This function must accept a single scalar argument *X* and return a scalar result. It must be defined over the closed interval [*A, B*].

For example, if we wish to integrate the cubic polynomial

$$y = x^3 + (x - 1)^2 + 3$$

we define a function CUBIC to express this relationship in the IDL language:

```
FUNCTION cubic, X
   RETURN, X^3 + (X - 1.0)^2 + 3.0
END
```

Note ──
  If QROMB is complex then only the real part is used for the computation.
──

A

The lower limit of the integration. *A* can be either a scalar or an array.

B

The upper limit of the integration. *B* can be either a scalar or an array.

Note ──

If arrays are specified for *A* and *B*, then QROMB integrates the user-supplied function over the interval [A_i, B_i] for each *i*. If either *A* or *B* is a scalar and the other an array, the scalar is paired with each array element in turn.

──

Keywords

DOUBLE

Set this keyword to force the computation to be done in double-precision arithmetic.

EPS

The desired fractional accuracy. For single-precision calculations, the default value is 1.0×10^{-6}. For double-precision calculations, the default value is 1.0×10^{-12}.

JMAX

$2^{(JMAX - 1)}$ is the maximum allowed number of steps. If this keyword is not specified, a default of 20 is used.

K

Integration is performed by Romberg's method of order 2K. If not specified, the default is K=5. (K=2 is Simpson's rule).

Examples

Example 1

To integrate the CUBIC function (listed above) over the interval [0, 3] and print the result:

```
PRINT, QROMB('cubic', 0.0, 3.0)
```

IDL prints:

```
32.2500
```

This is the exact solution.

Example 2

This example evaluates the volume under a surface using the following double integration:

$$\text{volume} = \int_0^1 \int_0^1 (9x^2y^2 + 4xy + 1)dxdy$$

The exact solution to this equation is 3.

The example consists of four routines: the main routine, the integration in the y direction, the second integration of the x coefficient, and the second integration of the x^2 coefficient. The main routine is the last routine in the program. To run this example, copy the text of all four routines, paste them into an IDL editor window, and save the window's contents as `DoubleIntegration.pro`.

```
FUNCTION XSquaredCoef, x

   ; Integration of the x squared coefficient.
   secondIntegration = 9.*x^2
   RETURN, secondIntegration

END

FUNCTION XCoef, x

   ; Integration of the linear x coefficient.
   secondIntegration = x
   RETURN, secondIntegration

END

FUNCTION YDirection, y

   ; Re-write equation to consider both x coefficents.
   firstIntegration = QROMB('XSquaredCoef', 0., 1.)*y^2 $
   + 4.*(QROMB('XCoef', 0., 1.))*y + 1.
   RETURN, firstIntegration

END

PRO DoubleIntegration

   ; Determine the volume under the surface represented
   ; by 9x^2y^2 + 4xy + 1 over a specific region.
   volume = QROMB('YDirection', 0., 1. )
```

```
        ; Output results.
        PRINT, 'Resulting Volume:  ', volume

    END
```

Example 3

This example evaluates the mass of a volume using the following triple integration on a three-dimensional equation representing its density:

$$\text{mass} = \int_0^1 \int_0^1 \int_0^1 (9x^2y^2 + 8xyz + 1)dxdydz$$

The exact solution to this equation is 3.

The example consists of six routines: the main routine, the integration in the z-direction, the second integration of the xy coefficient, the second integration of the second x^2y^2 coefficient, the third integration in the x coefficient, and the third integration in the x^2 coefficient. The main routine is the last routine in the program. To run this example, copy the text of all six routines, paste them into an IDL editor window, and save the window's contents as `TripleIntegration.pro`.

```
    FUNCTION XSquaredCoef, x

        ; Integration of the x squared coefficient.
        thirdIntegration = 9.*x^2
        RETURN, thirdIntegration

    END

    FUNCTION XCoef, x

        ; Integration of the linear x coefficient.
        thirdIntegration = x
        RETURN, thirdIntegration

    END

    FUNCTION XSquaredYSquaredCoef, y

        ; Integration of the y squared coefficient.
        secondIntegration = QROMB('XSquaredCoef', 0., 1.)*y^2
        RETURN, secondIntegration

    END
```

```
FUNCTION XYCoef, y

   ; Integration of the linear y coefficient.
   secondIntegration = QROMB('XCoef', 0., 1.)*y
   RETURN, secondIntegration

END

FUNCTION ZDirection, z

   ; Re-write equation to consider all the x and y
   ; coefficients.
   firstIntegration = QROMB('XSquaredYSquaredCoef', 0., 1.) + $
   8.*(QROMB('XYCoef', 0., 1.))*z + 1.
   RETURN, firstIntegration

END

PRO TripleIntegration

   ; Determine the mass of the density represented
   ; by 9x^2y^2 + 8xyz + 1 over a specific region.
   mass = QROMB('ZDirection', 0., 1. )

   ; Output results.
   PRINT, 'Resulting Mass:  ', mass

END
```

INT_2D, INT_3D, INT_TABULATED, QROMO, QSIMP

QROMO

The QROMO function evaluates the integral of a function over the open interval (*A, B*) using a modified Romberg's method.

QROMO is based on the routine qromo described in section 4.4 of *Numerical Recipes in C: The Art of Scientific Computing* (Second Edition), published by Cambridge University Press, and is used by permission.

Syntax

Result = QROMO(*Func*, *A* [, *B*] [, /DOUBLE] [, EPS=*value*] [, JMAX=*value*] [, K=*value*] [, /MIDEXP | , /MIDINF | , /MIDPNT | , /MIDSQL | , /MIDSQU])

Return Value

Returns the integral of the function.

Arguments

Func

A scalar string specifying the name of a user-supplied IDL function to be integrated. This function must accept a single scalar argument *X* and return a scalar result. It must be defined over the open interval (*A, B*).

For example, if we wish to integrate the fourth-order polynomial

$$y = 1 / x^4$$

we define a function HYPER to express this relationship in the IDL language:

```
FUNCTION hyper, X
   RETURN, 1.0 / X^4
END
```

Note

If QROMO is complex then only the real part is used for the computation.

A

The lower limit of the integration. *A* can be either a scalar or an array.

B

The upper limit of the integration. *B* can be either a scalar or an array. If the MIDEXP keyword is specified, *B* is assumed to be infinite, and should not be supplied by the user.

Note: If arrays are specified for *A* and *B*, then QROMO integrates the user-supplied function over the interval [A_i, B_i] for each *i*. If either *A* or *B* is a scalar and the other an array, the scalar is paired with each array element in turn.

Keywords

DOUBLE

Set this keyword to force the computation to be done in double-precision arithmetic.

EPS

The fractional accuracy desired, as determined by the extrapolation error estimate. For single-precision calculations, the default value is 1.0×10^{-6}. For double-precision calculations, the default value is 1.0×10^{-12}.

JMAX

Set to specify the maximum allowed number of mid quadrature points to be $3^{(JMAX - 1)}$. The default value is 14.

K

Integration is performed by Romberg's method of order 2K. If not specified, the default is K=5.

MIDEXP

Use the `midexp()` function (see *Numerical Recipes*, section 4.4) as the integrating function. If the MIDEXP keyword is specified, argument B is assumed to be infinite, and should not be supplied by the user.

MIDINF

Use the `midinf()` function (see *Numerical Recipes*, section 4.4) as the integrating function.

MIDPNT

Use the `midpnt()` function (see *Numerical Recipes*, section 4.4) as the integrating function. This is the default if no other integrating function keyword is specified.

MIDSQL

Use the `midsql()` function (see *Numerical Recipes*, section 4.4) as the integrating function.

MIDSQU

Use the `midsqu()` function (see *Numerical Recipes*, section 4.4) as the integrating function.

Examples

Consider the following function:

```
FUNCTION hyper, X
    RETURN, 1.0 / X^4
END
```

This example integrates the HYPER function over the open interval (2, ∞) and prints the result:

```
PRINT, QROMO('hyper', 2.0, /MIDEXP)
```

IDL prints:

```
0.0412050
```

Warning
When using the MIDEXP keyword, the upper integration limit is assumed to be infinity and is not supplied.

Version History

4.0	Introduced

QSIMP

The QSIMP function performs numerical integration of a function over the closed interval [*A, B*] using Simpson's rule.

QSIMP is based on the routine `qsimp` described in section 4.2 of *Numerical Recipes in C: The Art of Scientific Computing* (Second Edition), published by Cambridge University Press, and is used by permission.

Syntax

Result = QSIMP(*Func*, *A*, *B* [, /DOUBLE] [, EPS=*value*] [, JMAX=*value*])

Return Value

The result will have the same structure as the smaller of *A* and *B*, and the resulting type will be single- or double-precision floating, depending on the input types.

Arguments

Func

A scalar string specifying the name of a user-supplied IDL function to be integrated. This function must accept a single scalar argument *X* and return a scalar result. It must be defined over the closed interval [*A, B*].

For example, if we wish to integrate the fourth-order polynomial

$$y = (x^4 - 2x^2) \sin(x)$$

we define a function SIMPSON to express this relationship in the IDL language:

```
FUNCTION simpson, X
   RETURN, (X^4 - 2.0 * X^2) * SIN(X)
END
```

Note

If QSIMP is complex then only the real part is used for the computation.

A

The lower limit of the integration. *A* can be either a scalar or an array.

B

The upper limit of the integration. *B* can be either a scalar or an array.

Note ───────────────────────────────────

If arrays are specified for *A* and *B*, then QSIMP integrates the user-supplied function over the interval [A_i, B_i] for each *i*. If either *A* or *B* is a scalar and the other an array, the scalar is paired with each array element in turn.

───

Keywords

DOUBLE

Set this keyword to force the computation to be done in double-precision arithmetic.

EPS

The desired fractional accuracy. For single-precision calculations, the default value is 1.0×10^{-6}. For double-precision calculations, the default value is 1.0×10^{-12}.

JMAX

$2^{(\text{JMAX} - 1)}$ is the maximum allowed number of steps. If not specified, a default of 20 is used.

Examples

To integrate the SIMPSON function (listed above) over the interval [0, $\pi/2$] and print the result:

```
; Define lower limit of integration:
A = 0.0

; Define upper limit of integration:
B = !PI/2.0

PRINT, QSIMP('simpson', A, B)
```

IDL prints:

```
-0.479158
```

The exact solution can be found using the integration-by-parts formula:

```
FB = 4.*B*(B^2-7.)*SIN(B) - (B^4-14.*B^2+28.)*COS(B)
FA = 4.*A*(A^2-7.)*SIN(A) - (A^4-14.*A^2+28.)*COS(A)
exact = FB - FA
PRINT, exact
```

IDL prints:

```
 -0.479156
```

INT_2D, INT_3D, INT_TABULATED, QROMB, QROMO

QUERY_* Routines

Query routines allow users to obtain information about an image or ASCII file without having to read the file. The following QUERY_* routines are available in IDL:

- QUERY_BMP
- QUERY_DICOM
- QUERY_GIF
- QUERY_IMAGE
- QUERY_JPEG
- QUERY_MRSID
- QUERY_PICT
- QUERY_PNG
- QUERY_PPM
- QUERY_SRF
- QUERY_TIFF
- QUERY_WAV

Return Values

All of the QUERY_* routines return a result, which is a long with the value of 1 if the query was successful (and the file type was correct) or 0 on failure. If the query was successful, the return argument is an anonymous structure containing all of the available information for that format.

The status is intended to be used to determine if it is appropriate to use the corresponding READ_ routine for a given file. The return status of the QUERY_* will indicate success if the corresponding READ_ routine is likely to be able to read the file. The return status will indicate failure for cases that contain formats that are not supported by the READ_ routines, even though the files may be valid outside of the IDL environment. For example, IDL's READ_BMP does not support 1-bit-deep images and so the QUERY_BMP function would return failure in the case of a monochrome BMP file.

For image formats, the returned anonymous structure has (minimally) the following fields. If the file does not support multiple images in a single file, the NUM_IMAGES field will always be 1 and the IMAGE_INDEX field will always be 0. Individual routines document additional fields which are returned for a specific format.

The QUERY_ASCII routine has its own return structure; for more information, see its documentation.

General Query * Routine Info Structures

Field	IDL data type	Description
CHANNELS	Long	Number of samples per pixel
DIMENSIONS	2-D long array	Size of the image in pixels
HAS_PALETTE	Integer	True if a palette is present
NUM_IMAGES	Long	Number of images in the file
IMAGE_INDEX	Long	Image number for which this structure is valid
PIXEL_TYPE	Integer	IDL basic type code for a pixel sample
TYPE	String	String identifying the file format

Table 19-1: Query Routines Info Structure

All the routines accept the IMAGE_INDEX keyword although formats which do not support multiple images in a single file will ignore this keyword.

QUERY_TIFF-Specific Routine Info Structures

Field	IDL data type	Description
BITS_PER_SAMPLE	Long	Number of bits per channel. Possible values are 1, 4, 8, 16, or 32.
DESCRIPTION	String	The contents of the TIFF ImageDescription tag, or a null string of undefined.
DOCUMENT_NAME	String	The contents of the TIFF DocumentName tag, or a null string if undefined.

Table 19-2: QUERY_TIFF Routine Info Structure

Field	IDL data type	Description
DATE_TIME	String	The contents of the TIFF DateTime tag, or a null string if undefined.
ORIENTATION	Long	Image orientation (columns, rows): • 1 = Left to right, top to bottom (default) • 2 = Right to left, top to bottom • 3 = Right to left, bottom to top • 4 = Left to right, bottom to top • 5 = Top to bottom, left to right • 6 = Top to bottom, right to left • 7 = Bottom to top, right to left • 8 = Bottom to top, left to right
PLANAR_CONFIG	Long	How the components of each pixel are stored. Possible values are: • 1 = Pixel interleaved RGB image or a two-dimensional image (no interleaving exists). Pixel components (such as RGB) are stored contiguously. • 2 = Image interleaved. Pixel components are stored in separate planes.

Table 19-2: QUERY_TIFF Routine Info Structure (Continued)

Field	IDL data type	Description
POSITION	Float array	Two-element vector [X position, Y position] containing the X and Y offsets in the same units as reported in the UNITS field. The X position is relative to the left side of the image. The Y position is relative to the top of the image, with positive Y increasing downwards. If the XPosition or YPosition tag is not defined in the file then a value of 0.0 is returned for that element.
PHOTOMETRIC	Long	Color mode used for the image data. Possible values are: • 0 = White is zero • 1 = Black is zero • 2 = RGB color model • 3 = Palette color model • 4 = Transparency mask • 5 = Separated (usually CMYK)
RESOLUTION	Float array	Two-element vector [*X resolution*, *Y resolution*] containing the number of pixels per *unit* (as reported in the UNITS field).

Table 19-2: QUERY_TIFF Routine Info Structure (Continued)

Field	IDL data type	Description
UNITS	Long	Units of measurement for RESOLUTION: • 1 = No units • 2 = Inches (the default) • 3 = Centimeters For example, if the UNITS field contains the value 2, then the values in the RESOLUTION field represent pixels per inch.
TILE_SIZE	Long array	Two-element vector [*Tile width*, *Tile height*]. Non-tiled images will contain [*Image width*, 1]

Table 19-2: QUERY_TIFF Routine Info Structure (Continued)

QUERY_ASCII

The QUERY_ASCII function tests a file for compatibility with READ_ASCII and returns an optional structure containing information about the file.

This routine is written in the IDL language. Its source code can be found in the file `query_ascii.pro` in the `lib` subdirectory of the IDL distribution.

Syntax

Result = QUERY_ASCII(*Filename* [, *Info*])

Return Value

This routine returns a long integer with the value of 1 (one) if the query was successful (and the file type was correct) or 0 (zero) on failure. The following criteria are used to decide whether a file is a valid ASCII file:

• If 80% of the first 32768 bytes in the file are valid ASCII characters, then the file is considered to be valid

• Byte values in the range 7-13 (bell, backspace, horizontal tab, line feed, vertical tab, form feed, carriage return) or in the range 32-127 (standard characters) are considered valid ASCII characters

These criteria provide an efficient and robust method to filter ASCII files from non-ASCII files. The 80% figure lets an ASCII file have a certain number of non-ASCII characters, perhaps in a header portion or for special characters such as fractions or symbols.

Arguments

Filename

A scalar string containing the full pathname of the file to query.

Info

Set this optional argument to a named variable in which to return an anonymous structure containing information about the file. This structure is valid only when the return value of the function is 1. The structure has the following fields:

Field	IDL Type	Description
NAME	String	File name, including full path
TYPE	String	File format (always 'ASCII')
BYTES	Long64	File length in bytes
LINES	Long64	Number of lines
WORDS	Long64	Number of words

Table 19-3: The Info Argument's Anonymous Structure

For the WORDS field, words are assumed to be separated by whitespace, including carriage returns, line feeds, tabs, and spaces.

Note
IDL uses the file's first 32768 characters to determine whether it is ASCII or not. If the file is valid, IDL processes the remainder of the file and fills in the *Info* structure for the complete file. If the file is not valid, IDL does not modify the *Info* variable.

Tip
If you have a data file that contains only columns of data (without any header lines), the number of words (WORDS) divided by the number of lines (LINES) should give you the number of columns.

Keywords

None

Example

Use the following code to retrieve information from a text file:

```
file = FILEPATH( "irreg_grid1.txt", $
   SUBDIRECTORY=['examples','data'] )
result = QUERY_ASCII( file, info )
if (result) then HELP, info, /STRUCTURES $
   else PRINT, 'File not found or is not a valid ASCII file.'
```

Version History

6.2	Introduced

ASCII_TEMPLATE, READ_ASCII

QUERY_BMP

QUERY_BMP is a method of obtaining information about a BMP image file without having to read the file. See "QUERY_* Routines" on page 1943 for more information.

Syntax

Result = QUERY_BMP (*Filename* [, *Info*])

Return Value

This routine returns a long with the value of 1 (one) if the query was successful (and the file type was correct) or 0 (zero) on failure.

Arguments

Filename

A scalar string containing the pathname of the BMP file to query.

Info

Returns an anonymous structure containing information about the image in the file. The Info.TYPE field will return the value 'BMP'.

Note

See "General Query * Routine Info Structures" on page 1944 for detailed structure information.

Keywords

There are no keywords for this routine.

Version History

5.2	Introduced

See Also

QUERY_* Routines, READ_BMP, WRITE_BMP

QUERY_DICOM

The QUERY_DICOM function tests a file for compatibility with READ_DICOM and returns an optional structure containing information about images in the DICOM file. This function supports cases in which a blank DICOM tag is supplied.

This routine is written in the IDL language. Its source code can be found in the file query_dicom.pro in the lib subdirectory of the IDL distribution.

Syntax

Result = QUERY_DICOM(*Filename* [, *Info*] [, IMAGE_INDEX=*index*] [, /DICOMEX])

Return Value

This routine returns a long with the value of 1 (one) if the query was successful or 0 (zero) on failure. A result of 1 means it is likely that the file can be read by READ_DICOM.

Arguments

Filename

A scalar string containing the full pathname of the file to query.

Info

Returns an anonymous structure containing information about the image in the file. The Info.TYPE field will return the value 'DICOM'.

Note
See "General Query * Routine Info Structures" on page 1944 for detailed structure information.

Keywords

IMAGE_INDEX

Set this keyword to the index (zero based) of the image being queried in the file. This keyword has no effect on files containing a single image.

DICOMEX

This keyword is set by default. When an additional cost DICOM Read/Write license or Read/Write runtime license is available, and an IDLffDicomEx object can be created, IDL uses the IDLffDicomEx object to query the DICOM file. If these conditions are not met, or if this keyword is set to 0, IDL uses the IDLffDICOM object to query the DICOM file instead.

Examples

DICOM palette vectors are 16 bit quantities and may not cover the entire dynamic range of the image. To view a paletted DICOM image use the following:

```
IF (QUERY_DICOM('file.dcm',info)) THEN BEGIN
   IF (info.has_palette) THEN BEGIN
      TV, READ_IMAGE('file.dcm',r, g, b), /ORDER
      TVLCT,r/256, g/256, b/256
   ENDIF
ENDIF
```

Version History

5.2	Introduced
6.2	Added DICOMEX keyword

See Also

READ_DICOM

QUERY_GIF

QUERY_GIF is a method of obtaining information about a GIF image file without having to read the file. See "QUERY_* Routines" on page 1943 for more information.

Note

The GIF format uses compression technologies that may be subject to license restrictions. If you receive a warning when attempting to use this routine, contact ITT Visual Information Solutions for information about licensing options.

Syntax

Result = QUERY_GIF (*Filename* [, *Info*])

Return Value

This routine returns a long with the value of 1 (one) if the query was successful (and the file type was correct) or 0 (zero) on failure.

Arguments

Filename

A scalar string containing the pathname of the GIF file to query.

Info

Returns an anonymous structure containing information about the image in the file. The Info.TYPE field will return the value 'GIF'.

Note

See "QUERY_* Routines" on page 1943 for detailed structure info.

Keywords

None

Version History

5.2	Introduced

See Also

QUERY_* Routines, READ_GIF, WRITE_GIF

QUERY_IMAGE

The QUERY_IMAGE function determines whether a file is recognized as a supported image file. QUERY_IMAGE first checks the filename suffix, and if found, calls the corresponding QUERY_ routine. For example, if the specified file is image.bmp, QUERY_BMP is called to determine if the file is a valid .bmp file. If the file does not contain a filename suffix, or if the query fails on the specified filename suffix, QUERY_IMAGE checks against all supported file types.

Syntax

Result = QUERY_IMAGE(*Filename [, Info]* [, CHANNELS=*variable*]
   [, DIMENSIONS=*variable*] [, HAS_PALETTE=*variable*]
   [, IMAGE_INDEX=*index*] [, NUM_IMAGES=*variable*]
   [, PIXEL_TYPE=*variable*] [, SUPPORTED_READ=*variable*]
   [, SUPPORTED_WRITE=*variable*] [, TYPE=*variable*])

Return Value

Result is a long with the value of 1 if the query was successful (the file was recognized as an image file) or 0 on failure. The return status will indicate failure for files that contain formats that are not supported by the corresponding READ_* routine, even though the file may be valid outside the IDL environment.

If the file is a supported image file, an optional structure containing information about the image is returned. If the file is not a supported image file, QUERY_IMAGE returns 0.

Arguments

Filename

A required scalar string containing the name of the file to query.

Info

An optional anonymous structure containing information about the image. This structure is valid only when the return value of the function is 1. The Info structure for all image types has the following fields:

Tag	Type
CHANNELS	Long
DIMENSIONS	Two-dimensional long array
FILENAME	Scalar string
HAS_PALETTE	Integer
IMAGE_INDEX	Long
NUM_IMAGES	Long
PIXEL_TYPE	Integer
TYPE	Scalar string

Table 19-4: The Info Structure for All Image Types

Keywords

CHANNELS

Set this keyword to a named variable to retrieve the number of channels in the image.

DIMENSIONS

Set this keyword to a named variable to retrieve the image dimensions as a two-dimensional array.

HAS_PALETTE

Set this keyword to a named variable to equal to 1 if a palette is present, else 0.

IMAGE_INDEX

Set this keyword to the index of the image to query from the file. The default is 0, the first image.

NUM_IMAGES

Set this keyword to a named variable to retrieve the number of images in the file.

PIXEL_TYPE

Set this keyword to a named variable to retrieve the IDL Type Code of the image pixel format. See "IDL Type Codes and Names" under the SIZE function for a complete list of IDL Type Codes.

The valid types for PIXEL_TYPE are:

- 1 = Byte
- 2 = Integer
- 3 = Longword Integer
- 4 = Floating Point
- 5 = Double-precision Floating Point
- 12 = Unsigned Integer
- 13 = Unsigned Longword Integer
- 14 = 64-bit Integer
- 15 = Unsigned 64-bit Integer

SUPPORTED_READ

Set this keyword to a named variable to retrieve a string array of image types recognized by READ_IMAGE. If the SUPPORTED_READ keyword is used the filename and info arguments are optional.

SUPPORTED_WRITE

Set this keyword to a named variable to retrieve a string array of image types recognized by WRITE_IMAGE. If the SUPPORTED_WRITE keyword is used the filename and info arguments are optional.

TYPE

Set this keyword to a named variable that will contain the image type as a scalar string. Possible return values are BMP, GIF, JPEG, JPEG2000, PNG, PPM, SRF, TIFF, or DICOM.

Examples

The following example uses QUERY_IMAGE to determine whether or not an image has an associated palette. For an example that uses QUERY_IMAGE to determine the interleaving of an RGB image, see "Returning Image File Information" (Chapter 4, *Using IDL*).

Displaying Indexed Images with Direct Graphics

An indexed image contains up to 256 colors, typically defined by a color table associated with the image. The value of each pixel relates to a color within the associated color table. Combinations of the primary colors (red, green, and blue) make up the colors within the color table. Most indexed images are stored as byte and therefore do not require scaling prior to display.

The following example imports an indexed image from the avhrr.png image file. This indexed image is a satellite photograph of the world. Complete the following steps for a detailed description of the process.

Example Code

See displayindexedimage_direct.pro in the examples/doc/image subdirectory of the IDL installation directory for code that duplicates this example. Run the example procedure by entering displayindexedimage_direct at the IDL command prompt or view the file in an IDL Editor window by entering .EDIT displayindexedimage_direct.pro. The BLOCK keyword is set when using the XLOADCT utility to force the example routine to wait until the **Done** button is pressed to continue.

1. Determine the path to the avhrr.png file:

   ```
   file = FILEPATH('avhrr.png', $
      SUBDIRECTORY = ['examples', 'data'])
   ```

2. Use QUERY_IMAGE to query the file to determine image parameters:

   ```
   queryStatus = QUERY_IMAGE(file, imageInfo)
   ```

3. Output the results of the file query:

   ```
   PRINT, 'Query Status = ', queryStatus
   HELP, imageInfo, /STRUCTURE
   ```

   The following text appears in the Output Log:

   ```
   Query Status =            1
   ** Structure <141d0b0>, 7 tags, length=36, refs=1:
      CHANNELS        LONG         1
   ```

```
DIMENSIONS      LONG      Array[2]
HAS_PALETTE     INT       1
IMAGE_INDEX     LONG      0
NUM_IMAGES      LONG      1
PIXEL_TYPE      INT       1
TYPE            STRING    'PNG'
```

4. Set the image size parameter from the query information:

   ```
   imageSize = imageInfo.dimensions
   ```

   The HAS_PALETTE tag has a value of 1. Thus, the image has a palette (color table), which is also contained within the file. The color table is made up of its three primary components (the red component, the green component, and the blue component).

5. Use READ_IMAGE to import the image and its associated color table from the file:

   ```
   image = READ_IMAGE(file, red, green, blue)
   ```

6. If you are running IDL on a TrueColor display, set the DECOMPOSED keyword to the DEVICE command to zero before your first color table related routine is used within an IDL session or program.

   ```
   DEVICE, DECOMPOSED = 0
   ```

7. Load the red, green, and blue components of the image's associated color table:

   ```
   TVLCT, red, green, blue
   ```

8. Create a window and display the original image with the TV procedure:

   ```
   WINDOW, 0, XSIZE = imageSize[0], YSIZE = imageSize[1], $
      TITLE = 'An Indexed Image'
   TV, image
   ```

9. Use the XLOADCT utility to display the associated color table:

   ```
   XLOADCT
   ```

   Click on the **Done** button of XLOADCT to exit out of the utility.

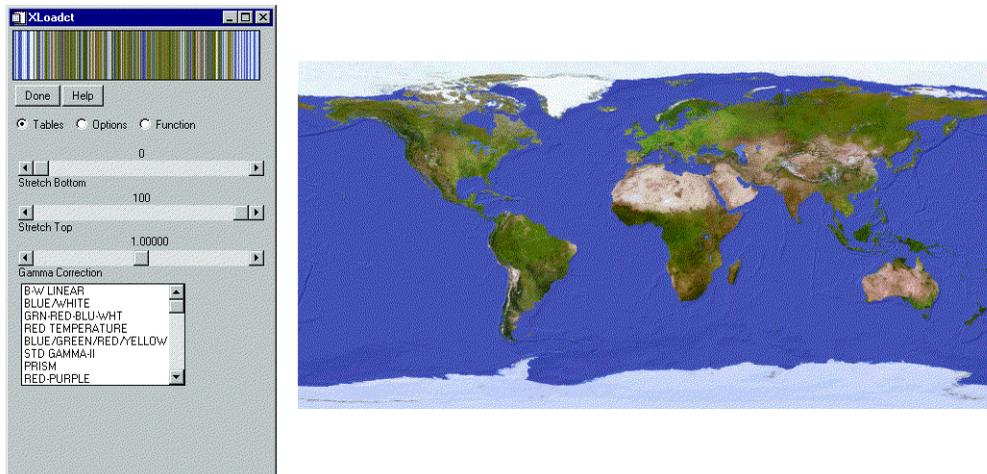
The following figure shows the resulting indexed image and its color table.


Figure 19-1: Indexed Image and Associated Color Table in Direct Graphics

The data values within the image are indexed to specific colors within the table. You can change the color table associated with this image to show how an indexed image is dependent upon its related color table.

10. Change the current color table to the EOS B pre-defined color table:

```
LOADCT, 27
```

11. Redisplay the image to show the color table change:

```
TV, image
```

Note

This step is not always necessary to redisplay the image. On PseudoColor (8-bit) or DirectColor systems, the display will update automatically when the current color table is changed.

12. Use the XLOADCT utility to display the current color table:

```
XLOADCT
```

Click on the **Done** button of XLOADCT to exit out of the utility.

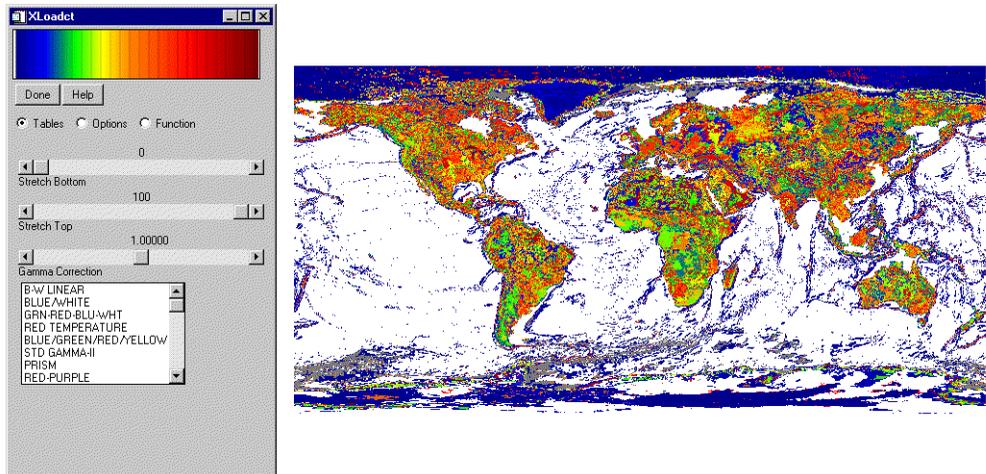
The following figure shows the indexed image with the EOS B color table.


Figure 19-2: Indexed Image and EOS B Color Table in Direct Graphics

QUERY_JPEG

QUERY_JPG is a method of obtaining information about a JPEG image file without having to read the file. See "QUERY_* Routines" on page 1943 for more information.

Syntax

Result = QUERY_JPEG (*Filename* [, *Info*])

Return Value

This routine returns a long with the value of 1 (one) if the query was successful (and the file type was correct) or 0 (zero) on failure.

Arguments

Filename

A scalar string containing the pathname of the JPEG file to query.

Info

Returns an anonymous structure containing information about the image in the file. The Info.TYPE field will return the value 'JPEG'.

Note
See "General Query * Routine Info Structures" on page 1944 for detailed structure information.

Keywords

None.

Version History

5.2	Introduced

QUERY_* Routines, READ_JPEG, WRITE_JPEG

QUERY_JPEG2000

The QUERY_JPEG2000 function allows you to obtain information about a JPEG2000 image file without having to read the file. It is a wrapper around the IDLffJPEG2000 object interface that presents JPEG2000 image loading in a way familiar to users of the QUERY_* image routines. (See "QUERY_* Routines" on page 1943 for more information.) However this function is not as efficient as the object interface and the object interface should be used whenever possible. See "IDLffJPEG2000" (Chapter 30, *IDL Reference Guide*) for information about the object interface.

Syntax

Result = QUERY_JPEG2000(*Filename* [, *Info*])

Return Value

This routine returns a long integer with the value of 1 if the query was successful (and the file type was correct) or 0 on failure.

Arguments

Filename

A scalar string containing the full path and filename of the JPEG2000 file to query.

Info

Returns an anonymous structure containing information about the image in the file. The Info.TYPE field will return the value 'JPEG2000'.

Note ──
See "General Query * Routine Info Structures" on page 1944 for detailed structure information.
──

In addition to the standard structure fields, the JPEG2000 query structure contains the following additional fields:

Field	IDL Data Type	Description
N_LAYERS	Long	The number of quality layers.
N_LEVELS	Long	The number of wavelet decomposition levels.
OFFSET	Two-element vector	The X and Y offsets for all image components.

Table 19-5: JPEG2000 Query Structure

Keywords

None.

Example

For a relevant example, see READ_JPEG2000.

Version History

6.1	Introduced

See Also

QUERY_* Routines, READ_JPEG2000, WRITE_JPEG2000

QUERY_MRSID

The QUERY_MRSID function allows you to obtain information about a MrSID image file without having to read the file. It is a wrapper around the object interface that presents MrSID image loading in a familiar way to users of the QUERY_* image routines. (See "QUERY_* Routines" on page 1943 for more information.) However this function is not as efficient as the object interface and the object interface should be used whenever possible. See "IDLffMrSID" on page 3367 for information about the object interface.

Note ───
This routine is only available under Microsoft Windows.
───

Syntax

Result = QUERY_MRSID(*Filename* [, *Info*] [, LEVEL=*lvl*])

Return Value

This routine returns a long with the value of 1 (one) if the query was successful (and the file type was correct) or 0 (zero) on failure.

Arguments

Filename

A scalar string containing the full path and filename of the MrSID file to query.

Info

Returns an anonymous structure containing information about the image in the file. The Info.TYPE field will return the value 'MrSID'.

Note ───
See "General Query * Routine Info Structures" on page 1944 for detailed structure information.
───

The info structure also has the following the MRSID-specific fields:

- info.LEVELS – a named variable that will contain a two-element integer vector of the form [minlvl, maxlvl] that specifies the range of levels within the

current image. Higher levels are lower resolution. A level of 0 equals full resolution. Negative values specify higher levels of resolution.

• Info.GEO_VALID – a long integer with a value of 1 if the file contains valid georeferencing data, or 0 if the georeferencing data is nonexistent or unsupported.

> **Note** ──
>
>   Always verify that this keyword returns 1 before using the data returned by any other GEO_* keyword.
>
> ──

• Info.GEO_PROJTYPE – unsigned integer.
• Info.GEO_ORIGIN – 2-element double precision array.
• Info.GEO_RESOLUTION – 2-element double precision array.

See "IDLffMrSID::GetProperty" on page 3375 for more information on GEO_* values.

Keywords

LEVEL

Set this keyword to an integer that specifies the level to which the DIMENSIONS field of the info structure corresponds. This can be used, for example, to determine what level is required to fit the image into a certain area. If this keyword is not specified, the dimensions at level 0 are returned.

Examples

```
; Select the image file.
file = QUERY_MRSID(FILEPATH('test_gs.sid', $
   SUBDIRECTORY=['examples', 'data']), info, LEVEL = -2)

HELP, file
; IDL returns 1 indicating the correct file type
; and successful query.

; Print the range of levels of resolution available within
; the file.
PRINT, 'Range of image levels = ', info.LEVELS

; Print the image dimensions when the image level is set to -2
; as specified by LEVEL = -2 in the QUERY_MRSID statement.

QUERY_PICT

QUERY_PICT is a method of obtaining information about a PICT image file without having to read the file. See "QUERY_* Routines" on page 1943 for more information.

Syntax

Result = QUERY_PICT (*Filename* [, *Info*])

Return Value

This routine returns a long with the value of 1 (one) if the query was successful (and the file type was correct) or 0 (zero) on failure.

Arguments

Filename

A scalar string containing the pathname of the PICT file to query.

Info

Returns an anonymous structure containing information about the image in the file. The Info.TYPE field will return the value 'PICT'.

Note ───
See "General Query * Routine Info Structures" on page 1944 for detailed structure information.

QUERY_PNG

QUERY_PNG is a method of obtaining information about a PNG image file without having to read the file. See "QUERY_* Routines" on page 1943 for more information.

Syntax

Result = QUERY_PNG (*Filename* [, *Info*])

Return Value

This routine returns a long with the value of 1 (one) if the query was successful (and the file type was correct) or 0 (zero) on failure.

Arguments

Filename

A scalar string containing the pathname of the PNG file to query.

Info

Returns an anonymous structure containing information about the image in the file. The Info.TYPE field will return the value 'PNG'.

Note
See "General Query * Routine Info Structures" on page 1944 for detailed structure information.

Keywords

None

Examples

Query included in creating RGBA (16-bit/channel) and Color Indexed (8-bits/channel) image.

```
rgbdata = UINDGEN(4,320,240)
cidata = BYTSCL(DIST(256))
red = indgen(256)
```

```
green = indgen(256)
blue = indgen(256)
WRITE_PNG,'rgb_image.png',rgbdata
WRITE_PNG,'ci_image.png',cidata,red,green,blue

; Query and Read the data:
names = ['rgb_image.png','ci_image.png','unknown.png']

FOR i=0,N_ELEMENTS(names)-1 DO BEGIN
   ok = QUERY_PNG(names[i],s)
   IF (ok) THEN BEGIN
   HELP,s,/STRUCTURE
   IF (s.HAS_PALETTE) THEN BEGIN
      img = READ_PNG(names[i],rpal,gpal,bpal)
      HELP,img,rpal,gpal,bpal
   ENDIF ELSE BEGIN
      img = READ_PNG(names[i])
      HELP,img
   ENDELSE
   ENDIF ELSE BEGIN
      PRINT,names[i],' is not a PNG file'
   ENDELSE
ENDFOR
END
```

QUERY_PPM

QUERY_PPM is a method of obtaining information about a PPM image file without having to read the file. See "QUERY_* Routines" on page 1943 for more information.

Syntax

Result = QUERY_PPM (*Filename* [, *Info*] [, MAXVAL=*variable*])

Return Value

This routine returns a long with the value of 1 (one) if the query was successful (and the file type was correct) or 0 (zero) on failure.

Arguments

Filename

A scalar string containing the pathname of the PPM file to query.

Info

Returns an anonymous structure containing information about the image. The Info.TYPE field will return the value 'PPM'.

Additional field in the Info structure: MAXVAL - maximum pixel value in the image.

Note

See "General Query * Routine Info Structures" on page 1944 for detailed structure information.

Keywords

MAXVAL

Set this keyword to a named variable to retrieve the maximum pixel value in the image.

QUERY_* Routines, READ_PPM, WRITE_PPM

QUERY_SRF

QUERY_SRF is a method of obtaining information about an SRF image file without having to read the file. See "QUERY_* Routines" on page 1943 for more information.

Syntax

Result = QUERY_SRF (*Filename* [, *Info*])

Return Value

This routine returns a long with the value of 1 (one) if the query was successful (and the file type was correct) or 0 (zero) on failure.

Arguments

Filename

A scalar string containing the pathname of the SRF file to query.

Info

Returns an anonymous structure containing information about the image in the file. The Info.TYPE field will return the value 'SRF'.

Note

See "General Query * Routine Info Structures" on page 1944 for detailed structure information.

Keywords

None.

Version History

5.2	Introduced

QUERY_* Routines, READ_SRF, WRITE_SRF

QUERY_TIFF

QUERY_TIFF is a method of obtaining information about a TIFF image file without having to read the file. See "QUERY_* Routines" on page 1943 for more information.

Syntax

Result = QUERY_TIFF (*Filename* [, *Info*] [, GEOTIFF=*variable*]
    [, IMAGE_INDEX=*index*])

Return Value

This routine returns a long with the value of 1 (one) if the query was successful (and the file type was correct) or 0 (zero) on failure.

Arguments

Filename

A scalar string containing the pathname of the TIFF file to query.

Info

Returns an anonymous structure containing information about the image in the file. The Info.TYPE field will return the value 'TIFF'.

Note

See "General Query * Routine Info Structures" on page 1944 for detailed structure information.

Note

In addition to the fields returned in the Info structure for all image types, there are a number of extra fields in the Info structure for TIFF images. See "QUERY_TIFF-Specific Routine Info Structures" on page 1944 for detailed structure info.

Keywords

GEOTIFF

Set this keyword to a named variable in which to return an anonymous structure containing the GeoTIFF tags and keys found in the file. If no GeoTIFF information is present in the file, the returned variable is set to a scalar zero. For a description of the possible GeoTIFF tags see the GEOTIFF keyword in READ_TIFF.

Tip ———————————————————————————————————
This keyword returns the same information as the GEOTIFF keyword to READ_TIFF, but avoids the overhead of reading in the entire image.
——

IMAGE_INDEX

Image number index. If this value is larger than the number of images in the file, the function returns 0 (failure).

Examples

This is an example of using QUERY_TIFF to write and read a multi-image TIFF file. The first image is a 16-bit, single channel image stored using compression. The second image is an RGB image stored using 32-bits/channel uncompressed.

```
; Write the image data:
data = FIX(DIST(256))
rgbdata = LONARR(3,320,240)
WRITE_TIFF,'multi.tif',data,COMPRESSION=1,/SHORT
WRITE_TIFF,'multi.tif',rgbdata,/LONG,/APPEND

; Read the image data back:
ok = QUERY_TIFF('multi.tif',s)
IF (ok) THEN BEGIN
   FOR i=0,s.NUM_IMAGES-1 DO BEGIN
      imp = QUERY_TIFF('multi.tif',t,IMAGE_INDEX=i)
      img = READ_TIFF('multi.tif',IMAGE_INDEX=i)
      HELP,t,/STRUCTURE
      HELP,img
   ENDFOR
ENDIF
```

QUERY_WAV

The QUERY_WAV function checks that the file is actually a .WAV file and that the READ_WAV function can read the data in the file. Optionally, it can return additional information about the data in the file.

Syntax

Result = QUERY_WAV (*Filename*[, *Info*])

Return Value

This routine returns a long with the value of 1 (one) if the query was successful (and the file type was correct) or 0 (zero) on failure.

Arguments

Filename

A scalar string containing the full pathname of the .WAV file to read.

Info

An anonymous structure containing information about the data in the file. The fields are defined as:

Tag	Type	Definition
CHANNELS	INT	Number of data channels in the file.
SAMPLES_PER_SEC	LONG	Data sampling rate in samples per second.
BITS_PER_SAMPLE	INT	Number of valid bits in the data.

Chapter 20
Routines: R

R_CORRELATE

The R_CORRELATE function computes Spearman's (rho) or Kendalls's (tau) rank correlation of two sample populations *X* and *Y*. The result is a two-element vector containing the rank correlation coefficient and the two-sided significance of its deviation from zero. The significance is a value in the interval [0.0, 1.0]; a small value indicates a significant correlation.

$$\text{rho} = \frac{\displaystyle\sum_{i=0}^{N-1}(Rx_i - \overline{Rx})(Ry_i - \overline{Ry})}{\sqrt{\displaystyle\sum_{i=0}^{N-1}(Rx_i - \overline{Rx})^2}\sqrt{\displaystyle\sum_{i=0}^{N-1}(Ry_i - \overline{Ry})^2}}$$

where Rx_i and Ry_i are the magnitude-based ranks among *X* and *Y*, respectively. Elements of identical magnitude are ranked using a rank equal to the mean of the ranks that would otherwise be assigned.

This routine is written in the IDL language. Its source code can be found in the file r_correlate.pro in the lib subdirectory of the IDL distribution.

Syntax

Result = R_CORRELATE(*X*, *Y* [, D=*variable*] [, /KENDALL] [, PROBD=*variable*] [, ZD=*variable*])

Return Value

Returns a two-element vector indicating the rank correlation coefficient and the significance of its deviation from zero.

Arguments

X

An *n*-element integer, single-, or double-precision floating-point vector.

Y

An *n*-element integer, single-, or double-precision floating-point vector.

Keywords

D

Set this keyword to a named variable that will contain the sum-squared difference of ranks. If the KENDALL keyword is set, this parameter is returned as zero.

KENDALL

Set this keyword to compute Kendalls's (tau) rank correlation. By default, Spearman's (rho) rank correlation is computed.

PROBD

Set this keyword to a named variable that will contain the two-sided significance level of ZD. If the KENDALL keyword is set, this parameter is returned as zero.

ZD

Set this keyword to a named variable that will contain the number of standard deviations by which D deviates from its null-hypothesis expected value. If the KENDALL keyword is set, this parameter is returned as zero.

Examples

```
; Define two n-element sample populations:
X = [257, 208, 296, 324, 240, 246, 267, 311, 324, 323, 263, $
     305, 270, 260, 251, 275, 288, 242, 304, 267]
Y = [201, 56, 185, 221, 165, 161, 182, 239, 278, 243, 197, $
     271, 214, 216, 175, 192, 208, 150, 281, 196]

; Compute Spearman's (rho) rank correlation of X and Y.
result = R_CORRELATE(X, Y)
PRINT, 'Spearman's (rho) rank correlation: ', result

; Compute Kendalls's (tau) rank correlation of X and Y:
result = R_CORRELATE(X, Y, /KENDALL)
PRINT, 'Kendalls's (tau) rank correlation: ', result
```

IDL prints:

```
Spearman's (rho) rank correlation:   0.835967  4.42899e-006
Kendalls's (tau) rank correlation:   0.624347  0.000118729
```

R_TEST

The R_TEST function tests the hypothesis that a binary population (a sequence of 1s and 0s) represents a "random sampling".

This routine is written in the IDL language. Its source code can be found in the file r_test.pro in the lib subdirectory of the IDL distribution.

Syntax

Result = R_TEST(*X* [, N0=*variable*] [, N1=*variable*] [, R=*variable*])

Return Value

The result is a two-element vector containing the nearly-normal test statistic Z and its associated probability. This two-tailed test is based on the "theory of runs" and is often referred to as the "Runs Test for Randomness."

Arguments

X

An *n*-element integer, single-, or double-precision floating-point vector. Elements not equal to 0 or 1 are removed and the length of *X* is correspondingly reduced.

Keywords

N0

Set this keyword to a named variable that will contain the number of 0s in *X*.

N1

Set this keyword to a named variable that will contain the number of 1s in *X*.

R

Set this keyword to a named variable that will contain the number of runs (clusters of 0s and 1s) in *X*.

Examples

```
; Define a binary population:
X = [0, 1, 1, 0, 1, 0, 0, 0, 1, 0, 0, 1, 1, 0, 1, 0, 1, 0, 0, $
  1, 0, 1, 1, 0, 1, 0, 0, 1, 0, 1]

; Test the hypothesis that X represents a random sampling against
; the hypothesis that it does not represent a random sampling at
; the 0.05 significance level:
result = R_TEST(X, R = r, N0 = n0, N1 = n1)
PRINT, result
```

IDL prints:

```
[2.26487, 0.0117604]
```

Print the values of the keyword parameters:

```
PRINT, 'Runs: ', r & PRINT, 'Zeros: ', n0 & PRINT, 'Ones: ', n1
Runs:      22
Zeros:     16
Ones:      14
```

The computed probability (0.0117604) is less than the 0.05 significance level and therefore we reject the hypothesis that *X* represents a random sampling. The results show that there are too many runs, indicating a non-random cyclical pattern.

RADON

The RADON function implements the Radon transform, used to detect features within a two-dimensional image. This function can be used to return either the Radon transform, which transforms lines through an image to points in the Radon domain, or the Radon backprojection, where each point in the Radon domain is transformed to a straight line in the image.

Radon Transform Theory

The Radon transform is used to detect features within an image. Given a function $A(x, y)$, the Radon transform is defined as:

$$R(\theta, \rho) = \int_{-\infty}^{\infty} A(\rho \cos\theta - s \sin\theta, \rho \sin\theta + s \cos\theta) ds$$

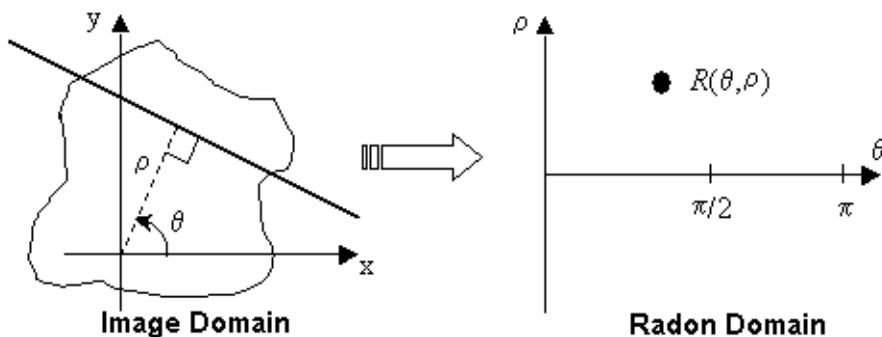
This equation describes the integral along a line s through the image, where ρ is the distance of the line from the origin and θ is the angle from the horizontal.


Figure 20-1: The Radon Transform

In medical imaging, each point $R(\theta, \rho)$ is called a ray-sum, while the resulting image is called a shadowgram. An image can be reconstructed from its ray-sums using the backprojection operator:

$$B(x, y) = \int_{0}^{\pi} R(\theta, x\cos\theta + y\sin\theta) d\theta$$

where the output, $B(x, y)$, is an image of $A(x, y)$ blurred by the Radon transform.

How IDL Implements the Radon Transform

To avoid the use of a two-dimensional interpolation and decrease the interpolation errors, the Radon transform equation is rotated by θ, and the interpolation is then done along the line *s*. The transform is divided into two regions, one for nearly-horizontal lines ($\theta \leq 45°$; $135° \leq \theta \leq 180°$), and the other for steeper lines ($45° < \theta < 135°$), where θ is assumed to lie on the interval [0°, 180°].

For nearest-neighbor interpolation (the default), the discrete transform formula for an image $A(m, n)$ [$m = 0, ..., M–1, n = 0, ..., N–1$] is:

$$
R(\theta, \rho) = \begin{cases} \dfrac{\Delta x}{|\sin\theta|} \displaystyle\sum_m A(m, [am + b]) & |\sin\theta| > \dfrac{\sqrt{2}}{2} \\[2em] \dfrac{\Delta y}{|\cos\theta|} \displaystyle\sum_n A([a'n + b'], n) & |\sin\theta| \leq \dfrac{\sqrt{2}}{2} \end{cases}
$$

where brackets [ ] indicate rounding to the nearest integer, and the slope and offsets are given by:

$$
a = -\frac{\Delta x}{\Delta y}\frac{\cos\theta}{\sin\theta} \qquad\qquad b = \frac{\rho - x_{min}\cos\theta - y_{min}\sin\theta}{\Delta y \sin\theta}
$$

$$
a' = \frac{1}{a} \qquad\qquad b' = \frac{\rho - x_{min}\cos\theta - y_{min}\sin\theta}{\Delta x \cos\theta}
$$

For linear interpolation, the transform is:

$$
R(\theta, \rho) = \begin{cases} \dfrac{\Delta x}{|\sin\theta|} \displaystyle\sum_m (1-w)A(m, \lfloor am + b \rfloor) + wA(m, \lfloor am + b \rfloor + 1) & |\sin\theta| > \dfrac{\sqrt{2}}{2} \\[2em] \dfrac{\Delta y}{|\cos\theta|} \displaystyle\sum_n (1-w)A(\lfloor a'n + b' \rfloor, n) + wA(\lfloor a'n + b' \rfloor + 1, n) & |\sin\theta| \leq \dfrac{\sqrt{2}}{2} \end{cases}
$$

where the slope and offsets are the same as above, and $\lfloor\ \rfloor$ indicates flooring to the nearest lower integer. The weighting *w* is given by the difference between *am + b* and its floored value, or between *a'n + b'* and its floored value.

How IDL Implements the Radon Backprojection

For the backprojection transform, the discrete formula for nearest-neighbor interpolation is:

$$B(m,n) \,=\, \Delta\theta \sum_t R(\theta_t, [\rho])$$

with the nearest-neighbor for ρ given by:

$$\rho \,=\, \{(m\Delta x + x_{min})\cos\theta_t + (n\Delta y + y_{min})\sin\theta_t - \rho_{min}\}\Delta\rho^{-1}$$

For backprojection with linear interpolation:

$$B(m,n) = \Delta\theta \sum_t (1-w)R(\theta_t, \lfloor\rho\rfloor) + wR(\theta_t, \lfloor\rho\rfloor + 1)$$

$$w = \rho - \lfloor\rho\rfloor$$

and ρ is the same as in the nearest-neighbor.

Syntax

Radon Transform:

Result = RADON(*Array* [, /DOUBLE] [, DRHO=*scalar*] [, DX=*scalar*]
  [, DY=*scalar*] [, /GRAY] [, /LINEAR] [, NRHO=*scalar*] [, NTHETA=*scalar*]
  [, RHO=*variable*] [, RMIN=*scalar*] [, THETA=*variable*] [, XMIN=*scalar*]
  [, YMIN=*scalar*])

Radon Backprojection:

Result = RADON(*Array, /*BACKPROJECT, RHO=*variable*, THETA=*variable*
  [, /DOUBLE] [, DX=*scalar*] [, DY=*scalar*] [, /LINEAR] [, NX=*scalar*]
  [, NY=*scalar*] [, XMIN=*scalar*] [, YMIN=*scalar*])

Return Value

The result of this function is a two-dimensional floating-point array, or a complex array if the input image is complex. If *Array* is double-precision, or if the DOUBLE keyword is set, the result is double-precision, otherwise, the result is single-precision.

Arguments

Array

The two-dimensional array of size *M* by *N* to be transformed.

Keywords

BACKPROJECT

If set, the backprojection is computed, otherwise, the forward transform is computed.

Note ——————————————————————————

The Radon backprojection does not return the original image. Instead, it returns an image blurred by the Radon transform. Because the Radon transform is not one-to-one, multiple (x, y) points are mapped to a single (θ, ρ).

————————————————————————————————

DOUBLE

Set this keyword to force the computation to be done using double-precision arithmetic.

DRHO

Set this keyword equal to a scalar specifying the spacing between ρ coordinates, expressed in the same units as *Array*. The default is one-half of the diagonal distance between pixels, $0.5[(DX^2 + DY^2)]^{1/2}$. Smaller values produce finer resolution, and are useful for zooming in on interesting features. Larger values may result in undersampling, and are not recommended. If BACKPROJECT is specified, this keyword is ignored.

DX

Set this keyword equal to a scalar specifying the spacing between the horizontal (x) coordinates. The default is 1.0.

DY

Set this keyword equal to a scalar specifying the spacing between the vertical (y) coordinates. The default is 1.0.

GRAY

Set or omit this keyword to perform a weighted Radon transform, with the weighting given by the pixel values. If GRAY is explicitly set to zero, the image is treated as a binary image with all nonzero pixels considered as 1.

LINEAR

Set this keyword to use linear interpolation rather than the default nearest-neighbor sampling. Results are more accurate but slower when linear interpolation is used.

NRHO

Set this keyword equal to a scalar specifying the number of ρ coordinates to use. The default is $2 \ \mathrm{CEIL}([\mathrm{MAX}(x^2 + y^2)]^{1/2} / \mathrm{DRHO}) + 1$. If BACKPROJECT is specified, this keyword is ignored.

NTHETA

Set this keyword equal to a scalar specifying the number of θ coordinates to use over the interval $[0, \pi]$. The default is $\mathrm{CEIL}(\pi \ [(M^2 + N^2)/2]^{1/2})$. Larger values produce smoother results, and are useful for filtering before backprojection. Smaller values result in broken lines in the transform, and are not recommended. If BACKPROJECT is specified, this keyword is ignored.

NX

If BACKPROJECT is specified, set this keyword equal to a scalar specifying the number of horizontal coordinates in the output *Result*. The default is $\mathrm{FLOOR}(2 \ \mathrm{MAX}(|\mathrm{RHO}|)(DX^2 + DY^2)^{-1/2} + 1)$. For the forward transform this keyword is ignored.

NY

If BACKPROJECT is specified, set this keyword equal to a scalar specifying the number of vertical coordinates in the output *Result*. The default is $\mathrm{FLOOR}(2 \ \mathrm{MAX}(|\mathrm{RHO}|)(DX^2 + DY^2)^{-1/2} + 1)$. For the forward transform, this keyword is ignored.

RHO

For the forward transform, set this keyword to a named variable that will contain the radial (ρ) coordinates, in units defined by the DX and DY keywords (pixels by default). If BACKPROJECT is specified, this keyword must contain the ρ

coordinates of the input *Array*. The ρ coordinates should be evenly spaced and in increasing order.

RMIN

Set this keyword equal to a scalar specifying the minimum ρ coordinate to use for the forward transform. The default is –0.5(NRHO – 1) DRHO. If BACKPROJECT is specified, this keyword is ignored.

THETA

For the forward transform, set this keyword to a named variable containing a vector of angular (θ) coordinates (in radians) to use for the transform. If NTHETA is specified instead, and THETA is set to a named variable, on exit THETA will contain the θ coordinates. If BACKPROJECT is specified, this keyword must contain the θ coordinates of the input *Array*.

XMIN

Set this keyword equal to a scalar specifying the *x*-coordinate of the lower-left corner of the input *Array*. The default is – (*M*–1)/2, where *Array* is an *M* by *N* array. If BACKPROJECT is specified, set this keyword equal to a scalar specifying the *x*-coordinate of the lower-left corner of the *Result*. In this case the default is -DX (NX-1)/2.

YMIN

Set this keyword equal to a scalar specifying the *y*-coordinate of the lower-left corner of the input *Array*. The default is – (*N*–1)/2, where *Array* is an *M* by *N* array. If BACKPROJECT is specified, set this keyword equal to a scalar specifying the *y*-coordinate of the lower-left corner of the *Result*. In this case, the default is -DY (NY-1)/2.

Examples

Note

RANDOMN

The RANDOMN function returns one or more normally-distributed, floating-point, pseudo-random numbers with a mean of zero and a standard deviation of one. RANDOMN uses the Box-Muller method for generating normally-distributed (Gaussian) random numbers.

Syntax

Result = RANDOMN(*Seed [, D_1 [, ..., D_8]]* [[, BINOMIAL=*[trials, probability]*] [, /DOUBLE] [, GAMMA=*integer*{>0}] [, /NORMAL] [, POISSON=*value*] [, /UNIFORM] | [, /LONG]])

Return Value

Returns an array containing the random numbers of the specified dimensions.

Arguments

Seed

A variable or constant used to initialize the random sequence on input, and in which the state of the random number generator is saved on output.

The state of the random number generator is contained in a long integer vector. This state is saved in the Seed argument when the argument is a named variable. To continue the pseudo-random number sequence, input the variable containing the saved state as the Seed argument in the next call to RANDOMN or RANDOMU. Each independent random number sequence should maintain its own state variable. To maintain a state over repeated calls to a procedure, the seed variable may be stored in a COMMON block.

In addition to states maintained by the user in variables, the RANDOMU and RANDOMN functions contain a single shared generic state that is used if a named variable is not supplied as the Seed argument or the named variable supplied is undefined. The generic state is initialized once using the time-of-day, and may be re-initialized by providing a Seed argument that is a constant or expression.

If the Seed argument is:

- An undefined variable — the generic state is used and the resulting generic state array is stored in the variable.

- A named variable that contains a longword array of the proper length — it is used to continue the pseudo-random sequence, and is updated.

- A named variable containing a scalar — the scalar value is used to start a new sequence and the resulting state array is stored back in the variable.

- A constant or expression — the value is used to re-initialize the generic state.

Note

RANDOMN and RANDOMU use the same sequence. Starting or restarting the sequence for one starts or restarts the sequence for the other. Some IDL routines use the random number generator, so using them will initialize the seed sequence. An example of such a routine is CLUST_WTS.

Note

Do not alter the seed value returned by this function. The only valid use for the seed argument is to pass it back to a subsequent call. Changing the value of the seed will corrupt the random sequence.

D_i

Either an array or a series of scalar expressions specifying the dimensions of the result. If a single argument is specified, it can be either a scalar expression or an array of up to eight elements. If multiple arguments are specified, they must all be scalar expressions. Up to eight dimensions can be specified. If no dimensions are specified, RANDOMN returns a scalar result

Keywords

The formulas for the binomial, gamma, and Poisson distributions are from section 7.3 of *Numerical Recipes in C: The Art of Scientific Computing* (Second Edition), published by Cambridge University Press.

BINOMIAL

Set this keyword to a 2-element array, [*n*, *p*], to generate random deviates from a binomial distribution. If an event occurs with probability *p*, with *n* trials, then the number of times it occurs has a binomial distribution.

Note ———
For $n > 1.0$ x 10^7, you should set the DOUBLE keyword.

DOUBLE

Set this keyword to force the computation to be done using double-precision arithmetic.

RANDOMN constructs double-precision uniform random deviates using the formula:

$$Y = \frac{(i1 - 1) \cdot imax + i2}{imax^2 + 1}$$

where *i1* and *i2* are integer random deviates in the range [1...*imax*], and *imax* = 2^{31} - 2 is the largest possible integer random deviate. The *Y* values will be in the range $0 < Y < 1$.

GAMMA

Set this keyword to an integer order $i > 0$ to generate random deviates from a gamma distribution. The gamma distribution is the waiting time to the *i*th event in a Poisson random process of unit mean. A gamma distribution of order equal to 1 is the same as the exponential distribution.

Note ———
For GAMMA > 1.0 x 10^7, you should set the DOUBLE keyword.

LONG

Set this keyword to return integer uniform random deviates in the range $[1...2^{31} - 2]$. If LONG is set, all other keywords are ignored.

NORMAL

Set this keyword to generate random deviates from a normal distribution.

POISSON

Set this keyword to the mean number of events occurring during a unit of time. The POISSON keyword returns a random deviate drawn from a Poisson distribution with that mean.

Note ───
For POISSON $> 1.0 \times 10^{7}$, you should set the DOUBLE keyword.
───

UNIFORM

Set this keyword to generate random deviates from a uniform distribution.

Examples

If you start the sequence with an *undefined* variable—if RANDOMN has already been called, *Seed* is no longer undefined—IDL initializes the sequence with the system time:

```
; Generate one random variable and initialize the sequence with an
; undefined variable:
randomValue = RANDOMN(seed)
```

The new state is saved in seed. To generate repeatable experiments, begin the sequence with a particular seed:

```
seed_value = 5L

; Generate one random variable and initialize the sequence with 5:
randomValue = RANDOMN(seed_value)

PRINT, randomValue
```

IDL prints:

```
0.521414
```

To restart the sequence with a particular seed, re-initialize the variable:

```
seed = 5L

;Get a normal random number, and restart the sequence with a seed
;of 5.
randomValue = RANDOMN(seed)

PRINT, randomValue
```

IDL prints:

```
0.521414
```

To continue the same sequence:

```
PRINT, RANDOMN(seed)
```

IDL prints:

```
-0.945489
```

To create a 10 by 10 array of normally-distributed, random numbers, type:

```
R = RANDOMN(seed, 10, 10)
```

Since seed is undefined, the generic state is used to initialize the random number generator. Print the resulting values by entering:

```
PRINT, R
```

A more interesting example plots the probability function of 2000 numbers returned by RANDOMN. Type:

```
PLOT, HISTOGRAM(RANDOMN(SEED, 2000), BINSIZE=0.1)
```

To obtain a sequence of 1000 exponential (gamma distribution, order 1) deviates, type:

```
Result = RANDOMN(seed, 1000, GAMMA=1)
```

Intuitively, the result contains a random series of waiting times for events occurring an average of one per time period.

To obtain a series of 1000 random elapsed times required for the arrival of two events, type:

```
;Returns a series of 1000 random elapsed times required for the
;arrival of two events.
Result = RANDOMN(seed, 1000, GAMMA=2)
```

To obtain a 128 x 128 array filled with Poisson deviates, with a mean of 1.5, type:

```
Result = RANDOMN(seed, 128, 128, POISSON=1.5)
```

To simulate the count of "heads" obtained when flipping a coin 10 times, type:

```
Result = RANDOMN(seed, BINOMIAL=[10,.5])
```

RANDOMU

RANDOMU

The RANDOMU function returns one or more uniformly-distributed, floating-point, pseudo-random numbers in the range $0 < Y < 1.0$.

The random number generator is taken from: "Random Number Generators: Good Ones are Hard to Find", Park and Miller, *Communications of the ACM*, Oct 1988, Vol 31, No. 10, p. 1192. To remove low-order serial correlations, a Bays-Durham shuffle is added, resulting in a random number generator similar to ran1() in Section 7.1 of *Numerical Recipes in C: The Art of Scientific Computing* (Second Edition), published by Cambridge University Press.

Syntax

Result = RANDOMU(*Seed [, D$_1$ [, ..., D$_8$]]*] [[, BINOMIAL=*[trials*, *probability]*]
 [, /DOUBLE] [, GAMMA=*integer*{>0}] [, /NORMAL] [, POISSON=*value*]
 [, /UNIFORM] | [, /LONG]])

Return Value

Returns an array of uniformly distributed random numbers of the specified dimensions.

Arguments

Seed

A variable or constant used to initialize the random sequence on input, and in which the state of the random number generator is saved on output.

The state of the random number generator is contained in a long integer vector. This state is saved in the Seed argument when the argument is a named variable. To continue the pseudo-random number sequence, input the variable containing the saved state as the Seed argument in the next call to RANDOMN or RANDOMU. Each independent random number sequence should maintain its own state variable. To maintain a state over repeated calls to a procedure, the seed variable may be stored in a COMMON block.

In addition to states maintained by the user in variables, the RANDOMU and RANDOMN functions contain a single shared generic state that is used if a named variable is not supplied as the Seed argument or the named variable supplied is

undefined. The generic state is initialized once using the time-of-day, and may be re-initialized by providing a Seed argument that is a constant or expression.

If the Seed argument is:

- an undefined variable — the generic state is used and the resulting generic state array is stored in the variable.

- a named variable that contains a longword array of the proper length — it is used to continue the pseudo-random sequence, and is updated.

- a named variable containing a scalar — the scalar value is used to start a new sequence and the resulting state array is stored back in the variable.

- a constant or expression — the value is used to re-initialize the generic state.

Note ───

RANDOMN and RANDOMU use the same sequence, so starting or restarting the sequence for one starts or restarts the sequence for the other. Some IDL routines use the random number generator, so using them will initialize the seed sequence. An example of such a routine is CLUST_WTS.

───

Note ───

Do not alter the seed value returned by this function. The only valid use for the seed argument is to pass it back to a subsequent call. Changing the value of the seed will corrupt the random sequence.

───

D_i

Either an array or a series of scalar expressions specifying the dimensions of the result. If a single argument is specified, it can be either a scalar expression or an array of up to eight elements. If multiple arguments are specified, they must all be scalar expressions. Up to eight dimensions can be specified. If no dimensions are specified, RANDOMU returns a scalar result

Keywords

The formulas for the binomial, gamma, and Poisson distributions are from Section 7.3 of *Numerical Recipes in C: The Art of Scientific Computing* (Second Edition), published by Cambridge University Press.

BINOMIAL

Set this keyword to a 2-element array, [*n*, *p*], to generate random deviates from a binomial distribution. If an event occurs with probability *p*, with *n* trials, then the number of times it occurs has a binomial distribution.

Note ───
For $n > 1.0 \times 10^7$, you should set the DOUBLE keyword.
──

DOUBLE

Set this keyword to force the computation to be done using double-precision arithmetic.

RANDOMU constructs double-precision uniform random deviates using the formula:

$$Y = \frac{(i1 - 1) \cdot imax + i2}{\mathrm{imax}^2 + 1}$$

where *i1* and *i2* are integer random deviates in the range [1...*imax*], and $imax = 2^{31} - 2$ is the largest possible integer random deviate. The *Y* values will be in the range $0 < Y < 1$.

GAMMA

Set this keyword to an integer order $i > 0$ to generate random deviates from a gamma distribution. The gamma distribution is the waiting time to the *i*th event in a Poisson random process of unit mean. A gamma distribution of order equal to 1 is the same as the exponential distribution.

Note ───
For $GAMMA > 1.0 \times 10^7$, you should set the DOUBLE keyword.
──

LONG

Set this keyword to return integer uniform random deviates in the range $[1...2^{31} - 2]$. If LONG is set, all other keywords are ignored.

NORMAL

Set this keyword to generate random deviates from a normal distribution.

POISSON

Set this keyword to the mean number of events occurring during a unit of time. The POISSON keyword returns a random deviate drawn from a Poisson distribution with that mean.

Note ───

For POISSON $> 1.0 \times 10^7$, you should set the DOUBLE keyword.

───

UNIFORM

Set this keyword to generate random deviates from a uniform distribution.

Examples

This example simulates rolling two dice 10,000 times and plots the distribution of the total using RANDOMU. Enter:

```
PLOT, HISTOGRAM(FIX(6 * RANDOMU(S, 10000)) + $
    FIX(6 * RANDOMU(S, 10000)) + 2)
```

In the above statement, the expression RANDOMU(S, 10000) is a 10,000-element, floating-point array of random numbers greater than or equal to 0 and less than 1. Multiplying this array by 6 converts the range to $0 \le Y < 6$.

Applying the FIX function yields a 10,000-point integer vector with values from 0 to 5, one less than the numbers on one die. This computation is done twice, once for each die, then 2 is added to obtain a vector from 2 to 12, the total of two dice.

The HISTOGRAM function makes a vector in which each element contains the number of occurrences of dice rolls whose total is equal to the subscript of the element. Finally, this vector is plotted by the PLOT procedure.

An example of reusing a state vector to generate a repeatable sequence:

```
; Init seed for a repeatable sequence:
seed = 1001L

; Print 1st 5 numbers of sequence:
print,randomu(seed,5)
```

IDL prints:

```
     0.705884      0.285924      0.231151      0.715447      0.532836
```

Reuse a state vector:

```
; Re-init seed to same sequence:
seed = 1001L

; Get 5 number of sequence with 5 calls:
for i=0,4 do print, randomu(seed)
```

IDL prints:

```
        0.705884
        0.285924
        0.231151
        0.715447
        0.532836
```

RANDOMN

RANKS

The RANKS function computes the magnitude-based ranks of a sample population *X*. Elements of identical magnitude "ties" are ranked according to the mean of the ranks that would otherwise be assigned.

This routine is written in the IDL language. Its source code can be found in the file ranks.pro in the lib subdirectory of the IDL distribution.

Syntax

Result = RANKS(*X*)

Return Value

The result is a vector of ranks equal in length to *X*.

Arguments

X

An *n*-element integer, single-, or double-precision floating-point vector. The elements of this vector must be in ascending order based on their magnitude.

Keywords

None.

Examples

```
; Define an n-element sample population:
X = [-0.8, 0.1, -2.3, -0.6, 0.2, 1.1, -0.3, 0.6, -0.2, 1.1, $
    -0.7, -0.2, 0.6, 0.4, -0.1, 1.1, -0.3, 0.3, -1.3, 1.1]

; Allocate a two-column, n-row array to store the results:
array = FLTARR(2, N_ELEMENTS(X))

; Sort the sample population and store in the 0th column of ARRAY:
array[0, *] = X[SORT(X)]
; Compute the ranks of the sorted sample population and store in
; the 1st column of ARRAY:
array[1, *] = RANKS(X[SORT(X)])
```

```
; Display the sorted sample population and corresponding ranks
; with a two-decimal format:
PRINT, array, FORMAT = '(2(5x, f5.2))'
```

IDL prints:

```
-2.30      1.00
-1.30      2.00
-0.80      3.00
-0.70      4.00
-0.60      5.00
-0.30      6.50
-0.30      6.50
-0.20      8.50
-0.20      8.50
-0.10     10.00
 0.10     11.00
 0.20     12.00
 0.30     13.00
 0.40     14.00
 0.60     15.50
 0.60     15.50
 1.10     18.50
 1.10     18.50
 1.10     18.50
 1.10     18.50
```

R_CORRELATE

RDPIX

The RDPIX procedure interactively displays the X position, Y position, and pixel value at the cursor.

This routine is written in the IDL language. Its source code can be found in the file `rdpix.pro` in the `lib` subdirectory of the IDL distribution.

Using RDPIX

RDPIX displays a stream of X, Y, and pixel values when the mouse cursor is moved over a graphics window. Press the left or center mouse button to create a new line of output. Press the right mouse button to exit the procedure.

Syntax

RDPIX, *Image* [, *X0*, *Y0*]

Arguments

Image

The array that contains the image being displayed. This array may be of any type. Rather than reading pixel values from the display, values are taken from this parameter, avoiding scaling difficulties.

X0, Y0

The location of the lower-left corner of the image area on screen. If these parameters are not supplied, they are assumed to be zero.

Keywords

None.

CURSOR, TVRD

READ/READF

The READ procedures perform formatted input into variables.

READ performs input from the standard input stream (IDL file unit 0), while READF requires a file unit to be explicitly specified.

Syntax

READ, [*Prompt*,] *Var$_1$*, ..., *Var$_n$*

READF, [*Prompt*,] *Unit*, *Var$_1$*, ..., *Var$_n$*

Keywords: [, AM_PM=*[string, string]*] [, DAYS_OF_WEEK=*string_array*{7 names}] [, FORMAT=*value*] [, MONTHS=*string_array*{12 names}] [, PROMPT=*string*]

Arguments

Prompt

Note ───

The PROMPT keyword should be used instead of the *Prompt* argument for compatibility with window-based versions of IDL.

───

A string or explicit expression (i.e, not a named variable) to be used as a prompt. This argument should not be included if the FORMAT keyword is specified. Also, if this argument begins with the characters "$(", it is taken to be a format specification as described below under "Format Compatibility".

Using the *Prompt* argument does not work well with IDL for Windows. The desired prompt string is written to the log window instead of the command input window. To create custom prompts compatible with these versions of IDL, use the PROMPT keyword, described below.

Unit

For READF, Unit specifies the file unit from which the input is taken.

Var$_i$

The named variables to receive the input.

Note ───

Var$_i$ may *not* be an element of an array variable (`arrayvar[n]`) or a field within a structure variable (`structvar.tag`). See "Parameter Passing Mechanism" (Chapter 5, *Application Programming*) for details.

───

If the variable specified for the *Var$_i$* argument has not been previously defined, the input data is assumed to be of type float, and the variable will be created as a float.

Keywords

AM_PM

Supplies a string array of two names to be used for the names of the AM and PM string when processing explicitly formatted dates (CAPA, CApA, and CapA format codes) with the FORMAT keyword.

DAYS_OF_WEEK

Supplies a string array of 7 names to be used for the names of the days of the week when processing explicitly formatted dates (CDWA, CDwA, and CdwA format codes) with the FORMAT keyword.

FORMAT

If FORMAT is not specified, IDL uses its default rules for formatting the input. FORMAT allows the format of the input to be specified in precise detail, using a FORTRAN-style specification. See "Using Explicitly Formatted Input/Output" (Chapter 18, *Application Programming*).

Note ───

The format specification affects the way data is read from the input stream or file. It does not change the datatype of the variables into which data is being read.

───

MONTHS

Supplies a string array of 12 names to be used for the names of the months when processing explicitly formatted dates (CMOA, CMoA, and CmoA format codes) with the FORMAT keyword.

PROMPT

Set this keyword to a scalar string to be used as a customized prompt for the READ command. If the PROMPT keyword or *Prompt* argument is not supplied, IDL uses a colon followed by a space (": ") as the input prompt.

Format Compatibility

If the FORMAT keyword is not present and READ is called with more than one argument, and the first argument is a scalar string starting with the characters "$(", this initial argument is taken to be the format specification, just as if it had been specified via the FORMAT keyword. This feature is maintained for compatibility with version 1 of VMS IDL.

Examples

To read a string value into the variable B from the keyboard, enter:

```
; Define B as a string before reading:
B = ''

; Read input from the terminal:
READ, B, PROMPT='Enter Name: '
```

To read formatted data from the previously-opened file associated with logical unit number 7 into variable C, use the command:

```
READF, 7, C
```

READS, READU, WRITEU

READ_ASCII

The READ_ASCII function reads data from an ASCII file into an IDL structure variable. READ_ASCII may be used with templates created by the ASCII_TEMPLATE function.

This routine handles ASCII files consisting of an optional header of a fixed number of lines, followed by columnar data. One or more rows of data constitute a *record*. Each data element within a record is considered to be in a different column, or *field*. The data in one field must be of, or promotable to, a single type (e.g., FLOAT). Adjacent fields may be collected into multi-column fields, called *groups*. Files may also contain comments, which exist between a user-specified comment string and the corresponding end-of-line.

READ_ASCII is designed to be used with templates created by the ASCII template function.

This routine is written in the IDL language. Its source code can be found in the file read_ascii.pro in the lib subdirectory of the IDL distribution.

Syntax

Result = READ_ASCII([*Filename]* [, COMMENT_SYMBOL=*string*]
    [, COUNT=*variable*] [, DATA_START=*lines_to_skip*] [, DELIMITER=*string*]
    [, HEADER=*variable*] [, MISSING_VALUE=*value*] [, NUM_RECORDS=*value*]
    [, RECORD_START=*index*] [, TEMPLATE=*value*] [, /VERBOSE])

Return Value

The result is an IDL structure array containing the data. Each field in the structure corresponds to a different column of data and each element in the array corresponds to a different record (a row of data).

Arguments

Filename

A string containing the name of an ASCII file to read into an IDL variable. If *filename* is not specified, a dialog allows the user to choose a file.

Keywords

You can define the attributes of a field in two ways. If you use a template, you can either use a previously generated template, or create a template with ASCII_TEMPLATE. You can use COMMENT_SYMBOL, DATA_START, DELIMITER, or MISSING_VALUE to either override template attributes or to provide one-time attributes for the file to be read, without a template.

COMMENT_SYMBOL

Set this keyword to a string that identifies the character used to delineate comments in the ASCII file to be read. When READ_ASCII encounters the comment character, it discards data from that point until it reaches the end of the current line, identifying the rest of the line as a comment. The default character the null string, '', specifying that no comments will be recognized.

COUNT

Set this keyword equal to a named variable that will contain the number of records read.

DATA_START

Set this keyword equal to the number of header lines you want to skip. The default value is 0 if no template is specified.

DELIMITER

Set this keyword to a string that identifies the end of a field. If no delimiter is specified, READ_ASCII uses information provided by the template in use. The default is a space, ' ', specifying that an empty element constitutes the end of a field.

HEADER

Set this keyword equal to a named variable that will contain the header in a string array of length DATA_START. If no header exists, an empty string is returned.

MISSING_VALUE

Set this keyword equal to a value used to replace any missing or invalid data. The default value, if no template is supplied, is !VALUES.F_NAN. See "!VALUES" on page 5492 for details.

NUM_RECORDS

Set this keyword equal to the number of records to read. The default is to read up to and including the last record.

RECORD_START

Set this keyword equal to the index of the first record to read. The default is the first record of the file (record 0).

TEMPLATE

Use this keyword to specify the ASCII file template (generated by the function ASCII_TEMPLATE), that defines attributes of the file to be read. Specific attributes of the template may be overridden by the following keywords: COMMENT_SYMBOL, DATA_START, DELIMITER, MISSING_VALUE.

VERBOSE

Set this keyword to print runtime messages.

Examples

To read ASCII data using default file attributes, except for setting the number of skipped header lines to 10, type:

```
data = READ_ASCII(file, DATA_START=10)
```

To use a template to define file attributes, overriding the number of skipped header lines defined in the template, type:

```
data = READ_ASCII(file, TEMPLATE=template, DATA_START=10)
```

To use the ASCII_TEMPLATE GUI to generate a template within the function, type:

```
data = READ_ASCII(myfile, TEMPLATE=ASCII_TEMPLATE(myfile))
```

Working with a READ_ASCII Data Structure

READ_ASCII returns a structure containing ASCII data, which is formatted according to specified keywords or a template. The following example returns a structure containing the data in the sine_waves.txt file, found in the examples/data subdirectory of the IDL installation directory.

1. Enter the following statement at the IDL command line to open the **ASCII Template** dialog:

```
sTemplate = ASCII_TEMPLATE()
```

2. Complete the steps described in "Using the ASCII Template Dialog" on page 111 to define the format of the data.

3. Use READ_ASCII to access the data, defined by the template created in the previous step;

```
data = READ_ASCII(FILEPATH('sine_waves.txt', $
    SUBDIRECTORY=['examples', 'data']), TEMPLATE = sTemplate)
```

4. The variable data now contains the ASCII data. Use the format *structureName.fieldName* to access individual fields of data. The following lines plot each data field in an iPlot display:

```
iPLOT, data.SmoothSine
iPLOT, data.NoisySine, color = [255, 0, 0], /OVERPLOT
```

Note
The Variable Watch window contains the sTemplate and data structures. Expand these items for information about the structure fields.

ASCII_TEMPLATE, QUERY_ASCII

READ_BINARY

The READ_BINARY function reads the contents of a binary file using a passed template or basic command line keywords. Data is read from the given filename or from the current file position in the open file pointed to by *FileUnit*. If no template is provided, keywords can be used to read a single IDL array of data.

Syntax

Result = READ_BINARY ([*Filename*] | *FileUnit* [, TEMPLATE=*template*] |
   [[, DATA_START=*value*] [, DATA_TYPE=*typecodes*] [, DATA_DIMS=*array*]
   [, ENDIAN=*string*]])

Return Value

The result is an array or anonymous structure containing all of the entities read from the file.

Arguments

Filename

A scalar string containing the name of the binary file to read. If *filename* and file unit are not specified, a dialog allows the user to choose a file.

FileUnit

A scalar containing an open IDL file unit number to read from.

Keywords

DATA_DIMS

Set this keyword to a scalar or array of up to eight elements specifying the size of the data to be read and returned. For example, DATA_DIMS=[512,512] specifies that a two-dimensional, 512 by 512 array be read and returned. DATA_DIMS=0 specifies that a single, scalar value be read and returned. Default is -1, which, if a TEMPLATE is not supplied that specifies otherwise, indicates that READ_BINARY will read to end-of-file and store the result in a 1-D array.

DATA_START

Set this keyword to specify where to begin reading in a file. This value is as an offset, in bytes, that will be applied to the initial position in the file. The default is 0.

DATA_TYPE

Set this keyword to an IDL typecode of the data to be read. See documentation for the SIZE function for a listing of typecodes. Default is 1 (IDL's BYTE typecode).

ENDIAN

Set this keyword to one of three string values: "big", "little" or "native" which specifies the byte ordering of the file to be read. If the computer running READ_BINARY uses byte ordering that is different than that of the file, READ_BINARY will swap the order of bytes in multi-byte data types read from the file. (Default: "native" = perform no byte swapping.) See "Files and I/O" (Chapter 9, *Application Programming*) for more information on byte order and cross-platform programming.

TEMPLATE

Set this keyword to a template structure (created using the BINARY_TEMPLATE function) describing the file to be read. The TEMPLATE keyword cannot be used simultaneously with keywords DATA_START, DATA_TYPE, DATA_DIMS, or ENDIAN.

When a template is used with READ_BINARY, the return value is a structure containing fields specified by the template. If a template is not used, the return value is an array.

Examples

The following reads the data in a binary file, head.data, and passes the data to an iVolume display:

```
vHeadData = READ_BINARY(FILEPATH('head.dat', $
   SUBDIRECTORY=['examples', 'data']), DATA_DIMS=[80,100,57])
IVOLUME, vHeadData
```

When the iVolume window appears, click **Render** on the Volume panel to display the data.

Also see the following examples:

-
-
-

Working with a READ_Binary Data Structure

READ_BINARY returns a structure containing binary data, which is formatted according to specified keywords or a template. The following example returns a structure containing the data in the `surface.dat` file, found in the `examples/data` subdirectory of the IDL installation directory.

1. Enter the following statement at the IDL command line to open the **Binary Template** dialog:

   ```
   sTemplate = BINARY_TEMPLATE()
   ```

2. Complete the steps described in "Using the BINARY_TEMPLATE Interface" on page 166 to define the format of the data.

3. Use READ_BINARY to access the data, defined by the template created in the previous step;

   ```
   data = READ_BINARY(FILEPATH('surface.dat', $
       SUBDIRECTORY=['examples', 'data']), TEMPLATE = sTemplate)
   ```

4. The variable `data` now contains the binary data. Use the format *structureName.fieldName* to access individual fields of data. The following lines display the data in an iSurface tool:

   ```
   ISURFACE, data.marbells
   ```

Note
The Variable Watch window contains the `sTemplate` and `data` structures. Expand these items for information about the structure fields.

Displaying Binary Images with Direct Graphics

Binary images are composed of pixels having one of two values, usually zero or one. With most color tables, pixels having values of zero or one are displayed with almost the same color, such as with a the default grayscale color table. Thus, a binary image is usually scaled to display the zeros as black and the ones as white.

The following example imports a binary image of the world from the `continent_mask.dat` binary file. In this image, the oceans are zeros (black) and

the continents are ones (white). This type of image can be used to mask out data over the oceans. The image contains byte data values and is 360 pixels by 360 pixels. Complete the following steps for a detailed description of the process.

Example Code

See `displaybinaryimage_direct.pro` in the `examples/doc/image` subdirectory of the IDL installation directory for code that duplicates this example. Run the example procedure by entering `displaybinaryimage_direct` at the IDL command prompt or view the file in an IDL Editor window by entering `.EDIT displaybinaryimage_direct.pro`.

1. Determine the path to the `continent_mask.dat` file:

   ```
   file = FILEPATH('continent_mask.dat', $
      SUBDIRECTORY = ['examples', 'data'])
   ```

2. Initialize the image size parameter:

   ```
   imageSize = [360, 360]
   ```

3. Use READ_BINARY to import the image from the file:

   ```
   image = READ_BINARY(file, DATA_DIMS = imageSize)
   ```

4. If you are running IDL on a TrueColor display, set the DECOMPOSED keyword to the DEVICE command to zero before your first color table related routine is used within an IDL session or program. This command implies a color table will be used.

   ```
   DEVICE, DECOMPOSED = 0
   ```

5. Load a grayscale color table:

   ```
   LOADCT, 0
   ```

6. Create a window and display the original image with the TV procedure:

   ```
   WINDOW, 0, XSIZE = imageSize[0], YSIZE = imageSize[1], $
      TITLE = 'A Binary Image, Not Scaled'
   TV, image
   ```

   The resulting window should be all black (blank). The binary image contains zeros and ones, which are almost the same color (black). Binary images should be displayed with the TVSCL procedure in order to scale the ones to white.

7. Create another window and display the scaled binary image:

   ```
   WINDOW, 1, XSIZE = imageSize[0], YSIZE = imageSize[1], $
      TITLE = 'A Binary Image, Scaled'
   TVSCL, image
   ```

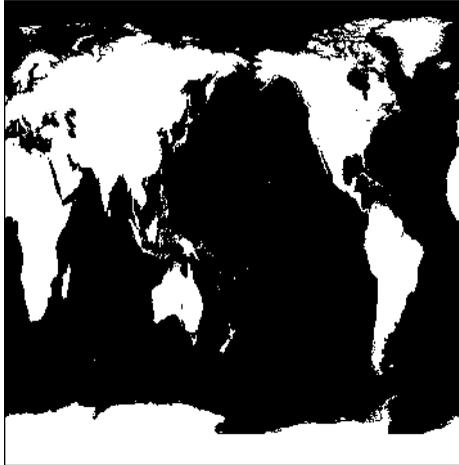
The following figure shows the results of scaling this display.


Figure 20-3: Binary Image in Direct Graphics

Displaying a Grayscale Binary Image

Features within grayscale images are created by pixels that have varying intensities. Pixel values range from least intense (black) to the most instance (white). Since a grayscale image is composed of pixels of varying intensities, it is best displayed with a color table that progresses linearly from black to white. Although IDL has several such predefined color tables, the grayscale color table (B-W LINEAR), is the most fitting choice when displaying grayscale images. IDL's B-W LINEAR color table is represented by an index value of 0. See "Loading a Default Color Table" (Chapter 5, *Using IDL*) for more information on IDL's predefined color tables.

The following example imports a grayscale image from the convec.dat binary file. This grayscale image shows the convection of the Earth's mantle. The image contains byte data values and is 248 pixels by 248 pixels. Since the data type is byte, this image does not need to be scaled before display. If the data was of any type other than byte and the data values were not within the range from 0 to 255, the image would need to be scaled prior to being displayed. (See the TVSCL description for more information.) Complete the following steps for a detailed description of the process.

Example Code _____

See displaygrayscaleimage_direct.pro in the examples/doc/image subdirectory of the IDL installation directory for code that duplicates this example.

Run the example procedure by entering `displaygrayscaleimage_direct` at the IDL command prompt or view the file in an IDL Editor window by entering `.EDIT displaygrayscaleimage_direct.pro`.

1. Determine the path to the `convec.dat` file:

   ```
   file = FILEPATH('convec.dat', $
      SUBDIRECTORY = ['examples', 'data'])
   ```

2. Initialize the image size parameter:

   ```
   imageSize = [248, 248]
   ```

3. Using READ_BINARY, import the image from the file:

   ```
   image = READ_BINARY(file, DATA_DIMS = imageSize)
   ```

4. If you are running IDL on a TrueColor display, set the DECOMPOSED keyword to the DEVICE command to zero before your first color table related routine is used within an IDL session or program.

   ```
   DEVICE, DECOMPOSED = 0
   ```

5. Load a grayscale color table:

   ```
   LOADCT, 0
   ```

6. Create a window and display the original image with the TV procedure:

   ```
   WINDOW, 0, XSIZE = imageSize[0], YSIZE = imageSize[1], $
      TITLE = 'A Grayscale Image'
   TV, image
   ```

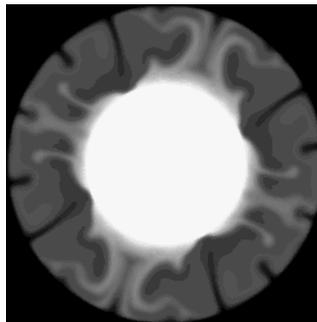
The following figure shows the resulting grayscale image display.


Figure 20-4: Grayscale Image in Direct Graphics

BINARY_TEMPLATE

READ_BMP

The READ_BMP function reads a Microsoft Windows Version 3 device independent bitmap file (.BMP) and returns the image.

READ_BMP does not handle 1-bit-deep images or compressed images, and is not fast for 4-bit images. The algorithm works best on images where the number of bytes in each scan-line is evenly divisible by 4.

This routine is written in the IDL language. Its source code can be found in the file read_bmp.pro in the lib subdirectory of the IDL distribution.

Note
To find information about a potential BMP file before trying to read its data, use the QUERY_BMP function.

Syntax

Result = READ_BMP(*Filename*, [, *R*, *G*, *B*] [, *Ihdr*] [, /RGB])

Return Value

Returns a byte array containing the image. Dimensions are taken from the BITMAPINFOHEADER of the file. In the case of 4-bit or 8-bit images, the dimensions of the resulting array are (biWidth, biHeight).

For 24-bit images, the dimensions are (3, biWidth, biHeight). Color interleaving is blue, green, red; i.e., Result[*0,i,j*] = blue, Result[*1,i,j*] = green, etc.

Arguments

Filename

A scalar string specifying the full path name of the bitmap file to read.

R, G, B

Named variables that will contain the color tables from the file. There 16 elements each for 4 bit images, 256 elements each for 8 bit images. Color tables are not defined or used for 24 bit images.

Ihdr

A named variable that will contain a structure holding the BITMAPINFOHEADER from the file. Tag names are as defined in the MS Windows Programmer's Reference Manual.

Keywords

RGB

If this keyword is set, color interleaving of 16- and 24-bit images will be R, G, B, i.e., Result[*0,i,j*] = red, Result[*1,i,j*] = green, Result[2,*i,j*] = blue.

Examples

To open, read, and display the BMP file named `foo.bmp` in the current directory and store the color vectors in the variables R, G, and B, enter:

```
; Read and display an image:
TV, READ_BMP('foo.bmp', R, G, B)

; Load its colors:
TVLCT, R, G, B
```

Many applications that use 24-bit BMP files outside IDL expect BMP files to be stored as BGR. For example, enter the following commands.

```
; Make a red square image:
a = BYTARR(3, 200, 200, /NOZERO)
a[0, *, *] = 255

;View the image:
TV, a, /TRUE
WRITE_BMP, 'foo.bmp', a
```

If you open the `.bmp` file in certain bitmap editors, you may find that the square is blue.

```
image = READ_BMP('foo.bmp')

; IDL reads the image back in and interprets it as red:
TV, image, /TRUE

; Flip the order of the indices by adding the RGB keyword:
image = READ_BMP('foo.bmp', /RGB)

; Displays the image in blue:
TV, image, /TRUE
```

WRITE_BMP, QUERY_BMP

READ_DICOM

The READ_DICOM function reads an image from a DICOM file along with any associated color table.The return array type depends on the DICOM image pixel type.

This routine is written in the IDL language. Its source code can be found in the file read_dicom.pro in the lib subdirectory of the IDL distribution.

Syntax

Result = READ_DICOM (*Filename* [, *Red*, *Green*, *Blue*] [, IMAGE_INDEX=*index*] [, /DICOMEX])

Return Value

The return value can be a 2-D array for grayscale or a 3-D array for TrueColor images. TrueColor images are always returned in pixel interleave format.

Arguments

Filename

This argument is a scalar string that contains the full pathname of the file to read.

Red, Green, Blue

Named variables that will contain the red, green, and blue color vectors from the DICOM file if they exist.

Note ——————————————————————————————

DICOM color vectors contain 16- bit color values that may need to be converted for use with IDL graphics routines.

——

Keywords

IMAGE_INDEX

Set this keyword to the index of the image to read from the file.

DICOMEX

This keyword is set by default. When an additional cost DICOM Read/Write license or Read/Write runtime license is available, and an IDLffDicomEx object can be created, IDL uses the IDLffDicomEx object to read the DICOM file. If these conditions are not met, or if this keyword is set to 0, IDL uses the IDLffDICOM object to read the DICOM file instead.

Note

READ_DICOM always returns the image array in DICOM format where the first pixel in the returned array is the top left-hand pixel in the frame. By default, the IDLffDicomEx::GetPixelData method returns pixel data in standard IDL format where the first pixel in the returned array is the bottom left-hand pixel in the frame. Set the GetPixelData ORDER keyword to return the array in DICOM format.

Examples

```
TVSCL,READ_DICOM(FILEPATH('mr_knee.dcm',$
   SUBDIR=['examples','data']))
```

Version History

5.2	Introduced
6.2	Added DICOMEX keyword

QUERY_DICOM

READ_GIF

The READ_GIF procedure reads the contents of a GIF format image file and returns the image and color table vectors (if present) in the form of IDL variables. Only 8-bit images are supported.

Note ──

The GIF format uses compression technologies that may be subject to license restrictions. If you receive a warning when attempting to use this routine, contact ITT Visual Information Solutions for information about licensing options.

──

This routine is written in the IDL language. Its source code can be found in the file read_gif.pro in the lib subdirectory of the IDL distribution.

Note ──

To find information about a potential GIF file before trying to read its data, use the QUERY_GIF function.

──

Syntax

READ_GIF, *Filename*, *Image* [, *R*, *G*, *B*] [, BACKGROUND_COLOR=*variable*]
    [, /CLOSE] [, DELAY_TIME=*variable*] [, DISPOSAL_METHOD=*variable*]
    [, /MULTIPLE] [, REPEAT_COUNT=*variable*] [, TRANSPARENT=*value*]
    [, USER_INPUT=*variable*]

Arguments

Filename

A scalar string specifying the full path name of the image file to read.

Image

A named variable that will contain the image data read from the file.

R, G, B

Named variables that will contain the Red, Green, and Blue color vectors, if the rasterfile contains colormaps. For GIF files with multiple images, when reading the second and subsequent images, R, G, and B are not returned unless there is a local color table for that image.

Keywords

BACKGROUND_COLOR

Set this keyword to a named variable that will contain the index of the background color within the global color table.

CLOSE

Set this keyword to close any open files. The CLOSE keyword is only useful if a file containing multiple images (as specified by the MULTIPLE keyword) is in use. Note that you do not need to specify the normal arguments to READ_GIF (*Filename*, *Image*, etc.) when using this keyword.

DELAY_TIME

Set this keyword to a named variable that will contain the delay in hundredths (1/100) of a second that the decoder should wait after displaying the current image. If the delay time is not defined in the file, a value of 0 will be returned. There can be a different value for each image within the file.

DISPOSAL_METHOD

Set this keyword to a named variable that will contain the disposal method that the decoder should use after displaying the current image. Possible values are:

0	No disposal specified. The decoder is not required to take any action.
1	Do not dispose. The graphic is to be left in place.
2	Restore to background color. The area used by the graphic must be restored to the background color.
3	Restore to previous. The decoder is required to restore the area overwritten by the graphic with what was there prior to rendering the graphic.

There can be a different value for each image within the file.

MULTIPLE

Set this keyword to read files that contain multiple images. Each call to READ_GIF returns the next image, with the file remaining open between calls. The *Filename* argument is ignored and may be omitted after the first call. Reading past the last image returns a scalar value of -1 in the variable specified in the *Image* argument, and closes the file.

REPEAT_COUNT

Set this keyword to a named variable that will contain the repeat count for the animation within the file. A repeat count of zero indicates an infinite repeat. If the repeat count is not defined within the file then a value of -1 is returned.

TRANSPARENT

Set this keyword to a named variable that will contain a byte value giving the index within the color table to be designated as the transparent color. If there is no transparency, then a value of -1 is returned. There can be a different value for each image within the file.

USER_INPUT

Set this keyword to a named variable that will contain the user input flag for the current image. A value of 0 indicates that no user input should be required, while a value of 1 indicates that the application should wait before continuing processing. The nature of the user input is determined by the application (carriage return, mouse button click, etc.). When both DELAY_TIME and USER_INPUT are present, the decoder should continue processing when user input is received or when the delay time expires, whichever occurs first. For multiple images there may be a different value for each image within the file.

Example

To open and read the GIF image file named `foo.gif` in the current directory, store the image in the variable `image1`.

```
; Store the color vectors in the variables R, G, and B:
READ_GIF, 'foo.gif', image1, R, G, B

; Load the new color table and display the image:
TVLCT, R, G, B
TV, image1
```

Version History

Pre-4.0	Introduced
6.4	Added BACKGROUND_COLOR, DELAY_TIME, DISPOSAL_METHOD, REPEAT_COUNT, TRANSPARENT, and USER_INPUT keywords

See Also

WRITE_GIF, QUERY_GIF

READ_IMAGE

The READ_IMAGE function reads the image contents of a file and returns the image in an IDL variable. If the image contains a palette it can be returned as well in three IDL variables. READ_IMAGE returns the image in the form of a two-dimensional array (for grayscale images) or a (3, n, m) array (for TrueColor images). READ_IMAGE can read most types of image files supported by IDL. See QUERY_IMAGE for a list of supported formats.

Syntax

Result = READ_IMAGE (*Filename* [, *Red*, *Green*, *Blue*] [, IMAGE_INDEX=*index*])

Return Value

Result is the image array read from the file or scalar value of -1 if the file could not be read.

Arguments

Filename

A scalar string containing the name of the file to read.

Red

An optional named variable to receive the red channel of the color table if a color table exists.

Green

An optional named variable to receive the green channel of the color table if a color table exists.

Blue

An optional named variable to receive the blue channel of the color table if a color table exists.

Keywords

IMAGE_INDEX

Set this keyword to the index of the image to read from the file. The default is 0, the first image.

Example

The following statements open and display a DICOM image file:

```
image = READ_IMAGE (FILEPATH('mr_knee.dcm',$
   SUBDIR=['examples', 'data']))
TV, image
```

Version History

5.3	Introduced

READ_INTERFILE

The READ_INTERFILE procedure reads image data stored in Interfile (v3.3) format.

READ_INTERFILE can only read a series of images if all images have the same height and width. It does not get additional keyword information beyond what is needed to read the image data. If any problems occur when reading the file, READ_INTERFILE prints a message and stops.

If the data is stored on a bigendian machine and read on a littleendian machine (or vice versa) the order of bytes in each pixel element may be reversed, requiring a call to BYTEORDER

This routine is written in the IDL language. Its source code can be found in the file read_interfile.pro in the lib subdirectory of the IDL distribution.

Syntax

READ_INTERFILE, *File*, *Data*

Return Value

Returns a 3-D array containing the image data.

Arguments

File

A scalar string containing the name of the Interfile to read. Note: if the Interfile has a header file and a data file, this should be the name of the header file (also called the administrative file).

Data

A named variable that will contain a 3-D array of data as read from the file. Assumed to be a series of 2-D images.

Keywords

None.

Examples

```
READ_INTERFILE, '0_11.hdr', X
```

Version History

Pre-4.0	Introduced

READ_JPEG

The READ_JPEG procedure reads JPEG (Joint Photographic Experts Group) format compressed images from files or memory. JPEG is a standardized compression method for full-color and gray-scale images. This procedure reads JFIF, the JPEG File Interchange Format, including those produced by WRITE_JPEG. Such files are usually simply called JPEG files

READ_JPEG can optionally quantize TrueColor images contained in files to a pseudo-color palette with a specified number of colors, and with optional color dithering.

This procedure is based in part on the work of the Independent JPEG Group. For a brief explanation of JPEG, see "WRITE_JPEG" on page 2950.

Note ──
All JPEG files consist of byte data. Input data is converted to bytes before being written to a JPEG file.
──

Note ──
To find information about a potential JPEG file before trying to read its data, use the QUERY_JPEG function.
──

Syntax

READ_JPEG [, *Filename*], *Image* [, *Colortable*] [, BUFFER=*variable*]
   [, COLORS=*value*{8 to 256}] [, DITHER={0 | 1 | 2}] [, /GRAYSCALE]
   [, /ORDER] [, TRUE={1 | 2 | 3}] [, UNIT=*lun*][, /TWO_PASS_QUANTIZE]

Arguments

Filename

A scalar string specifying the full pathname of the JFIF format (JPEG) file to be read. If this parameter is not present, the UNIT and/or the BUFFER keywords must be specified.

Image

A named variable that will contain the image data read from the file.

Colortable

A named variable that will contain a colormap created by color-quantizing the TrueColor image being read. On completion, this variable contains a byte array with dimensions (*nColors*, 3), where *nColors* is derived from the value of the COLORS keyword. If this argument is not present, or if the specified JPEG image is grayscale, no color-quantization is performed.

Keywords

BUFFER

Set this keyword to a named variable that is used for a buffer. A buffer variable need only be supplied when reading multiple images per file. Initialize the buffer variable to empty by setting it to 0.

COLORS

If the image file contains a TrueColor image that is to be displayed on an indexed color destination, set COLORS to the desired number of colors to be quantized. COLORS can be set to a value from 8 to 256. The DITHER and TWO_PASS_QUANTIZE keywords affect the method, speed, and quality of the color quantization. These keywords have no effect if the file contains a grayscale image.

DITHER

Set this keyword to use dithering with color quantization (i.e., if the COLORS keyword is in use). Dithering is a method that distributes the color quantization error to surrounding pixels, to achieve higher-quality results. Set the DITHER keyword to one of the following values:

- 0 = No dithering. Images are read quickly, but quality is low.

- 1 = Floyd-Steinberg dithering. This method is relatively slow, but produces the highest quality results. This is the default behavior.

- 2 = Ordered dithering. This method is faster than Floyd-Steinberg dithering, but produces lower quality results.

GRAYSCALE

Set this keyword to return a monochrome (grayscale) image, regardless of whether the file contains an RGB or grayscale image.

ORDER

JPEG/JFIF images are normally written in top-to-bottom order. If the image is to be stored into the *Image* array in the standard IDL order (from bottom-to-top) set ORDER to 0. This is the default. If the image array is to be top-to-bottom order, set ORDER to 1.

TRUE

Use this keyword to specify the index of the dimension for color interleaving when reading a TrueColor image. The default is 1, for pixel interleaving, (3, *m*, *n*). A value of 2 indicates line interleaving (*m*, 3, *n*), and 3 indicates band interleaving, (*m*, *n*, 3).

TWO_PASS_QUANTIZE

Set this keyword to use a two-pass color quantization method when quantization is in effect (i.e., the COLORS keyword is in use). This method requires more memory and time, but produces superior results to the default one-pass quantization method.

UNIT

This keyword can be used to designate the logical unit number of an already open JFIF file, allowing the reading of multiple images per file or the embedding of JFIF images in other data files. When using this keyword, *Filename* should not be specified.

Note

When opening a file intended for use with the UNIT keyword, if the filename does not end in .jpg, or .jpeg, you must specify the STDIO keyword to OPEN in order for the file to be compatible with READ_JPEG.

Examples

```
; Read a JPEG grayscale image:
READ_JPEG, 'test.jpg', a

; Display the image:
TV, a

; Read and display a JPEG TrueColor image on a TrueColor display:
READ_JPEG, 'test.jpg', a, TRUE=1
```

```
; Display the image returned with pixel interleaving
; (i.e., with dimensions 3, m, n):
TV, a, TRUE=1
```

Read the image, setting the number of colors to be quantized to the maximum number of available colors.

```
; Read a JPEG TrueColor image on an 8-bit pseudo-color display:
READ_JPEG, 'test.jpg', a, ctable, COLORS=!D.N_COLORS-1

; Display the image:
TV, a

; Load the quantized color table:
TVLCT, ctable
```

We could have also included the TWO_PASS_QUANTIZE and DITHER keywords to improve the image's appearance.

Using the BUFFER keyword.

```
; Initialize buffer:
buff = 0
OPENR, 1, 'images.jpg'

; Process each image:
FOR i=1, nimages DO BEGIN
   ; Read next image:
   READ_JPEG, UNIT=1, BUFFER=buff, a

   ; Display the image:
    TV, a
ENDFOR

; Done:
CLOSE, 1
```

Version History

WRITE_JPEG, QUERY_JPEG

READ_JPEG2000

The READ_JPEG2000 function extracts and returns image data from a JPEG2000 file. This function is a wrapper around the IDLffJPEG2000 object interface that presents JPEG2000 image loading in a familiar way to users of the READ_* image routines. However this function is not as efficient as the object interface and the object interface should be used whenever possible. See "IDLffJPEG2000" (Chapter 30, *IDL Reference Guide*) for information about the object interface.

Syntax

Result = READ_JPEG2000(*Filename* [, *Red*, *Green*, *Blue*]
   [, DISCARD_LEVELS=*value*] [, MAX_LAYERS=*value*] [, /ORDER]
   [, REGION=[*StartX*, *StartY*, *Width*, *Height*]])

Return Value

The *Result* is a two or three-dimensional array containing the image data. The dimensions of the result are [*nComponents*, *Width*, *Height*], where *nComponents* is the number of components present in the file. Images with only one component will be returned as a two dimensional array [*Width*, *Height*].

The data type of the result is automatically determined using the bit-depth and signed properties of the returned components. For bit-depth = 8 the result will be of type byte. For bit-depths ≥ 9 and ≤ 16 the result will be of type integer or uint. For bit-depths > 16 the result will be long or ulong. Components with differing bit-depths will be returned using the largest bit-depth. Components which are a mix of signed and unsigned will be returned as signed.

Note
The returned image is automatically ordered from bottom-to-top, where the first pixel returned is located at the bottom-left corner of the image. The ORDER keyword may be used to override this behavior.

Arguments

Filename

A scalar string containing the full path and filename of the JPEG2000 file to read.

Red, Green, Blue

Set these arguments to named variables that will contain the Red, Green, and Blue color vectors of the color palette from the file.

Keywords

DISCARD_LEVELS

Set this keyword to an integer giving the number of highest resolution levels which will not appear in the result.

The resulting image dimensions are given by:

```
CEIL((Dimensions + Offset)/(2^DL)) - CEIL(Offset/(2^DL))
```

where *Dimensions* and *Offset* are the image dimensions and offset, and *DL* is the value of DISCARD_LEVELS.

For example, if the image in the file has dimensions of 1024 x 1026, and DISCARD_LEVELS is set to 3, the resulting image will have dimensions of 128 x 129, which is the ceiling of [1024, 1026] divided by 2^3. The number of resolution levels in a file may be determined by checking the value of the N_LEVELS field within the QUERY_JPEG2000 structure.

MAX_LAYERS

Set this keyword to an integer giving the maximum number of quality layers which will be returned in the result. Each layer contains the information required to represent the image at a higher quality, given the information from all the previous layers. A value of 0, the default, implies that all layers should be returned. For example, specifying MAX_LAYERS=4 processes only the first four quality layers. The number of quality layers in a file may be determined by checking the value of the N_LAYERS field within the QUERY_JPEG2000 structure.

ORDER

JPEG2000 images are assumed to be stored in top-to-bottom order, while IDL usually assumes images are in bottom-to-top order. By default (ORDER = 0), READ_JPEG2000 will automatically flip the result to match IDL's bottom-to-top order. Setting ORDER to a nonzero value will return the JPEG2000 image without doing the vertical flip.

REGION

Set this keyword to a four-element vector containing the rectangular region of the image to read, in the canvas coordinate system. The region is specified as [*StartX*, *StartY*, *Width*, *Height*], where *StartX* and *StartY* must be in the range $0...2^{32}$-2, and *Width* and *Height* must be in the range $1 ... 2^{32}$-1. The region must contain at least some portion of the image, or an error will occur. If the region is larger than the image, or extends outside of the image, then only that portion that lies within the image will be returned.

Note

The region parameters should be specified in the canvas coordinate system, taking into account the canvas offset and canvas dimensions. The dimensions and offset may be determined from the QUERY_JPEG2000 structure. See "The JPEG2000 Canvas Coordinate System" (Chapter 30, *IDL Reference Guide*) for more information.

Example

```
; Read in a 24-bit JPEG image.
input = FILEPATH('marsglobe.jpg', SUBDIR=['examples','data'])
READ_JPEG, input, image

; Create a JPEG2000 with 6 quality layers.
WRITE_JPEG2000, 'marsglobe.jp2', image, N_LAYERS=6

; Verify the file information.
success = QUERY_JPEG2000('marsglobe.jp2', info)
help, info, /STRUCT

WINDOW, 0, XSIZE=2*info.dimensions[0], YSIZE=info.dimensions[1]

; Use the DISCARD_LEVELS keyword.
for discard=0,5 do TV, /TRUE, $
    READ_JPEG2000('marsglobe.jp2', DISCARD_LEVELS=discard)

; Extract a region.
image = READ_JPEG2000('marsglobe.jp2', $
    REGION=[0,0,200,100])
TV, REBIN(image, 3, 400, 200), 400, 0, /TRUE

; Use the MAX_LAYERS keyword.
image = READ_JPEG2000('marsglobe.jp2', MAX_LAYERS=1, $
    REGION=[0,0,200,100])
TV, REBIN(image, 3, 400, 200), 400, 200, /TRUE
```

Figure 20-5: Varying Quality Images

In the previous figure, the left-hand side shows the full resolution image, plus the 5 lower resolution versions (DISCARD_LEVELS=1,2,3,4,5). The right-hand side shows a magnified portion of the full quality image (bottom), and a lower quality version (top, MAX_LAYERS=1).

QUERY_JPEG2000, WRITE_JPEG2000

READ_MRSID

The READ_MRSID function extracts and returns image data from a MrSID file at the specified level and location. It is a wrapper around the object interface that presents MrSID image loading in a familiar way to users of the READ_* image routines. However this function is not as efficient as the object interface and the object interface should be used whenever possible. See "IDLffMrSID" on page 3367 for information about the object interface.

Note

This routine is only available under Microsoft Windows.

Syntax

Result = READ_MRSID (*Filename* [, LEVEL=*lvl*] [, SUB_RECT=*rect*])

Return Value

ImageData returns an *n*-by-*w*-by-*h* array containing the image data where *n* is 1 for grayscale or 3 for RGB images, *w* is the width and *h* is the height.

Note

The returned image is ordered bottom-up, the first pixel returned is located at the bottom-left of the image. This differs from how data is stored in the MrSID file where the image is top-down, meaning the pixel at the start of the file is located at the top-left of the image.

Arguments

Filename

A scalar string containing the full path and filename of the MrSID file to read.

Keywords

LEVEL

Set this keyword to an integer that specifies the level at which to read the image. If this keyword is not set, the maximum level (see QUERY_MRSID) is used which returns the minimum resolution.

SUB_RECT

Set this keyword to a four-element vector [x, y, xdim, ydim] specifying the position of the lower left-hand corner and the dimensions of the sub-rectangle of the MrSID image to return. This is useful for displaying only a portion of the high-resolution image. If this keyword is not set, the entire image will be returned. This may require significant memory if a high-resolution level is selected. If the sub-rectangle is greater than the bounds of the image at the selected level the area outside the image bounds will be set to black.

Note

The elements of SUB_RECT are measured in pixels at the current level. This means the point $x = 10$, $y = 10$ at level 1 will be located at $x = 20$, $y = 20$ at level 0 and $x = 5$, $y = 5$ at level 2.

Examples

```
; Query the file.
result = QUERY_MRSID(FILE_SEARCH(!DIR, 'test_gs.sid'), info)

; If result is not zero, read in an image from the file and
; display it.
IF (result NE 0) THEN BEGIN
   PRINT, info
   imageData = READ_MRSID(FILE_SEARCH(!DIR, 'test_gs.sid'), $
      SUB_RECT = [0, 0, 200, 200], LEVEL = 3)
   oImage = OBJ_NEW('IDLgrImage', imageData, ORDER = 0)
   XOBJVIEW, oImage, BACKGROUND = [255,255,0]
ENDIF

; Use the file access object to query the file.
oMrSID = OBJ_NEW('IDLffMrSID', FILE_SEARCH(!DIR, 'test_gs.sid'))
oMrSID->GetProperty, PIXEL_TYPE=pt, $
   CHANNELS = chan, DIMENSIONS = dims, $
   TYPE = type, LEVELS = lvls
PRINT, pt, chan, dims, type, lvls

; Use the object to read in an image from the file.
lvls = -3
dimsatlvl = oMrSID->GetDimsAtLevel(lvls)
PRINT, dimsatlvl
imageData = oMrSID->GetImageData(LEVEL = 3)
PRINT, size(imageData)
OBJ_DESTROY, oImage
```

READ_PICT

The READ_PICT procedure reads the contents of a PICT (version 2) format image file and returns the image and color table vectors (if present) in the form of IDL variables. The PICT format is used by Apple Macintosh computers.

This routine is written in the IDL language. Its source code can be found in the file read_pict.pro in the lib subdirectory of the IDL distribution.

Note ───

To find information about a potential PICT file before trying to read its data, use the QUERY_PICT function.

──

Syntax

READ_PICT, *Filename*, *Image* [, *R*, *G*, *B*]

Arguments

Filename

A scalar string specifying the full pathname of the PICT file to read.

Image

A named variable that will contain the 2-D image read from *Filename*.

R, G, B

Named variables that will contain the Red, Green, and Blue color vectors read from the PICT file.

Keywords

None.

Examples

To open and read the PICT image file named `foo.pict` in the current directory, store the image in the variable `image1`, and store the color vectors in the variables R, G, and B, enter:

```
READ_PICT, 'foo.pict', image1, R, G, B
```

To load the new color table and display the image, enter:

```
TVLCT, R, G, B
TV, image1
```

Version History

Pre-4.0	Introduced

WRITE_PICT, QUERY_PICT

READ_PNG

The READ_PNG routine reads the image contents of a Portable Network Graphics (PNG) file and returns the image in an IDL variable. If the image contains a palette (see QUERY_PNG), it can be returned as well in three IDL variables. READ_PNG supports 1, 2, 3 and 4 channel images with channel depths of 8 or 16 bits.

Note ───
IDL supports version 1.2.7 of the PNG Library.

Note ───
Only single channel 8-bit images may have palettes. If an 8-bit, single-channel image has index values marked as "transparent," these can be retrieved as well.

Note ───
To find information about a potential PNG file before trying to read its data, use the QUERY_PNG function.

Syntax

Result = READ_PNG (*Filename* [, *R*, *G*, *B*] [,/ORDER] [, /VERBOSE]
    [, TRANSPARENT=*variable*])

or

READ_PNG, *Filename, Image* [, *R*, *G*, *B*] [,/ORDER] [, /VERBOSE]
    [, TRANSPARENT=*variable*]

Return Value

For 8-bit images, *Result* will be a two- or three-dimensional array of type byte. For 16-bit images, *Result* will be of type unsigned integer (UINT).

Arguments

Filename

A scalar string containing the full pathname of the PNG file to read.

Image

A named variable in which the image array will be stored, if READ_PNG is called as a procedure. For 8-bit images, *Image* will be a two- or three-dimensional array of type byte. For 16-bit images, *Image* will be of type unsigned integer (UINT).

R, G, B

Named variables that will contain the Red, Green, and Blue color vectors if a color table exists.

Keywords

ORDER

Set this keyword to indicate that the rows of the image should be read from bottom to top. The rows are read from top to bottom by default. ORDER provides compatibility with PNG files written using versions of IDL prior to IDL 5.4, which wrote PNG files from bottom to top.

VERBOSE

Set this keyword to produce additional diagnostic output during the read operation.

TRANSPARENT

Set this keyword equal to a named variable that will contain an array of pixel index values that are to be treated as "transparent" for the purposes of image display. If there are no transparent values then TRANSPARENT will be set to a long-integer scalar with the value 0.

Examples

Create an RGBA (16-bits/channel) and a Color Indexed (8-bit/channel) image with a palette:

```
rgbdata = UINDGEN(4,320,240)
cidata = BYTSCL(DIST(256))
red = indgen(256)
green = indgen(256)
blue = indgen(256)
WRITE_PNG,'rgb_image.png',rgbdata
WRITE_PNG,'ci_image.png',cidata,red,green,blue
;Query and read the data
names = ['rgb_image.png','ci_image.png','unknown.png']
```

```
FOR i=0,N_ELEMENTS(names)-1 DO BEGIN
   ok = QUERY_PNG(names[i],s)
   IF (ok) THEN BEGIN
      HELP,s,/STRUCTURE
      IF (s.HAS_PALETTE) THEN BEGIN
         img = READ_PNG(names[i],rpal,gpal,bpal)
         HELP,img,rpal,gpal,bpal
      ENDIF ELSE BEGIN
         img = READ_PNG(names[i])
         HELP,img
      ENDELSE
   ENDIF ELSE BEGIN
      PRINT,names[i],' is not a PNG file'
   ENDELSE
ENDFOR
END
```

Version History

5.2	Introduced

WRITE_PNG, QUERY_PNG

READ_PPM

The READ_PPM procedure reads the contents of a PGM (gray scale) or PPM (portable pixmap for color) format image file and returns the image in the form of a 2-D byte array (for grayscale images) or a (3, *n*, *m*) byte array (for TrueColor images).

Files to be read should adhere to the PGM/PPM standard. The following file types are supported: P2 (graymap ASCII), P5 (graymap RAWBITS), P3 (TrueColor ASCII pixmaps), and P6 (TrueColor RAWBITS pixmaps). Maximum pixel values are limited to 255. Images are always stored with the top row first.

PPM/PGM format is supported by the PBMPLUS toolkit for converting various image formats to and from portable formats, and by the Netpbm package.

This routine is written in the IDL language. Its source code can be found in the file read_ppm.pro in the lib subdirectory of the IDL distribution.

Note

To find information about a potential PPM file before trying to read its data, use the QUERY_PPM function.

Syntax

READ_PPM, *Filename*, *Image* [, MAXVAL=*variable*]

Arguments

Filename

A scalar string specifying the full path name of the PGM or PPM file to read.

Image

A named variable that will contain the image. For grayscale images, *Image* is a 2-D byte array. For TrueColor images, *Image* is a (3, *n*, *m*) byte array.

Keywords

MAXVAL

A named variable that will contain the maximum pixel value.

Examples

To open and read the PGM image file named "foo.pgm" in the current directory and store the image in the variable IMAGE1:

```
READ_PPM, 'foo.pgm', IMAGE1
```

READ_SPR

The READ_SPR function reads a row-indexed sparse array. Row-indexed sparse arrays are created using the SPRSIN function and written to a file using the WRITE_SPR function.

This routine is written in the IDL language. Its source code can be found in the file read_spr.pro in the lib subdirectory of the IDL distribution.

Syntax

Result = READ_SPR(*Filename*)

Return Value

Returns the row-indexed sparse array from the specified file.

Arguments

Filename

A scalar string specifying the name of the file containing a row-indexed sparse array.

Examples

Suppose we have already saved a row-indexed sparse array to a file named sprs.as, as described in the documentation for the WRITE_SPR routine. To read the sparse array from the file and store it in a variable sprs, use the following command:

```
sprs = READ_SPR('sprs.as')
```

Version History

Pre-4.0	Introduced

FULSTR, LINBCG, SPRSAB, SPRSAX, SPRSIN, WRITE_SPR

READ_SRF

The READ_SRF procedure reads the contents of a Sun rasterfile and returns the image and color table vectors (if present) in the form of IDL variables.

READ_SRF only handles 1-, 8-, 24-, and 32-bit rasterfiles of type RT_OLD and RT_STANDARD. See the file /usr/include/rasterfile.h for the structure of Sun rasterfiles.

This routine is written in the IDL language. Its source code can be found in the file read_srf.pro in the lib subdirectory of the IDL distribution.

Note ───────────────────────────────────────

To find information about a potential SRF file before trying to read its data, use the QUERY_SRF function.

───

Syntax

READ_SRF, *Filename*, *Image* [, *R*, *G*, *B*]

Arguments

Filename

A scalar string containing the name of the rasterfile to read.

Image

A named variable that will contain the 2-D byte array (image).

R, G, B

Named variables that will contain the Red, Green, and Blue color vectors, if the rasterfile contains colormaps.

Keywords

None

Examples

To open and read the Sun rasterfile named `sun.srf` in the current directory, store the image in the variable `image1`, and store the color vectors in the variables `R`, `G`, and `B`, enter:

```
READ_SRF, 'sun.srf', image1, R, G, B
```

To load the new color table and display the image, enter:

```
TVLCT, R, G, B
TV, image1
```

WRITE_SRF, QUERY_SRF

READ_SYLK

The READ_SYLK function reads the contents of a SYLK (Symbolic Link) format spreadsheet data file and returns the contents of the file, or of a cell data range, in an IDL variable.

Note

This routine reads only numeric and string SYLK data. It ignores all spreadsheet and cell formatting information (cell width, text justification, font type, date, time, and monetary notations, etc). Note also that the data in a given cell range must be of the same data type (all integers, for example) in order for the read operation to succeed. See the example below for further information.

This routine is written in the IDL language. Its source code can be found in the file `read_sylk.pro` in the `lib` subdirectory of the IDL distribution.

Syntax

Result = READ_SYLK(*File* [, /ARRAY] [, /COLMAJOR] [, NCOLS=*columns*]
  [, NROWS=*rows*] [, STARTCOL=*column*] [, STARTROW=*row*]
  [, /USEDOUBLES] [, /USELONGS])

Return Value

READ_SYLK returns either a vector of structures or a 2-D array containing the spreadsheet cell data. By default, READ_SYLK returns a vector of structures, each of which contains the data from one *row* of the table being read. In this case, the individual fields in the structures have the tag names "Col0", "Col1", ..., "Col*n*". If the COLMAJOR keyword is specified, each of the structures returned contains data from one *column* of the table, and the tag names are "Row0", "Row1", ..., "Row*n*".

Arguments

File

A scalar string specifying the full path name of the SYLK file to read.

Keywords

ARRAY

Set this keyword to return an IDL array rather than a vector of structures. Note that all the data in the cell range specified must be of the same data type to successfully return an array.

COLMAJOR

Set this keyword to create a vector of structures each containing data from a single *column* of the table being read. If you are creating an array rather than a vector of structures (the ARRAY keyword is set), setting COLMAJOR has the same effect as transposing the resulting array.

This keyword should be set when importing spreadsheet data which has column major organization (data stored in columns rather than rows).

NCOLS

Set this keyword to the number of spreadsheet columns to read. If not specified, all of the cell columns found in the file are read.

NROWS

Set this keyword to the number of spreadsheet rows to read. If not specified, all of the cell rows found in the file are read.

STARTCOL

Set this keyword to the first column of spreadsheet cells to read. If not specified, the read operation begins with the first column found in the file (column 0).

STARTROW

Set this keyword to the first row of spreadsheet cells to read. If not specified, the read operation begins with the first row of cells found in the file (row 0).

USEDOUBLES

Set this keyword to read any floating-point cell data as double-precision rather than the default single-precision.

USELONGS

Set this keyword to read any integer cell data as long integer type rather than the default integer type.

Examples

Suppose the following spreadsheet table, with the upper left cell (value = "Index") at location (0, 0), has been saved as the SYLK file "file.slk":

```
Index  Name  Gender  Platform
1      Beth  F       Windows
2      Lubos M       UNIX
3      Louis M       Windows
4      Thierry M      UNIX
```

Note that the data format of the title row (*string*, *string*, *string*, *string*) is inconsistent with the following four rows (*int*, *string*, *string*, *string*) in the table. Because of this, it is impossible to read all of the table into a single IDL variable. The following two commands, however, will read all of the data:

```
title = READ_SYLK("file.slk", NROWS = 1)
table = READ_SYLK("file.slk", STARTROW = 1)

;Display the top row of the table.
PRINT, title
```

IDL prints:

```
{ Index Name Gender Platform}
```

Print the table:

```
PRINT, table
```

IDL prints:

```
{1 Beth F Windows}{2 Lubos M UNIX}{3 Louis M Windows}{4 Thierry M
UNIX}
```

To retrieve only the "Name" column:

```
names = READ_SYLK("file.slk", /ARRAY, STARTROW = 1, $
    STARTCOL = 1, NCOLS = 1)
PRINT, names
```

IDL prints:

```
Beth Lubos Louis Thierry
```

To retrieve the "Name" column in column format:

```
namescol = READ_SYLK("file.slk", /ARRAY, /COLMAJOR, $
    STARTROW = 1, STARTCOL = 1, NCOLS = 1)
PRINT, namescol
```

IDL prints:

```
Beth
Lubos
Louis
Thierry
```

WRITE_SYLK

READ_TIFF

The READ_TIFF function reads single or multi-channel images from TIFF format files and returns the image and color table vectors in the form of IDL variables.

Note ──

To find information about a potential TIFF file before trying to read its data, use the QUERY_TIFF function. The obsolete routine TIFF_DUMP may also be used to examine the structure and tags of a TIFF file.

──

Syntax

Result = READ_TIFF(*Filename* [, *R*, *G*, *B*] [, CHANNELS=*scalar or vector*]
   [, DOT_RANGE=*variable*] [, GEOTIFF=*variable*] [, ICC_PROFILE=*variable*]
   [, IMAGE_INDEX=*value*] [, INTERLEAVE={0 | 1 |2}]
   [, ORIENTATION=*variable*] [, PHOTOSHOP=*variable*]
   [, PLANARCONFIG=*variable*] [, SUB_RECT=*[x*, *y*, *width*, *height]*]
   [, /VERBOSE])

Return Value

READ_TIFF returns a byte, unsigned integer, long, or float array (based on the data format in the TIFF file) containing the image data. The dimensions of the *Result* are [*Columns*, *Rows*] for single-channel images, or [*Channels*, *Columns*, *Rows*] for multi-channel images, unless a different type of interleaving is specified with the INTERLEAVE keyword.

For 1-bit (bilevel) images, the image values are 0 or 1. For 4-bit grayscale images the image values are in the range 0 to 15.

RGB images are a special case of multi-channel images, and contain three channels. Most TIFF readers and writers can handle only images with one or three channels.

As a special case, for three-channel TIFF image files that are stored in planar interleave format, and if four parameters are provided, READ_TIFF returns the integer value zero, sets the variable defined by the PLANARCONFIG keyword to 2, and returns three separate images in the variables defined by the *R*, *G*, and *B* arguments.

Arguments

Filename

A scalar string specifying the full pathname of the TIFF file to read.

R, G, B

Named variables that will contain the Red, Green, and Blue color vectors of the color table from the file if one exists. If the TIFF file is written as a three-channel image, interleaved by plane, and the R, G, and B parameters are present, the three channels of the image are returned in the R, G, and B variables.

Keywords

CHANNELS

Set this keyword to a scalar or vector giving the channel numbers to be returned for a multi-channel image, starting with zero. The default is to return all of the channels. This keyword is ignored for single-channel images, or for three-channel planar-interleaved images when the *R*, *G*, and *B* arguments are specified.

DOT_RANGE

Set this keyword to a named variable in which to return a two-element integer array containing the TIFF DotRange tag value. If DotRange is not defined in the TIFF file, then a scalar zero will be returned instead. The DotRange tag is typically only present in CMYK TIFF files. DOT_RANGE[0] gives the image value that corresponds to a 0% dot, while DOT_RANGE[1] gives the image value that corresponds to a 100% dot.

GEOTIFF

Returns an anonymous structure containing one field for each of the GeoTIFF tags and keys found in the file. If no GeoTIFF information is present in the file, the returned variable is undefined.

The GeoTIFF structure is formed using fields named from the following table.

Anonymous Structure Field Name	IDLDatatype
TAGS:	
"MODELPIXELSCALETAG"	DOUBLE[3]
"MODELTRANSFORMATIONTAG"	DOUBLE[4,4]

Anonymous Structure Field Name	IDLDatatype
"VERTICALCITATIONGEOKEY"	STRING
"VERTICALDATUMGEOKEY"	INT
"VERTICALUNITSGEOKEY"	INT

Table 20-1: GEOTIFF Structures (Continued)

Note

If a GeoTIFF key appears multiple times in a file, only the value for the first instance of the key is returned.

IMAGE_INDEX

Selects the image number within the file to be read (see QUERY_TIFF to determine the number of images in the file).

ICC_PROFILE

Set this keyword to a named variable in which to return a byte array containing the TIFF ICC_PROFILE tag value. If the ICC_PROFILE tag is not contained in the TIFF file then a scalar zero will be returned instead. The ICC_PROFILE array is returned as an opaque array of byte values which the user can then pass to the WRITE_TIFF routine.

Note

The ICC_PROFILE tag is returned as an opaque array of byte values. It is assumed that the tag will be read from an existing file, and written out to a new file without modification.

INTERLEAVE

For multi-channel images, set this keyword to one of the following values to force the *Result* to have a specific interleaving, regardless of the type of interleaving in the file being read:

Value	Description
0	Pixel interleaved: *Result* will have dimensions [*Channels*, *Columns*, *Rows*].
1	Scanline (row) interleaved: *Result* will have dimensions [*Columns*, *Channels*, *Rows*].
2	Planar interleaved: *Result* will have dimensions [*Columns*, *Rows*, *Channels*].

Table 20-2: INTERLEAVE Keyword Values

If this keyword is not specified, the *Result* will always be pixel interleaved, regardless of the type of interleaving in the file being read. For files stored in planar-interleave format, this keyword is ignored if the *R*, *G*, and *B* arguments are specified.

ORIENTATION

Set this keyword to a named variable that will contain the orientation value from the TIFF file. Possible return values are:

Value	Description
0	Column 0 represents the left-hand side, and row 0 represents the bottom (same as 4)
1	Column 0 represents the left-hand side, and row 0 represents the top.
2	Column 0 represents the right-hand side, and row 0 represents the top.
3	Column 0 represents the right-hand side, and row 0 represents the bottom.

Table 20-3: ORIENTATION Keyword Values

Value	Description
4	Column 0 represents the left-hand side, and row 0 represents the bottom (same as 0)
5	Column 0 represents the top, and row 0 represents the left-hand side.
6	Column 0 represents the top, and row 0 represents the right-hand side.
7	Column 0 represents the bottom, and row 0 represents the right-hand side.
8	Column 0 represents the bottom, and row 0 represents the left-hand side.

Table 20-3: ORIENTATION Keyword Values (Continued)

If an orientation value does not appear in the TIFF file, an orientation of 0 is returned.

Note

The presentation of the image data is not modified based on the ORIENTATION keyword. You are responsible for configuring the display to present the image in accordance with the stored ORIENTATION value.

You can use the IDL ROTATE function to efficiently position the image data as specified by the file's ORIENTATION property. Set the ROTATE function DIRECTION value to one of the following based on the ORIENTATION value:

ORIENTATION Value	Rotate Function DIRECTION Value
0	0
1	7
2	2
3	5
4	0
5	1

ORIENTATION Value	Rotate Function DIRECTION Value
6	6
7	3
8	4

Note

You can also use the IDLgrModel::Rotate method to position the image data in the display.

PHOTOSHOP

Set this keyword to a named variable in which to return a byte array containing the TIFF PHOTOSHOP tag value. If the PHOTOSHOP tag is not contained in the TIFF file, then a scalar zero will be returned instead. The PHOTOSHOP array is returned as an opaque array of byte values which the user can then pass to the WRITE_TIFF routine.

Note

The PHOTOSHOP tag is returned as an opaque array of byte values. It is assumed that the tag will be read from an existing file, and written out to a new file without modification.

PLANARCONFIG

Set this keyword to a named variable that will contain the interleave parameter for the TIFF file. This parameter is returned as 1 for TIFF files that are GrayScale, Palette, or interleaved by pixel. This parameter is returned as 2 for multi-channel TIFF files interleaved by image.

SUB_RECT

Set this keyword to a four-element array, [*x*, *y*, *width*, *height*], that specifies a rectangular region within the file to extract. Only the rectangular portion of the image selected by this keyword is read and returned. The rectangle is measured in pixels from the lower left corner (right hand coordinate system).

Tip ───────────────────────────────────────

For tiled TIFF images, use the TILE_SIZE tag returned by QUERY_TIFF to determine the optimal sizes for the SUB_RECT keyword.

───

VERBOSE

Produce additional diagnostic output during the read.

Examples

Example 1

Read the file `my.tif` in the current directory into the variable `image`, and save the color tables in the variables, `R`, `G`, and `B` by entering:

```
image = READ_TIFF('my.tif', R, G, B)
```

To view the image, load the new color table and display the image by entering:

```
TVLCT, R, G, B
TV, image
```

Example 2

Write and read a multi-image TIFF file. The first image is a 16-bit single-channel image stored using compression. The second image is an RGB image stored using 32-bits/channel uncompressed.

```
; Write the image data:
data = FIX(DIST(256))
rgbdata = LONARR(3,320,240)
WRITE_TIFF,'multi.tif',data,COMPRESSION=1,/SHORT
WRITE_TIFF,'multi.tif',rgbdata,/LONG,/APPEND

; Read the image data back:
ok = QUERY_TIFF('multi.tif',s)
IF (ok) THEN BEGIN
FOR i=0,s.NUM_IMAGES-1 DO BEGIN
imp = QUERY_TIFF('multi.tif',t,IMAGE_INDEX=i)
img = READ_TIFF('multi.tif',IMAGE_INDEX=i)
HELP,t,/STRUCTURE
HELP,img
ENDFOR
ENDIF
```

Example 3

Write and read a multi-channel image:

```
data = LINDGEN(10, 256, 256)   ; 10 channels

; Write the image data:
WRITE_TIFF, 'multichannel.tif', data, /LONG

; Read back only channels [0,2,4,6,8], using planar-interleaving
img = READ_TIFF('multichannel.tif', CHANNELS=[0,2,4,6,8], $
   INTERLEAVE=2)

HELP, img
```

IDL prints:

```
IMG      LONG     = Array[256, 256, 5]
```

WRITE_TIFF, QUERY_TIFF

READ_WAV

The READ_WAV function reads the audio stream from the named .WAV file. Optionally, it can return the sampling rate of the audio stream.

Syntax

Result = READ_WAV (*Filename* [, *Rate*])

Return Value

In the case of a single channel stream, the returned variable is a BYTE or INT (depending on the number of bits per sample) one-dimensional array. In the case of a file with multiple channels, a similar two-dimensional array is returned, with the leading dimension being the channel number.

Arguments

Filename

A scalar string containing the full pathname of the .WAV file to read.

Rate

Returns an IDL long containing the sampling rate of the stream in samples per second.

Keywords

None.

Version History

5.3	Introduced

READ_WAVE

The READ_WAVE procedure reads a `.wave` or `.bwave` file created by the Wavefront Advanced Data Visualizer into a series of IDL variables.

Note ───

READ_WAVE only preserves the structure of the variables if they are regularly gridded.

───

This routine is written in the IDL language. Its source code can be found in the file `read_wave.pro` in the `lib` subdirectory of the IDL distribution.

Syntax

READ_WAVE, *File*, *Variables*, *Names*, *Dimensions* [, MESHNAMES=*variable*]

Arguments

File

A scalar string containing the name of the Wavefront file to read.

Variables

A named variable that will contain a block of the variables contained in the wavefront file. Since each variable in a wavefront file can have more than one field (for instance, a vector variable has 3 fields), the fields of each variable make up the major index into the variable block. For instance, if a Wavefront file had one scalar variable and one vector variable, the scalar would be extracted as follows:

```
scalar_variable = variables[0,*,*,*]
```

and the vector variable would be extracted as follows:

```
vector_variable = variables[1:3,*,*,*]
```

To find the dimensions of the returned variable, see the description of the *Dimensions* argument.

Names

A named variable that will contain the string names of each variable contained in the file.

Dimensions

A named variable that will contain a long array describing how many fields in the large returned variable block each variable occupies. In the above example of one scalar variable followed by a vector variable, the dimension variable would be [1,3].

This indicates that the first field of the returned variable block would be the scalar variable and the following 3 fields would comprise the vector variable.

Keywords

MESHNAMES

Set this keyword to a named variable that will contain the name of the mesh used in the Wavefront file for each variable.

READ_X11_BITMAP

The READ_X11_BITMAP procedure reads bitmaps stored in the X Windows X11 format. The X Windows `bitmap` program produces a C header file containing the definition of a bitmap produced by that program. This procedure reads such a file and creates an IDL byte array containing the bitmap. It is used primarily to read bitmaps to be used as IDL widget button labels.

This routine is written in the IDL language. Its source code can be found in the file `read_x11_bitmap.pro` in the `lib` subdirectory of the IDL distribution.

Syntax

READ_X11_BITMAP, *File*, *Bitmap* [, *X*, *Y*] [, /EXPAND_TO_BYTES]

Arguments

File

A scalar string containing the name of the file containing the bitmap.

Bitmap

A named variable that will contain the bitmap. This variable is returned as a byte array.

X

A named variable that will contain the width of the bitmap.

Y

A named variable that will contain the height of the bitmap.

Keywords

EXPAND_TO_BYTES

Set this keyword to instruct READ_X11_BITMAP to return a 2-D array which has one bit per byte (0 for a 0 bit, 255 for a 1 bit) instead.

Examples

To open and read the X11 bitmap file named my.x11 in the current directory, store the bitmap in the variable bitmap1, and the width and height in the variables X and Y, enter:

```
READ_X11_BITMAP, 'my.x11', bitmap1, X, Y
```

To display the new bitmap, enter:

```
READ_X11_BITMAP, 'my.x11', image, /EXPAND_TO_BYTES
TV, image, /ORDER
```

READ_XWD

READ_XWD

The READ_XWD function reads the contents of a file created by the xwd (X Windows Dump) command and returns the image and color table vectors in the form of IDL variables.

Note ————————————————————————————

This function is intended to be used only on files containing 8-bit pixmaps created with xwd version 6 or later.

————————————————————————————————

This routine is written in the IDL language. Its source code can be found in the file read_xwd.pro in the lib subdirectory of the IDL distribution.

Syntax

Result = READ_XWD(*Filename*[, *R*, *G*, *B*])

Return Value

READ_XWD returns a 2-D byte array containing the image. If the file cannot be open or read, the return value is zero.

Arguments

Filename

A scalar string specifying the full pathname of the XWD file to read.

R, G, B

Named variables that will contain the Red, Green, and Blue color vectors, if the XWD file contains color tables.

Keywords

None

Examples

To open and read the X Windows Dump file named `my.xwd` in the current directory, store the image in the variable `image1`, and store the color vectors in the variables, `R`, `G`, and `B`, enter:

```
image1 = READ_XWD('my.xwd', R, G, B)
```

To load the new color table and display the image, enter:

```
TVLCT, R, G, B
TV, image1
```

READ_X11_BITMAP

READS

The READS procedure performs formatted input from a string variable and writes the results into one or more output variables. This procedure differs from the READ procedure only in that the input comes from memory instead of a file.

This routine is useful when you need to examine the format of a data file before reading the information it contains. Each line of the file can be read into a string using READF. Then the components of that line can be read into variables using READS.

Syntax

READS, *Input*, *Var$_1$*, ..., *Var$_n$* [, AM_PM=*[string, string]*]
    [, DAYS_OF_WEEK=*string_array*{7 names}] [, FORMAT=*value*]
    [, MONTHS=*string_array*{12 names}]

Arguments

Input

The string variable from which the input is taken. If the supplied argument is not a string, it is automatically converted. The argument can be scalar or array. If *Input* is an array, the individual string elements are treated as successive lines of input.

Var$_i$

The named variables to receive the input.

Note

If the variable specified for the *Var$_i$* argument has not been previously defined, the input data is assumed to be of type float, and the variable will be cast as a float.

Keywords

AM_PM

Supplies a string array of 2 names to be used for the names of the AM and PM string when processing explicitly formatted dates (CAPA, CApA, and CapA format codes) with the FORMAT keyword.

DAYS_OF_WEEK

Supplies a string array of 7 names to be used for the names of the days of the week when processing explicitly formatted dates (CDWA, CDwA, and CdwA format codes) with the FORMAT keyword.

FORMAT

If FORMAT is not specified, IDL uses its default rules for formatting the input. FORMAT allows the format of the input to be specified in precise detail, using a FORTRAN-style specification. See "Using Explicitly Formatted Input/Output" (Chapter 18, *Application Programming*).

MONTHS

Supplies a string array of 12 names to be used for the names of the months when processing explicitly formatted dates (CMOA, CMoA, and CmoA format codes) with the FORMAT keyword.

Version History

4.0	Introduced

See Also

READ/READF, READU

READU

The READU procedure reads unformatted binary data from a file into IDL variables. READU transfers data directly with no processing of any kind performed on the data.

Syntax

READU, *Unit*, *Var$_1$*, ..., *Var$_n$* [, TRANSFER_COUNT=*variable*]

Arguments

Unit

The IDL file unit from which input is taken.

Var*$_i$*

Named variables to receive the data. For non-string variables, the number of bytes required for *Var* are read. When READU is used with a variable of type string, IDL reads exactly the number of bytes contained in the existing string. For example, to read a 5-character string, enter:

```
temp = '12345'
READU, unit, temp
```

If the variable specified for the *Var$_i$* argument has not been previously defined, the input data is assumed to be of type float, and the variable will be created as a float.

Keywords

TRANSFER_COUNT

Set this keyword to a named variable in which to return the number of elements transferred by the input operation. Note that the number of elements is not the same as the number of bytes (except in the case where the data type being transferred is bytes). For example, transferring 256 floating-point numbers yields a transfer count of 256, not 1024 (the number of bytes transferred).

This keyword is useful with files opened with the RAWIO keyword to the OPEN routines. Normally, attempting to read more data than is available from a file causes the unfilled space to be zeroed and an error to be issued. This does not happen with files opened with the RAWIO keyword. Instead, the programmer must keep track of the transfer count.

Examples

The following commands can be used to open the IDL distribution file people.dat and read an image from that file:

```
; Open the file for reading as file unit 1:
OPENR, 1, FILEPATH('people.dat', SUBDIR = ['examples','data'])

; The image is a 192 by 192 byte array, so make B that size:
B = BYTARR(192, 192, NOZERO)

; Read the data into B:
READU, 1, B

; Close the file:
CLOSE, 1

; Display the image:
TV, B
```

REAL_PART

The REAL_PART function returns the real part of its complex-valued argument.

Syntax

Result = REAL_PART(*Z*)

Return Value

If the complex-valued argument is double-precision, the result will be double-precision, otherwise the result will be single-precision floating-point. If the argument is not complex, then the result will be double-precision if the argument is double-precision, otherwise the result will be single-precision.

Arguments

Z

A scalar or array for which the real part is desired. Z may be of any numeric type.

Examples

The following example demonstrates how you can use REAL_PART to obtain the real parts of an array of complex variables.

```
; Create an array of complex values:
cValues = COMPLEX([1, 2, 3],[4, 5, 6])

; Print just the real parts of each element in cValues:
PRINT, REAL_PART(cValues)
```

IDL prints:

```
   1.00000    2.00000    3.00000
```

5.5	Introduced

See Also

COMPLEX, DCOMPLEX, IMAGINARY

REBIN

The REBIN function resizes a vector or array to dimensions given by the parameters D_i. The supplied dimensions must be integral multiples or factors of the original dimension. The expansion or compression of each dimension is independent of the others, so that each dimension can be expanded or compressed by a different value.

If the dimensions of the desired result are not integer multiples of the original dimensions, use the CONGRID function.

Syntax

Result = REBIN(*Array*, D_1 [, ..., D_8] [, /SAMPLE])

Return Value

Returns the resized array or vector of the specified dimensions.

Arguments

Array

The array to be resampled. *Array* can be of any basic type except complex or string.

D$_i$

Either an array or a series of scalar expressions specifying the dimensions of the result. If a single argument is specified, it can be either a scalar expression or an array of up to eight elements. If multiple arguments are specified, they must all be scalar expressions. Up to eight dimensions can be specified.

Note

The dimensions of the resulting resampled array must be integer multiples or factors of the corresponding original dimensions.

Keywords

SAMPLE

Normally, REBIN uses bilinear interpolation when magnifying and neighborhood averaging when minifying. Set the SAMPLE keyword to use nearest neighbor

sampling for both magnification and minification. Bilinear interpolation gives higher quality results but requires more time.

Rules Used by REBIN

Assume the original vector *X* has *n* elements and the result is to have *m* elements.

Let $f = n/m$, the ratio of the size of the original vector, *X* to the size of the result. $1/f$ must be an integer if $n < m$ (expansion). *f* must be an integer if compressing, $(n > m)$. The various resizing options can be described as:

- Expansion, $n < m$, SAMPLE = 0: $Y_i = F(X, f \cdot i)$ $i = 0, 1, \dots, m\text{-}1$

  The linear interpolation function, $F(X, p)$ that interpolates *X* at location *p*, is defined as:

$$F(X, p) = \begin{cases} X_{\lfloor p \rfloor} + (p - \lfloor p \rfloor) \cdot (X_{\lfloor p \rfloor + 1} - X_{\lfloor p \rfloor}) & \text{if } p < n - 1 \\ X_{\lfloor p \rfloor} & \text{if } p \geq n - 1 \end{cases}$$

- Expansion, $n < m$, SAMPLE = 1:

$$Y_i = X_{\lfloor fi \rfloor}$$

- Compression, $n > m$, SAMPLE = 0:

$$Y_i = (1/f) \sum_{j = fi}^{f(i + 1) - 1} X_j$$

- Compression, $n > m$, SAMPLE = 1:

$$Y_i = X_{\lfloor fi \rfloor}$$

- No change, $n = m$: $Y_i = X_i$

Endpoint Effects When Expanding

When expanding an array, REBIN *interpolates*, it never *extrapolates*. Each of the *n*-1 intervals in the *n*-element input array produces *m/n* interpolates in the *m*-element output array. The last *m/n* points of the result are obtained by duplicating element *n*-1 of the input array because their interpolates would lie outside the input array.

For example

```
; A four point vector:
A = [0, 10, 20, 30]

; Expand by a factor of 3:
B = REBIN(A, 12)

PRINT, B
```

IDL prints:

```
0 3 6 10 13 16 20 23 26 30 30 30
```

Note that the last element is repeated three times. If this effect is undesirable, use the INTERPOLATE function. For example, to produce 12 equally spaced interpolates from the interval 0 to 30:

```
B = INTERPOLATE(A, 3./11. * FINDGEN(12))
PRINT, B
```

IDL prints:

```
0 2 5 8 10 13 16 19 21 24 27 30
```

Here, the sampling ratio is $(n - 1)/(m - 1)$.

Examples

Create and display a simple image by entering:

```
D = SIN(DIST(50)/4) & TVSCL, D
```

Resize the image to be 5 times its original size and display the result by entering:

```
D = REBIN(D, 250, 250) & TVSCL, D
```

CONGRID

RECALL_COMMANDS

The RECALL_COMMANDS function returns a string array containing the entries in IDL's command recall buffer.

Syntax

Result = RECALL_COMMANDS()

Return Value

The size of the returned array is the size of recall buffer, even if fewer than commands have been entered (any "empty" buffer entries will contain null strings). The default size of the command recall buffer is 20 lines. (See "!EDIT_INPUT" on page 5502 for more information about the command recall buffer.)

Element zero of the returned array contains the most recent command.

Arguments

None.

Keywords

None.

Version History

5.0	Introduced

RECON3

The RECON3 function can reconstruct a three-dimensional data array from two or more images (or projections) of an object. For example, if you placed a dark object in front of a white background and then photographed it three times (each time rotating the object a known amount) then these three images could be used with RECON3 to approximate a 3-D volumetric representation of the object. RECON3 also works with translucent projections of an object. RECON3 returns a 3-D byte array.

This routine is written in the IDL language. Its source code can be found in the file `recon3.pro` in the `lib` subdirectory of the IDL distribution.

Using RECON3

Images used in reconstruction should show strong light/dark contrast between the object and the background. If the images contain low (dark) values where the object is and high (bright) values where the object isn't, the MODE keyword should be set to +1 and the returned volume will have low values where the object is, and high values where the object isn't. If the images contain high (bright) values where the object is and low (dark) values where the object isn't, the MODE keyword should be set to -1 and the returned volume will have high values where the object is, and low values where the object isn't.

In general, the object must be CONVEX for a good reconstruction to be possible. Concave regions are not easily reconstructed. An empty coffee cup, for example, would be reconstructed as if it were full.

The more images the better. Images from many different angles will improve the quality of the reconstruction. It is also important to supply images that are parallel and perpendicular to any axes of symmetry. Using the coffee cup as an example, at least one image should be looking through the opening in the handle. Telephoto images are also better for reconstruction purposes than wide angle images.

Syntax

Result = RECON3(*Images*, *Obj_Rot*, *Obj_Pos*, *Focal*, *Dist*,*Vol_Pos*, *Img_Ref*, *Img_Mag*, *Vol_Size* [, /CUBIC] [, MISSING=*value*] [, MODE=*value*] [, /QUIET])

Return Value

Returns a 3-D data array.

Arguments

Images

A 3-D array containing the images to use to reconstruct the volume. Execution time increases linearly with more images. *Images* must be an 8-bit (byte) array with dimensions (*x*, *y*, *n*) where *x* is the horizontal image dimension, *y* is the vertical image dimension, and *n* is the number of images. Note that *n* must be at least 2.

Obj_Rot

A 3 x *n* floating-point array specifying the amount the object is rotated to make it appear as it does in each image. The object is first rotated about the X axis, then about the Y axis, and finally about the Z axis (with the object's reference point at the origin). *Obj_Rot*[0, *] is the X rotation for each image, *Obj_Rot*[1, *] is the Y rotation, and *Obj_Rot*[2, *] is the Z rotation.

Obj_Pos

A 3 x *n* floating-point array specifying the position of the object's reference point relative to the camera lens. The camera lens is located at the coordinate origin and points in the negative Z direction (the view up vector points in the positive Y direction). *Obj_Pos* should be expressed in this coordinate system. *Obj_Pos*[0, *] is the X position for each image, *Obj_Pos*[1, *] is the Y position, and *Obj_Pos*[2, *] is the Z position. All the values in *Obj_Pos*[2, *] should be less than zero. Note that the values for *Obj_Pos*, *Focal*, *Dist*, and *Vol_Pos* should all be expressed in the same units (mm, cm, m, in, ft, etc.).

Focal

An *n*-element floating-point array specifying the focal length of the lens for each image. Focal may be set to zero to indicate a parallel image projection (infinite focal length).

Dist

An *n*-element floating-point array specifying the distance from the camera lens to the image plane (film) for each image. *Dist* should be greater than *Focal*.

Vol_Pos

A 3 x 2 floating-point array specifying the two opposite corners of a cube that surrounds the object. *Vol_Pos* should be expressed in the object's coordinate system relative to the object's reference point. *Vol_Pos*[*, 0] specifies one corner and *Vol_Pos*[*, 1] specifies the opposite corner.

Img_Ref

A 2 x *n* integer or floating-point array that specifies the pixel location at which the object's reference point appears in each of the images. *Img_Ref*[0, *] is the X coordinate for each image and *Img_Ref*[1, *] is the Y coordinate.

Img_Mag

A 2 x *n* integer or floating-point array that specifies the magnification factor for each image. This number is actually the length (in pixels) that a test object would appear in an image if it were *n* units long and *n* units distant from the camera lens. *Img_Mag*[0, *] is the X dimension (in pixels) of a test object for each image, and *Img_Mag*[1, *] is the Y dimension. All elements in *Img_Mag* should be greater than or equal to 1.

Vol_Size

A 3-element integer or floating-point array that specifies the size of the 3-D byte array to return. Execution time (and resolution) increases exponentially with larger values for *Vol_Size*. *Vol_Size*[0] specifies the X dimension of the volume, *Vol_Size*[1] specifies the Y dimension, and *Vol_Size*[2] specifies the Z dimension.

Keywords

CUBIC

Set this keyword to use cubic interpolation. The default is to use tri-linear interpolation, which is slightly faster.

MISSING

Set this keyword equal to a byte value for cells in the 3-D volume that do not map to any of the supplied images. The value of MISSING is passed to the INTERPOLATE function. The default value is zero.

MODE

Set this keyword to a value less than zero to define each cell in the 3-D volume as the *minimum* of the corresponding pixels in the images. Set MODE to a value greater than zero to define each cell in the 3-D volume as the *maximum* of the corresponding pixels in the images. If MODE is set equal to zero then each cell in the 3-D volume is defined as the *average* of the corresponding pixels in the images.

MODE should usually be set to -1 when the images contain a bright object in front of a dark background or to +1 when the images contain a dark object in front of a light background. Setting MODE=0 (the default) requires more memory since the volume array must temporarily be kept as an integer array instead of a byte array.

QUIET

Set this keyword to suppress the output of informational messages when the processing of each image is completed.

Examples

Assumptions for this example:

- The object's major axis is parallel to the Z axis.
- The object's reference point is at its center.
- The camera lens is pointed directly at this reference point.
- The reference point is 5000 mm in front of the camera lens.
- The focal length of the camera lens is 200 mm.

If the camera is focused on the reference point, then the distance from the lens to the camera's image plane must be:

dist = (d * f) / (d - f) = (5000 * 200) / (5000 - 200) = (1000000 / 4800) = 208.333 mm

The object is roughly 600 mm wide and 600 mm high. The reference point appears in the exact center of each image.

If the object is 600 mm high and 5000 mm distant from the camera lens, then the object image height must be:

hi = (h * f) / (d - f) = (600 * 200) / (5000 - 200) = (120000 / 4800) = 25.0 mm

The object image appears 200 pixels high so the final magnification factor is:

img_mag = (200 / 25) = 8.0

From these assumptions, we can set up the following reconstruction:

```
; First, define the variables:
imgx = 256
imgy = 256
frames = 3
images = BYTARR(imgx, imgy, frames)
obj_rot = Fltarr(3, frames)
obj_pos = Fltarr(3, frames)
focal = Fltarr(frames)
dist = Fltarr(frames)
vol_pos = Fltarr(3, 2)
img_ref = Fltarr(2, frames)
img_mag = Fltarr(2, frames)
vol_size = [40, 40, 40]

; The object is 5000 mm directly in front of the camera:
obj_pos[0, *] = 0.0
obj_pos[1, *] = 0.0
obj_pos[2, *] = -5000.0

; The focal length of the lens is constant for all the images:
focal[*] = 200.0

; The distance from the lens to the image plane is also constant:
dist[*] = 208.333

; The cube surrounding the object is 600 mm x 600 mm:
vol_pos[*, 0] = [-300.0, -300.0, -300.0]
vol_pos[*, 1] = [ 300.0, 300.0, 300.0]

; The image reference point appears at the center of all the
; images:
img_ref[0, *] = imgx / 2
img_ref[1, *] = imgy / 2

; The image magnification factor is constant for all images.
; (The images haven't been cropped or resized):
img_mag[*,*] = 8.0

; Only the object rotation changes from one image to the next.
; Note that the object is rotated about the X axis first, then Y,
; and then Z. Create some fake images for this example:
images[30:160, 20:230, 0] = 255
images[110:180, 160:180, 0] = 180
obj_rot[*, 0] = [-90.0, 0.0, 0.0]
images[70:140, 100:130, 1] = 255
obj_rot[*, 1] = [-70.0, 75.0, 0.0]
images[10:140, 70:170, 2] = 255
```

```
images[80:90, 170:240, 2] = 150
obj_rot[*, 2] = [-130.0, 215.0, 0.0]

; Reconstruct the volume:
vol = RECON3(images, obj_rot, obj_pos, focal, dist, $
   vol_pos, img_ref, img_mag, vol_size, Missing=255B, Mode=(-1))

; Display the volume:
shade_volume, vol, 8, v, p
scale3, xrange=[0,40], yrange=[0,40], zrange=[0,40]
image = polyshade(v, p, /t3d, xs=400, ys=400)
tvscl, image
```

REDUCE_COLORS

The REDUCE_COLORS procedure reduces the number of colors used in an image by eliminating pixel values without members.

The pixel distribution histogram is obtained and the WHERE function is used to find bins with non-zero values. Next, a lookup table is made where table[old_pixel_value] contains new_pixel_value, and is then applied to the image.

This routine is written in the IDL language. Its source code can be found in the file reduce_colors.pro in the lib subdirectory of the IDL distribution.

Syntax

REDUCE_COLORS, *Image*, *Values*

Arguments

Image

On input, a variable that contains the original image array. On output, this variable contains the color-reduced image array, writing over the original.

Values

A named variable that, on output, contains a vector of non-zero pixel values. If *Image* contains pixel values from 0 to M, *Values* will be an M+1 element vector containing the mapping from the old values to the new. *Values[i]* contains the new color index of old pixel index *i*.

Keywords

None.

Examples

To reduce the number of colors and display an image with the original color tables R, G, B enter the commands:

```
REDUCE_COLORS, image, v
TVLCT, R[V], G[V], B[V]
```

Version History

COLOR_QUAN

REFORM

The REFORM function changes the dimensions of an array without changing the total number of elements.

Syntax

Result = REFORM(*Array*, *D₁* *[, ..., D₈]* [, /OVERWRITE])

Return Value

If no dimensions are specified, REFORM returns a copy of *Array* with all dimensions of size 1 removed. If dimensions are specified, the result is given those dimensions. Only the dimensions of *Array* are changed – the actual data remains unmodified.

Arguments

Array

The array to have its dimensions modified.

D$_i$

Either an array or a series of scalar expressions specifying the dimensions of the result. If a single argument is specified, it can be either a scalar expression or an array of up to eight elements. If multiple arguments are specified, they must all be scalar expressions. *Array* must have the same number of elements as specified by the product of the new dimensions.

Keywords

OVERWRITE

Set this keyword to cause the specified dimensions to overwrite the present dimensions of the *Array* parameter. No data are copied, only the internal array descriptor is changed. The result of the function, in this case, is the *Array* parameter with its newly-modified dimensions. For example, to change the dimensions of the variable a, without moving data, enter:

```
a = REFORM(a, n1, n2, /OVERWRITE)
```

Examples

REFORM can be used to remove "degenerate" leading dimensions of size one. Such dimensions can appear when a subarray is extracted from an array with more dimensions. For example

```
; a is a 3-dimensional array:
a = INTARR(10,10,10)

; Extract a "slice" from a:
b = a[5,*,*]

; Use HELP to show what REFORM does:
HELP, b, REFORM(b)
```

Executing the above statements produces the output:

```
B            INT = Array[1, 10, 10]
<Expression> INT = Array[10, 10]
```

The statements:

```
b = REFORM(a,200,5)
b = REFORM(a,[200,5])
```

have identical effect. They create a new array, b, with dimensions of (200, 5), from a.

Note
For an additional example, see Displaying RGB Images and Converting to Grayscale in the TV procedure Examples section.

REGION_GROW

The REGION_GROW function performs region growing for a given region within an N-dimensional array by finding all pixels within the array that are connected neighbors to the region pixels and that fall within provided constraints. The constraints are specified either as a threshold range (a minimum and maximum pixel value) or as a multiple of the standard deviation of the region pixel values. If the threshold is used (this is the default), the region is grown to include all connected neighboring pixels that fall within the given threshold range. If the standard deviation multiplier is used, the region is grown to include all connected neighboring pixels that fall within the range of the mean (of the region's pixel values) plus or minus the given multiplier times the sample standard deviation.

Syntax

Result = REGION_GROW(*Array*, *ROIPixels* [, /ALL_NEIGHBORS] [, /NAN]
[, STDDEV_MULTIPLIER=*value* | THRESHOLD=[*min*,*max*]])

Return Value

REGION_GROW returns the vector of array indices that represent pixels within the grown region. The grown region will not include pixels at the edges of the input array. If no pixels fall within the grown region, this function will return the value -1.

Arguments

Array

An N-dimensional array of data values. The region will be grown according to the data values within this array.

ROIPixels

A vector of indices into *Array* that represent the initial region that is to be grown.

Keywords

ALL_NEIGHBORS

Set this keyword to indicate that all adjacent neighbors to a given pixel should be considered during region growing (sometimes known as 8-neighbor searching when

the array is two-dimensional). The default is to search only the neighbors that are exactly one unit in distance from the current pixel (sometimes known as 4-neighbor searching when the array is two-dimensional).

NAN

Set this keyword to cause the routine to check for occurrences of the IEEE floating-point values *NaN* or *Infinity* in the input data. Elements with the value *NaN* or *Infinity* are treated as missing data. (See "Special Floating-Point Values" (Chapter 8, *Application Programming*) for more information on IEEE floating-point values.)

STDDEV_MULTIPLIER

Set this keyword to a scalar value that serves as the multiplier of the sample standard deviation of the original region pixel values. The expanded region includes neighboring pixels that fall within the range of the mean of the region's pixel values plus or minus the given multiplier times the sample standard deviation as follows:

Mean +/- StdDevMultiplier * StdDev

This keyword is mutually exclusive of THRESHOLD. If both keywords are specified, a warning message will be issued and the THRESHOLD value will be used.

THRESHOLD

Set this keyword to a two-element vector, [*min*,*max*], of the inclusive range within which the pixel values of the grown region must fall. The default is the range of pixel values within the initial region. This keyword is mutually exclusive of STDDEV_MULTIPLIER. If both keywords are specified, a warning message will be issued and the THRESHOLD value will be used.

Note

If neither keyword is specified, THRESHOLD is used by default. The range of threshold values is based upon the pixel values within the original region and therefore does not have to be provided.

Examples

The following example demonstrates how you can grow a pre-defined region within an image of human red blood cells.

```
; Load an image.
fname = FILEPATH('rbcells.jpg', SUBDIR=['examples','data'])
READ_JPEG, fname, img
imgDims = SIZE(img, /DIMENSIONS)
```

```
; Define original region pixels.
x = FINDGEN(16*16) MOD 16 + 276.
y = LINDGEN(16*16) / 16 + 254.
roiPixels = x + y * imgDims[0]

; Grow the region.
newROIPixels = REGION_GROW(img, roiPixels)

; Load a grayscale color table.
DEVICE, DECOMPOSED = 0
LOADCT, 0

; Set the topmost color table entry to red.
topClr = !D.TABLE_SIZE-1
TVLCT, 255, 0, 0, topClr

; Show the results.
tmpImg = BYTSCL(img, TOP=(topClr-1))
tmpImg[roiPixels] = topClr
WINDOW, 0, XSIZE=imgDims[0], YSIZE=imgDims[1], $
   TITLE='Original Region'
TV, tmpImg

tmpImg = BYTSCL(img, TOP=(topClr-1))
tmpImg[newROIPixels] = topClr
WINDOW, 2, XSIZE=imgDims[0], YSIZE=imgDims[1], $
   TITLE='Grown Region'
TV, tmpImg
```

Note ———

Version History

5.5	Introduced
6.1	Added NAN keyword

REGISTER_CURSOR

The REGISTER_CURSOR procedure associates the given name with the given cursor information. This name can then be used with the IDLgrWindow::SetCurrentCursor method.

Tip ————————————————————————————————

You can use the CREATE_CURSOR function to translate a string array into an image array suitable for the *Image* argument. You can also return values for the MASK and HOTSPOT keywords using this function.

———

Syntax

REGISTER_CURSOR, *Name*, *Image*[, MASK=*value*] [, HOTSPOT=*value*]
   [, /OVERWRITE]

Arguments

Name

This argument sets the name to associate with this cursor. The name is case-insensitive. Once registered, the name can be used with the IDLgrWindow::SetCurrentCursor method.

Image

Set this argument to a 16 line by 16 column bitmap, contained in a 16-element short integer vector, specifying the cursor pattern. The offset from the upper-left pixel to the point that is considered the hot spot can be provided using the HOTSPOT keyword.

Keywords

MASK

This keyword can be used to simultaneously specify the mask that should be used. In the mask, bits that are set indicate bits in the IMAGE that should be seen and bits that are not are masked out.

HOTSPOT

Set this keyword to a two-element vector specifying the [*x*, *y*] pixel offset of the cursor "hot spot", the point which is considered to be the mouse position, from the lower-left corner of the cursor image. The cursor image is displayed top-down (the first row is displayed at the top).

OVERWRITE

By default, if the cursor already exists, the values are not changed. By setting this keyword to true, the current cursor value is updated with the values provided by this routine call.

Version History

5.6	Introduced

IDLgrWindow::SetCurrentCursor, CREATE_CURSOR

REGRESS

The REGRESS function performs a multiple linear regression fit and returns an *Nterm*-element column vector of coefficients.

REGRESS fits the function:

$$y_i = const + a_0 x_{0,\,i} + a_1 x_{1,\,i} + ... + a_{Nterms-1} x_{Nterms-1,\,i}$$

This routine is written in the IDL language. Its source code can be found in the file regress.pro in the lib subdirectory of the IDL distribution.

Syntax

Result = REGRESS(*X*, *Y*, [, CHISQ=*variable*] [, CONST=*variable*]
   [, CORRELATION=*variable*] [, /DOUBLE] [, FTEST=*variable*]
   [, MCORRELATION=*variable*] [, MEASURE_ERRORS=*vector*]
   [, SIGMA=*variable*] [, STATUS=*variable*] [, YFIT=*variable*])

Return Value

REGRESS returns a 1 x *Nterm* array of coefficients. If the DOUBLE keyword is set, or if *X* or *Y* are double-precision, then the result will be double precision, otherwise the result will be single precision.

Arguments

X

An *Nterms* by *Npoints* array of independent variable data, where *Nterms* is the number of coefficients (independent variables) and *Npoints* is the number of samples.

Y

An *Npoints*-element vector of dependent variable points.

Keywords

CHISQ

Set this keyword equal to a named variable that will contain the value of the unreduced chi-square goodness-of-fit statistic.

CONST

Set this keyword to a named variable that will contain the constant term of the fit.

CORRELATION

Set this keyword to a named variable that will contain the vector of linear correlation coefficients.

DOUBLE

Set this keyword to force computations to be done in double-precision arithmetic.

FTEST

Set this keyword to a named variable that will contain the F-value for the goodness-of-fit test.

MCORRELATION

Set this keyword to a named variable that will contain the multiple linear correlation coefficient.

MEASURE_ERRORS

Set this keyword to a vector containing standard measurement errors for each point *Y*[*i*]. This vector must be the same length as *X* and *Y*.

Note

For Gaussian errors (e.g., instrumental uncertainties), MEASURE_ERRORS should be set to the standard deviations of each point in *Y*. For Poisson or statistical weighting, MEASURE_ERRORS should be set to SQRT(*Y*).

SIGMA

Set this keyword to a named variable that will contain the 1-sigma uncertainty estimates for the returned parameters.

Note

If MEASURE_ERRORS is omitted, then you are assuming that the regression model is the correct model for your data, and therefore, no independent goodness-of-fit test is possible. In this case, the values returned in SIGMA are multiplied by SQRT(CHISQ/(N–M)), where N is the number of points in X, and M is the number of coefficients. See section 15.2 of *Numerical Recipes in C* (Second Edition) for details.

STATUS

Set this keyword to a named variable that will contain the status of the operation. Possible status values are:

- 0 = successful completion

- 1 = singular array (which indicates that the inversion is invalid)

- 2 = warning that a small pivot element was used and that significant accuracy was probably lost.

Note

If STATUS is not specified, any error messages will be output to the screen.

YFIT

Set this keyword to a named variable that will contain the vector of calculated *Y* values.

Examples

```
; Create two vectors of independent variable data:
X1 = [1.0, 2.0, 4.0, 8.0, 16.0, 32.0]
X2 = [0.0, 1.0, 2.0, 3.0, 4.0, 5.0]
; Combine into a 2x6 array
X = [TRANSPOSE(X1), TRANSPOSE(X2)]

; Create a vector of dependent variable data:
Y = 5 + 3*X1 - 4*X2

; Assume Gaussian measurement errors for each point:
measure_errors = REPLICATE(0.5, N_ELEMENTS(Y))
```

```
; Compute the fit, and print the results:
result = REGRESS(X, Y, SIGMA=sigma, CONST=const, $
   MEASURE_ERRORS=measure_errors)
PRINT, 'Constant: ', const
PRINT, 'Coefficients: ', result[*]
PRINT, 'Standard errors: ', sigma
```

IDL prints:

```
Constant:     4.99999
Coefficients:    3.00000    -3.99999
Standard errors:     0.0444831     0.282038
```

Version History

Original	Introduced
5.4	Deprecated the *Weights*, *Yfit*, *Const*, *Sigma*, *Ftest*, *R*, *Rmul*, *Chisq*, and *Status* arguments, RELATIVE_WEIGHT keyword.

For information on obsolete keywords, see Appendix I, "Obsolete Features".

See Also

CURVEFIT, GAUSSFIT, LINFIT, LMFIT, POLY_FIT, SFIT, SVDFIT

REPEAT...UNTIL

The REPEAT...UNTIL statement repeats its subject statement(s) until an expression evaluates to true. The condition is checked after the subject statement is executed. Therefore, the subject statement is always executed at least once, even if the expression evaluates to true the first time.

Note

For information on using REPEAT_UNTIL and other IDL program control statements, see Chapter 7, "Program Control" (*Application Programming*).

Syntax

REPEAT *statement* UNTIL *expression*

or

REPEAT BEGIN

　statements

ENDREP UNTIL *expression*

Examples

This example shows that because the subject of a REPEAT statement is evaluated before the expression, it is always executed at least once:

```
i = 1

REPEAT BEGIN

    PRINT, i

ENDREP UNTIL (i EQ 1)
```

Version History

Original	Introduced

REPLICATE

The REPLICATE function returns an array with the given dimensions, filled with the scalar value specified as the first parameter.

Syntax

Result = REPLICATE(*Value*, D_1 *[, ..., D_8]*)

Return Value

Returns the array of the given dimensions.

Arguments

Value

The scalar value with which to fill the resulting array. The type of the result is the same as that of *Value*. *Value* can be any single element expression such as a scalar or 1 element array. This includes structures.

D_i

Either an array or a series of scalar expressions specifying the dimensions of the result. If a single argument is specified, it can be either a scalar expression or an array of up to eight elements. If multiple arguments are specified, they must all be scalar expressions. Up to eight dimensions can be specified.

Keywords

Thread Pool Keywords

This routine is written to make use of IDL's *thread pool*, which can increase execution speed on systems with multiple CPUs. The values stored in the !CPU system variable control whether IDL uses the thread pool for a given computation. In addition, you can use the thread pool keywords TPOOL_MAX_ELTS, TPOOL_MIN_ELTS, and TPOOL_NOTHREAD to override the defaults established by !CPU for a single invocation of this routine. See Appendix C, "Thread Pool Keywords" for details.

Examples

Create D, a 5-element by 5-element array with every element set to the string "IDL" by entering:

```
D = REPLICATE('IDL', 5, 5)
```

REPLICATE can also be used to create arrays of structures. For example, the following command creates a structure named "emp" that contains a string name field and a long integer employee ID field:

```
employee = {emp, NAME:' ', ID:0L}
```

To create a 10-element array of this structure, enter:

```
emps = REPLICATE(employee, 10)
```

Version History

MAKE_ARRAY

REPLICATE_INPLACE

The REPLICATE_INPLACE procedure updates an existing array by replacing all or selected parts of it with a specified value. REPLICATE_INPLACE can be faster and use less memory than the IDL function REPLICATE or the IDL array notation for large arrays that already exist.

Note —————————————————————————————————————
REPLICATE_INPLACE is much faster when operating on entire arrays and rows, than when used on columns or higher dimensions.

Syntax

REPLICATE_INPLACE, *X*, *Value* [, *D1*, *Loc1* [, *D2*, *Range*]]

Arguments

X

The array to be updated. *X* can be of any numeric type. REPLICATE_INPLACE does not change the size and type of *X*.

Value

The value which will fill all or part of *X*. *Value* may be any scalar or one-element array that IDL can convert to the type of *X*. REPLICATE_INPLACE does not change *Value*.

D1

An optional parameter indicating which dimension of *X* is to be updated.

Loc1

An array with the same number of elements as the number of dimensions of *X*. The *Loc1* and *D1* arguments together determine which one-dimensional subvector (or subvectors, if *D1* and *Range* are provided) of *X* is to be updated.

D2

An optional parameter, indicating in which dimension of *X* a group of one-dimensional subvectors are to be updated. *D2* should be different from *D1*.

Range

An array of indices of dimension *D2* of *X*, indicating where to put one-dimensional updates of *X*.

Keywords

Thread Pool Keywords

This routine is written to make use of IDL's *thread pool*, which can increase execution speed on systems with multiple CPUs. The values stored in the !CPU system variable control whether IDL uses the thread pool for a given computation. In addition, you can use the thread pool keywords TPOOL_MAX_ELTS, TPOOL_MIN_ELTS, and TPOOL_NOTHREAD to override the defaults established by !CPU for a single invocation of this routine. See Appendix C, "Thread Pool Keywords" for details.

Examples

```
; Create a multidimensional zero array:
A = FLTARR( 40, 90, 10)

; Populate it with the value 4.5. (i.e., A[*]= 4.5 ):
REPLICATE_INPLACE, A, 4.5
;Update a single subvector.(i.e., A[*,4,0]= 20. ):
REPLICATE_INPLACE, A, 20, 1, [0,4,0]

; Update a group of subvectors.(i.e., A[ 0, [0, 5,89], * ] = -8 ):
REPLICATE_INPLACE, A, -8, 3, [0,0,0], 2, [0,5,89]

; Update a 2-dimensional slice of A (i.e., A[9,*, *] = 0.):
REPLICATE_INPLACE, A, 0., 3, [9,0,0] , 2, LINDGEN(90)
```

REPLICATE, BLAS_AXPY

RESOLVE_ALL

The RESOLVE_ALL procedure iteratively resolves (by compiling) any uncompiled procedures or functions that are called in any already-compiled procedure or function. The process ends when there are no unresolved routines left to compile. If an unresolved procedure or function is not in the IDL search path, RESOLVE_ALL exits with an error, and no additional routines are compiled.

RESOLVE_ALL is of special interest when using SAVE to construct an IDL SAVE file containing the compiled code for a package of routines. If you are constructing such a SAVE file and it contains calls to built-in IDL system functions that are not present under all operating systems (e.g., IOCTL), you must make sure to use FORWARD_FUNCTION to tell IDL that these names are functions. Otherwise, IDL may interpret them as arrays and generate unintended results. If you are creating a SAVE file that relies upon iTools components, you must use ITRESOLVE instead of RESOLVE_ALL to create a valid SAVE file.

Warning ———

RESOLVE_ALL does not resolve procedures or functions that are called via quoted strings such as CALL_PROCEDURE, CALL_FUNCTION, or EXECUTE, or in keywords that can contain procedure names such as TICKFORMAT or EVENT_PRO. You must manually compile these routines if they are not called normally elsewhere.

Similarly, RESOLVE_ALL does not resolve widget event handler procedures based on a call to the widget routine that uses the event handler. In general, it is best to include the event handling routine in the same program file as the widget creation routine—building widget programs in this way ensures that RESOLVE_ALL will "catch" the event handler for a widget application.

——

This routine is written in the IDL language. Its source code can be found in the file resolve_all.pro in the lib subdirectory of the IDL distribution.

Syntax

RESOLVE_ALL [, CLASS=*string*] [, /CONTINUE_ON_ERROR] [, /QUIET]
   [, RESOLVE_EITHER=*string*] [, RESOLVE_FUNCTION=*string*]
   [, RESOLVE_PROCEDURE=*string*] [, SKIP_ROUTINES=*string*]
   [, UNRESOLVED=*variable*]

Note ───

To properly resolve routines, make sure you run RESOLVE_ALL in an IDL session in which no compilation errors have occurred. This is important because if IDL has previously attempted (and failed) to compile a routine, that routine will be added to IDL's list of user-defined routines as an uncompiled routine. A subsequent call to RESOLVE_ALL will attempt to compile the uncompiled routine, potentially causing another error.

You can ensure that an IDL session is "clean" either by exiting and restarting IDL or by issuing the .RESET_SESSION executive command.

───

Arguments

None

Keywords

CLASS

Set this keyword to a string or string array containing object class names.

RESOLVE_ALL's rules for finding uncompiled functions and procedures are not able to find object definitions or methods, because those things are not known to IDL until the object classes are actually instantiated and the methods called. However, if the CLASS keyword is set, RESOLVE_ALL will ensure that the `*__define.pro` files for the specified classes and their superclasses are compiled and executed. RESOLVE_ALL then locates all methods for the specified classes and their superclasses, and makes sure they are also compiled.

CONTINUE_ON_ERROR

Set this keyword to allow continuation upon error.

QUIET

Set this keyword to suppress informational messages.

RESOLVE_EITHER

Set this keyword to a string or string array of routine names to resolve. Use this keyword instead of RESOLVE_FUNCTION or RESOLVE_PROCEDURE if you do not know the type of the routine being resolved. If the routines are already compiled, they are not recompiled.

RESOLVE_FUNCTION

Set this keyword to a string or string array of function names to resolve. If the functions are already compiled, they are not recompiled.

RESOLVE_PROCEDURE

Set this keyword to a string or string array of procedure names to resolve. If the procedures are already compiled, they are not recompiled.

SKIP_ROUTINES

Set this keyword to a string array containing the names of routines *not* to resolve. Using this keyword is useful when a library file containing the designated routines will be later included.

UNRESOLVED

Set this keyword to a variable that will contain the names of the unresolved procedures and functions if CONTINUE_ON_ERROR is set. Routines in the SKIP_ROUTINES list are also included in the result.

Version History

4.0	Introduced
6.0	Added CLASS keyword

See Also

.COMPILE, RESOLVE_ROUTINE, ROUTINE_INFO

RESOLVE_ROUTINE

The RESOLVE_ROUTINE procedure compiles user-written or library procedures or functions, given their names. Routines are compiled even if they are already defined. RESOLVE_ROUTINE looks for the given filename in IDL's search path. If the file is not found in the path, then the routine exits with an error.

Syntax

RESOLVE_ROUTINE, *Name* [, /COMPILE_FULL_FILE]
   [, /EITHER | , /IS_FUNCTION] [, /NO_RECOMPILE]

Arguments

Name

A scalar string or string array containing the name or names of the procedures to compile. If *Name* contains functions rather than procedures, set the IS_FUNCTION keyword. The *Name* argument cannot contain the path to the .pro file—it must contain only a .pro filename. If you want to specify a path to the .pro file, use the .COMPILE executive command.

Keywords

COMPILE_FULL_FILE

When compiling a file to find a specified routine, IDL normally stops compiling when the desired routine (*Name*) is found. If set, COMPILE_FULL_FILE compiles the entire file.

EITHER

If set, indicates that the caller does not know whether the supplied routine names are functions or procedures, and will accept either. This keyword overrides the IS_FUNCTION keyword.

IS_FUNCTION

Set this keyword to compile functions rather than procedures.

NO_RECOMPILE

Normally, RESOLVE_ROUTINE compiles all specified routines even if they have already been compiled. Setting NO_RECOMPILE indicates that such routines are not recompiled.

Version History

4.0	Introduced

.COMPILE, RESOLVE_ALL, ROUTINE_INFO

RESTORE

The RESTORE procedure restores the IDL variables and routines saved in a file by the SAVE procedure.

RESTORE provides a very simple interface that restores the entire contents of the specified SAVE file in a single atomic operation. If you wish to query the contents of a SAVE file without first restoring the data, or if you wish to restore only selected items, use the interface provided by the IDL_Savefile object class instead.

Warning ―――――――――――――――――――――――――――――――――――
While files containing IDL data variables can be restored by any version of IDL that supports the data types of the saved variables (in particular, by any version of IDL later than the version that created the SAVE file), files containing IDL routines and system variables can only be restored by versions of IDL that share the same internal code representation. Since the internal code representation changes regularly, you should always archive the IDL language source files (.pro files) for routines you are placing in IDL .sav files so you can recompile the code when a new version of IDL is released.

―――

Syntax

RESTORE [[, *Filename*] | [, FILENAME=*name*]] [, DESCRIPTION=*variable*]
   [, /RELAXED_STRUCTURE_ASSIGNMENT]
   [, RESTORED_OBJECTS=*variable*] [, /VERBOSE]

Arguments

Filename

A scalar string that contains the name of the SAVE file to be restored. If *Filename* is not an absolute path name, it is considered to be relative to the current working directory. If neither the *Filename* argument or the FILENAME keyword are present, IDL attempts to restore a file named idlsave.dat in the current working directory.

Keywords

DESCRIPTION

Set this keyword equal to a named variable that will contain the user-supplied *description string* for the specified save file. If no description was provided when the

save file was created (via the DESCRIPTION keyword to the SAVE routine), the variable specified by this keyword will contain a null string.

FILENAME

This keyword serves exactly the same purpose as the *Filename* argument—only one of them needs to be provided. If both the *Filename* argument and the FILENAME keyword are provided, the file specified by the *Filename* argument is restored.

RELAXED_STRUCTURE_ASSIGNMENT

Normally, RESTORE is unable to restore a structure variable if the definition of its type has changed since the SAVE file was written. A common case where this occurs is when objects are saved and the class structure of the objects change before they are restored in another IDL session. In such cases, RESTORE issues an error, skips the structure, and continues restoring the remainder of the SAVE file.

Setting the RELAXED_STRUCTURE_ASSIGNMENT keyword causes RESTORE to restore such incompatible values using "relaxed structure assignment," in which all possible data are restored using a field-by-field copy. (See the description of the STRUCT_ASSIGN procedure for additional details.)

RESTORED_OBJECTS

Set this keyword equal to a named variable that will contain an array of object references for any objects restored. The resulting list of objects is useful for programmatically calling the objects' restore methods. If no objects are restored, the variable will contain a null object reference.

VERBOSE

Set this keyword to have IDL print an informative message for each restored object.

Examples

Suppose that you have saved all the variables from a previous IDL session with the command:

```
SAVE, /VARIABLES, FILENAME = 'session1.sav'
```

If the file session1.sav is located in your current working directory, the variable associated with the file can be restored by entering:

```
RESTORE, 'session1.sav'
```

Note ————————————————————————————————————
> To restore a file that is not in your current working directory, you must specify the
> file path.

IDL_Savefile, Chapter 4, "Creating SAVE Files of Programs and Data" (*Application
Programming*)

RETALL

The RETALL command returns control to the main program level. The effect is the same as entering the RETURN command at the interactive command prompt until the main level is reached.

Syntax

RETALL

Arguments

None

Version History

Original	Introduced

See Also

RETURN

RETURN

The RETURN command causes the program context to revert to the next-higher program level. RETURN can be called at the interactive command prompt (see ".RETURN" on page 55), inside a procedure definition, or inside a function definition.

Calling RETURN from the main program level has no effect other than to print an informational message in the command log.

Calling RETURN inside a procedure definition returns control to the calling routine, or to the main level. Since the END statement in a procedure definition also returns control to the calling routine, it is only necessary to use RETURN in a procedure definition if you wish control to revert to the calling routine before the procedure reaches its END statement.

In a function definition, RETURN serves to define the value passed out of the function. Only a single value can be returned from a function.

Note

The value can be an array or structure containing multiple data items.

Syntax

RETURN [, *Return_value*]

Arguments

Return_value

In a function definition, the *Return_value* is the value passed out of the function when it completes its processing.

Return values are not allowed in procedure definitions, or when calling RETURN at the interactive command prompt.

Examples

You can use RETURN within a procedure definition to exit the procedure at some point other than the end. For example, note the following procedure:

```
PRO RET_EXAMPLE, value
   IF (value NE 0) THEN BEGIN
      PRINT, value, ' is nonzero'
      RETURN
      END
   PRINT, 'Input argument was zero.'
END
```

If the input argument is non-zero, the routine prints the value and exits back to the calling procedure or main level. If the input argument is zero, control proceeds until the END statement is reached.

When defining functions, use RETURN to specify the value returned from the function. For example, the following function:

```
FUNCTION RET_EXAMPLE2, value
   RETURN, value * 2
END
```

multiplies the input value by two and returns the result. If this function is defined at the main level, calling it from the IDL command prompt produces the following:

```
PRINT, RET_EXAMPLE2(4)
```

IDL prints:

```
8
```

RETALL

REVERSE

The REVERSE function reverses the order of one dimension of an array.

This routine is written in the IDL language. Its source code can be found in the file reverse.pro in the lib subdirectory of the IDL distribution.

Syntax

Result = REVERSE(*Array* [, *Subscript_Index*] [, /OVERWRITE])

Return Value

Returns the reversed dimension of the array.

Arguments

Array

The array containing the original data.

Subscript_Index

An integer specifying the dimension index (1, 2, 3, etc.) that will be reversed. This argument must be less than or equal to the number of dimensions of *Array*. If this argument is omitted, the first subscript is reversed.

Keywords

OVERWRITE

Set this keyword to conserve memory by doing the transformation "in-place." The result overwrites the previous contents of the array. This keyword is ignored for one- or two-dimensional arrays.

Examples

Reverse the order of an array where each element is set to the value of its subscript:

```
; Create an array:
A = [[0,1,2],[3,4,5],[6,7,8]]
```

```
; Print the array:
PRINT, 'Original Array:'
PRINT, A

; Reverse the columns of A.
PRINT, 'Reversed Columns:'
PRINT, REVERSE(A)

; Reverse the rows of A:
PRINT, 'Reversed Rows:'
PRINT, REVERSE(A, 2)
```

IDL prints:

```
Original Array:
      0          1          2
      3          4          5
      6          7          8
Reversed Columns:
      2          1          0
      5          4          3
      8          7          6
Reversed Rows:
      6          7          8
      3          4          5
      0          1          2
```

RK4

The RK4 function uses the fourth-order Runge-Kutta method to advance a solution to a system of ordinary differential equations one time-step *H*, given values for the variables *Y* and their derivatives *Dydx* known at *X*.

RK4 is based on the routine `rk4` described in section 16.1 of *Numerical Recipes in C: The Art of Scientific Computing* (Second Edition), published by Cambridge University Press, and is used by permission.

Syntax

Result = RK4(*Y*, *Dydx*, *X*, *H*, *Derivs* [, /DOUBLE])

Return Value

Returns the integrations of the ordinary differential equations.

Arguments

Y

A vector of values for *Y* at *X*

Note ——

If RK4 is complex then only the real part is used for the computation.

——

Dydx

A vector of derivatives for *Y* at *X*.

X

A scalar value for the initial condition.

H

A scalar value giving interval length or step size.

Derivs

A scalar string specifying the name of a user-supplied IDL function that calculates the values of the derivatives *Dydx* at *X*. This function must accept two arguments: A

scalar floating value *X*, and one *n*-element vector *Y*. It must return an *n*-element vector result.

For example, suppose the values of the derivatives are defined by the following relations:

$$dy_0 / dx = -0.5y_0, \qquad dy_1 / dx = 4.0 - 0.3y_1 - 0.1y_0$$

We can write a function DIFFERENTIAL to express these relationships in the IDL language:

```
FUNCTION differential, X, Y
   RETURN, [-0.5 * Y[0], 4.0 - 0.3 * Y[1] - 0.1 * Y[0]]
END
```

Keywords

DOUBLE

Set this keyword to force the computation to be done in double-precision arithmetic.

Examples

To integrate the example system of differential equations for one time step, H:

```
; Define the step size:
H = 0.5

; Define an initial X value:
X = 0.0

; Define initial Y values:
Y = [4.0, 6.0]

; Calculate the initial derivative values:
dydx = DIFFERENTIAL(X,Y)

; Integrate over the interval (0, 0.5):
result = RK4(Y, dydx, X, H, 'differential')

; Print the result:
PRINT, result
```

IDL prints:

```
   3.11523  6.85767
```

This is the exact solution vector to five-decimal precision.

ROBERTS

The ROBERTS function returns an approximation to the Roberts edge enhancement operator for images:

$$G_{jk} = \left| F_{jk} - F_{j+1, k+1} \right| + \left| F_{j, k+1} - F_{j+1, k} \right|$$

where (j, k) are the coordinates of each pixel F_{jk} in the *Image*. This is equivalent to a convolution using the masks,

$$\begin{bmatrix} 0 & -1 \\ \underline{1} & 0 \end{bmatrix} \text{and} \begin{bmatrix} 1 & 0 \\ \underline{0} & -1 \end{bmatrix}$$

where the underline indicates the current pixel F_{jk}. The last column and row are set to zero.

Syntax

Result = ROBERTS(*Image*)

Return Value

ROBERTS returns a two-dimensional array of the same size as *Image*. If *Image* is of type byte or integer, then the result is of integer type, otherwise the result is of the same type as *Image*.

Note

To avoid overflow for integer types, the computation is done using the next larger signed type and the result is transformed back to the correct type. Values larger than the maximum for that integer type are truncated. For example, for integers the function is computed using type long, and on output, values larger than 32767 are set equal to 32767.

Arguments

Image

The two-dimensional array containing the image to which edge enhancement is applied.

Keywords

None.

Examples

If the variable myimage contains a two-dimensional image array, a Roberts
sharpened version of myimage can be displayed with the command:

```
TVSCL, ROBERTS(myimage)
```

Note ———————————————————————————————

ROT

The ROT function rotates an image by an arbitrary amount. At the same time, it can magnify, demagnify, and/or translate an image.

Note ───

If you want to rotate an array by a multiple of 90 degrees, you should use the ROTATE function for faster results.

───

This routine is written in the IDL language. Its source code can be found in the file rot.pro in the lib subdirectory of the IDL distribution.

Syntax

Result = ROT(*A*, *Angle*, [*Mag*, X_0, Y_0] [, /INTERP] [, CUBIC=*value*{-1 to 0}]
    [, MISSING=*value*] [, /PIVOT])

Return Value

Returns the rotated and optionally transformed image.

Arguments

A

The image array to be rotated. This array can be of any type, but must have two dimensions. The output image has the same dimensions and data type of the input image.

ANGLE

Angle of rotation in degrees *clockwise*.

MAG

An optional magnification factor. A value of 1.0 results in no change. A value greater than one performs magnification. A value less than one but greater than zero performs demagnification.

X$_0$

X subscript for the center of rotation. If omitted, X_0 equals the number of columns in the image divided by 2.

Y$_0$

Y subscript for the center of rotation. If omitted, Y_0 equals the number of rows in the image divided by 2.

Keywords

INTERP

Set this keyword to use bilinear interpolation. The default is to use nearest neighbor sampling.

CUBIC

Set this keyword to a value between -1 and 0 to use the cubic convolution interpolation method with the specified value as the interpolation parameter. Setting this keyword equal to a value greater than zero specifies a value of -1 for the interpolation parameter. Park and Schowengerdt (see reference below) suggest that a value of -0.5 significantly improves the reconstruction properties of this algorithm.

Cubic convolution is an interpolation method that closely approximates the theoretically optimum sinc interpolation function using cubic polynomials. According to sampling theory, details of which are beyond the scope of this document, if the original signal, *f*, is a band-limited signal, with no frequency component larger than ω_0, and *f* is sampled with spacing less than or equal to $1/(2\omega_0)$, then *f* can be reconstructed by convolving with a sinc function: $\mathrm{sinc}(x) = \sin(\pi x) / (\pi x)$.

In the one-dimensional case, four neighboring points are used, while in the two-dimensional case 16 points are used.

Note ───
  Cubic convolution interpolation is significantly slower than bilinear interpolation.
───

For further details see:

Rifman, S.S. and McKinnon, D.M., "Evaluation of Digital Correction Techniques for ERTS Images; Final Report", Report 20634-6003-TU-00, TRW Systems, Redondo Beach, CA, July 1974.

S. Park and R. Schowengerdt, 1983 "Image Reconstruction by Parametric Cubic Convolution", Computer Vision, Graphics & Image Processing 23, 256.

MISSING

Set this keyword to a value to be substituted for pixels in the output image that map outside the input image.

PIVOT

Set this keyword to cause the image to pivot around the point (X_0, Y_0) so that this point maps into the same point in the output image. By default, the point (X_0, Y_0) in the input image is mapped into the center of the output image.

Examples

```
; Create a byte image:
A = BYTSCL(DIST(256))

; Display it:
TV, A

; Rotate the image 33 degrees, magnify it 15 times, and use
; bilinear interpolation to make the output look nice:
B = ROT(A, 33, 1.5, /INTERP)

; Display the rotated image:
TV, B
```

Note

Also see "Rotating Images" (Chapter 2, *Image Processing in IDL*) for a more extensive example.

Version History

Original	Introduced

ROTATE

ROTATE

The ROTATE function returns a rotated and/or transposed copy of *Array*. ROTATE can only rotate arrays in multiples of 90 degrees. To rotate by amounts other than multiples of 90 degrees, use the ROT function. Note, however, that ROTATE is more efficient.

ROTATE can also be used to reverse the order of elements in vectors. For example, to reverse the order of elements in the vector X, use the expression ROTATE(X,2). If X = [0,1,2,3] then ROTATE(X,2) yields the resulting array, [3,2,1,0].

Note ───

Transposition, if specified, is performed before rotation.

───

Syntax

Result = ROTATE(*Array*, *Direction*)

Return Value

Returns the rotated and/or transposed array.

Arguments

Array

The array to be rotated. *Array* can have only one or two dimensions. The result has the same type as *Array*. The dimensions of the result are the same as those of *Array* if *Direction* is equal to 0 or 2. The dimensions are transposed if the direction is 4 or greater.

Direction

Direction specifies the operation to be performed as follows:

Direction	Transpose?	Rotation Counterclockwise	X_1	Y_1
0	No	None	X_0	Y_0
1	No	90°	$-Y_0$	X_0

Table 20-4: Rotation Directions

Direction	Transpose?	Rotation Counterclockwise	X_1	Y_1
2	No	180°	$-X_0$	$-Y_0$
3	No	270°	Y_0	$-X_0$
4	Yes	None	Y_0	X_0
5	Yes	90°	$-X_0$	Y_0
6	Yes	180°	$-Y_0$	$-X_0$
7	Yes	270°	X_0	$-Y_0$

Table 20-4: Rotation Directions (Continued)

In the table above, (X_0, Y_0) are the original subscripts, and (X_1, Y_1) are the subscripts of the resulting array. The notation $-Y_0$ indicates a reversal of the Y axis, $Y_1 = N_y - Y_0 - 1$. *Direction* is taken modulo 8, so a rotation of -1 is the same as 7, 9 is the same as 1, etc.

Note

The assertion that *Array* is rotating counterclockwise may cause some confusion. Remember that when arrays are displayed on the screen (using TV or TVSCL, for example), the image is drawn by default with the origin (0,0) at the bottom left corner of the window. (This default can be changed by changing the value of the !ORDER system variable.) When arrays are printed on the console or command log window (using the PRINT command, for example), the (0,0) element is drawn in the upper left corner of the array. This means that while an image displayed in a graphics window appears to rotate counterclockwise, an array printed in the command log appears to rotate clockwise.

Examples

Create and display a wedge image by entering:

```
F = REPLICATE(1, 256) # FINDGEN(256) & TVSCL, F
```

To display the image rotated 90 degrees counterclockwise, enter:

```
TVSCL, ROTATE(F, 1)
```

Note ———————————————————————————————

Also see "Rotating Images" (Chapter 2, *Image Processing in IDL*) for a more extensive example.

ROT, TRANSPOSE

ROUND

The ROUND function rounds the argument to its closest integer.

Syntax

Result = ROUND(*X* [, /L64])

Return Value

Returns the integer closest to its argument. If the input value *X* is integer type, *Result* has the same value and type as *X*. Otherwise, *Result* is returned as a 32-bit longword integer with the same structure as *X*.

Arguments

X

The value for which the ROUND function is to be evaluated. This value can be any numeric type (integer, floating, or complex). Note that only the real part of a complex argument is rounded and returned.

Keywords

L64

If set, the result type is 64-bit integer no matter what type the input has. This is useful for situations in which a floating point number contains a value too large to be represented in a 32-bit integer.

Thread Pool Keywords

This routine is written to make use of IDL's *thread pool*, which can increase execution speed on systems with multiple CPUs. The values stored in the !CPU system variable control whether IDL uses the thread pool for a given computation. In addition, you can use the thread pool keywords TPOOL_MAX_ELTS, TPOOL_MIN_ELTS, and TPOOL_NOTHREAD to override the defaults established by !CPU for a single invocation of this routine. See Appendix C, "Thread Pool Keywords" for details.

Examples

Print the rounded values of a 2-element vector:

```
PRINT, ROUND([5.1, 5.9])
```

IDL prints:

```
      5       6
```

Print the result of rounding 3000000000.1, a value that is too large to represent in a 32-bit integer:

```
PRINT, ROUND(3000000000.1D, /L64)
```

IDL prints:

```
3000000000
```

ROUTINE_INFO

The ROUTINE_INFO function provides information about currently-compiled procedures and functions.

Syntax

Result = ROUTINE_INFO([*Routine*] [, /PARAMETERS] [, /SOURCE]
   [, /UNRESOLVED] [, /VARIABLES] [, /SYSTEM] [, /DISABLED]
   [, /ENABLED] [, /FUNCTIONS])

Return Value

Returns a string array consisting of the names of defined procedures or functions, or of parameters or variables used by a single procedure or function.

Arguments

Routine

A scalar string containing the name of routine for which information will be returned. *Routine* can be either a procedure or a function. If *Routine* is not supplied, ROUTINE_INFO returns a list of all currently-compiled procedures.

Keywords

DISABLED

Set this keyword to get the names of currently disabled system procedures or functions (in conjunction with the FUNCTIONS keyword). Use of DISABLED implies use of the SYSTEM keyword, since user routines cannot be disabled.

ENABLED

Set this keyword to get the names of currently enabled system procedures or functions (in conjunction with the FUNCTIONS keyword). Use of ENABLED implies use of the SYSTEM keyword, since user routines cannot be disabled.

FUNCTIONS

Set this keyword to return a string array containing currently-compiled functions. By default, ROUTINE_INFO returns a list of compiled procedures. If the SYSTEM

keyword is also set, ROUTINE_INFO returns a list of all IDL built-in internal functions.

PARAMETERS

Set this keyword to return an anonymous structure with the following fields:

- **NUM_ARGS** — An integer containing the number of positional parameters used in *Routine*.

- **NUM_KW_ARGS** — An integer containing the number of keyword parameters used in *Routine*.

- **ARGS** — A string array containing the names of the positional parameters used in *Routine*.

- **KW_ARGS** — A string array containing the names of the keyword parameters used in *Routine*.

You must supply the *Routine* argument when using this keyword. If *Routine* is a function, you must specify the FUNCTIONS keyword as well. Note that specifying the SYSTEM keyword along with this keyword will generate an error.

If *Routine* does not take any arguments, the ARGS field is not included in the anonymous structure. Similarly, if *Routine* does not take any keywords, the KW_ARGS field is not included.

SOURCE

Set this keyword to return an array of anonymous structures with the following fields:

- **NAME** — A string containing the name of the procedure or function.

- **PATH** — A string containing the full path specification of the file that contains the definition of the procedure or function.

If *Routine* is specified, information for the specified procedure is returned. If *Routine* is not specified, information for all compiled procedures is returned. If the FUNCTIONS keyword is also set, ROUTINE_INFO returns information for the specified function or for all compiled functions.

If a routine is unresolved or its path information is unavailable, the PATH field will contain a null string. If a routine has been SAVEd and then RESTOREd, the PATH field will contain the path to the SAVE file.

Note
Specifying the SYSTEM keyword along with this keyword will generate an error.

SYSTEM

Set this keyword to return a string array listing all IDL built-in internal procedures. Built-in internal procedures are part of the IDL executable, and are *not* written in the IDL language. If the FUNCTIONS keyword is also set, ROUTINE_INFO returns a list of all IDL built-in internal functions.

UNRESOLVED

Set this keyword to return a string array listing procedures that are referenced in any currently-compiled procedure or function, but which are themselves not yet compiled. If the FUNCTIONS keyword is also set, ROUTINE_INFO returns a list of functions that are referenced but not yet compiled.

Note that specifying the SYSTEM keyword along with this keyword will generate an error.

VARIABLES

Set this keyword to return a string array listing variables defined in the procedure. If the FUNCTIONS keyword is also set, ROUTINE_INFO returns a string array listing variables defined in the function.

You must supply the *Routine* argument when using this keyword. Note that specifying the SYSTEM keyword along with this keyword will generate an error.

RESOLVE_ALL, RESOLVE_ROUTINE

ROUTINE_FILEPATH

The ROUTINE_FILEPATH function returns the full path to a currently-compiled procedure or function (or a list of procedures and functions).

Syntax

Result = ROUTINE_FILEPATH(*Routine* [, /EITHER] [, /IS_FUNCTION])

Return Value

Returns a scalar string or string array containing the full path for each element of the *Routine* argument. If the routine is not in the list of currently-compiled routines, a null string is returned.

Arguments

Routine

Routine is a scalar string or string array containing routine names for which the file path is desired. If *Routine* contains functions rather than procedures, you must set the IS_FUNCTION or EITHER keyword.

Keywords

EITHER

If set, this keyword indicates that the caller does not know whether the supplied routine names are functions or procedures, and will accept paths for either. This keyword overrides the IS_FUNCTION keyword.

IS_FUNCTION

Set this keyword to search for functions rather than procedures.

Version History

7.0	Introduced

RESOLVE_ROUTINE, ROUTINE_INFO

RS_TEST

The RS_TEST function tests the hypothesis that two sample populations *X* and *Y* have the same mean of distribution against the hypothesis that they differ. *X* and *Y* may be of different lengths. This type of test is often referred to as the "Wilcoxon Rank-Sum Test" or the "Mann-Whitney U-Test."

The Mann-Whitney statistics for *X* and *Y* are defined as follows:

$$U_x = N_x N_y + \frac{N_x(N_x + 1)}{2} - W_x$$

$$U_y = N_x N_y + \frac{N_y(N_y + 1)}{2} - W_y$$

where *Nx* and *Ny* are the number of elements in *X* and *Y*, respectively, and *Wx* and *Wy* are the rank sums for *X* and *Y*, respectively. The test statistic Z, which closely follows a normal distribution for sample sizes exceeding 10 elements, is defined as follows:

$$Z = \frac{U_x - (N_x N_y)/2}{\sqrt{(N_x N_y(N_x + N_y + 1))/12}}$$

This routine is written in the IDL language. Its source code can be found in the file `rs_test.pro` in the `lib` subdirectory of the IDL distribution.

Syntax

Result = RS_TEST(*X*, *Y* [, UX=*variable*] [, UY=*variable*])

Return Value

The result is a two-element vector containing the nearly-normal test statistic Z and the one-tailed probability of obtaining a value of Z or greater.

Arguments

X

An *n*-element integer, single-, or double-precision floating-point vector.

Y

An *m*-element integer, single-, or double-precision floating-point vector.

Keywords

UX

Set this keyword to a named variable that will contain the Mann-Whitney statistic for *X*.

UY

Set this keyword to a named variable that will contain the Mann-Whitney statistic for *Y*.

Examples

```
; Define two sample populations:
X = [-14, 3, 1, -16, -21, 7, -7, -13, -22, -17, -14, -8, $
      7, -18, -13, -9, -22, -25, -24, -18, -13, -13, -18, -5]
Y = [-18, -9, -16, -14, -3, -9, -16, 10, -11, -3, -13, $
     -21, -2, -11, -16, -12, -13, -6, -9, -7, -11, -9]

; Test the hypothesis that two sample populations, {xi, yi}, have
; the same mean of distribution against the hypothesis in that they
; differ at the 0.05 significance level:
PRINT, RS_TEST(X, Y, UX = ux, UY = uy)

; Print the Mann-Whitney statistics:
PRINT, 'Mann-Whitney Statistics: Ux = ', ux, ', Uy = ', uy
```

IDL prints:

```
[1.45134, 0.0733429]
Mann-Whitney Statistics: Ux = 330.000, Uy = 198.000
```

The computed probability (0.0733429) is greater than the 0.05 significance level and therefore we do not reject the hypothesis that X and Y have the same mean of distribution.

Version History

4.0	Introduced

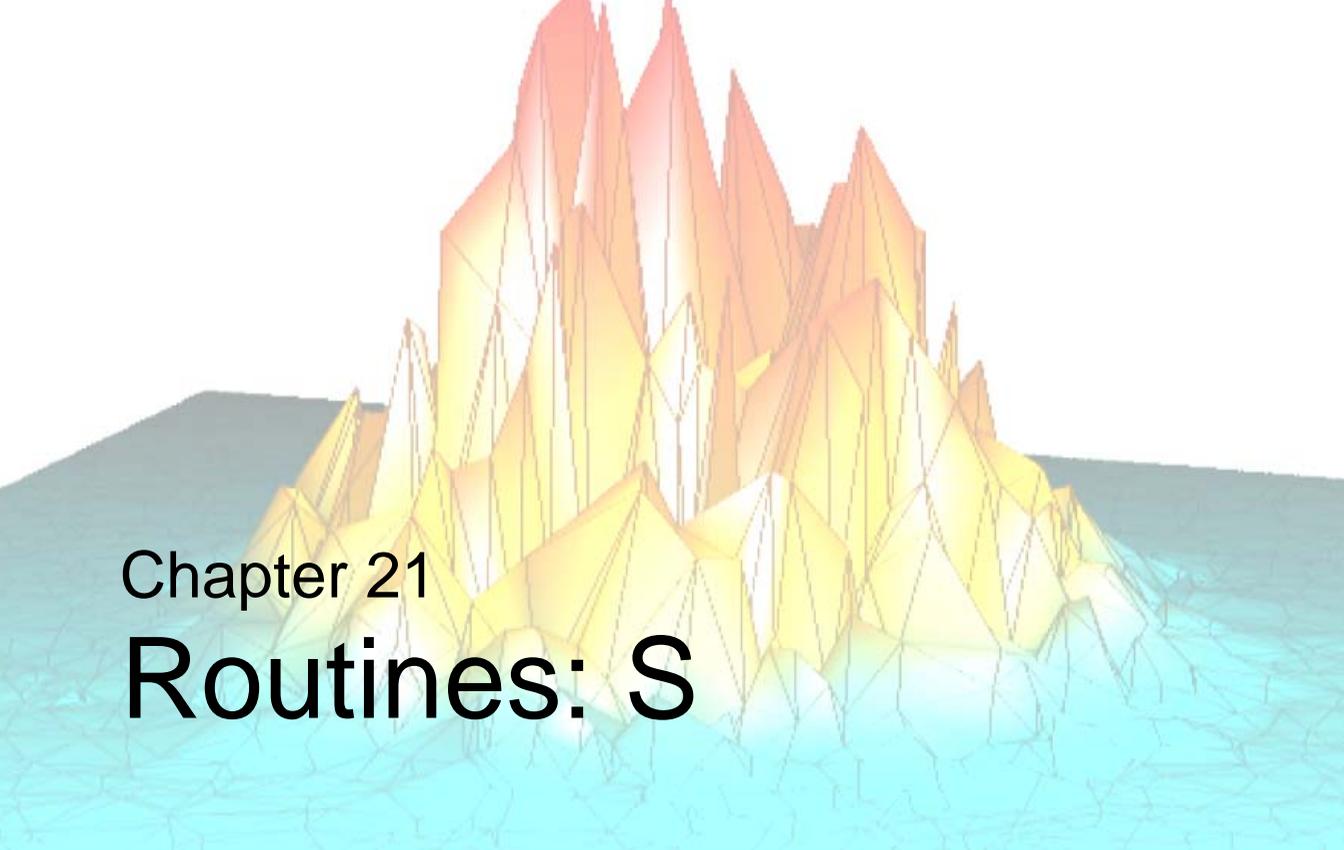
FV_TEST, KW_TEST, S_TEST, TM_TEST


Chapter 21
Routines: S

S_TEST

The S_TEST function tests the hypothesis that two sample populations *X* and *Y* have the same mean of distribution against the hypothesis that they differ.

This routine is written in the IDL language. Its source code can be found in the file `s_test.pro` in the `lib` subdirectory of the IDL distribution.

Syntax

Result = S_TEST(*X*, *Y* [, ZDIFF=*variable*])

Return Value

The result is a two-element vector containing the maximum number of signed differences between corresponding pairs of *xi* and *yi* and its one-tailed significance. This type of test is often referred to as the "Sign Test."

Arguments

X

An *n*-element integer, single-, or double-precision floating-point vector.

Y

An *n*-element integer, single-, or double-precision floating-point vector.

Keywords

ZDIFF

Set this keyword to a named variable that will contain the number of differences between corresponding pairs of *xi* and *yi* resulting in zero. Paired data resulting in a difference of zero are excluded from the ranking and the sample size is correspondingly reduced.

Examples

```
; Define two n-element sample populations:
X = [47, 56, 54, 49, 36, 48, 51, 38, 61, 49, 56, 52]
Y = [71, 63, 45, 64, 50, 55, 42, 46, 53, 57, 75, 60]
```

```
; Test the hypothesis that the two sample populations have the same
; mean of distribution against the hypothesis that they differ at
; the 0.05 significance level:
PRINT, S_TEST(X, Y, ZDIFF = zdiff)
```

IDL prints:

```
[9.00000, 0.0729981]
```

The computed probability (0.0729981) is greater than the 0.05 significance level and therefore we do not reject the hypothesis that *X* and *Y* have the same mean of distribution.

SAVE

The SAVE procedure saves variables, system variables, and IDL routines in a SAVE file using the XDR (eXternal Data Representation) format for later recovery by RESTORE. Note that variables and routines cannot be saved in the same file. Note also that SAVE files containing routines may not be compatible between different versions of IDL, but that files containing data are always backwards-compatible.

Note
While IDL routines or data can be saved in a file with any extension, it is common to use the extension `.sav` for SAVE files. Using the `.sav` extension has two benefits: it makes it clear to another IDL user that the file contains IDL routines or data that can be restored, and it allows IDL to locate routines with the same base name as the file in SAVE files located in IDL's path.

Note
Do not confuse the process of saving an *instance* of an object with saving its *definition*. A reference to an instantiated object is stored in an IDL variable, and must be saved in a SAVE file as a variable. An object definition, on the other hand, is an IDL routine, and must be saved in a SAVE file as a routine. *It is important to remember that restoring an instance of an object does not restore the object's definition.* If the object is defined in `.pro` code, you must save the object definition routine and the object instance variable in separate SAVE files, and restore both instance and definition in the target IDL session.

Warning
IDL cannot save data objects that rely on state information stored in an external library. Examples of such objects include IDLffXMLDOM, IDLffJPEG2000, and IDLffDICOMEX. These objects are *not* stored in a SAVE file.

Syntax

SAVE [, *Var₁*, ..., *Varₙ*] [, /ALL] [, /COMM, /VARIABLES] [, /COMPRESS]
   [, DESCRIPTION=*string*] [, /EMBEDDED] [, FILENAME=*string*]
   [, /ROUTINES] [, /SYSTEM_VARIABLES] [, /VERBOSE]

Arguments

Var*n*

The names of one or more variables that are to be saved. If the ROUTINES keyword is present, the *Var* arguments should be strings containing the names of the routines to be saved. If no *Var* arguments are provided, the items specified by the supplied keywords are saved.

Keywords

ALL

Set this keyword to save all common blocks, system variables, and local variables from the current IDL session.

Note ───

Routines and variables cannot be saved in the same file. Setting the ALL keyword does not save routines.

───

COMM

Set this keyword to save all main level common block definitions. Note that setting this keyword does not cause the contents of the common block to be saved unless the VARIABLES keyword is also set.

COMPRESS

If COMPRESS is set, IDL writes all data to the SAVE file using the ZLIB compression library to reduce its size. IDL's SAVE file compression support is based on the freely available ZLIB library by Mark Adler and Jean-loup Gailly.

Compressed SAVE files can be restored by the RESTORE procedure in exactly the same manner as any other SAVE file. The only visible differences are that the files will be smaller, and writing and reading them will be somewhat slower under typical conditions.

DESCRIPTION

Set this keyword equal to a string that will be saved in the SAVE file:

```
SAVE, data, $
   DESCRIPTION="Solar Obs: 2452884.9, 40 deg 0' N 105 deg 16' W"
```

This string can be later recovered using the RESTORE procedure or the IDL_Savefile object class. The ability to associate a descriptive string to a SAVE file can be used by IDL programs to identify data, and can also be used as an aid in managing large collections of data.

EMBEDDED

Set this keyword to request that the generated SAVE file contain an embedded license. The SAVE procedure will add an embedded license to the SAVE file if the IDL session has access to a Developer's Kit license. Use of this keyword is equivalent to selecting the **Licensed Save File (.sav)** option on the **IDL Project Properties** page of the **Project Properties** dialog. (See Running and Building IDL Projects for details.)

Note ───
Use this keyword with the ROUTINES keyword.
──

FILENAME

A string containing the name of the file into which the IDL objects should be saved. While there are no arbitrary limitations on the name of a file created with the SAVE procedure, use the .sav extension for your files for consistency. If this keyword is not specified, the file idlsave.dat is used.

ROUTINES

Set this keyword to save user defined procedures and functions in a machine independent, binary form. If parameters are present, they must be strings containing the names of the procedures and/or functions to be saved. If no parameters are present, all compiled routines are saved. Routines and variables cannot be saved in the same file.

Warning ───
SAVE (.sav) files containing routines are not guaranteed to be compatible between successive versions of IDL. You will not be able to RESTORE SAVE files containing routines if they are made with incompatible versions of IDL. In this case, you should recompile your original code with the newer version of IDL. A SAVE file containing data will always be restorable.
──

SYSTEM_VARIABLES

Set this keyword to save the current state of all system variables.

Warning

Saving system variables is not recommended, as the structure may change between versions of IDL.

VARIABLES

Set this keyword to save all variables in the current program unit. This option is the default.

VERBOSE

Set this keyword to print an informative message for each saved object.

Examples

Save the status of all currently-defined variables in the file variables1.sav by entering:

```
SAVE, /VARIABLES, FILENAME = 'variables1.sav'
```

The variables can be restored with the RESTORE procedure.

Save the user procedures MYPROC and MYFUN:

```
SAVE, /ROUTINES, 'MYPROC', 'MYFUN', FILENAME = 'myroutines.sav'
```

Version History

SAVGOL

The SAVGOL function returns the coefficients of a Savitzky-Golay smoothing filter, which can then be applied using the CONVOL function. The Savitzky-Golay smoothing filter, also known as least squares or DISPO (digital smoothing polynomial), can be used to smooth a noisy signal.

The filter is defined as a weighted moving average with weighting given as a polynomial of a certain degree. The returned coefficients, when applied to a signal, perform a polynomial least-squares fit within the filter window. This polynomial is designed to preserve higher moments within the data and reduce the bias introduced by the filter. The filter can use any number of points for this weighted average.

This filter works especially well when the typical peaks of the signal are narrow. The heights and widths of the curves are generally preserved.

Tip

You can use this function in conjunction with the CONVOL function for smoothing and optionally for numeric differentiation.

This routine is written in the IDL language. Its source code can be found in the file savgol.pro in the lib subdirectory of the IDL distribution.

SAVGOL is based on the Savitzky-Golay Smoothing Filters described in section 14.8 of *Numerical Recipes in C: The Art of Scientific Computing* (Second Edition), published by Cambridge University Press, and is used by permission.

Syntax

Result = SAVGOL(*Nleft*, *Nright*, *Order*, *Degree* [, /DOUBLE])

Return Value

This function returns an array of floating-point numbers that are the coefficients of the smoothing filter.

Arguments

Nleft

An integer specifying the number of data points to the left of each point to include in the filter.

Nright

An integer specifying the number of data points to the right of each point to include in the filter.

Note ——————————————————————————————

Larger values of *Nleft* and *Nright* produce a smoother result at the expense of flattening sharp peaks.

Order

An integer specifying the order of the derivative desired. For smoothing, use order 0. To find the smoothed first derivative of the signal, use order 1, for the second derivative, use order 2, etc.

Note ——————————————————————————————

Order must be less than or equal to the value specified for *Degree*.

Note ——————————————————————————————

For ORDER > 0, SAVGOL returns unnormalized coefficients. To use the SAVGOL coefficients with CONVOL, you should multiple the returned coefficients by FACTORIAL(ORDER)/(dx^{ORDER}), where *dx* is the sampling interval between data points. See the example below.

Degree

An integer specifying the degree of smoothing polynomial. Typical values are 2 to 4. Lower values for *Degree* will produce smoother results but may introduce bias, higher values for *Degree* will reduce the filter bias, but may "over fit" the data and give a noisier result.

Note ——————————————————————————————

Degree must be less than the filter width (*Nleft* + *Nright* + 1).

Keywords

DOUBLE

Set this keyword to force the computation to be done in double-precision arithmetic.

Tip ——
The DOUBLE keyword is recommended for *Degree* greater than 9.

——

Examples

The following example creates a noisy 400-point vector with 4 Gaussian peaks of decreasing width. It then plots the original vector, the vector smoothed with a 33-point Boxcar smoother (the SMOOTH function), and the vector smoothed with 33-point wide Savitzky-Golay filter of degree 4. The bottom plot shows the second derivative of the signal (without noise) and the second derivative of the noisy data using the Savitzky-Golay filter of degree 4:

```
PRO Savgol_example

n = 401 ; number of points
np = 4  ; number of peaks

; Form the baseline:
y = REPLICATE(0.5, n)

; Sampling interval:
dt = 0.1

; Index the array:
x = dt*FINDGEN(n)

; Add each Gaussian peak:
FOR i=0, np-1 DO BEGIN
   c = dt*(i + 0.5) * FLOAT(n)/np; Center of peak
   peak = 3 * (x-c) / (dt*(75. / 1.5 ^ i))
   ; Add Gaussian. Cutoff of -50 avoids underflow errors for
   ; tiny exponentials:
   y = y + EXP((-peak^2)>(-50))
ENDFOR

; Add noise:
y1 = y + 0.10 * RANDOMN(-121147, n)

; Display first plot
iPlot, x, y1, NAME='Signal+Noise', VIEW_GRID=[1,2]

; Get an object reference to the iTool and insert legend.
void = ITGETCURRENT(TOOL=oTool)
void = oTool->DoAction('Operations/Insert/Legend')
```

```
iPlot, x, SMOOTH(y1, 33, /EDGE_TRUNCATE), /OVERPLOT, $
   COLOR=[255, 0, 0], $
   NAME='Smooth (width 33)'
void = oTool->DoAction('Operations/Insert/LegendItem')

; Savitzky-Golay with 33, 4th degree polynomial:

SCALE3

The SCALE3 procedure sets up transformation and scaling parameters for basic 3-D viewing. This procedure is similar to SURFR and SCALE3D, except that the data ranges must be specified and the scaling does not vary with rotation. Results are stored in the system variables !P.T, !X.S, !Y.S, and !Z.S.

This routine is written in the IDL language. Its source code can be found in the file scale3.pro in the lib subdirectory of the IDL distribution.

Syntax

SCALE3 [, XRANGE=*vector*] [, YRANGE=*vector*] [, ZRANGE=*vector*]
   [, AX=*degrees*] [, AZ=*degrees*]

Arguments

None.

Keywords

XRANGE

A two-element vector containing the minimum and maximum X values. If omitted, the X-axis scaling remains unchanged.

YRANGE

A two-element vector containing the minimum and maximum Y values. If omitted, the Y-axis scaling remains unchanged.

ZRANGE

A two-element vector containing the minimum and maximum Z values. If omitted, the Z-axis scaling remains unchanged.

AX

Angle of rotation about the X axis. The default is 30 degrees.

AZ

Angle of rotation about the Z axis. The default is 30 degrees.

Examples

Set up a 3-D transformation where the data range is 0 to 20 for each of the 3 axes and the viewing area is rotated 20 degrees about the X axis and 55 degrees about the Z axis:

```
SCALE3, XRANGE=[0, 20], YRANGE=[0, 20], ZRANGE=[0, 20], AX=20,
    AZ=55
```

SCALE3 and More Complicated Transformations

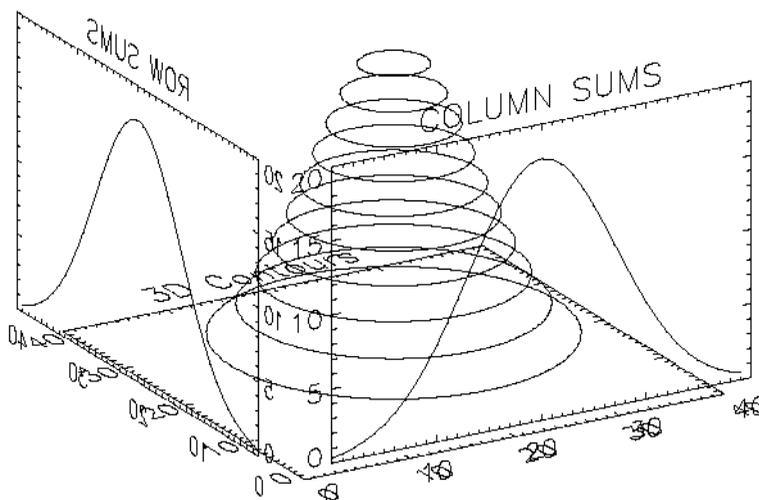
The figure below illustrates the application of three-dimensional transforms to the output of CONTOUR and PLOT. Using the two-dimensional Gaussian array **z** defined in "Surface of a Gaussian Function" on page 2418, it draws a three-dimensional contour plot with the contours stacked above the axes in the *z* direction. It then plots the sum of the columns, also a Gaussian, in the *xz*-plane, and the sum of the rows in the *yz* plane.


Figure 21-2: PLOT and CONTOUR with a Three-dimensional Transform

It was constructed as follows:

- First, the SCALE3 procedure is called to establish the default three- to two-dimensional transformation used by SURFACE, as explained in "Transformation Created by SURFACE" on page 2421. The default rotations are 30 degrees about both the *x*- and *z*-axes.

- Next, a vector, POS, defining the cube containing the plot window is defined in normalized coordinates. The cube extends from 0.1 to 1.0 in the *x* and *y* directions and from 0 to 1 in the *z* direction. Each call to CONTOUR and PLOT must explicitly specify this window to align the plots. This is necessary because the default margins around the plot window are different in each direction.

- CONTOUR is called to draw the stacked contours with the axes at $z = 0$. Clipping is disabled to allow drawing outside the default plot window, which is only two-dimensional.

- The procedure T3D is called to exchange the *y*- and *z*-axes. The original *xyz* coordinate system is now *xzy.*

- PLOT is called to draw the column sums which appear in front of the contour plot. The expression Z#REPLICATE(1., N_y) creates a row vector containing the sum of each row in the two-dimensional array *z*. The NOERASE and NOCLIP keywords are specified to prevent erasure and clipping. This plot appears in the *xz*-plane because of the previous axis exchange.

- T3D is called again to exchange the *x*- and *z*-axes. This makes the original *xyz* coordinate system, which was converted to *xzy*, now correspond to *yzx*.

- PLOT is called to produce the column sums in the *yz*-plane in the same manner as the first plot. The original *x*-axis is drawn in the *y*-plane, and the *y*-axis is in the *z*-plane. One unavoidable side effect of this method is that the annotation of this plot is backwards. If the plot is transformed so the letters read correctly, the *x*-axis of the plot would be reversed in relation to the *y*-axis of the contour plot.

The IDL code used to draw the figure is as follows:

```
; Create the Z variable:
Z = SHIFT(DIST(40), 20, 20)
Z = EXP(-(Z/10)^2)
; NX and NY are the X and Y dimensions of the Z array:
NX = (SIZE(Z))(1)
NY = (SIZE(Z))(2)
; Set up !P.T with default SURFACE transformation.
SCALE3
; Define the three-dimensional plot
; window: x = 0.1 to 1, Y=0.1 to 1, and z = 0 to 1.
POS=[.1, .1, 1, 1, 0, 1]
; Make the stacked contours. Use 10 contour levels.
CONTOUR, Z, /T3D, NLEVELS=10, /NOCLIP, POSIT=POS, CHARSIZE=2
; Swap y and z axes. The original xyz system is now xzy:
T3D, /YZEXCH
```

```
; Plot the column sums in front of the contour plot:
PLOT, Z#REPLICATE(1., NY), /NOERASE, /NOCLIP, /T3D, $
   TITLE='COLUMN SUMS', POSITION = POS, CHARSIZE = 2
; Swap x and z—original xyz is now yzx:
T3D, /XZEXCH
; Plot the row sums along the right side of the contour plot:
PLOT, REPLICATE(1., NX)#Z, /NOERASE, /T3D, /NOCLIP, $
   TITLE = 'ROW SUMS', POSITION = POS, CHARSIZE = 2
```

Example Code

If you prefer not to enter the IDL code by hand, run the batch file `cntour06` with
the following command at the IDL prompt:

```
@cntour06
```

See if IDL does not find the batch file.

SCALE3D, SURFACE, SURFR, T3D

SCALE3D

The SCALE3D procedure scales the 3-D unit cube (a cube with the length of each side equal to 1) into the viewing area. Eight data points are created at the vertices of the 3-D unit cube. The vertices are then transformed by the value of the system variable !P.T. The system is translated to bring the minimum (x,y,z) point to the origin, and then scaled to make each coordinate's maximum value equal to 1. The !P.T system variable is modified as a result.

This routine is written in the IDL language. Its source code can be found in the file scale3D.pro in the lib subdirectory of the IDL distribution.

HELP, SCOPE_VARFETCH, SCOPE_TRACEBACK, SCOPE_VARNAME, ROUTINE_INFO

SCOPE_TRACEBACK

The SCOPE_TRACEBACK function is used to obtain an array containing the current interpreter call stack, which is a list describing the sequence of routine calls that have brought IDL execution to the current point. Each element of the array describes the routine as well as the source file and line number at which it was running at a given interpreter level. See "Interpreter Frames, Level, and Variable Scope" on page 2172 for more information.

In general, you should strive to write routines that execute properly no matter how they are called or by which routines. As such, your programs should rarely require call-stack information. Code that looks at what routine called it and alters its behavior accordingly can quickly become difficult to understand and maintain, and is generally considered to represent poor programming style. For this reason, avoid using the SCOPE functions.

Syntax

Result = SCOPE_TRACEBACK([/STRUCTURE] [, /SYSTEM])

Return Value

Returns an array containing the current interpreter call stack. Each element of this result corresponds to one routine. Element 0 of the result contains information about the outer main program ($MAIN$), and each subsequent element contains information about the following routine. The final element of the result describes the currently executing caller of SCOPE_TRACEBACK.

If the STRUCTURE keyword is set, the array contains one IDL_TRACEBACK structure per stack frame containing detailed information about that invocation. Otherwise, a string array is returned, each element of which contains the name of the program module, source file name, and line number.

Keywords

STRUCTURE

Set this keyword to return an array of IDL_TRACEBACK structures containing detailed information about the call stack. Each IDL_TRACEBACK structure contains the following fields:

Field	Description
ROUTINE	Name of the routine.
FILENAME	If the routine was compiled from an IDL program file, FILENAME gives the name of the file. If it was restored from an IDL SAVE file, it gives the name of the SAVE file. FILENAME is a null string if the routine is a built-in system routine.
LINE	If the routine was compiled from an IDL program file, LINE contains the current line number within the file given by FILENAME. It is 0 if the routine is from an IDL SAVE file or is a built-in system routine.
LEVEL	For user-level IDL language routines, the interpreter level of this frame of execution. See the documentation of the SCOPE_LEVEL function for more information on interpreter level. Interpreter levels only apply to routines written in the IDL language and are 0 (zero) or greater. This field is set to -1 for system routines.
IS_FUNCTION	This field is 1 if the routine is a function and 0 (zero) if it is a procedure.
METHOD	This field is 1 if the routine is an object method and 0 (zero) if it is a regular routine.
RESTORED	This field is 1 if the routine was restored from an IDL SAVE file and 0 (zero) otherwise.
SYSTEM	This field is 1 if the routine is a built-in system routine and 0 (zero) if it is a user-level routine written in the IDL language.

Table 21-1: IDL_TRACEBACK Structure Fields

SYSTEM

By default, SCOPE_TRACEBACK shows the call stack of IDL routines. Set the SYSTEM keyword to have the function also include any IDL system routines that are currently active within the call chain. Such system routines are present whenever an IDL system routine makes a nested call to the IDL interpreter to run a routine written in the IDL language. For example, WIDGET_CONTROL, WIDGET_EVENT, and any call to an IDL object method all involve such interpreter callbacks.

HELP, SAVE, SCOPE_LEVEL, SCOPE_VARFETCH, SCOPE_VARNAME

SCOPE_VARFETCH

The SCOPE_VARFETCH function returns variables outside the local scope of the currently running procedure or function. You can use it to examine or alter variables that are not otherwise visible, or to create new variables in other scopes.

In normal IDL operation, routines are not allowed to see variables outside their own scope. This restriction is a fundamental and important property of structured modular programming. Code that accesses non-local scope to alter variables within other active routines can quickly become extremely difficult to understand and maintain. For this reason, avoid using the IDL scope routines.

Despite this warning, there is an important class of application that requires the functionality provided by these routines. Programs, usually with graphical user interfaces, that import and export data from the callers' scope need to be able to access the user's data variables directly, and without requiring them to explicitly pass those variables to the application as parameters. The SCOPE_VARFETCH function is used to access those variables, and SCOPE_VARNAME is used to obtain the correct names with which to refer to them. SCOPE_LEVEL returns the scope level of the currently executing routine. The IDL iTools and the ENVI image processing software are examples of programs that need to be able to perform these operations.

Note ───

To use this routine successfully, you need to understand the information in "Altering Accessed Variables and Avoiding Unwanted Copies" on page 2175.

───

Interpreter Frames, Level, and Variable Scope

When IDL starts, it is implicitly running within a main program named $MAIN$. You can call procedures or functions from $MAIN$, and those routines can in turn call other routines. Each such routine invocation is represented internally by IDL using an *interpreter frame*, which IDL uses to maintain access to all variables known to that invocation of that routine. These variables can be local to the routine, parameters passed into the routine by its caller, or global variables (such as common block variables or heap variables). The set of variables visible within a given interpreter frame forms the *variable scope* of the corresponding routine. As routines are called, IDL pushes interpreter frames onto a call stack, and as those routines return, their frames are removed from the call stack. In the case of a recursive routine (a routine that calls itself), each invocation of the routine is given its own distinct and unshared frame.

The frames on the interpreter stack are numbered starting at 1 and increasing by 1 for each routine. This number is the *level* of the frame and, by implication, the scope that the frame accesses. The call stack always contains the frame for $MAIN$, which is the routine in which IDL execution starts and the only routine in IDL from which you cannot return. $MAIN$ is therefore always level 1. Any routine called from $MAIN$ will be at level 2, routines called from there will be level 3, and so forth.

Syntax

Result = SCOPE_VARFETCH(*VarName* [, COMMON=*string*] [, /ENTER]
   [, LEVEL=*value*] [, /REF_EXTRA])

Return Value

Returns the variable specified by *VarName* relative to the scope specified by the LEVEL keyword. The value returned by SCOPE_VARFETCH can be used by the caller to directly access, or alter, that variable.

Arguments

VarName

If the COMMON keyword is not set: *VarName* is the name of the variable to be returned from scope specified by the LEVEL keyword.

If the COMMON keyword is set: If *VarName* is of non-string type, it is the positional index of the variable to be returned within the specified common block. If *VarName* is a string, it is the name of the variable to be returned within the common block. In this case, the name corresponds to the name used for that common block variable in the first routine that defined the common block.

Note
   For more information, see "COMMON Variable Names" on page 2182.

Keywords

COMMON

Set this keyword to a string containing the name of a common block to cause SCOPE_VARFETCH to return a variable contained within the specified block. The variable to return is determined by the value of *VarName*, as discussed above.

The COMMON keyword cannot be used in conjunction with ENTER, LEVEL, or REF_EXTRA.

ENTER

By default, SCOPE_VARFETCH will return only variables that already exist in the specified scope. Attempts to access a nonexistent variable will cause IDL to issue an error and halt execution of the program. Set this keyword to alter this behavior. If ENTER is set and the desired variable does not exist in the specified scope, SCOPE_VARFETCH will create a new variable within that scope and return the new variable. This keyword can be used to export data into other scopes. Generally, the scope of the calling routine and that of $MAIN$ are most likely to be useful destinations.

The ENTER keyword cannot be used in conjunction with either COMMON or REF_EXTRA.

LEVEL

Set this keyword to an integer that specifies the scope within which the desired variable should be found. The level can be either an absolute value or relative to the current scope, as shown in the following table:

Value	Meaning
0	Level 0 always refers to the frame for the currently executing routine. This is the default value.
< 0	Negative levels are a relative specification and refer to the frames of active routines relative to the currently executing routine. Level -1 is the direct caller of the current routine, -2 is the caller of the caller of the current routine, and so forth. If you specify a level that is deeper than the current call stack, SCOPE_VARFETCH clips the value not to go past $MAIN$.
> 0	Positive levels are an absolute specification and refer directly to the specified frame. Level 1 is $MAIN$, level 2 is the routine called from $MAIN$, and so forth. If you specify a level that is past the currently executing routine, SCOPE_VARFETCH clips the value to the level of the current routine.

Table 21-2: LEVEL Values

The LEVEL keyword cannot be used in conjunction with the COMMON keyword.

REF_EXTRA

Set this keyword to cause SCOPE_VARFETCH to return the variable with the keyword name given by *VarName* from the _REF_EXTRA keywords within the specified level. Normally, a routine is not able to access the _REF_EXTRA keywords passed to it, and can pass them on only to other routines it calls. However, the SCOPE_VARFETCH REF_EXTRA keyword provides a mechanism by which a routine can examine its own _REF_EXTRA keywords.

Note ───

See "Keyword Inheritance" (Chapter 5, *Application Programming*) for more information.

───

The REF_EXTRA keyword cannot be used in conjunction with either COMMON or ENTER.

Altering Accessed Variables and Avoiding Unwanted Copies

The variable returned by SCOPE_VARFETCH can be used directly in IDL expressions to access the value of a variable from another scope. For example, the following statements access the value of a variable named mydata within the scope of the main program, $MAIN$:

```
PRINT, SCOPE_VARFETCH('mydata', LEVEL=1)
local_data = SCOPE_VARFETCH('mydata', LEVEL=1) + 100
```

Note that local_data contains only a copy of mydata, not a reference, so you can change local_data without affecting mydata.

If you do want to alter the value of a variable such as mydata, you must surround the call to SCOPE_VARFETCH with parentheses. For example, the following statements set mydata to a FINDGEN vector, and then increment it and add a constant to it. Finally, the value of the 5th element of the array is changed to 1000:

```
(SCOPE_VARFETCH('mydata', LEVEL=1)) = FINDGEN(100)
(SCOPE_VARFETCH('mydata', LEVEL=1))++
(SCOPE_VARFETCH('mydata', LEVEL=1)) += 57
(SCOPE_VARFETCH('mydata', LEVEL=1))[4] = 1000
```

To prevent IDL from making unwanted copies of the variable returned from SCOPE_VARFETCH, you should operate on the result of the SCOPE_VARFETCH function directly and not assign it to other variables.

For example, consider the following code, which prints the value of a variable `mydata` from the main program, $MAIN$:

```
temp = SCOPE_VARFETCH('mydata', LEVEL=1)
PRINT, temp
```

This code will produce the desired result, but at a higher than necessary cost. Assigning the variable returned by SCOPE_VARFETCH to the variable `temp` causes IDL to allocate new memory for `temp` and to make a copy of the `mydata` variable from $MAIN$ into `temp`. This process is slower, and will use twice as much memory as necessary, which can be a significant problem if the original `mydata` variable is very large. Instead, you should write the code this way:

```
PRINT, SCOPE_VARFETCH('mydata', LEVEL=1)
```

In cases where your code simply needs the value of a variable from another scope, assigning the result of SCOPE_VARFETCH to a local variable will use more memory and time, but is otherwise equivalent to using the direct result of the function. However, if your code wants to alter the original variable, using a local variable will produce the wrong answer. Consider the assignment code from above, modified to use a local variable:

```
temp = SCOPE_VARFETCH('mydata', LEVEL=1)
temp = FINDGEN(100)
temp++
temp += 57
temp[4] = 1000
```

This code alters the value of the local variable `temp`, but the original variable `mydata` remains unaltered. The first line makes a copy of `mydata`, the second line discards that copy, and the remaining lines operate on the local variable.

SCOPE_VARFETCH allows transparent access to variables from other scopes as long as you call it in every place where the variable is needed. Any assignment of the result from SCOPE_VARFETCH to another variable will create a copy. Altering the value of this copy will not alter the original.

Examples

Example 1: Creating a New Variable in the Main Level

The following creates a variable in the main program scope, named `newdata`. It sets the value using the DIST function, and then uses SURFACE to display it:

```
(SCOPE_VARFETCH('newdata', /ENTER, LEVEL=1)) = DIST(128)
SURFACE, SCOPE_VARFETCH('newdata', LEVEL=1)
```

Example 2: Using the REF_EXTRA Keyword

The following procedure will print the values of all keywords passed to it via the by-reference _REF_EXTRA keyword inheritance mechanism. In addition, it displays the name or names by which that variable is known in all currently active interpreter frames:

```
PRO example, _REF_EXTRA=ref
   FOR ridx = 0, N_ELEMENTS(ref)-1 DO BEGIN
      kw = ref[ridx]
      PRINT, 'Value of _REF_EXTRA keyword ', kw, ':'
      HELP, SCOPE_VARFETCH( kw, /REF_EXTRA )

      calls = SCOPE_TRACEBACK()
      FOR i=N_ELEMENTS(calls)-1, 0, -1 DO BEGIN
         name = SCOPE_VARNAME( SCOPE_VARFETCH(kw, /REF_EXTRA), $
            LEVEL=-i )
         cname = STREGEX( calls[i], '[^ ]*', /EXTRACT )
         PRINT, FORMAT='(%" _REF_EXTRA %s name in level %s: %s")', $
            kw, cname, name ? name : ''
      ENDFOR
   ENDFOR
END
```

Using this procedure, consider the output from the following IDL statements:

```
IDL> a = 1
IDL> b = 2
IDL> example, k_a=a, k_b=b
Value of _REF_EXTRA keyword K_A:
<No name>      INT      =      1
_REF_EXTRA K_A name in level EXAMPLE:
_REF_EXTRA K_A name in level $MAIN$: A
Value of _REF_EXTRA keyword K_B:
<No name>      INT      =      2
_REF_EXTRA K_B name in level EXAMPLE:
_REF_EXTRA K_B name in level $MAIN$: B
```

HELP, SCOPE_LEVEL, SCOPE_TRACEBACK, SCOPE_VARNAME,
ROUTINE_INFO

SCOPE_VARNAME

The SCOPE_VARNAME function returns the names of variables outside the local scope of the currently running procedure or function. Given a variable within the local scope of the currently running routine, SCOPE_VARNAME can supply the name under which it is known in an earlier routine in the current chain of active routines. Similarly, given the positional index of a common block variable, SCOPE_VARNAME can report the name that the variable was given in the routine that first defined that common block within the current IDL session.

In normal IDL operation, routines are not allowed to see variables outside their own scope. This restriction is a fundamental and important property of structured modular programming. Code that accesses non-local scope to alter variables within other active routines can quickly become extremely difficult to understand and maintain. For this reason, avoid using the IDL scope routines.

Despite this warning, there is an important class of application that requires the functionality provided by these routines. Programs, usually with graphical user interfaces, that import and export data from the callers' scope need to be able to access the user's data variables directly, and without requiring them to explicitly pass those variables to the application as parameters. The SCOPE_VARFETCH function is used to access those variables, and SCOPE_VARNAME is used to obtain the correct names with which to refer to them. SCOPE_LEVEL returns the scope level of the currently executing routine. The IDL iTools and the ENVI image processing software are examples of programs that need to be able to perform these operations.

Note ───

For more information, see "Interpreter Frames, Level, and Variable Scope" on page 2172.

───

Syntax

Result = SCOPE_VARNAME([*Var₁*[, *...*, *Varₙ*]] [, COMMON=*string*]
 [, COUNT=*variable*] [, LEVEL=*value*])

Return Value

The value returned by SCOPE_VARNAME depends on whether or not the COMMON keyword is set, and whether or not plain arguments are provided in the call. In all cases, the result is of a scalar string or a string array of variable names.

COMMON Keyword Not Set

Arguments Present

The result is a string array, with each element giving the name of the corresponding argument variable within the scope of the routine specified by the LEVEL keyword. If an argument does not exist within the target scope, a scalar null string is returned.

Arguments Not Present

The result is a string array containing the names of all known variables within the scope of the routine specified by the LEVEL keyword. If the specified scope has no variables, a scalar null string is returned.

See the description of the LEVEL keyword for additional information.

COMMON Keyword Set

Arguments Present

Each argument supplies the positional index of a variable within the common block. The result is a string array, with each element giving the name of the corresponding variable with that index within that common block.

Arguments Not Present

The result is a string array containing the names of all known variables defined within a specified common block, given in the order in which they exist in the block.

Arguments

Var$_i$

If the COMMON keyword is not set, the arguments to SCOPE_VARNAME are variables for which names are to be returned relative to the scope specified by the LEVEL keyword.

If the COMMON keyword is set, the arguments to SCOPE_VARNAME are integers, giving the positional index of variables within the specified common block for which names are to be returned.

Keywords

COMMON

Set this keyword to a string containing the name of a common block to cause SCOPE_VARNAME to return the names of variables contained within the specified block. If COMMON is set, the arguments to SCOPE_VARNAME are integers that give the positional index of variables within the specified common block for which names are to be returned.

Note ───

See "COMMON Variable Names" on page 2182 for more information on the names returned.

───

The COMMON keyword cannot be used in conjunction with the LEVEL keyword.

COUNT

Set this keyword to a named variable that will contain the number of elements returned in the array value returned by SCOPE_VARNAME. If SCOPE_VARNAME returns a null string, a 0 is returned. This circumstance will occur if there are no arguments, the COMMON keyword is not set, and the specified scope has no variables.

LEVEL

Set this keyword to an integer that specifies the scope within which the desired variable should be found. The level can be either an absolute value or relative to the current scope, as shown in the following table:

Value	Meaning
0	Level 0 always refers to the frame for the currently executing routine. This is the default value.

Table 21-3: LEVEL Values

Value	Meaning
< 0	Negative levels are a relative specification and refer to the frames of active routines relative to the currently executing routine. Level -1 is the direct caller of the current routine, -2 is the caller of the caller of the current routine, and so forth. If you specify a level that is deeper than the current call stack, SCOPE_VARNAME clips the value not to go past $MAIN$.
> 0	Positive levels are an absolute specification and refer directly to the specified frame. Level 1 is $MAIN$, level 2 is the routine called from $MAIN$, and so forth. If you specify a level that is past the currently executing routine, SCOPE_VARNAME clips the value to the level of the current routine.

Table 21-3: LEVEL Values (Continued)

The LEVEL keyword cannot be used in conjunction with the COMMON keyword.

COMMON Variable Names

Variables in IDL common blocks do not actually have names. Rather, IDL represents common blocks internally as an array of variables, and these variables are referenced by their positional index. Hence, the first variable is at position 0, the second at position 1, and so forth. When you specify a COMMON declaration in an IDL routine, you specify names to be used for these variables *within the scope of that routine*. In fact, different routines are allowed to use entirely different names to refer to a given variable. However, this can quickly become confusing, and most programmers use the same names in every case.

The first routine in which a COMMON block is defined is remembered by IDL as part of the state of that block. When another routine defines the same common block, it is allowed to omit the variable names. In this case, IDL uses the same names used in the original defining routine.

When the COMMON keyword is specified to the SCOPE_VARNAME function, the names returned are the names that were defined by the originally defining routine. Because good programming practice dictates that the same names be used everywhere, this result usually causes no confusion. However, in an environment where different names are in use in different scopes, you should be aware of the difference. For example, execute the following COMMON statement at the IDL prompt:

```
COMMON DOGS, poodle, spaniel, retriever
```

Now execute the following IDL routine:

```
PRO dogs

   COMMON DOGS, breed1, breed2, breed3

   PRINT, 'In this scope: ', SCOPE_VARNAME(breed1, breed2, breed3)
   PRINT, 'In $MAIN$: ', SCOPE_VARNAME(breed1, breed2, breed3, $
      LEVEL=-1)
   PRINT, 'In COMMON: ', SCOPE_VARNAME(COMMON='dogs', 0, 1, 2)
END
```

The following output is produced when procedure DOGS is called:

```
In this scope:  BREED1 BREED2 BREED3
In $MAIN$:  POODLE SPANIEL RETRIEVER
In COMMON:  POODLE SPANIEL RETRIEVER
```

If you do not specify the COMMON keyword, SCOPE_VARNAME translates the names of all variables, common or regular, relative to the specified scope. Hence, the variables in the DOGS common block appear as POODLE, SPANIEL, and RETRIEVER in $MAIN$, and as BREED1, BREED2, and BREED3 within procedure DOGS, despite the fact that they refer to the same variables. When you direct SCOPE_VARNAME to work from the common block instead of from an interpreter frame, the function uses the names from the scope of the routine that defined the common block, which in this example is $MAIN$.

Following this advice can minimize confusion:

- Use the same names for common block variables in all definitions. A convenient way to do so is to take advantage of the abbreviated form of the COMMON declaration, in which second and following declarations can leave off the variable names, and IDL will substitute the names from the initial definition.

- When possible, routines that use SCOPE_VARNAME should not specify the COMMON keyword. Instead, translate their names relative to the caller's scope.

Example

The following procedure outputs the names of all variables currently defined in the IDL main program, $MAIN$. It also prints the name of its argument, in its own scope, in that of its caller, and in that of $MAIN$.

```
PRO test_scope_varname, arg
```

```
PRINT, 'All variables in $MAIN$: ', SCOPE_VARNAME(LEVEL=1)
PRINT, 'Argument name in local scope: ', SCOPE_VARNAME(arg)
PRINT, 'Argument name in caller scope: ', SCOPE_VARNAME(arg, $
   LEVEL=-1)
PRINT, 'Argument name in $MAIN$ scope: ', SCOPE_VARNAME(arg, $
   LEVEL=1)
END
```

SEARCH2D

The SEARCH2D function finds "objects" or regions of similar data values within a two-dimensional array. Given a starting location and a range of values to search for, SEARCH2D finds all the cells within the array that are within the specified range and have some path of connectivity through these cells to the starting location. In addition to searching for cells within a global range of data values, SEARCH2D can also search for adjacent cells whose values deviate from their neighbors within specified tolerances.

This routine is written in the IDL language. Its source code can be found in the file search2d.pro in the lib subdirectory of the IDL distribution.

Syntax

Result = SEARCH2D(*Array*, *Xpos*, *Ypos*, *Min_Val*, *Max_Val* [, DECREASE=*value*, INCREASE=*value*[, LPF_BAND=*integer*{≥3}]] [, /DIAGONAL])

Return Value

SEARCH2D returns a longword array that contains a list of the array subscripts that define the located object or region. The original X and Y indices of the array subscripts returned by SEARCH2D can be found with the following IDL code:

```
index_y = Result / (SIZE(Array))[1]
index_x = Result - (index_y * (SIZE(Array))[1])
```

where *Result* is the array returned by SEARCH2D and *Array* is the original input array. The object within *Array* can be subscripted as *Array*(*Region*) or *Array*(index_x, index_y).

Arguments

Array

A two-dimensional array, of any data type, to be searched.

Xpos

The X coordinate (dimension 0 of *Array*) of the starting location.

Ypos

The Y coordinate (dimension 1 of *Array*) of the starting location.

Min_Val

The minimum data value for which to search. All array subscripts of all cells that are connected to the starting cell, and have a value between *Min_Val* and *Max_Val* (inclusive) are returned.

Max_Val

The maximum data value for which to search.

Keywords

DECREASE

This keyword and the INCREASE keyword allow you to compensate for changing intensities of data values within an object. An edge-enhanced copy of *Array* is made and compared to the orginal array if this keyword is set. The search is limited to pixels for which the edge-enhanced gradient value lies between the DECREASE and INCREASE values. When DECREASE or INCREASE is set, any adjacent cells are found if their corresponding data values in the edge enhanced array are greater than DECREASE and less than INCREASE. In any case, the adjacent cells will never be selected if their data values are not between *Min_Val* and *Max_Val*. The default for this keyword is 0.0 if INCREASE is specified.

INCREASE

This keyword and the DECREASE keyword allow you to compensate for changing intensities of data values within an object. An edge-enhanced copy of *Array* is made and compared to the orginal array if this keyword is set. The search is limited to pixels for which the edge-enhanced gradient value lies between the DECREASE and INCREASE values. When DECREASE or INCREASE is set, any adjacent cells are found if their corresponding data values in the edge enhanced array are greater than DECREASE and less than INCREASE. In any case, the adjacent cells will never be selected if their data values are not between *Min_Val* and *Max_Val*. The default for this keyword is 0.0 if DECREASE is specified.

LPF_BAND

Set this keyword to an integer value of 3 or greater to perform low-pass filtering on the edge-enhanced array. The value of LPF_BAND is used as the width of the smoothing window. This keyword is only effective when the DECREASE or INCREASE keywords are also specified. The default is no smoothing.

DIAGONAL

Set this keyword to cause SEARCH2D to find cells meeting the search criteria whose surrounding squares share a common corner. Normally, cells are considered adjacent only when squares surrounding the cells share a common edge. Setting this option requires more memory and execution time.

Examples

Find all the indices corresponding to an object in an image:

```
; Create an image with different valued regions:
img = FLTARR(512, 512)
img[3:503, 9:488] = 0.7
img[37:455, 18:438] = 0.5
img[144:388, 90:400] = 0.7
img[200:301, 1:255] = 1.0
img[155:193, 333:387] = 0.3
TVSCL, img    ;Display the image.

; Search for an object starting at (175, 300) whose data values are
; between (0.6) and (0.8):
region = SEARCH2D(img, 175, 300, 0.6, 0.8, /DIAGONAL)

; Scale the background cells into the range 0 to 127:
img = BYTSCL(img, TOP=127B)

; Highlight the object region by setting it to 255:
img[region] = 255B

; Display the array with the highlighted object in it:
TVSCL, img
```

SEARCH3D

SEARCH3D

The SEARCH3D function finds "objects" or regions of similar data values within a 3-D array of data. Given a starting location and a range of values to search for, SEARCH3D finds all the cells within the volume that are within the specified range of values and have some path of connectivity through these cells to the starting location. In addition to searching for cells within a global range of data values, SEARCH3D can also search for adjacent cells whose values deviate from their neighbors within specified tolerances.

This routine is written in the IDL language. Its source code can be found in the file `search3d.pro` in the `lib` subdirectory of the IDL distribution.

Syntax

Result = SEARCH3D(*Array*, *Xpos*, *Ypos*, *Zpos*, *Min_Val*, *Max_Val* [, /DECREASE , /INCREASE [, LPF_BAND=*integer*{≥3}]] [, /DIAGONAL])

Return Value

SEARCH3D returns a longword array that contains a list of the array subscripts that define the selected object or region. The original X and Y indices of the array subscripts returned by SEARCH3D can be found with the following IDL code:

```
S = SIZE(Array)
index_z = Result / (S[1] * S[2])
index_y = (Result - (index_z * S[1] * S[2])) / S[1]
index_x = (Result - (index_z * S[1] * S[2])) - (index_y * S[1])
```

where *Result* is the array returned by SEARCH3D and *Array* is the original input volume. The object within *Array* can be subscripted as `Array[Region]` or `Array[index_x, index_y, index_z]`.

Arguments

Array

The three-dimensional array, of any data type except string, to be searched.

Xpos

The X coordinate (dimension 0 or *Array*) of the starting location.

Ypos

The Y coordinate (dimension 1 of *Array*) of the starting location.

Zpos

The Z coordinate (dimension 2 of *Array*) of the starting location.

Min_Val

The minimum data value for which to search. All array subscripts of all the cells that are connected to the starting cell, and have a value between *Min_Val* and *Max_Val* (inclusive) are returned.

Max_Val

The maximum data value for which to search.

Keywords

DECREASE

This keyword and the INCREASE keyword allow you to compensate for changing intensities of data values within an object. An edge-enhanced copy of *Array* is made and compared to the orginal array if this keyword is set. When DECREASE or INCREASE is set, any adjacent cells are found if their corresponding data values in the edge enhanced array are greater than DECREASE and less than INCREASE. In any case, the adjacent cells will never be selected if their data values are not between *Min_Val* and *Max_Val*. The default for this keyword is 0.0 if INCREASE is specified.

INCREASE

This keyword and the DECREASE keyword allow you to compensate for changing intensities of data values within an object. An edge-enhanced copy of *Array* is made and compared to the orginal array if this keyword is set. When DECREASE or INCREASE is set, any adjacent cells are found if their corresponding data values in the edge enhanced array are greater than DECREASE and less than INCREASE. In any case, the adjacent cells will never be selected if their data values are not between *Min_Val* and *Max_Val*. The default for this keyword is 0.0 if DECREASE is specified.

LPF_BAND

Set this keyword to an integer value of 3 or greater to perform low-pass filtering on the edge-enhanced array. The value of LPF_BAND is used as the width of the smoothing window. This keyword is only effective when the DECREASE or INCREASE keywords are also specified. The default is no smoothing.

DIAGONAL

Set this keyword to cause SEARCH3D to find cells meeting the search criteria whose surrounding cubes share a common corner or edge. Normally, cells are considered adjacent only when cubes surrounding the cells share a common edge. Setting this option requires more memory and execution time.

Examples

Find all the indices corresponding to an object contained in a 3-D array:

```
; Create some data.
vol = RANDOMU(s, 40, 40, 40)
vol[3:13, 1:15, 17:33] = 1.3
vol[15:25, 5:25, 15:25] = 0.2
vol[5:30,17:38,7:28] = 1.3
vol[9:23, 16:27, 7:33] = 1.5

; Search for an object starting at (6, 22, 16) whose data values
; are between (1.2) and (1.4):
region = SEARCH3D(vol, 6, 22, 16, 1.2, 1.4, /DIAGONAL)

; Scale the background cells into the range 0 to 127:
vol = BYTSCL(vol, TOP=127B)

; Highlight the object region by setting it to 255:
vol[Region] = 255B
WINDOW, 0, XSIZE=640, YSIZE=512, RETAIN=2

; Set up a 3-D view:
CREATE_VIEW, XMAX=39, YMAX=39, ZMAX=39, AX=(-30), AZ=30, ZOOM=0.8

; Display the volume with the highlighted object in it:
TVSCL, PROJECT_VOL(vol, 64, 64, 40, DEPTH_Q=0.4)
```

SEM_CREATE

A *semaphore* is a software mechanism used to provide synchronization between multiple processes or between different threads of a single process. Often, semaphores are used to protect or restrict access to shared or key resources, such as shared memory segments.

The SEM_CREATE function creates a reference to a semaphore in the current IDL process. If the specified semaphore already exists in the system, a reference to the existing semaphore is created. If the semaphore does not exist, a new semaphore is created in the system and a reference to it is created in the current IDL process.

It is important to note that the semaphore itself is independent of any IDL process, but that the *reference* to the semaphore is unique to the IDL process that calls SEM_CREATE.

Syntax

Result = SEM_CREATE(*strName* [, /DESTROY_SEMAPHORE])

Return Value

The result is 1 (one) if the semaphore was created successfully or already exists in the system, or 0 (zero) if the semaphore does not exist but an error occurred during creation.

Arguments

strName

A scalar string containing the name associated with the semaphore. *strName* must conform to the rules for a valid file name on the target operating system.

Note
Semaphore names must be 24 characters or less on Macintosh platforms.

Tip
Use the IDL_VALIDNAME function to ensure that *strName* will be a valid semaphore name on all supported platforms.

Keywords

DESTROY_SEMAPHORE

Note

This keyword is ignored on Windows systems.

On Windows systems, a semaphore will be destroyed by a call to SEM_DELETE (in any IDL process) if no other processes have a reference to the semaphore.

Set the DESTROY_SEMAPHORE keyword to allow a call to SEM_DELETE in the current IDL process to destroy the semaphore, even if it was created in a different IDL process.

SEM_CREATE creates semaphores that persist in the operating system kernel until they are explicitly destroyed using the SEM_DELETE routine, or until the system is rebooted. A client program can access a semaphore, obtain or remove a lock, and then disconnect at any time. This is convenient in situations where the need for the semaphore is long lived, and programs that need it come and go. This behavior can create a problem, however, in that semaphores that are not explicitly destroyed can cause resource leaks in the operating system. It is important to properly destroy semaphores when they are no longer required.

The default behavior on UNIX systems is for IDL to destroy a semaphore when the SEM_DELETE routine is called *only* if the semaphore was created by the same IDL process — that is, if the call to SEM_CREATE in that IDL process created the semaphore itself and not just a reference to an existing semaphore. If the semaphore was created by another process, the call to SEM_DELETE destroys the *reference* to the semaphore within the current IDL process, but does not destroy the semaphore itself. This keyword alters the default behavior in the following way:

Value	Behavior
not set	The semaphore will only be destroyed by a call to SEM_DELETE in the same IDL process that *created* it. This is the default behavior.

Table 21-4: Behavior of the DESTROY_SEMAPHORE Keyword on UNIX Systems

Value	Behavior
1	The semaphore will be destroyed by a call to SEM_DELETE in the current IDL process, even if the call to SEM_CREATE only created a *reference* to the semaphore.
0	The semaphore will not be destroyed by a call to SEM_DELETE in the current IDL process, even if it was created by the current process.

*Table 21-4: Behavior of the DESTROY_SEMAPHORE Keyword
on UNIX Systems (Continued)*

Example

See SEM_LOCK for an example using this function.

Version History

6.3	Introduced

See Also

SEM_DELETE, SEM_LOCK, SEM_RELEASE, SHMMAP

SEM_DELETE

The SEM_DELETE procedure destroys the reference to the specified semaphore within the current IDL process. (Semaphores themselves are independent of any IDL process.)

SEM_DELETE behaves differently on UNIX and Windows systems:

UNIX Systems

On UNIX systems, a semaphore can exist even if no process has a reference to it. In addition to destroying the reference to the specified semaphore within the current IDL process, SEM_DELETE will schedule the semaphore itself for destruction in the following situations:

- If the semaphore itself was created by the current IDL process, and the DESTROY_SEMAPHORE keyword was *not* explicitly set equal to zero.

- If the reference to the semaphore was created in the current IDL process with the DESTROY_SEMAPHORE keyword set equal to one.

    See "DESTROY_SEMAPHORE" on page 2193 for additional information.

A semaphore that has been scheduled for destruction will be destroyed when the last process that has a reference to it destroys its reference.

Windows Systems

On Windows systems, a semaphore only exists as long as some process has a reference to it. SEM_DELETE simply destroys the reference to the specified semaphore.

Syntax

SEM_DELETE, *strName*

Arguments

strName

A scalar string containing the name associated with the semaphore. This is the name used when creating the semaphore with SEM_CREATE.

Note ───

Semaphore names must be 24 characters or less on Macintosh platforms.

───

Keywords

None

Example

See SEM_LOCK for an example using this function.

Version History

6.3	Introduced

See Also

SEM_CREATE, SEM_LOCK, SEM_RELEASE

SEM_LOCK

The SEM_LOCK function attempts to gain the lock on an existing semaphore (created by a call to the SEM_CREATE function) for the current IDL process. Once the lock has been obtained by one IDL process, other IDL processes will not be able to gain the lock until the SEM_RELEASE process is called within the IDL process that owns the lock.

Syntax

Result = SEM_LOCK(*strName*)

Return Value

The result is 1 (one) if the lock on the specified semaphore was successfully obtained, or 0 (zero) if the lock could not be obtained.

Arguments

strName

A scalar string containing the name associated with the semaphore. This is the name used when creating the semaphore with SEM_CREATE.

Note
Semaphore names must be 24 characters or less on Macintosh platforms.

Keywords

None

Example

This example illustrates the way semaphores operate using two independent IDL sessions on the same machine.

1. The user starts IDL session 1.

2. The user creates a semaphore using the following command:

```
status = SEM_CREATE('semaphore1')
```

This creates a semaphore called "semaphore1".

3. The user sets a lock on the semaphore using the following command:

    ```
    status = SEM_LOCK('semaphore1')
    ```

    If the lock is obtained, status is set equal to 1.

4. The user starts IDL session 2.

5. In session 2, the user creates a reference to the same semaphore created in session 1:

    ```
    status = SEM_CREATE('semaphore1')
    ```

6. In session 2, the user attempts to gain the lock on the semaphore with the following command:

    ```
    status = SEM_LOCK('semaphore1')
    ```

    Since the lock is owned by session 1, status is set equal to 0 (the lock was not obtained).

7. In session 1, the lock on the semaphore is released using the following command:

    ```
    SEM_RELEASE, 'semaphore1'
    ```

8. Once the lock has been released in session 1, the user once again attempts to gain the lock on the semaphore in session 2:

    ```
    status = SEM_LOCK('semaphore1')
    ```

    In this case, status is set equal to 1, indicating session 2 now has the lock

9. In session 1, attempting to retrieve the lock will result in failure, since session 2 has the lock on the semaphore.

10. In session 2, the user executes the following command:

    ```
    SEM_DELETE, 'semaphore1'
    ```

    This removes the reference to the semaphore in session 2, but does not destroy the actual semaphore in the operating system.

11. In session 1, the user executes the following command:

    ```
    SEM_DELETE, 'semaphore1'
    ```

    This removes both the reference to the semaphore in session 1 and the actual semaphore in the operating system, because:

    •   If the user is on a UNIX system, the semaphore itself is destroyed because it was created in session 1 and there are no other references it.

- If the user is on a Windows system, the semaphore itself is destroyed because session 1 has the last reference to it.

SEM_CREATE, SEM_DELETE, SEM_RELEASE

SEM_RELEASE

The SEM_RELEASE procedure releases the lock on the specified semaphore held by the current IDL process. If the current IDL process does not own the lock on the specified semaphore, this routine returns quietly.

Syntax

SEM_RELEASE, *strName*

Arguments

strName

The name associated with the semaphore. This is the name used when creating the semaphore (SEM_CREATE).

Note ───

Semaphore names must be 24 characters or less on Macintosh platforms.

SEM_CREATE, SEM_DELETE, SEM_LOCK

SET_PLOT

The SET_PLOT procedure sets the output device used by the IDL Direct Graphics procedures. Keyword parameters control how the color tables are transferred to the newly selected graphics device. SET_PLOT performs the following actions:

- It sets the read-only system variable !D to reflect the configuration of the new device.

- It sets the default color !P.COLOR to the maximum color index minus one or, in the case of devices with white backgrounds, such as PostScript, to 0 (black).

- If the COPY keyword is set, the device color tables are copied directly from IDL's internal color tables. If the new device's color tables contain more indices than those of the old device, the new device's tables are not completely filled.

- If the INTERPOLATE keyword is set, the internal color tables are interpolated to fill the range of the new device.

- It sets the clipping rectangle to the entire device surface.

Warning

After calling SET_PLOT to change graphics devices, the scaling contained in the axis structures !X, !Y, and !Z is invalid. Any routines that rely on data coordinates should not be called until a new data coordinate system has been established. Be careful when switching devices as the number of color indices frequently differs between devices. When in doubt, reload the color table of the new device explicitly.

Syntax

SET_PLOT, *Device* [, /COPY] [, /INTERPOLATE]

Arguments

Device

A scalar string containing the name of the device to use. The case of *Device* is ignored by IDL. See Appendix A, "IDL Direct Graphics Devices" for a list of device names.

Keywords

COPY

Set this keyword to copy the device's color table from the internal color table, preserving the current color mapping. The default is not to load the color table upon selection.

Warning ───

Unless this keyword is set, IDL's internal color tables will incorrectly reflect the state of the device's color tables until they are reloaded by TVLCT or the LOADCT procedure. Assuming that the previously-selected device's color table contains *M* elements, and the new device's color table contains *N* elements, then the minimum of *M* and *N* elements are loaded.

───

INTERPOLATE

Set this keyword to indicate that the current contents of the internal color table should be interpolated to cover the range of the newly-selected device. Otherwise, the internal color tables are not changed.

Examples

Change the IDL graphics device to PostScript by entering:

```
SET_PLOT, 'PS'
```

After changing the plotting device, all graphics commands are sent to that device until changed again by another use of the SET_PLOT routine.

Color Tables—Switching Between Devices

Use the SET_PLOT procedure to direct the graphics output to different devices. Because devices have differing capabilities and not all are capable of representing the same number of colors, the treatment of color tables when switching devices is somewhat tricky.

After selecting a new graphics output device, SET_PLOT will perform one of the following color-table actions depending upon which keyword parameters are specified:

- The default is to do nothing. The problem with this treatment is that the internal color tables incorrectly reflect the state of the device's color tables until TVLCT is called (usually via LOADCT).

- If the COPY keyword parameter is set, the internal color tables are copied into the device. This is straightforward if both devices have the same number of color indices. If the new device has more colors than the old device, some color indices will be invalid. If the new device has less colors than the old, not all the colors are saved. This is the preferred method if you are displaying graphics and each color index is explicitly loaded.

- When the INTERPOLATE keyword is set, the new device's table is loaded by interpolating the old color table to span the new number of color indices. This method works best when displaying images with continuous color ranges.

Version History

Original	Introduced

SET_SHADING

The SET_SHADING procedure modifies the light source shading parameters that affect the output of SHADE_SURF and POLYSHADE. Parameters can be changed to control the light-source direction, shading method, and the rejection of hidden surfaces. SET_SHADING first resets the shading parameters to their default values. (Defaults are Gouraud interpolation, light-source direction [0, 0, 1], and rejection of hidden faces enabled.) The parameter values specified in the call then overwrite the default values. To reset all parameters to their default values, simply call this procedure with no parameters.

Syntax

SET_SHADING [, /GOURAUD] [, LIGHT=*[x, y, z]*] [, /REJECT]
   [, VALUES=*[darkest, brightest]*]

Arguments

None.

Keywords

GOURAUD

This keyword controls the method of shading the surface polygons by the POLYSHADE procedure. The SHADE_SURF procedure always uses the Gouraud method. Set this keyword to a nonzero value (the default), to use Gouraud shading. Set this keyword to zero to shade each polygon with a constant intensity.

Gouraud shading interpolates intensities from each vertex along each edge. Then, when scan converting the polygons, the shading is interpolated along each scan line from the edge intensities. Gouraud shading is slower than constant shading but usually results in a more realistic appearance.

LIGHT

A three-element vector that specifies the direction of the light source. The default light source vector is [0,0,1], with the light rays parallel to the Z axis.

REJECT

Set this keyword (the default) to reject polygons as being hidden if their vertices are ordered in a clockwise direction as seen by the viewer. This keyword should always be set when rendering enclosed solids whose original vertex lists are in counterclockwise order. When rendering surfaces that are not closed or are not in counterclockwise order this keyword can be set to zero although shading anomalies at boundaries between visible and hidden surfaces may occur.

Note —————————————————————————————

The REJECT keyword has no effect on the output of SHADE_SURF—it is used only with solids.

VALUES

A two-element array that specifies the range of pixel values (color indices) to use. The first element is the color index for the darkest pixel. The second element is the color index for the brightest pixel. For example, to render a shaded surface with the darkest shade set to pixel value 100 and the brightest value set to 150, use the commands:

```
SET_SHADING, VALUES=[100, 150]
SHADE_SURF, dataset
```

Examples

Change the light source so that the light rays are parallel to the X axis:

```
SET_SHADING, LIGHT = [1, 0, 0]
```

Note —————————————————————————————

POLYSHADE, SHADE_SURF

SETENV

The SETENV procedure adds or changes an environment string in the process environment.

Syntax

SETENV, *Environment_Expression*

Arguments

Environment_Expression

A scalar string or string array containing one or more environment expressions to be added to the environment.

Keywords

None.

Examples

Change the current shell variable by entering:

```
SETENV,'SHELL=/bin/sh'
```

Make sure to eliminate any whitespace around the equal sign:

```
; This is an incorrect usage--there are spaces around the equal
; sign:
SETENV, 'VAR = H:\itt'

; This is correct--VAR is set to H:\itt:
SETENV, 'VAR=H:\itt'
```

GETENV

SFIT

The SFIT function determines a polynomial fit to a surface and returns a fitted array. The function fitted is:

$$f(x, y) = \sum kx_{j, i} \cdot x^i \cdot y^j$$

This routine is written in the IDL language. Its source code can be found in the file `sfit.pro` in the `lib` subdirectory of the IDL distribution.

Syntax

Result = SFIT(*Data*, *Degree* [, /IRREGULAR, KX=*variable*, /MAX_DEGREE])

Arguments

Data

The two-dimensional array of data to fit. The sizes of the dimensions might be unequal, as indicated by the IRREGULAR keyword.

Degree

The maximum degree of fit (in one dimension).

Keywords

IRREGULAR

If set, *Data* is a 3-by-*n* array containing the *x*, *y*, and *z* locations of n points sampled on the surface. If not set, *Data* is assumed to be sampled over a regular 2D grid, and should be in an *n*-by-*n* array, where the column and row subscripts implicitly contain the *x* and *y* location of the point.

KX

Set this keyword to a named variable that will contain the array of coefficients for a polynomial function of *x* and *y* to fit data. If MAX_DEGREE is not set, this parameter is returned as a *Degree*+1 by *Degree*+1 array. If MAX_DEGREE is set, this parameter is returned as a *Degree*+1 by (*Degree*+2)/2 element vector.

MAX_DEGREE

If set, *Degree* represents the maximum degree of the fitting polynomial of all dimensions combined, rather than the maximum degree of the polynomial in a single variable.

For example, if *Degree* is 2 and MAX_DEGREE is not set, then the terms returned are $[[k, y, y^2], [x, xy, xy^2], [x^2, x^2y, x^2y^2]]$. If MAX_DEGREE is set, the terms returned are in a vector, $[k, y, y^2, x, xy, x^2]$, in which no terms has a power higher than two in x and y combined, and the powers of y vary the fastest.

Examples

```
; Create a grid from zero to six radians in the X and Y directions:
X = (FINDGEN(61)/10) # REPLICATE(1,61)
Y = TRANSPOSE(X)

; Evaluate a function at each point:
F = -SIN(2*X) + COS(Y/2)

; Compute a sixth-degree polynomial fit to the function data:
result = SFIT(F, 6)

; Display the original function on the left and the fitted function
; on the right, using identical axis scaling:
WINDOW, XSIZE = 800, YSIZE = 400

; Set up side-by-side plots:
!P.MULTI = [0, 2, 1]

; Set background color to white:
!P.BACKGROUND = 255

; Set plot color to black:
!P.COLOR = 0

SURFACE, F, X, Y, ZRANGE = [-3, 3], ZSTYLE = 1
SURFACE, result, X, Y
```

The following figure shows the result of this example:

SHADE_SURF

The SHADE_SURF procedure creates a shaded-surface representation of a regular or nearly-regular gridded surface with shading from either a light source model or from a user-specified array of intensities. Displays are easily constructed depicting the surface elevation of a variable shaded as a function of itself or another variable. This procedure and its parameters are similar to SURFACE, but it renders the visible surface as a shaded image rather than a mesh. Given a regular or near-regular grid of elevations it produces a shaded-surface representation of the data with hidden surfaces removed.

The SET_SHADING procedure can be used to control the direction of the light source and other shading parameters.

If the graphics output device has scalable pixels (e.g., PostScript), the output image is scaled so that its largest dimension is less than or equal to 512 (unless the PIXELS keyword is set to some other value). This default resolution may not be high enough for some datasets. If your output looks jagged or "stair-stepped", try specifying a larger value with the PIXELS keyword.

When outputting to a device that prints black on a white background, (e.g., PostScript), pixels that contain the background color index of 0 are set to white.

Note
See "Polygon Shading Method" (Chapter 5, *Using IDL*) for information on how polygon shading is computed.

Restrictions

If the *(X, Y)* grid is not regular or nearly regular, errors in hidden line removal will occur. If the T3D keyword is set, the 3-D to 2-D transformation matrix contained in !P.T must project the Z axis to a line parallel to the device Y axis, or errors will occur. The SHADE_SURF_IRR procedure can be used to render many datasets that do not meet these requirements. Irregularly-gridded data can also be made interpolated to a regular grid using the TRIGRID and TRIANGULATE routines.

Syntax

SHADE_SURF, *Z* [, *X*, *Y*] [, AX=*degrees*] [, AZ=*degrees*] [, IMAGE=*variable*]
   [, MAX_VALUE=*value*] [, MIN_VALUE=*value*] [, PIXELS=*pixels*] [, /SAVE]
   [, SHADES=*array*] [, /XLOG] [, /YLOG]

Graphics Keywords: [, CHARSIZE=*value*] [, CHARTHICK=*integer*]
[, COLOR=*value*][, /DATA | , /DEVICE | , /NORMAL] [, FONT=*integer*]
[, /NODATA] [, POSITION=*[X$_0$, Y$_0$, X$_1$, Y$_1$]*] [, SUBTITLE=*string*] [, /T3D]
[, THICK=*value*] [, TICKLEN=*value*] [, TITLE=*string*]
[, {X | Y | Z}CHARSIZE=*value*]
[, {X | Y | Z}GRIDSTYLE=*integer*{0 to 5}]
[, {X | Y | Z}MARGIN=*[left, right]*]
[, {X | Y | Z}MINOR=*integer*]
[, {X | Y | Z}RANGE=*[min, max]*]
[, {X | Y | Z}STYLE=*value*]
[, {X | Y | Z}THICK=*value*]
[, {X | Y | Z}TICKFORMAT=*string*]
[, {X | Y | Z}TICKINTERVAL= *value*]
[, {X | Y | Z}TICKLAYOUT=*scalar*]
[, {X | Y | Z}TICKLEN=*value*]

[, {X | Y | Z}TICKUNITS=*string*]
[, {X | Y | Z}TICKV=*array*]
[, {X | Y | Z}TICK_GET=*variable*]
[, {X | Y | Z}TITLE=*string*]
[, ZVALUE=*value*{0 to 1}]

Arguments

Z

The two-dimensional array to be displayed. If *X* and *Y* are provided, the surface is plotted as a function of the (*X*, *Y*) locations specified by their contents. Otherwise, the surface is generated as a function of the array index of each element of *Z*.

This argument is converted to double-precision floating-point before plotting. Plots created with SHADE_SURF are limited to the range and precision of double-precision floating-point values.

X

A vector or two-dimensional array specifying the X coordinates of the grid. If this argument is a vector, each element of *X* specifies the X coordinate for a column of *Z* (e.g., X[0] specifies the X coordinate for Z[0,*]). If *X* is a two-dimensional array, each element of *X* specifies the X coordinate of the corresponding point in *Z* (X_{ij} specifies the X coordinate for Z_{ij}).

This argument is converted to double-precision floating-point before plotting.

Y

A vector or two-dimensional array specifying the Y coordinates of the grid. If this argument is a vector, each element of *Y* specifies the Y coordinate for a row of *Z* (e.g., Y[0] specifies the Y coordinate for Z[*,0]). If *Y* is a two-dimensional array, each element of *Y* specifies the Y coordinate of the corresponding point in *Z* (Y_{ij} specifies the Y coordinate for Z_{ij}).

This argument is converted to double-precision floating-point before plotting.

Keywords

AX

This keyword specifies the angle of rotation, about the X axis, in degrees towards the viewer. This keyword is effective only if !P.T3D and the T3D keyword are not set. If !P.T3D is set, the three-dimensional to two-dimensional transformation used by SURFACE is contained in the 4 by 4 array !P.T.

The surface represented by the two-dimensional array is first rotated, AZ (see below) degrees about the Z axis, then by AX degrees about the X axis, tilting the surface towards the viewer (AX > 0), or away from the viewer.

The AX and AZ keyword parameters default to +30 degrees if omitted.

The three-dimensional to two-dimensional transformation represented by AX and AZ, can be saved in !P.T by including the SAVE keyword.

AZ

This keyword specifies the counterclockwise angle of rotation about the Z axis. This keyword is effective only if !P.T3D is not set. The order of rotation is AZ first, then AX.

IMAGE

A named variable into which an image containing the shaded surface is stored. If this keyword is omitted, the image is displayed but not saved.

MAX_VALUE

The maximum value to be plotted. If this keyword is present, data values greater than the value of MAX_VALUE are treated as missing and are not plotted. Note that the IEEE floating-point value NaN is also treated as missing data. (See "Special

Floating-Point Values" (Chapter 8, *Application Programming*) for more information on IEEE floating-point values.)

MIN_VALUE

The minimum value to be plotted. If this keyword is present, data values less than the value of MIN_VALUE are treated as missing and are not plotted. Note that the IEEE floating-point value NaN is also treated as missing data. (See "Special Floating-Point Values" (Chapter 8, *Application Programming*) for more information on IEEE floating-point values.)

PIXELS

Set this keyword to a scalar value that specifies the maximum size of the image dimensions, in pixels. PIXELS only applies when the output device uses scalable pixels (e.g., the PostScript device). Use this keyword to increase the resolution of the output image if the default looks jagged or "stair-stepped".

SAVE

Set this keyword to save the 3-D to 2-D transformation matrix established by SHADE_SURF in the system variable field !P.T. Use this keyword when combining the output of SHADE_SURF with the output of other routines in the same plot.

SHADES

An array expression, of the same dimensions as *Z*, that contains the color index at each point. The shading of each pixel is interpolated from the surrounding SHADE values. If this parameter is omitted, light-source shading is used. For most displays, this parameter should be scaled into the range of bytes.

Warning

When using the SHADES keyword on True Color devices, we recommend that decomposed color support be turned off, by setting DECOMPOSED=0 for DEVICE.

XLOG

Set this keyword to specify a logarithmic X axis.

YLOG

Set this keyword to specify a logarithmic Y axis.

Graphics Keywords Accepted

See Appendix B, "Graphics Keywords" for the description of the following graphics and plotting keywords:

CHARSIZE, CHARTHICK, COLOR, DATA, DEVICE, FONT, NODATA, NORMAL, POSITION, SUBTITLE, T3D, THICK, TICKLEN, TITLE, [XYZ]CHARSIZE, [XYZ]GRIDSTYLE, [XYZ]MARGIN, [XYZ]MINOR, [XYZ]RANGE, [XYZ]STYLE, [XYZ]THICK, [XYZ]TICKFORMAT, [XYZ]TICKINTERVAL, [XYZ]TICKLAYOUT, [XYZ]TICKLEN, [XYZ]TICKNAME, [XYZ]TICKS, [XYZ]TICKUNITS, [XYZ]TICKV, [XYZ]TICK_GET, [XYZ]TITLE, ZVALUE

Examples

Note

Also see "Mapping an Image onto Elevation Data" (Chapter 3, *Image Processing in IDL*) for additional examples.

```
; Create a simple dataset:
D = DIST(40)
; Display the dataset as a light-source shaded surface:
SHADE_SURF, D, TITLE = 'Shaded Surface'
```

Instead of light-source shading, an array of the same size as the elevation dataset can be used to color the surface. This technique creates four-dimensional displays.

```
; Create an array of shades to use:
S = SIN(D)

; Now create a new shaded surface that uses the array of shading
; values instead of the light source:
SHADE_SURF, D, SHADES = BYTSCL(S)
```

Note that the BYTSCL function is used to scale S into the range of bytes.

The following figure illustrates the application of SHADE_SURF, with light-source shading, to the two-dimensional Gaussian (also drawn as a mesh in Figure 21-19). This figure was produced by the following statements.

```
; Create a 40-by-40 array in which each element
; is equal to the Euclidean distance from the center.
Z = SHIFT(DIST(40), 20, 20)
; Make Gaussian with a 1/e width of 10:
Z = EXP(-(Z/10)^2)
SHADE_SURF, Z
```

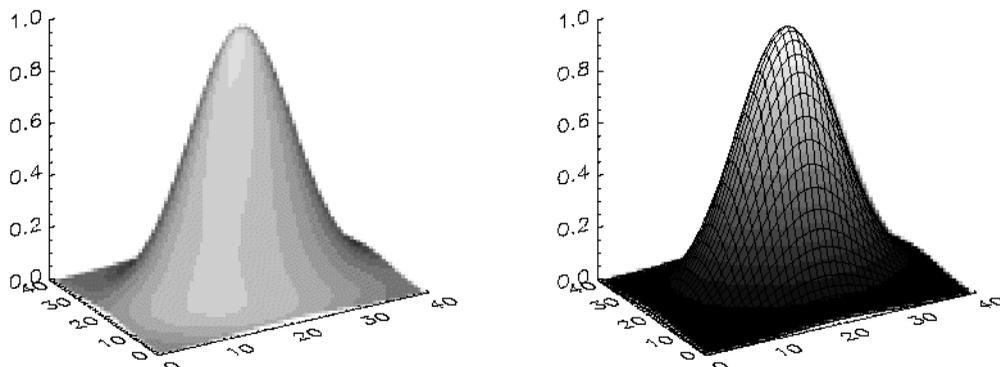
The right half of the following figure shows the use of an array of shades, which in this case is simply the surface elevation scaled into the range of bytes.


Figure 21-4: Shaded Representations of a Two-Dimensional Gaussian

The output of SURFACE is superimposed over the shaded image with the statements below.

```
; Show Gaussian with shades created by scaling
; elevation into the range of bytes.
SHADE_SURF, Z, SHADES=BYTSCL(Z, TOP = !D.TABLE_SIZE)
; Draw the mesh surface over the shaded figure.
; Suppress the axes:
SURFACE, Z, XST = 4, YST = 4, ZST = 4, /NOERASE
```

The next figure shows the Maroon Bells data as a light-source shaded surface (this data is also shown in the right half of Figure 21-20). It was produced by the following statements:

```
; Restore variables.
@cntour01
SHADE_SURF, elev, AZ=210, AX=45, XST=4, YST=4, ZST=4
```

The AX and AZ keywords specify the orientation. The axes are suppressed by the axis-style keyword parameters; as in this orientation, the axes are behind the surface.

SHADE_SURF_IRR

The SHADE_SURF_IRR procedure creates a shaded surface representation of an irregularly gridded elevation dataset.

The data must be representable as an array of quadrilaterals. This routine should be used when the (*X, Y, Z*) arrays are too irregular to be drawn by SHADE_SURF, but are still semi-regular.

This routine is written in the IDL language. Its source code can be found in the file `shade_surf_irr.pro` in the `lib` subdirectory of the IDL distribution.

Syntax

SHADE_SURF_IRR, *Z*, *X*, *Y* [, AX=*degrees*] [, AZ=*degrees*] [, IMAGE=*variable*]
    [, PLIST=*variable*] [, /T3D]

Arguments

Z

An *n* x *m* array of elevations.

X

An *n* x *m* array containing the *X* location of each *Z* value.

Y

An *n* x *m* array containing the *Y* location of each *Z* value.

The grid described by *X* and *Y* must consist of quadrilaterals, must be semi-regular, and must be in "clockwise" order. Clockwise ordering means that:

```
;for all j
x[i,j] <= x[i+1, j]
```

and

```
;for all i
y[i,j] <= y[i, j+1]
```

Keywords

AX

The angle of rotation about the X axis. The default is 30 degrees.

AZ

The angle of rotation about the Z axis. The default is 30 degrees.

IMAGE

Set this keyword to a named variable that will contain the resulting shaded surface image. The variable is returned as a byte array of the same size as the currently selected graphics device.

PLIST

Set this keyword to a named variable that will contain the polygon list on return. This feature is useful when you want to make a number of images from the same set of vertices and polygons.

T3D

Set this keyword to indicate that the generalized transformation matrix in !P.T is to be used (in which case the keyword values for AX and AZ are ignored)

Examples

The following example creates a semi-regular data set in the proper format at displays the resulting irregular surface.

```
; Create some elevation data:
z = DIST(10,10)*100.0
; Create arrays to hold X and Y data:
x = FLTARR(10,10) & y = FLTARR(10,10)
; Ensure that X and Y arrays are in "clockwise" order:
FOR i = 0,9 do x[0:9,i] = FINDGEN(10)
FOR j = 0,9 DO y[j,0:9] = FINDGEN(10)
; Make X and Y arrays irregular:
x = x + RANDOMU(seed,10,10)*0.49
y = y + RANDOMU(seed,10,10)*0.49
; Display the irregular surface:
SHADE_SURF_IRR, z, x, y
```

SHADE_SURF, TRIGRID

SHADE_VOLUME

Given a 3-D volume and a contour value, SHADE_VOLUME produces a list of vertices and polygons describing the contour surface. The polygons are described by a (3, *n*) array of vertices and a polygon list array that contains the vertices belonging to each polygon. Given a volume array with dimensions of (D_0, D_1, D_2), the resulting vertex coordinates range between 0 and $D_0 - 1$ in *x*, 0 and $D_1 - 1$ in y, and 0 and $D_2 - 1$ in *z*. This surface can then be displayed as a shaded surface by the POLYSHADE procedure. Shading is obtained from either a single light-source model or from user-specified values.

SHADE_VOLUME computes the polygons that describe a three dimensional contour surface. Each volume element (voxel) is visited to find the polygons formed by the intersections of the contour surface and the voxel edges. The method used by SHADE VOLUME is that of Klemp, McIrvin and Boyd, 1990: "PolyPaint—A Three-Dimensional Rendering Package," *American Meteorology Society Proceedings, Sixth International Conference on Interactive Information and Processing Systems*. This method is similar to the marching cubes algorithm described by Lorenson and Cline, 1987: "Marching Cubes: A High Resolution 3D Surface Construction Algorithm," *Computer Graphics 21*, 163-169.

This routine is limited to processing datasets that will fit in memory.

Syntax

SHADE_VOLUME, *Volume*, *Value*, *Vertex*, *Poly* [, /LOW] [, SHADES=*array*] [, /VERBOSE] [, XRANGE=*vector*] [, YRANGE=*vector*] [, ZRANGE=*vector*]

Arguments

Volume

A three-dimensional array that contains the dataset to be contoured. If the *Volume* array is dimensioned (D_0, D_1, D_2), the resulting vertex coordinates are as follows:

$0 < X < D_0 - 1; 0 < Y < D_1 - 1; 0 < Z < D_2 - 1.$

If floating-point NaN values are present in *Volume*, then SHADE_VOLUME may generate inconsistent surfaces and may return NaN values in the *Vertex* argument. The surfaces generated by SHADE_VOLUME may also vary across platforms if NaN data is present in the *Volume* parameter.

Value

The scalar contour value. This value specifies the constant-density surface (also called an isosurface) to be rendered.

Vertex

The name of a variable to receive the vertex array. On output, this variable is set to a (3, *n*) floating-point array, suitable for input to POLYSHADE.

Note ────────────────────────

If SHADE_VOLUME does not generate a surface because the surface defined by the *Value* argument does not cross any voxel edges in the *Volume* argument, SHADE_VOLUME sets the *Vertex* and *Poly* arguments to undefined variables.

────────────────────────────

Poly

A named variable to receive the polygon list, an *n*-element, longword array. This list describes the vertices of each polygon and is suitable for input to POLYSHADE. The vertices of each polygon are listed in counterclockwise order when observed from outside the surface. The vertex description of each polygon is a vector of the form: [*n*, i_0, i_1, ..., i_{n-1}] and the *Poly* array is the concatenation of the lists of each polygon. For example, when rendering a pyramid consisting of four triangles, *Poly* would contain 16 elements, made by concatenating four, four-element vectors of the form [3, V_0, V_1, V_2]. V_0, V_1, and V_2 are the indices of the vertices describing each triangle.

Note ────────────────────────

If SHADE_VOLUME does not generate a surface because the surface defined by the *Value* argument does not cross any voxel edges in the *Volume* argument, SHADE_VOLUME sets the *Vertex* and *Poly* arguments to undefined variables.

────────────────────────────

Keywords

LOW

Set this keyword to display the low side of the contour surface (i.e., the contour surfaces enclose high data values). If this keyword is omitted or is 0, the high side of the contour surface is displayed and the contour encloses low data values. If this parameter is incorrectly specified, errors in shading will result.

SHADES

An optional array, converted to byte type before use, that contains the user-specified shading color index for each voxel. This array must have the same dimensions as *Volume*. On completion, SHADE_VOLUME replaces this array with the interpolated shading for each vertex of the surface, contained in *Vertex*.

Warning

When using the SHADES keyword on True Color devices, we recommend that decomposed color support be turned off, by setting DECOMPOSED=0 for DEVICE.

VERBOSE

Set this keyword to print a message indicating the number of polygons and vertices that are produced.

XRANGE

An optional two-element vector that contains the limits, over the first dimension, of the sub-volume to be considered.

YRANGE

An optional two-element vector that contains the limits, over the second dimension, of the sub-volume to be considered.

ZRANGE

An optional two-element vector containing the limits, over the third dimension, of the sub-volume to be considered.

Examples

The following procedure shades a volume passed as a parameter. It uses the SCALE3 procedure to establish the viewing transformation. It then calls SHADE_VOLUME to produce the vertex and polygon lists, and POLYSHADE to draw the contour surface.

```
PRO SHOWVOLUME, vol, thresh, LOW = low
   ; Get the dimensions of the volume:
   s = SIZE(vol)
   ; Error, must be a 3-D array:
   IF s[0] NE 3 THEN MESSAGE, 'Error: vol must be a 3-D array'
   ; Establish the 3-D transformation and coordinate ranges:
```

```
       SCALE3, XRANGE=[0, S[1]], YRANGE=[0, S[2]], ZRANGE=[0, S[3]]
       ; Default = view high side of contour surface:
       IF N_ELEMENTS(low) EQ 0 THEN low = 0
       ; Produce vertices and polygons:
       SHADE_VOLUME, vol, thresh, v, p, LOW = low
       ; Produce image of surface and display:
       TV, POLYSHADE(v, p, /T3D)
    END
```

Creating an Isosurface Display

A common problem in data visualization is how to display a constant density surface
(also known as an isosurface), given a three-dimensional grid of density
measurements. In medical imaging, stacking a series of two-dimensional images
created by computed tomography or magnetic resonance creates a grid of density
measurements that can be contoured to display the surfaces of anatomical structures.
Atmospheric scientists create three-dimensional grids of water densities that can be
contoured at the proper density level to show the surface of clouds. It is relatively
easy to produce these surfaces using the SHADE_VOLUME procedure in
conjunction with the POLYSHADE function.

Cloud Example

This next figure, produced by the following IDL code, shows the three-dimensional contour surface of the precipitating region of a thunderstorm simulated by a three-dimensional cloud model.

Figure 21-6: A 3-dimensional Contour Surface of a Cloud's Precipitating Region

The data were provided by the National Center for Atmospheric Research. The original data are contained in an array called clouds, a (55, 55, 32) element floating-point array. Each array element contains the amount of water contained in the corresponding volume of air.

```
; Restore the data:
RESTORE, FILEPATH('clouds3d.dat', SUBDIR=['examples','data'])
; Create the contour surface polygons (v and p)
; at density 0.1, from clouds. Show the low side:
SHADE_VOLUME, clouds, 0.1, v, p, /LOW
; Obtain the dimensions of the volume.
; Variables S[1], S[2], and S[3] now contain
; the number of columns, rows, and slices in the volume:
s = SIZE(clouds)
```

```
; Use SCALE3 to establish the three-dimensional
; transformation matrix. Rotate 45 degrees about the z-axis:
SCALE3, XRANGE=[0,S[1]], YRANGE=[0,S[2]], $
   ZRANGE=[0,S[3]], AX=0, AZ=45
; Render and display the polygons:
TV, POLYSHADE(v, p, /T3D)
```

Example Code

If you prefer not to enter the IDL code by hand, run the batch file `clouds` with the following command at the IDL prompt:

```
@clouds
```

See if IDL does not find the referenced batch file.

Rotating the Shaded Volume

The shaded volume can be viewed from different rotations by changing the three-dimensional transformation matrix, !P.T, and calling POLYSHADE for each view. The following code displays 20 views of the volume, each separated by 18 degrees.

```
; Define number of views:
nframes = 20
FOR i = 0, nframes - 1 DO BEGIN & $
   ; Translate the center of the (0, 1) unit cube
   ; to (0,0) and rotate about the x-axis:
   T3D, TR=[-.5, -.5, -.5], ROT=[0, 360./NFRAMES, 0] & $
   ; Translate the center back to (0.5, 0.5, 0.5):
   T3D, TR = [.5, .5, .5] & $
   ; Show the surface:
   TV, POLYSHADE(v, p, /T3D) & $
ENDFOR
```

The animation rate of the above loop will not be very fast, especially with a larger number of polygons. Each image could be saved for rapid replay by writing it to a disk file. Given enough memory and/or display resources, the XINTERANIMATE procedure could be used to animate the views.

INTERVAL_VOLUME, IVOLUME, POLYSHADE, SHADE_SURF, XVOLUME

SHIFT

The SHIFT function shifts elements of vectors or arrays along any dimension by any number of elements. Positive shifts are to the right while left shifts are expressed as a negative number. All shifts are circular.

Elements shifted off one end wrap around and are shifted onto the other end. In the case of vectors the action of SHIFT can be expressed:

$$\text{Result}_{(i + s) \text{ modulation}} = \text{Array}_i \text{ for } (0 \le 1 < n)$$

where *s* is the amount of the shift, and *n* is the number of elements in the array.

Syntax

Result = SHIFT(*Array*, S_1, ..., S_n)

Return Value

The result is a vector or array of the same structure and type as *Array*.

Arguments

Array

The array to be shifted.

S_i

The shift parameters. The S_i arguments can be either a single array containing the shift parameters for each dimension, or a sequence of up to eight scalar shift values. For arrays of more than one dimension, the parameter S_n specifies the shift applied to the *n*-th dimension. S_1 specifies the shift along the first dimension and so on. If only one shift parameter is present and the parameter is an array, the array is treated as a vector (i.e., the array is treated as having one-dimensional subscripts).

A shift specification of 0 means that no shift is to be performed along that dimension.

Keywords

None

Examples

The following example demonstrates using SHIFT with a vector. by entering:

```
A = INDGEN(5)

; Print the original vector, the vector shifted one position to the
; right, and the vector shifted one position to the left:
PRINT, A, SHIFT(A, 1), SHIFT(A, -1)
```

IDL prints:

```
0   1   2   3   4
4   0   1   2   3
1   2   3   4   0
```

Notice how elements of the vector that shift off the end wrap around to the other end. This "wrap around" occurs when shifting arrays of any dimension.

Note

Also see "Shifting Images" (Chapter 2, *Image Processing in IDL*) for a more extensive example.

ISHFT

SHIFT_DIFF

The SHIFT_DIFF function applies a shift-difference filter to an image array to generate an array containing differences representing edges in the image.

Syntax

Result = SHIFT_DIFF (*Array* [, /ADD_BACK] [, BIAS=*value*] [, /CENTER]
 [, DIRECTION={0 | 1 | 2 | 3 | 4 | 5 | 6 | 7}] [, /EDGE_TRUNCATE]
 [, /EDGE_WRAP] [, /EDGE_ZERO] [, INVALID=*value*] [, MISSING=*value*]
 [, /NAN] [, /NORMALIZE])

Return Value

Returns the filtered array of the same dimensions as the input array. The input type is converted to an output type as follows:

Input	Output
BYTE	INT
INT	LONG
UINT	LONG
ULONG	LONG64
ULONG64	LONG64
Non-numeric types: not allowed	
All other types	Same as input type

Arguments

Array

A two-dimensional array of any numeric type containing the image.

Keywords

ADD_BACK

Set this keyword to cause the original input array to be added back to the difference array generated by the shift-difference operator. This is often useful for sharpening the image.

If the ADD_BACK keyword is set, the function returns an array of the same type and dimensions as the input array.

BIAS

Set this keyword to the bias offset to be added to each result value. If you have negative kernel values and a byte or unsigned integer input array, you can use this keyword to ensure that the result values are within the range of your data type.

Note

The same BIAS is added to each result value, regardless of any missing data as specified by the INVALID or NAN keywords. It is usually not appropriate to add the full BIAS if portions of the kernel were not applied due to missing data. In this case, you might want to use the NORMALIZE keyword instead.

CENTER

Set or omit this keyword to center the kernel over each array point. If CENTER is explicitly set to zero, the SHIFT_DIFF function works in the conventional mathematical sense.

Note

For the kernel to be centered, it must be symmetric about the point K[FLOOR(m/2)], where m is the number of elements in the kernel. In many signal and image processing applications, it is useful to center a symmetric kernel over the data, thereby aligning the result with the original array.

DIRECTION

An integer between 0 and 7 to specify the direction of the shift:

0	1	2
3	x	4
5	6	7

EDGE_TRUNCATE

Set this keyword to make SHIFT_DIFF compute the values of elements at the edge of *Array* (where *A* is an *n*-element vector, *K* is an *k*-element vector ($k \leq n$), and *S* is the scale factor) by repeating the subscripts of *Array* at the edge. For example, if CENTER is set to zero:

$$R_t = \frac{1}{S} \sum_{i=0}^{k} A_{((t-i)>0<(n-1))} K_i$$

where *n* is the number of elements in *Array*.

If none of the EDGE_* keywords are set, SHIFT_DIFF sets the values of *Result* to zero (or the value of BIAS) where the kernel extends beyond the edge.

EDGE_WRAP

Set this keyword to make SHIFT_DIFF compute the values of elements at the edge of *Array* (where *A* is an *n*-element vector, *K* is an *k*-element vector ($k \leq n$), and *S* is the scale factor) by "wrapping" the subscripts of *Array* at the edge. For example, if CENTER is set to zero:

$$R_t = \frac{1}{S} \sum_{i=0}^{k-1} A_{((t-i)\mod(n))} K_i$$

where n is the number of elements in *Array*.

If none of the EDGE_* keywords are set, SHIFT_DIFF sets the values of *Result* to zero (or the value of BIAS) where the kernel extends beyond the edge.

EDGE_ZERO

Set this keyword to make SHIFT_DIFF compute the values of elements at the edge of *Array* (where *A* is an *n*-element vector, *K* is an *k*-element vector ($k \leq n$), and *S* is the scale factor) as if the array were padded with zeroes. For example, if CENTER is set to zero:

$$
R_t = \begin{cases} \dfrac{1}{S} \displaystyle\sum_{i=0}^{k-1} A_{t-i}K_i & \text{if} \qquad t \geq k-1 \\[3ex] \dfrac{1}{S} \displaystyle\sum_{i=0}^{t} A_{t-i}K_i & \text{otherwise} \end{cases}
$$

If none of the EDGE_* keywords are set, SHIFT_DIFF sets the values of *Result* to zero (or the value of BIAS) where the kernel extends beyond the edge.

INVALID

Set this keyword to a scalar value of the same type as *Array* that should be used to indicate missing or invalid data within *Array*. Missing data are ignored when computing the convolution for neighboring elements. In *Result*, missing elements are replaced by the convolution of all other valid points within the kernel. If all points within the kernel are missing, the result at that point is given by the value of the MISSING keyword.

Tip ───

The INVALID keyword has the same effect as the NAN keyword, but is useful for byte or integer data which have missing values.

───

Note ──

The INVALID keyword uses a simple comparison to ignore values and should not be set to *NaN*. For floating-point data, you can use the INVALID and NAN keywords simultaneously to filter out both user-defined values and *NaN* or *Infinity* values.

───

MISSING

Set this keyword to the numeric value to return for elements that contain no valid points within the kernel. The default is zero for byte or integer input, and NaN for

floating-point input. This keyword is only used if the INVALID or NAN keyword is set.

NAN

Set this keyword to cause the routine to check for occurrences of the IEEE floating-point values *NaN* or *Infinity* in the input data. Elements with the value *NaN* or *Infinity* are treated as missing data. (See "Special Floating-Point Values" (Chapter 8, *Application Programming*) for more information on IEEE floating-point values.) Missing data are ignored when computing the convolution for neighboring elements. In the Result, missing elements are replaced by the convolution of all other valid points within the kernel. If all points within the kernel are missing, then the result at that point is given by the MISSING keyword.

Note ──

SHIFT_DIFF should never be called without the NAN keyword if the input array may possibly contain *NaN* or *Infinity* values.

──

NORMALIZE

Set this keyword to automatically compute a bias and apply it to the result values. If this keyword is set, the BIAS keyword is ignored.

For BYTE or UINT, the bias is defined as the sum of the absolute values of the negative *Kernel* values, multiplied by either (255/Scale) for BYTE or (65535/*Scale*) for UINT, where *Scale* is the computed scale factor. For all other types, the bias is zero.

Tip ───

If NORMALIZE is set and your input array has missing data (the INVALID or NAN keywords are set), for each result value the scale factor and bias are computed using only those kernel values that contributed to that result value. This ensures that all result values are comparable in magnitude, regardless of any missing data.

──

Thread Pool Keywords

This routine is written to make use of IDL's *thread pool*, which can increase execution speed on systems with multiple CPUs. The values stored in the !CPU system variable control whether IDL uses the thread pool for a given computation. In addition, you can use the thread pool keywords TPOOL_MAX_ELTS,

TPOOL_MIN_ELTS, and TPOOL_NOTHREAD to override the defaults established by !CPU for a single invocation of this routine. See Appendix C, "Thread Pool Keywords" for details.

Examples

This example produces an image with black gradients on the left and white gradients on the right.

```
TVSCL, SHIFT_DIFF(DIST(200), DIRECTION=4)
```

Note ──

Also see "Detecting Edges" (Chapter 8, *Image Processing in IDL*).

SHMDEBUG

The SHMDEBUG function enables a debugging mode in which IDL prints an informational message (including a traceback) every time a variable created with the SHMVAR function loses its reference to the underlying memory segment created by. There are many reasons why a such a variable might lose its reference; some reasons have to do with the internal implementation of the IDL interpreter and are not obvious or visible to the IDL user.

Note

The SHMDEBUG debugging mode should be used for problem solving only, and should not be part of production code.

Syntax

Result = SHMDEBUG(*Enable*)

Return Value

SHMDEBUG returns the previous setting of the debugging state.

Arguments

Enable

Set this argument equal to a non-zero value to enable debugging, or to zero to disable debugging.

Keywords

None.

Examples

Create a memory segment, tie a variable to it, enable debugging, and then cause the variable to lose the reference:

```
old_debug = SHMDEBUG(1) ; Enable debug mode
SHMMAP, 'A', 100 ; 100 element floating vector
z = SHMVAR('A') ; Variable tied to segment
z[0] = FINDGEN(100) ; Does not lose reference
```

```
z = FINDGEN(100) ; Loses reference
% Variable released shared memory segment: A
% Released at: $MAIN$
```

The assignment `z[0] = FINDGEN(100)` explicitly uses subscripting to assign the
FINDGEN value to the array. Under normal circumstances, using subscripting in this
way on the left hand side of an assignment is inefficient and not recommended. In this
case, however, it has the desirable side effect of causing the variable Z to maintain its
connection to its existing underlying memory. In contrast, the second (normally more
desirable) assignment without the subscript causes IDL to allocate different memory
for the variable Z, with the side effect of losing the connection to the shared memory
segment.

SHMMAP, SHMUNMAP, SHMVAR

SHMMAP

The SHMMAP procedure maps anonymous shared memory, or local disk files, into the memory address space of the currently executing IDL process. Mapped memory segments are associated with an IDL array specified by the user as part of the call to SHMMAP. The type and dimensions of the specified array determine the length of the memory segment.

The array can be of any type except pointer, object reference, or string. (Structure types are allowed as long as they do not contain any pointers, object references, or strings.) By default, the array type is single-precision floating-point; other types can be chosen by specifying the appropriate keyword.

Once such a memory segment exists, it can be tied to an actual IDL variable using the SHMVAR function, or unmapped using SHMUNMAP.

Why Use Mapped Memory?

- Shared memory is often used for interprocess communication. Any process that has a shared memory segment mapped into its address space is able to "see" any changes made by any other process that has access to the same segment. Shared memory is the default for SHMMAP, unless the FILENAME keyword is specified.

- Memory-mapped files allow you to treat the contents of a local disk file as if it were simple memory. Reads and writes to such memory are automatically written to the file by the operating system using its standard virtual memory mechanisms. Access to mapped files has the potential to be faster than standard Input/Output using Read/Write system calls because it does not go through the expensive system call interface, and because it does not require the operating system to copy data between user and kernel memory buffers when performing the I/O. However, it is not as general or flexible as the standard I/O mechanisms, and is therefore not a replacement for them.

Warning
Unlike most IDL functionality, incorrect use of SHMMAP can corrupt or even crash your IDL process. Proper use of these low level operating system features requires systems programming experience, and is not recommended for those without such experience. You should be familiar with the memory and file mapping features of your operating system and the terminology used to describe such features.

SHMMAP uses the facilities of the underlying operating system. Any of several alternatives may be used, as described in "Types Of Memory Segments" on page 2246. SHMMAP uses the following rules, in the specified order, to determine which method to use:

1. If the FILENAME keyword is present, SHMMAP creates a memory mapped file segment.

2. If the SYSV keyword is used under UNIX, a System V shared memory segment is created or attached. Use of the SYSV keyword under Windows will cause an error to be issued.

3. If none of the above options are specified, SHMMAP creates an anonymous shared memory segment. Under UNIX, this is done with Posix shared memory. Under Windows, the CreateFileMapping() system call is used.

Syntax

SHMMAP [, *SegmentName*] [, D_1, ..., D_8] [, /BYTE] [, /COMPLEX]
    [, /DCOMPLEX] [, /DESTROY_SEGMENT] [, DIMENSION=*value*]
    [, /DOUBLE] [, FILENAME=*value*] [, /FLOAT] [, GET_NAME=*value*]
    [, GET_OS_HANDLE=*value*] [, /INTEGER] [, /L64] [, /LONG]
    [, OFFSET=*value*] [, OS_HANDLE=*value*] [, /PRIVATE] [, SIZE=*value*]
    [, /SYSV] [, TEMPLATE=*value*] [, TYPE=*value*] [, /UINT] [, /UL64]
    [, /ULONG]

Arguments

SegmentName

A scalar string supplying the name by which IDL will refer to the shared memory segment. The *SegmentName* string must be constructed according to the same rules as an IDL variable name; see "Variable Names" (Chapter 13, *Application Programming*) for details. This name is only used by IDL, and does not necessarily correspond to the name used for the shared memory segment by the underlying operating system. See the discussion of the OS_HANDLE keyword for more information on the underlying operating system name. If *SegmentName* is not specified, IDL will generate a unique name. The *SegmentName* can be obtained using the GET_NAME keyword.

D_i

The dimensions of the result. The D_i arguments can be either a single array containing the dimensions or a sequence of scalar dimensions. Up to eight dimensions can be specified.

Keywords

BYTE

Set this keyword to specify that the memory segment should be treated as a byte array.

COMPLEX

Set this keyword to specify that the memory segment should be treated as a complex, single-precision floating-point array.

DCOMPLEX

Set this keyword to specify that the memory segment should be treated as a complex, double-precision floating-point array.

DESTROY_SEGMENT

The UNIX anonymous shared memory mechanisms (Posix shm_open() and System V shmget()) create shared memory segments that are not removed from the operating system kernel until explicitly destroyed (or the system is rebooted). At any time, a client program can attach to such an existing segment, read or write to it, and then detach. This can be convenient in situations where the need for the shared memory is long lived, and programs that need it come and go. It also can create a problem, however, in that shared memory segments that are not explicitly destroyed can cause memory leaks in the operating system. Hence, it is important to properly destroy such segments when they are no longer required.

For UNIX anonymous shared memory (Posix or System V), the default behavior is for IDL to destroy any shared memory segments it created when the segments are unmapped, and not to destroy segments it did not create. The DESTROY_SEGMENT keyword is used to override this default: set DESTROY_SEGMENT to 1 (one) to indicate that IDL should destroy the segment when it is unmapped, or 0 (zero) to indicate that it should not destroy it. All such destruction occurs when the segment is unmapped (via the SHMUNMAP procedure) and not during the call to SHMMAP.

The DESTROY_SEGMENT keyword is ignored under the Windows operating system. Under UNIX, it is ignored for mapped files.

DIMENSION

Set this keyword equal to a vector of 1 to 8 elements specifying the dimensions of the result. Setting this keyword is equivalent to specifying an array via the *D* argument.

DOUBLE

Set this keyword to specify that the memory segment should be treated as a double-precision floating-point array.

FILENAME

By default, SHMMAP maps anonymous shared memory. Set the FILENAME keyword equal to a string containing the path name of a file to be mapped to create a memory-mapped file. A shared mapped file can serve as shared memory between unrelated processes. The primary difference between anonymous shared memory and mapped files is that mapped files require a file of the specified size to exist in the filesystem, whereas anonymous shared memory has no user-visible representation in the filesystem.

By default, files are mapped as shared, meaning that all processes that map the file will see any changes made. All changes are written back to the file by the operating system and become permanent. You must have write access to the file in order to map it as shared.

To change the default behavior, set the PRIVATE keyword. When a file is mapped privately, changes made to the file are *not* written back to the file by the operating system, and are not visible to any other processes. You do not need write access to a file in order to map it privately — read access is sufficient.

Note

The non-private form of file mapping corresponds to the MAP_SHARED flag to the UNIX mmap() function, or the PAGE_READWRITE to the Windows CreateFileMapping() system call.

FLOAT

Set this keyword to specify that the memory segment should be treated as a single-precision floating-point array.

GET_NAME

If *SegmentName* is not specified in a call to SHMMAP, IDL automatically generates a name. Set this keyword equal to a named variable that will receive the name assigned by IDL to the memory segment.

GET_OS_HANDLE

Set this keyword equal to a named variable that will receive the operating system name (or *handle*) for the memory segment. The meaning of the operating system handle depends on both the operating system and the type of memory segment used. See the description of the OS_HANDLE keyword for details.

INTEGER

Set this keyword to specify that the memory segment should be treated as an integer array.

L64

Set this keyword to specify that the memory segment should be treated as a 64-bit integer array.

LONG

Set this keyword to specify that the memory segment should be treated as a longword integer array.

OFFSET

If present and non-zero, this keyword specifies an offset (in bytes) from the start of the shared memory segment or memory mapped file that will be used as the base address for the IDL array associated with the memory segment.

Note ──

Most computer hardware is not able to access arbitrary data types at arbitrary memory addresses. Data must be properly aligned for its type or the program will crash with an alignment error (often called a *bus error*) when the data is accessed. The specific rules differ between machines, but in many cases the address of a data object must be evenly divisible by the size of that object. IDL will issue an error if you specify an offset that is not valid for the array specified.

──

Note ──

The actual memory mapping primitives provided by the underlying operating system require such offsets to be integer multiples of the virtual memory pagesize (sometimes called the *allocation granularity*) for the system. This value is typically a power of two such as 8K or 64K. In contrast, IDL allows arbitrary offsets as long as they satisfy the alignment constraints of the data type. This is implemented by

mapping the page that contains the specified offset, and then adjusting the memory address to point at the specified byte within that page. In rounding your offset request back to the nearest page boundary, IDL may map slightly more memory than your request would seem to require, but never more than a single page.

OS_HANDLE

Set this keyword equal to the name (or *handle*) used by the underlying operating system for the memory segment. If you do not specify the OS_HANDLE keyword, SHMMAP will under some circumstances provide a default value. The specific meaning and syntax of the OS_HANDLE depends on both the operating system and the form of memory used. See the following sections for operating-system specific behavior, and "Types Of Memory Segments" on page 2246 for behavior differences based on the form of memory used.

Posix (UNIX) Shared Memory

Use the OS_HANDLE keyword to supply a string value containing the system global name of the shared memory segment. Such names are expected to start with a slash (/) character, and not to contain any other slash characters. You can think of this as mimicking the syntax for a file in the root directory of the system, although no such file is created. See your system documentation for the shm_open() system call for specific details. If you do not supply the OS_HANDLE keyword, SHMMAP will create one for you by prepending a slash character to the value given by the *SegmentName* argument.

UNIX System V Shared Memory

Use the OS_HANDLE keyword to supply an integer value containing the system global identifier of an existing shared memory segment to attach to the process. If you do not supply the OS_HANDLE keyword, then SHMMAP creates a new memory segment. The identifier for this segment is available via the GET_OS_HANDLE keyword.

Windows Anonymous Shared Memory

Use the OS_HANDLE keyword to supply a global system name for the mapping object underlying the anonymous shared memory. If the OS_HANDLE keyword is not specified, SHMMAP uses the value of the *SegmentName* argument.

UNIX Memory Mapped Files

The OS_HANDLE keyword has no meaning for UNIX memory mapped files and is quietly ignored.

Windows Memory Mapped Files

Use the OS_HANDLE keyword to supply a global system name for the mapping object underlying the mapped file. Use of the OS_HANDLE will ensure that every process accessing the shared file will see a coherent view of its contents, and is thus recommended for Windows memory mapped files. However, if you do not supply the OS_HANDLE handle keyword for a memory mapped file, no global name is passed to the Windows operating system, and a unique mapping object for the file will be created.

PRIVATE

Set this keyword to specify that a private file mapping is required. In a private file mapping, any changes written to the mapped memory are visible only to the process that makes them, and such changes are not written back to the file. This keyword is ignored unless the FILENAME keyword is also present.

Mapping a file as shared requires that you have write access to the file, but a private mapping requires only read access. Use PRIVATE to map files for which you do not have write access, or when you want to ensure that the original file will not be altered by your process.

Note ──

Under UNIX, the private form of file mapping corresponds to the MAP_PRIVATE flag to the mmap() system call. Under Windows, the non-private form corresponds to the PAGE_WRITECOPY option to the Windows CreateFileMapping() system call. When your process alters data within a page of privately mapped memory, the operating system performs a *copy on write* operation in which the contents of that page are copied to a new memory page visible only to your process. This private memory usually comes from anonymous swap space or the system pagefile. Hence, private mapped files require more system resources than shared mappings.

It is possible for some processes to use private mappings to a given file while others use a public mapping to the same file. In such cases, the private mappings will see changes made by the public processes up until the moment the private process itself makes a change to the page. The pagesize granularity and timing issues between such processes can make such scenarios very difficult to control. Avoid combining simultaneous shared and private mappings to the same file.

───

SIZE

Set this keyword equal to a `size` vector specifying the type and dimensions to be associated with the memory segment. The format of a size vector is given in the description of the SIZE function.

SYSV

Under UNIX, the default form of anonymous memory is Posix shared memory, (`shm_open()` and `shm_unlink()`). Specify the SYSV keyword to use System V shared memory (`shmget()`, `shmctl()`, and `shmdt()`) instead. On systems where it is available, Posix shared memory is more flexible and has fewer limitations. System V shared memory is available on all UNIX implementations, and serves as an alternative when Posix memory does not exist, or when interfacing to exiting non-IDL software that uses System V shared memory. See "Types Of Memory Segments" on page 2246 for a full discussion.

TEMPLATE

Set this keyword equal to a variable of the type and dimensions to be associated with the memory segment.

TYPE

Set this keyword to specify the type code for the memory segment. See the description of the SIZE function for a list of IDL type codes.

UINT

Set this keyword to specify that the memory segment should be treated as an unsigned integer array.

ULONG

Set this keyword to specify that the memory segment should be treated as an unsigned longword integer array.

UL64

Set this keyword to specify that the memory segment should be treated as an unsigned 64-bit integer array.

Types Of Memory Segments

SHMMAP is a relatively direct interface to the shared memory and file mapping primitives provided by the underlying operating system. The SHMMAP interface attempts to minimize the differences between these primitives, and for simple shared memory use, it may not be necessary to fully understand the underlying mechanisms. For most purposes, however, it is necessary to understand the operating system primitives in order to understand how to use SHMMAP properly.

UNIX

In modern UNIX systems, the `mmap()` system call forms the primary basis for both file mapping and anonymous shared memory. The existence of System V shared memory, which is an older form of anonymous shared memory, adds some complexity to the situation.

UNIX Memory Mapped Files

To memory map a file under UNIX, you open the file using the `open()` system call, and then map it using `mmap()`. Once the file is mapped, you can close the file, and the mapping remains in place until explicitly unmapped, or until the process exits or calls `exec()` to run a different program.

If more than one process maps a file at the same time using the `MAP_SHARED` flag to `mmap()`, then those processes will be able to see each others' changes. Hence, memory mapped files are one form of shared memory. Although the requirement for a scratch file large enough to satisfy the mapping is inconvenient, limitations in System V shared memory have led many UNIX programmers to use memory mapped files in this way.

UNIX System V Shared Memory

Anonymous shared memory has traditionally been implemented via an API commonly referred to as System V IPC. The `shmget()` function is used to create a shared memory segment. The caller does not name the segment. Instead, the operating system assigns each such segment a unique integer ID when it is created. Once a shared memory segment exists, the `shmdt()` function can be used to map it into the address space of any process that knows the identifier. This segment persists in the OS kernel until it is explicitly destroyed via the `shmctl()` function, or until the system is rebooted. This is true even if there are no processes currently mapped to the segment. This can be convenient in situations where the need for the shared memory is long lived, and programs that need it come and go. It also can create a problem, however, since shared memory segments that are not explicitly destroyed

can cause memory leaks in the operating system. Hence, it is important to properly destroy such segments when they are no longer required.

System V shared memory has been part of UNIX for a long time. It is available on all UNIX platforms, and there is a large amount of existing code that uses it. There are, however, some limitations on its utility:

- Many systems place extremely small limits on the size allowed for such memory segments. These limits are often kernel parameters that can be adjusted by the system administrator. The details are highly system dependent. Consult your system documentation for details.

- The caller does not have the option of naming the shared memory segment. Instead, the operating system assigns an arbitrary number, which means that processes that want to map such a segment have to have a mechanism for finding the correct identifier to use before they can proceed. This, in turn, requires some additional form of interprocess communication.

Preferably, use Posix shared memory instead of System V shared memory for those platforms that support it and with applications that can use it. Under UNIX, SHMMAP defaults to Posix shared memory to implement anonymous shared memory. To use System V shared memory, you must specify the SYSV keyword. See the Examples section below for an example of using System V shared memory.

Posix Shared Memory

Posix shared memory is a newer alternative for anonymous shared memory. It is part of the UNIX98 standard, and although not all current UNIX systems support it, it will in time be available on all UNIX systems. Posix shared memory uses the shm_open() and ftruncate() system calls to create a memory segment that can be accessed via a file descriptor. This descriptor is then used with the mmap() system call to map the memory segment in the usual manner. The primary difference between this, and simply using mmap() on a scratch file to implement shared memory is that no scratch file is required (the disk space comes from the system swapspace). As with System V shared memory, Posix shared memory segments exist in the operating system until explicitly destroyed (using the shm_unlink() system call). Unlike System V shared memory, but like all the other forms, Posix shared memory allows the caller to supply the name of the segment. This simplifies the situation in which multiple processes want to map the same segment. One of them creates it, and the others simply map it, all of them using the same name to reference it.

Posix shared memory is the default for SHMMAP on all UNIX platforms — even those that do not yet support it. (To use System V shared memory instead, you must

specify the SYSV keyword.) There are several reasons for making Posix shared memory the default for all UNIX platforms:

- To remain UNIX compliant, all platforms will have to implement the UNIX98 standard. Most have, and the remainder are currently in the process of doing so. We believe that Posix shared memory will be available on all UNIX systems very soon.

- Having different defaults for different UNIX platforms would cause unnecessary confusion; the confusion would only increase as platforms added support for Posix shared memory, causing the platform's SHMMAP default to change with later IDL releases. Since in most cases you need to know the underlying mechanism in use, the default should be easy to determine, and should not change over time.

- In the long run, it is desirable for the best option to be the default.

Microsoft Windows

Under Microsoft Windows, the `CreateFileMapping()` system call forms the basis for shared memory as well as memory mapped files. To map a file, you open the file and then pass the handle for that file to `CreateFileMapping()`. To create a region of anonymous mapped memory instead of a mapped file, you pass a special file handle (`0xffffffff`) to `CreateFileMapping()`. In this case, the disk space used to back the shared memory is taken from the system pagefile. `CreateFileMapping()` accepts an optional parameter (`lpname`), which if present, is used to give the resulting memory mapping object a system global name. If you specify such a name, and a mapping object with that name already exists, you will receive a handle to the existing mapping object. Otherwise, `CreateFileMapping()` creates a new mapping object for the file. Hence, to create anonymous (no file) shared memory between unrelated processes, IDL calls `CreateFileMapping()` with the special `0xffffffff` file handle, and specifies a global name for it.

A global name (supplied via the OS_HANDLE keyword) is the only name by which an anonymous shared memory segment can be referenced within the system. Global names are not required for memory mapped files, because each process can create a separate mapping object and use it to refer to the same file. Although this does allow the unrelated processes to see each others' changes, their views of the file will not be *coherent* (that is, identical). With coherent access, all processes see exactly the same memory at exactly the same time because they are all mapping the same physical page of memory. To get coherent access to a memory mapped file, every process should specify the OS_HANDLE keyword to ensure that they use the same mapping object. Coherence is only an issue when the contents of the file are altered; when using read-only access to a mapped file, you need not be concerned with this issue.

The Windows operating system automatically destroys a mapping object when the last process with an open handle to it closes that handle. Destruction of the mapping object may be the result of an explicit call to `CloseHandle()`, or may involve an implicit close that happens when the process exits. This differs from the UNIX behavior for anonymous shared memory, and consequently the benefits and disadvantages are reversed. The advantage is that it is not possible to forget to destroy a mapping object, and end up with the operating system holding memory that is no longer useful, but which cannot be freed. On the other hand, you must ensure that at least one open handle to the object is open at all times, or the system might free an object that you intended to use again.

Note

Under Windows, when attaching to an existing memory object by providing the global segment name, IDL is not able to verify that the memory segment returned by the operating system is large enough to satisfy the IDL array specified to SHMMAP for its type and size. If the segment is not large enough, the IDL program will crash with an illegal memory access exception when it attempts to access memory addresses beyond the end of the segment. Hence, the IDL user must ensure that such pre-existing memory segments are long enough for the specified IDL array.

Reference Counts And Memory Segment Lifecycle

You can see a list of all current memory segments created with SHMMAP by issuing the statement

```
HELP, /SHARED_MEMORY
```

To access a current segment, it must be tied to an IDL variable using the SHMVAR function. IDL maintains a reference count of the number of variables currently accessing each memory segment, and does not allow a memory segment to be removed from the IDL process as long as variables that reference it still exist.

SHMMAP will not allow you to create a new memory segment with the same *SegmentName* as an existing segment. You should therefore be careful to pick unique segment names. One way to ensure that segment names are unique is to not provide the *SegmentName* argument when calling SHMMAP. In this case, SHMMAP will automatically choose a unique name, which can be obtained using the GET_NAME keyword.

The SHMUNMAP procedure is used to remove a memory segment from the IDL session. In addition, it may remove the memory segment from the system. (Whether the memory segment is removed from the system depends on the type of segment,

and on the arguments used with SHMMAP when the segment was initially attached.)
If no variables from the current IDL session are accessing the segment (that is, if the
IDL-maintained reference count is 0), the segment is removed immediately. If
variables in the current IDL session are still referencing the segment, the segment is
marked for removal when the last such variable drops its reference. Once
SHMUNMAP is called on a memory segment, no additional calls to SHMVAR are
allowed for it within the current IDL session; this means that a segment marked by
SHMUNMAP as *UnmapPending* cannot be used for new variables within the current
IDL session.

Note ───

IDL has no way to determine whether a process other than itself is accessing a
shared memory segment. As a result, it is possible for IDL to destroy a memory
segment that is in use by another process. The specific details depend on the type of
memory segment, and the options used with SHMMAP when the segment was
loaded. When creating applications that use shared memory, you should ensure that
all applications that use the segment (be they instances of IDL or any other
application) communicate regarding their use of the shared memory and act in a
manner that avoids this pitfall.

───

Examples

Example 1

Create a shared memory segment of 1000000 double-precision data elements, and
then fill it with a DINDGEN ramp:

```
SHMMAP, 'MYSEG', /DOUBLE, 1000000
z = SHMVAR('MYSEG')
z[0] = DINDGEN(1000000)
```

Note ───

When using shared memory, using the explicit subscript of the variable (z, in this
case) maintains the variable's connection with the shared memory segment. When
not using shared memory, assignment without subscripting is more efficient and is
recommended.

───

Example 2

Create the same shared memory segment as the previous example, but let IDL choose
the segment name:

```
SHMMAP, /DOUBLE, DIMENSION=[1000000], GET_NAME=segname
```

```
z = SHMVAR(segname)
z[0] = DINDGEN(1000000)
```

Example 3

Create the same shared memory segment as the previous example, but use a temporary file, mapped into IDL's address space, instead of anonymous shared memory. The file needs to be the correct length for the data we will be mapping onto it. We satisfy this need while simultaneously initializing it with the DINDGEN vector by writing the vector to the file. The use of the OS_HANDLE keyword improves performance and correctness under Windows while being quietly ignored under UNIX:

```
filename = FILEPATH('idl_scratch', /TMP)
OPENW, unit, filename, /GET_LUN
WRITEU, unit, DINDGEN(1000000)
CLOSE, unit
SHMMAP, /DOUBLE, DIMENSION=[1000000], GET_NAME=segname, $
FILENAME=filename, OS_HANDLE='idl_scratch'
z = SHMVAR(segname)
```

Example 4

Create an anonymous shared memory segment using UNIX System V shared memory. Use of System V shared memory differs from the other methods in two ways:

- The system identifier for the segment is a number chosen by the system instead of a name selected by the user.

- With SYSV memory, you have to explicitly indicate whether the operation is a create operation (no OS_HANDLE keyword) or merely an attach to an existing segment (OS_HANDLE is present). The other methods create the segment as needed, and will automatically attach to a memory segment with the desired operating system handle if it already exists. The SHMMAP call does not explicitly have to specify that the segment should be created.

In this example, we will use the type and size of the existing myvar variable to determine the size of the memory:

```
SHMMAP, TEMPLATE=myvar, GET_NAME=segname, /SYSV, $
   GET_OS_HANDLE=oshandle
```

In this case, the SYSV keyword forces the use of System V shared memory. The absence of the OS_HANDLE keyword tells SHMMAP to create the segment, instead of simply mapping an existing one. In a different IDL session running on the same

machine, if you knew the proper OS_HANDLE value for this segment, you could attach to the segment created above as follows:

```
SHMMAP, TEMPLATE=myvar, GET_NAME=segname, /SYSV, $
   OS_HANDLE=oshandle
```

In this case, the OS_HANDLE keyword tells SHMMAP the identifier of the memory segment, causing it to attach to the existing segment instead of creating a new one.

SHMDEBUG, SHMUNMAP, SHMVAR

SHMUNMAP

The SHMUNMAP procedure is used to remove a memory segment previously created by SHMMAP from the IDL session. In addition, it may remove the memory segment from the system. (Whether the memory segment is removed from the system depends on the type of segment, and on the arguments used with SHMMAP when the segment was initially attached.) If no variables from the current IDL session are accessing the segment (that is, if the IDL-maintained reference count is 0), the segment is removed immediately. If variables in the current IDL session are still referencing the segment, the segment is marked for removal when the last such variable drops its reference.

During this *UnmapPending* phase:

- The segment still exists in the system, so attempts to use SHMMAP to create a new segment with the same *SegmentName* will fail.

- Additional calls to SHMVAR to attach new variables to this segment will fail.

Note

IDL has no way to determine whether a process other than itself is accessing a shared memory segment. As a result, it is possible for IDL to destroy a memory segment that is in use by another process. The specific details depend on the type of memory segment, and the options used with SHMMAP when the segment was loaded. When creating applications that use shared memory, you should ensure that all applications that use the segment (be they instances of IDL or any other application) communicate regarding their use of the shared memory and act in a manner that avoids this pitfall.

Syntax

SHMUNMAP, *SegmentName*

Arguments

SegmentName

A scalar string containing the IDL name for the shared memory segment, as assigned by SHMMAP.

Keywords

None.

Examples

To destroy a memory segment previously created by SHMMAP with the segment name myseg:

```
SHMUNMAP, 'myseg'
```

SHMDEBUG, SHMMAP, SHMVAR

SHMVAR

The SHMVAR function creates an IDL array variable that uses the memory from a current mapped memory segment created by the SHMMAP procedure. Variables created by SHMVAR are used in much the same way as any other IDL variable, and provide the IDL user with the ability to alter the contents of anonymous shared memory or memory mapped files.

By default, the variable created by SHMVAR is given the type and dimensions that were specified to SHMMAP when the memory segment was created. However, this default can be changed by SHMVAR via a variety of keywords as well as via the D_i arguments. The created array can be of any type except for pointer, object reference, or string. Structure types are allowed as long as they do not contain any pointers, object references, or strings.

Note

When assigning values to the returned array variable, explicitly make the assignment to the first element of the returned array. For example, the following creates a shared memory segment of 1000000 double-precision data elements, and then fills it with a DINDGEN ramp

```
SHMMAP, 'MYSEG', /DOUBLE, 1000000
z = SHMVAR('MYSEG')
z[0] = DINDGEN(1000000)
```

This technique maintains the array variable's connection with the shared memory segment.

Syntax

Result = SHMVAR(*SegmentName* [, D_1, ..., D_8] [, /BYTE] [, /COMPLEX]
   [, /DCOMPLEX] [, DIMENSION=*value*] [, /DOUBLE] [, /FLOAT]
   [, /INTEGER] [, /L64] [, /LONG] [, SIZE=*value*] [, TEMPLATE=*value*]
   [, TYPE=*value*] [, /UINT] [, /UL64] [, /ULONG])

Return Value

An IDL array variable that uses memory from the specified mapped memory segment.

Arguments

SegmentName

A scalar string supplying the IDL name for the shared memory segment, as assigned by SHMMAP.

D_i

The dimensions of the result. The D_i arguments can be either a single array containing the dimensions or a sequence of scalar dimensions. Up to eight dimensions can be specified. If no dimensions are specified, the parameters specified to SHMMAP are used.

Keywords

BYTE

Set this keyword to specify that the memory segment should be treated as a byte array.

COMPLEX

Set this keyword to specify that the memory segment should be treated as a complex, single-precision floating-point array.

DCOMPLEX

Set this keyword to specify that the memory segment should be treated as a complex, double-precision floating-point array.

DIMENSION

Set this keyword equal to a vector of 1 to 8 elements specifying the dimensions of the result. This is equivalent to the array form of the D_i plain arguments. If no dimensions are specified, the parameters specified to SHMMAP are used.

DOUBLE

Set this keyword to specify that the memory segment should be treated as a double-precision floating-point array.

FLOAT

Set this keyword to specify that the memory segment should be treated as a single-precision floating-point array.

INTEGER

Set this keyword to specify that the memory segment should be treated as an integer array.

L64

Set this keyword to specify that the memory segment should be treated as a 64-bit integer array.

LONG

Set this keyword to specify that the memory segment should be treated as a longword integer array.

SIZE

Set this keyword equal to a size vector specifying the type and dimensions to be associated with the memory segment. The format of a size vector is given in the description of the SIZE function. If no dimensions are specified, the parameters specified to SHMMAP are used.

TEMPLATE

Set this keyword equal to a variable of the type and dimensions to be associated with the memory segment. If no dimensions are specified, the parameters specified to SHMMAP are used.

TYPE

Set this keyword to specify the type code for the memory segment. See the description of the SIZE function for a list of IDL type codes.

UINT

Set this keyword to specify that the memory segment should be treated as an unsigned integer array.

ULONG

Set this keyword to specify that the memory segment should be treated as an unsigned longword integer array.

UL64

Set this keyword to specify that the memory segment should be treated as an unsigned 64-bit integer array.

Examples

See the examples given for the SHMMAP procedure.

SHOW3

The SHOW3 procedure combines an image, a surface plot of the image data, and a contour plot of the images data in a single tri-level display.

This routine is written in the IDL language. Its source code can be found in the file show3.pro in the lib subdirectory of the IDL distribution.

Syntax

SHOW3, *Image* [, *X*, *Y*] [, /INTERP] [, E_CONTOUR=*structure*]
  [, E_SURFACE=*structure*] [, SSCALE=*scale*]

Arguments

Image

The two-dimensional array to display.

X

A vector containing the X values of each column of *Image*. If the *X* argument is omitted, columns have values 0, 1, ..., *n*columns-1.

Y

A vector containing the Y values of each row of *Image*. If the *Y* argument is omitted, rows have values 0, 1, ..., *n*rows-1.

Keywords

INTERP

Set this keyword to use bilinear interpolation on the pixel display. This technique is slightly slower, but for small images, it makes a better display.

E_CONTOUR

Set this keyword equal to an anonymous structure containing additional keyword parameters that are passed to the CONTOUR procedure. Tag names in the structure should be valid keyword arguments to CONTOUR, and the values associated with each tag should be valid keyword values.

E_SURFACE

Set this keyword equal to an anonymous structure containing additional keyword parameters that are passed to the SURFACE procedure. Tag names in the structure should be valid keyword arguments to SURFACE, and the values associated with each tag should be valid keyword values.

SSCALE

Reduction scale for surface. The default is 1. If this keyword is set to a value other than 1, the array size is reduced by this factor for the surface display. That is, the number of points used to draw the wire-mesh surface is reduced. If the array dimensions are not an integral multiple of SSCALE, the image is reduced to the next smaller multiple.

Examples

```
; Create a dataset:
A = BESELJ(SHIFT(DIST(30,20), 15, 10)/2.,0)

; Show it with default display:
SHOW3, A

; Specify X axis proportional to square root of values:
SHOW3, A, SQRT(FINDGEN(30))

; Label CONTOUR lines with double size characters, and include
; downhill tick marks:
SHOW3, A, E_CONTOUR={C_CHARSIZE:2, DOWN:1}

; Draw a surface with a skirt and scale Z axis from -2 to 2:
SHOW3, A, E_SURFACE={SKIRT:-1, ZRANGE:[-2,2]}
```

Combining Images with Three-Dimensional Graphics

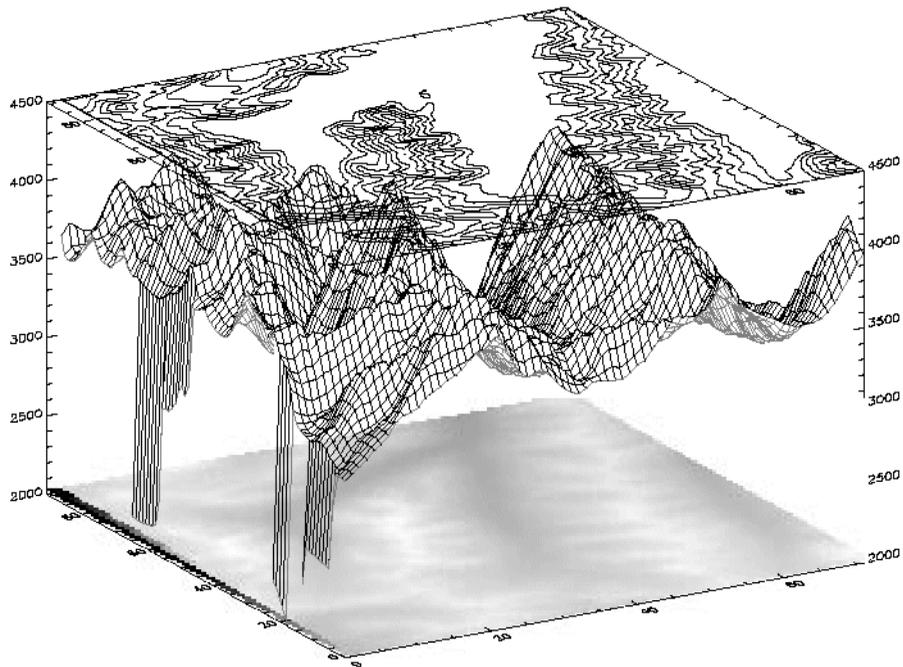
Images are combined with three-dimensional graphics, as shown in the figure below, using the transformation techniques described above.


Figure 21-7: Using SHOW3 to Overlay an Image, Surface Mesh, and Contour

The rectangular image must be transformed so that it fits underneath the mesh drawn by SURFACE. The general approach is as follows:

- Use SURFACE to establish the general scaling and geometrical transformation. Draw no data, as the graphics made by SURFACE will be over-written by the transformed image.

- For each of the four corners of the image, translate the data coordinate, which is simply the subscript of the corner, into a device coordinate. The data coordinates of the four corners of an (m, n) image are $(0, 0)$, $(m–1, 0)$, $(0, n–1)$, and $(m–1, n–1)$. Call this data coordinate system (x, y). Using a procedure or function similar to CVT_TO_2D (see "Three-Dimensional Direct Graphic Coordinate Conversion" on page 384) convert to device coordinates, which in this discussion are called (U, V).

- The image is transformed from the original *xy* coordinates to a new image in *UV* coordinates using the POLY_2D function. POLY_2D accepts an input image and the coefficients of a polynomial in UV giving the *xy* coordinates in the original image. The equations for *x* and *y* are below.

$$X = S_{0,0} + S_{1,0}U + S_{1,0}V + S_{1,1}UV$$

$$Y = T_{0,0} + T_{1,0}U + T_{1,0}V + T_{1,1}UV$$

We solve for the four unknown *S* coefficients using the four equations relating the *x* corner coordinates to their *U* coordinates. The *T* coefficients are similarly found using the *y* and *V* coordinates. This can be done using matrix operators and inversion or more simply, with the procedure POLY_WARP.

- The new image is a rectangle that encloses the quadrilateral described by the UV coordinates. Its size is specified in the formula below:

$(\text{MAX}(U) - \text{MIN}(U) + 2, \text{MAX}(V) - \text{MIN}(V) + 1)$

- POLY_2D is called to form the new image which is displayed at device coordinate $(\text{MIN}(U), \text{MIN}(V))$.

- SURFACE is called once again to display the mesh surface over the image.

- Finally, CONTOUR is called with ZVALUE set to 1.0, placing the contour above both the image and the surface.

The SHOW3 procedure performs these operations. It should be examined for details of how images and graphics can be combined.

The following IDL commands were used to create the previous image:

```
; Restore variables:
@cntour01
; Reduce the size of elev array:
new = REBIN(elev, 360/5, 460/5)
; Create an array of levels for CONTOUR:
levs = (FINDGEN(10)*100)+3500
; Use SHOW3. Note the use of keywords E_SURFACE
; and E_CONTOUR to pass values to the SURFACE and
; CONTOUR routines used within SHOW3.
SHOW3, new, E_SURFACE={min:2000}, E_CONTOUR={levels:levs}
```

Note

See "Running the Example Code" on page 42 if IDL does not find the referenced batch file.

SHOWFONT

The SHOWFONT procedure displays a TrueType or vector-drawn font (from the file hersh1.chr, located in the resource/fonts subdirectory of the IDL distribution) on the current graphics device.

This routine is written in the IDL language. Its source code can be found in the file showfont.pro in the lib subdirectory of the IDL distribution.

Syntax

SHOWFONT, *Font*, *Name* [, /ENCAPSULATED] [, /TT_FONT]

Arguments

Font

The index number of the font (may range from 3 to 29) or, if the TT_FONT keyword is set, a string that contains the name of the TrueType font to display.

Name

A string that contains the text of a title to appear at the top of the font display.

Keywords

ENCAPSULATED

Set this keyword, if the current graphics device is "PS", to make encapsulated PostScript output.

TT_FONT

If this keyword is set, the specified font will be interpreted as a TrueType font.

Examples

To create a display of the Helvetica italic TrueType font on the screen:

```
SHOWFONT, 'Helvetica Italic', 'Helvetica Italic', /TT_FONT
```

To create a display of Font 3 for PostScript:

```
; Set output to PostScript:
SET_PLOT, 'PS'

; Specify the output filename. If we didn't specify this, the file
; would be saved as idl.ps by default:
DEVICE, FILENAME='font3.ps'

;Display font 3:
SHOWFONT, 3, 'Simplex Roman'

; Close the new PS file:
DEVICE, /CLOSE
```

SIMPLEX

The SIMPLEX function uses the simplex method to solve linear programming problems. Given a set of *N* independent variables X_i, where $i = 0, ..., N$, the simplex method seeks to maximize the following function,

$$Z = a_1 X_1 + a_2 X_2 + \ldots a_N X_N$$

with the assumption that $X_i \geq 0$. The X_i are further constrained by the following equations:

$$b_{j1} X_1 + b_{j2} X_2 + \ldots b_{jN} X_N \leq c_j \quad j = 1, 2, \ldots, M_1$$

$$b_{j1} X_1 + b_{j2} X_2 + \ldots b_{jN} X_N \geq c_j \quad j = M_1 + 1, M_1 + 2, \ldots, M_1 + M_2$$

$$b_{j1} X_1 + b_{j2} X_2 + \ldots b_{jN} X_N = c_j \quad j = M_1 + M_2 + 1, M_1 + M_2 + 2, \ldots, M$$

where $M = M_1 + M_2 + M_3$ is the total number of equations, and the constraint values c_j must all be positive.

To solve the above problem using the SIMPLEX function, the *Z* equation is rewritten as a vector:

$$Z_{equation} = \begin{bmatrix} a_1 & a_2 & \ldots a_N \end{bmatrix}$$

The constraint equations are rewritten as a matrix with *N*+1 columns and *M* rows, where all of the *b* coefficients have had their sign reversed:

$$Constraints = \begin{bmatrix} c_1 & -b_{11} & -b_{12} \ldots -b_{1N} \\ c_2 & -b_{21} & -b_{22} \ldots -b_{2N} \\ \vdots & \vdots & \vdots \\ \vdots & \vdots & \vdots \\ c_M & -b_{M1} & -b_{M2} \ldots -b_{MN} \end{bmatrix}$$

Note ————————————————————————————————

The constraint matrix must be organized so that the coefficients for the less-than ($<$) equations come first, followed by the coefficients of the greater-than ($>$) equations, and then the coefficients of the equal ($=$) equations.

———————————————————————————————————————

The SIMPLEX function is based on the routine `simplx` described in section 10.8 of *Numerical Recipes in C: The Art of Scientific Computing* (Second Edition), published by Cambridge University Press, and is used by permission.

Syntax

Result = SIMPLEX(*Zequation*, *Constraints*, M_1, M_2, M_3
    [, *Tableau* [, *Izrov* [, *Iposv*]]] [, /DOUBLE] [, EPS = *value*]
    [, STATUS = *variable*])

Return Value

The *Result* is a vector of *N*+1 elements containing the maximum *Z* value and the values of the *N* independent *X* variables (the optimal feasible vector):

$$\text{Result} = \left[Z_{max} \ X_1 \ X_2 ... X_N \right]$$

Arguments

Zequation

A vector containing the *N* coefficients of the $Z_{equation}$ to be maximized.

Constraints

An array of *N*+1 columns by *M* rows containing the constraint values and coefficients for the constraint equations.

M1

An integer giving the number of less-than constraint equations contained in *Constraints*. *M1* may be zero, indicating that there are no less than constraints.

M2

An integer giving the number of greater-than constraint equations contained in *Constraints*. *M2* may be zero, indicating that there are no greater than constraints.

M3

An integer giving the number of equal-to constraint equations contained in *Constraints*. *M3* may be zero, indicating that there are no equal to constraints. The total of *M1* + *M2* + *M3* should equal M, the number of constraint equations.

Tableau

Set this optional argument to a named variable in which to return the output array from the simplex algorithm. For more detailed discussion about this argument, see the write-up in section 10.8 of *Numerical Recipes in C*.

Izrov

Set this optional argument to a named variable in which to return the output izrov variable from the simplex algorithm. For more detailed discussion about this argument, see the write-up in section 10.8 of *Numerical Recipes in C*.

Iposv

Set this optional argument to a named variable in which to return the output iposv variable from the simplex algorithm. For more detailed discussion about this argument, see the write-up in section 10.8 of *Numerical Recipes in C*.

Keywords

DOUBLE

Set this keyword to use double-precision for computations and to return a double-precision result. Set DOUBLE to 0 to use single-precision for computations and to return a single-precision result. The default is /DOUBLE if any of the inputs are double-precision, otherwise the default is 0.

EPS

Set this keyword to a number close to machine accuracy, which is used to test for convergence at each iteration. The default is 10^{-6}.

STATUS

Set this keyword to a named variable to receive the status of the operation. Possible status values are:

Value	Description
0	Successful completion.
1	The objective function is unbounded.

Table 21-5: SIMPLEX Function Status Values

Value	Description
2	No solution satisfies the given constraints.
3	The routine did not converge.

Table 21-5: SIMPLEX Function Status Values (Continued)

Examples

The following example is taken from *Numerical Recipes in C*.

Find the Z value which maximizes the equation $Z = X_1 + X_2 + 3 X_3 - 0.5 X_4$, with the following constraints:

$$X_1 + 2X_3 \leq 740$$
$$2X_2 - 7X_4 \leq 0$$
$$X_2 - X_3 + 2X_4 \geq 0.5$$
$$X_1 + X_2 + X_3 + X_4 = 9$$

To find the solution, enter the following code at the IDL command line:

```
; Set up the Zequation with the X coefficients.
Zequation = [1,1,3,-0.5]
; Set up the Constraints matrix.
Constraints = [ $
   [740, -1,  0, -2,  0], $
   [  0,  0, -2,  0,  7], $
   [0.5,  0, -1,  1, -2], $
   [  9, -1, -1, -1, -1] ]
; Number of less-than constraint equations.
m1 = 2
; Number of greater-than constraint equations.
m2 = 1
; Number of equal constraint equations.
m3 = 1
;
; Call the function.
result = SIMPLEX(Zequation, Constraints, m1, m2, m3)
;
; Print out the results.
PRINT, 'Maximum Z value is: ', result[0]
PRINT, 'X coefficients are: '
PRINT, result[1:*]
```

IDL prints:

```
Maximum Z value is:        17.0250
X coefficients are:
      0.000000      3.32500       4.72500       0.950000
```

Therefore, the optimal feasible vector is $X_1 = 0.0$, $X_2 = 3.325$, $X_3 = 4.725$, and $X_4 = 0.95$.

SIN

The periodic function SIN returns the trigonometric sine of X.

Syntax

Result = SIN(*X*)

Return Value

Returns the double-precision floating-point, complex or single-precision floating-point value.

Arguments

X

The angle for which the sine is desired, specified in radians. If *X* is double-precision floating or complex, the result is of the same type. All other types are converted to single-precision floating-point and yield floating-point results. When applied to complex numbers:

$$\text{SIN}(x) = (\text{EXP}(i*x) + 1/\text{EXP}(i*x))/(2*i)$$

where *i* is defined as COMPLEX(0, 1).

If input argument *X* is an array, the result has the same structure, with each element containing the sine of the corresponding element of *X*.

Keywords

Thread Pool Keywords

This routine is written to make use of IDL's *thread pool*, which can increase execution speed on systems with multiple CPUs. The values stored in the !CPU system variable control whether IDL uses the thread pool for a given computation. In addition, you can use the thread pool keywords TPOOL_MAX_ELTS, TPOOL_MIN_ELTS, and TPOOL_NOTHREAD to override the defaults established by !CPU for a single invocation of this routine. See Appendix C, "Thread Pool Keywords" for details.

Examples

To find the sine of 0.5 radians and print the result, enter:

```
PRINT, SIN(0.5)
```

The following example plots the SIN function between 0 and 2π with 100 intervals:

```
X = 2*!PI/100 * FINDGEN(100)
PLOT, X, SIN(X)
```

Note

!PI is a read-only system variable that contains the single-precision value for π.

SINDGEN

The SINDGEN function returns a string array with the specified dimensions. Each element of the array is set to the string representation of the value of its one-dimensional subscript, using IDL's default formatting rules.

Syntax

Result = SINDGEN(D_1 [, ..., D_8])

Return Value

Returns a string array of the specified dimensions.

Arguments

D*i*

Either an array or a series of scalar expressions specifying the dimensions of the result. If a single argument is specified, it can be either a scalar expression or an array of up to eight elements. If multiple arguments are specified, they must all be scalar expressions. Up to eight dimensions can be specified. If the dimension arguments are not integer values, IDL will convert them to integer values before creating the new array.

Examples

To create S, a six-element string vector with each element set to the string value of its subscript, enter:

```
S = SINDGEN(6)
```

SINH

The SINH function returns the hyperbolic sine of X.

Syntax

Result = SINH(*X*)

Return Value

Returns the double-precision floating-point, complex or single-precision floating-point value.

Arguments

X

The angle for which the hyperbolic sine is desired, specified in radians. If *X* is double-precision floating or complex, the result is of the same type. All other types are converted to single-precision floating-point and yield floating-point results. SINH is defined as:

$$\sinh x = (e^u - e^{-u}) / 2$$

If *X* is an array, the result has the same structure, with each element containing the hyperbolic sine of the corresponding element of *X*.

Keywords

Thread Pool Keywords

This routine is written to make use of IDL's *thread pool*, which can increase execution speed on systems with multiple CPUs. The values stored in the !CPU system variable control whether IDL uses the thread pool for a given computation. In addition, you can use the thread pool keywords TPOOL_MAX_ELTS, TPOOL_MIN_ELTS, and TPOOL_NOTHREAD to override the defaults established by !CPU for a single invocation of this routine. See Appendix C, "Thread Pool Keywords" for details.

Examples

To find the hyperbolic sine of each element in the array [.5, .2, .4] and print the result, enter:

```
PRINT, SINH([.5, .2, .4])
```

To plot the SINH function between 0 and 2π with 100 intervals, enter:

```
X = 2*!PI/100 * FINDGEN(100)
PLOT, X, SINH(X)
```

Note ──
!PI is a read-only system variable that contains the single-precision value of π.

SIZE

The SIZE function returns size and type information for its argument if no keywords are set. If a keyword is set, SIZE returns the specified quantity.

Syntax

Result = SIZE(*Expression* [, /L64] [, /DIMENSIONS | , /FILE_LUN | , /FILE_OFFSET | , /N_DIMENSIONS | , /N_ELEMENTS | , /SNAME, | , /STRUCTURE | , /TNAME | , /TYPE])

Return Value

If no keywords are set, SIZE returns a vector of integer type. The first element is equal to the number of dimensions of *Expression*. This value is zero if *Expression* is scalar or undefined. The next elements contain the size of each dimension, one element per dimension (none if *Expression* is scalar or undefined). After the dimension sizes, the last two elements contain the type code (zero if undefined) and the number of elements in *Expression*, respectively. The type codes are listed below.

If a keyword is set, SIZE returns the specified information.

IDL Type Codes and Names

The following table lists the IDL type codes and type names returned by the SIZE function:

Type Code	Type Name	Data Type
0	UNDEFINED	Undefined
1	BYTE	Byte
2	INT	Integer
3	LONG	Longword integer
4	FLOAT	Floating point
5	DOUBLE	Double-precision floating
6	COMPLEX	Complex floating

Table 21-6: IDL Type Codes and Names

Type Code	Type Name	Data Type
7	STRING	String
8	STRUCT	Structure
9	DCOMPLEX	Double-precision complex
10	POINTER	Pointer
11	OBJREF	Object reference
12	UINT	Unsigned Integer
13	ULONG	Unsigned Longword Integer
14	LONG64	64-bit Integer
15	ULONG64	Unsigned 64-bit Integer

Table 21-6: IDL Type Codes and Names (Continued)

Arguments

Expression

The expression for which size information is requested.

Keywords

With the exception of L64, the following keywords determine the return value of the SIZE function and are mutually exclusive — specify at most one of the following.

DIMENSIONS

Set this keyword to return the dimensions of *Expression*. If *Expression* is scalar, the result is a scalar containing a 0. For arrays, the result is an array containing the array dimensions. The result is a 32-bit integer when possible, and 64-bit integer if the number of elements in *Expression* requires it. Set L64 to force 64-bit integers to be returned in all cases.If *Expression* is undefined, IDL reports eight dimensions.

FILE_LUN

Set this keyword to return the file unit to which *Expression* is associated, if it is an IDL file variable, as created with the ASSOC function. If *Expression* is not a file variable, 0 is returned (0 is not a valid file unit for ASSOC).

FILE_OFFSET

Set this keyword to return the ASSOC file offset for *Expression*. In the case of ASSOC file variables, this is the value of the *Offset* argument specified to ASSOC when the variable was created. In the case of regular non-file variables, 0 is returned. The result will be 32-bit integer when possible, and 64-bit integer if the size of the offset requires it. Set L64 to force a 64-bit integer to be returned in all cases.

L64

By default, the result of SIZE is 32-bit integer when possible, and 64-bit integer if the number of elements in *Expression* requires it. Set L64 to force 64-bit integers to be returned in all cases. In addition to affecting the default result, L64 also affects the output from the DIMENSIONS, FILE_OFFSET, N_ELEMENTS, and STRUCTURE keywords.

Note ────────────────────────────────────

Only 64-bit versions of IDL are capable of creating variables requiring 64-bit SIZE output. Check the value of !VERSION.MEMORY_BITS to see if your IDL is 64-bit or not.

──

N_DIMENSIONS

Set this keyword to return the number of dimension in *Expression*, if it is an array. If *Expression* is scalar or undefined, 0 is returned.

N_ELEMENTS

Set this keyword to return the number of data elements in *Expression*. Setting this keyword is equivalent to using the N_ELEMENTS function. The result will be 32-bit integer when possible, and 64-bit integer if the number of elements in *Expression* requires it. Set L64 to force 64-bit integers to be returned in all cases. If *Expression* is undefined, 0 is returned.

SNAME

Set this keyword to return the name of the structure definition for *Expression*, if *Expression* is a named structure. If *Expression* is not a named structure, a null string is returned. The string returned by this keyword is the same as that returned by TAG_NAMES(/STRUCTURE_NAME).

STRUCTURE

Set this keyword to return all available information about *Expression* in a structure.

Note ───

Since the structure is a named structure, the size of its fields is fixed. The result is an IDL_SIZE (32-bit) structure when possible, and an IDL_SIZE64 structure otherwise. Set L64 to force an IDL_SIZE64 structure to be returned in all cases.

───

The following are descriptions of the fields in the returned structure:

Field	Description
TYPE_NAME	Name of IDL type of *Expression*
STRUCTURE_NAME	If *Expression* is a named (not anonymous) structure, the name of the structure definition; otherwise, a null string
TYPE	Type code of *Expression*
FILE_LUN	If *Expression* is an IDL file variable, as created with the ASSOC function, the file unit to which it is associated; otherwise, 0
FILE_OFFSET	If *Expression* is an IDL file variable, as created with the ASSOC function, the offset specified to ASSOC when the variable was created; otherwise, 0
N_ELEMENTS	Number of data elements in *Expression*
N_DIMENSIONS	If *Expression* is an array, the number of dimensions; otherwise, 0
DIMENSIONS	An 8-element array containing the dimensions of *Expression*

Table 21-7: Structure Fields

TNAME

Set this keyword to return the IDL type of *Expression* as a string. See "IDL Type Codes and Names" on page 2277 for details.

TYPE

Set this keyword to return the IDL type code for *Expression*. See "IDL Type Codes and Names" on page 2277 for details. For an example illustrating how to determine the type code of an expression, see "Example: Returning the IDL Type Code of an Expression" on page 2281.

Examples

Print the size information for a 10 by 20 floating-point array by entering:

```
PRINT, SIZE(FINDGEN(10, 20))
```

IDL prints:

```
    2   10   20    4   200
```

This IDL output indicates the array has 2 dimensions, equal to 10 and 20, a type code of 4, and 200 elements total. Similarly, to print only the number of dimensions of the same array:

```
PRINT, SIZE(FINDGEN(10, 20), /N_DIMENSIONS)
```

IDL prints:

```
    2
```

Example: Returning the IDL Type Code of an Expression

The following example illustrates two ways in which to determine the type code of the input expression (see "IDL Type Codes and Names" on page 2277 for a list). The type code is always the next to last element in the result returned by the SIZE function. Using this information, and the N_ELEMENTS procedure, you can quickly access the data's type code. For example:

```
array = [[1,2,3], [4,5,6], [7,8,9]]

; A more flexible method:
sz = SIZE(array)
n = N_ELEMENTS(sz)
type = sz[n-2]
```

The second method involves using the TYPE keyword to SIZE. In this case, the value returned by the SIZE function contains only the type code of the input expression. You can use the TNAME keyword to return the type name. Select any image file and the pixel data type will be printed in the Output window.

```
; Select an image file.
result = DIALOG_READ_IMAGE(FILE=selectedFile, IMAGE=image)
```

```
type = SIZE(image, /TYPE)
typeName = SIZE(image, /TNAME)
PRINT, "Type code = ",  type,  " type code name = ",  typename
```

Example: Returning Array Dimension Information

Assume A is an integer array with dimensions of (3,4,5). The statements:

```
arr = INDGEN(3,4,5)
S = SIZE(arr)
```

assign to the variable S a six-element vector containing:

Element	Value	Description
S_0	3	Three dimensions
S_1	3	First dimension
S_2	4	Second dimension
S_3	5	Third dimension
S_4	2	Integer type
S_5	60	Number of elements = 3*4*5

Table 21-8: SIZE Values

The following code segment checks to see if the variable arr is two-dimensional and extracts the dimensions:

```
;Create a variable.
arr = [[1,2,3],[4,5,6]]

;Get size vector.
S = SIZE(arr)

;Check if two dimensional.
IF S[0] NE 2 THEN $
   ;Print error message.
   MESSAGE, 'Variable a is not two dimensional.'

;Get number of columns and rows.
NX = S[1] & NY = S[2]

PRINT, 'Array is ', NX, ' columns by ', NY, ' rows.'
```

IDL prints:

```
Array is    3 columns by    2 rows.
```

Note
Also see "Padding Images" (Chapter 2, *Image Processing in IDL*) for an example
that uses SIZE to add pixels around the edges of an image. The padding provides
space for annotations or acts as a boundary when using advanced filtering
techniques.

Version History

Original	Introduced
6.1	Added FILE_OFFSET and SNAME keywords
	Added FILE_OFFSET and STRUCTURE_NAME fields to STRUCTURE

Information" (Chapter 4, *Using IDL*)

SKEWNESS

The SKEWNESS function computes the statistical skewness of an *n*-element vector. Skewness determines whether a distribution is symmetric about its maximum. Positive skewness indicates the distribution is skewed to the right, with a longer tail to the right of the distribution maximum. Negative skewness indicates the distribution is skewed to the left, with a longer tail to the left of the distribution maximum.

SKEWNESS calls the IDL function MOMENT.

Syntax

Result = SKEWNESS(*X* [, /DOUBLE] [, /NAN])

Return Value

Returns the floating point or double precision statistical skewness. If the variance of the vector is zero, the skewness is not defined, and SKEWNESS returns !VALUES.F_NAN as the result.

Arguments

X

A numeric vector.

Keywords

DOUBLE

Set this keyword to force computations to be done in double-precision arithmetic.

NAN

Set this keyword to cause the routine to check for occurrences of the IEEE floating-point values *NaN* or *Infinity* in the input data. Elements with the value *NaN* or *Infinity* are treated as missing data. (See "Special Floating-Point Values" (Chapter 8, *Application Programming*) for more information on IEEE floating-point values.)

Examples

```
; Define the n-element vector of sample data:
```

```
x = [65, 63, 67, 64, 68, 62, 70, 66, 68, 67, 69, 71, 66, 65, 70]
; Compute the skewness:
result = SKEWNESS(x)
PRINT, 'Skewness = ', result
```

IDL prints:

```
Skewness =    -0.0942851
```

SKIP_LUN

The SKIP_LUN procedure reads data in an open file and moves the file pointer. It is useful in situations where it is necessary to skip over a known amount of data in a file without the requirement of having the data available in an IDL variable. SKIP_LUN can skip over a fixed amount of data, specified in bytes or lines of text, or can skip over the remainder of the input file from the current position to end of file. Since SKIP_LUN actually performs an input operation to advance the file pointer, it is not as efficient as POINT_LUN for skipping over a fixed number of bytes in a disk file. For that reason, use of POINT_LUN is preferred when possible. SKIP_LUN is especially useful in situations such as:

- Skipping over a fixed number of lines of text. Since lines of text can have variable length, it can be difficult to use POINT_LUN to skip them.

- Skipping data from a file that is not a regular disk file (for example, data from an internet socket).

Syntax

SKIP_LUN, *FromUnit*, [, *Num*] [, /EOF] [, /LINES]
   [, /TRANSFER_COUNT=*variable*]

Arguments

FromUnit

An integer that specifies the file unit for the file in which the file pointer is to be moved. Data in *FromUnit* is skipped, starting at the current position of the file pointer. The file pointer is advanced as data is read and skipped. The file specified by *FromUnit* must be open, and must not have been opened with the RAWIO keyword to OPEN.

Num

The amount of data to skip. This value is specified in bytes, unless the LINES keyword is specified, in which case it is taken to be the number of text lines. If *Num* is not specified, SKIP_LUN acts as if the EOF keyword has been set, and skips all data in *FromUnit* (the source file) from the current position of the file pointer to the end of the file.

If *Num* is specified and the source file comes to end of file before the specified amount of data is skipped, SKIP_LUN issues an end-of-file error. The EOF keyword alters this behavior.

Keywords

EOF

Set this keyword to ignore the value given by *Num* (if present) and instead skip all data from the current position of the file pointer in *FromUnit* and the end of the file.

Note
If EOF is set, no end-of-file error is issued even if the amount of data skipped does not match the amount specified by *Num*. The TRANSFER_COUNT keyword can be used with EOF to determine how much data was skipped.

LINES

Set this keyword to indicate that the *Num* argument specifies the number of lines of text to be skipped. By default, the *Num* argument specifies the number of bytes of data to skip.

TRANSFER_COUNT

Set this keyword equal to a named variable that will contain the amount of data skipped. If LINES is specified, this value is the number of lines of text. Otherwise, it is the number of bytes. TRANSFER_COUNT is primarily useful in conjunction with the EOF keyword. If EOF is not specified, TRANSFER_COUNT will be the same as the value specified for *Num*.

Examples

Skip the next 8 lines of text from a file:

```
SKIP_LUN, FromUnit, 8, /LINES
```

Skip the remainder of the data in a file, and use the TRANSFER_COUNT keyword to determine how much data was skipped:

```
SKIP_LUN, FromUnit, /EOF, TRANSFER_COUNT=n
```

Skip the remainder of the text lines in a file, and use the TRANSFER_COUNT keyword to determine how many lines were skipped:

```
SKIP_LUN, FromUnit, /EOF, /LINES, TRANSFER_COUNT=n
```

SLICER3

The IDL SLICER3 is a widget-based application to visualize three-dimensional datasets. This program supersedes the SLICER program.

This routine is written in the IDL language. Its source code can be found in the file `slicer3.pro` in the `lib` subdirectory of the IDL distribution.

Note —————————————————————————————————

See "The SLICER3 Graphical User Interface" on page 2291 for details on working with volumetric data within this application.

———

Syntax

SLICER3 [, *hData3D*] [, DATA_NAMES=*string/string_array*] [, /DETACH]
   [, GROUP=*widget_id*] [, /MODAL]

Arguments

hData3D

A pointer to a three-dimensional data array, or an array of pointers to multiple three-dimensional arrays. If multiple arrays are specified, they all must have the same X, Y, and Z dimensions. If *hData3D* is not specified, SLICER3 creates a 2 x 2 x 2 array of byte data using the IDL BYTARR function. You can also load data interactively via the File menu of the SLICER3 application (see "Examples" on page 2305 for details).

Note —————————————————————————————————

If data are loaded in this fashion, any data passed to SLICER3 via a pointer (or pointers) is deleted, and the pointers become invalid.

———

Keywords

DATA_NAMES

Set this keyword equal to a string array of names for the data. The names appear on the droplist widget for the current data. If the number of elements of DATA_NAMES is less than the number of elements in *hData3D* then default names will be generated for the unnamed data.

DETACH

Set this keyword to place the drawing area in a window that is detached from the SLICER3 control panel. The drawing area can only be detached if SLICER3 is not run as a modal application.

GROUP

Set this keyword equal to the Widget ID of an existing widget that serves as the "group leader" for the SLICER3 graphical user interface. When a group leader is destroyed, all widgets in the group are also destroyed. If SLICER3 is started from a widget application, then GROUP should *always* be specified.

MODAL

Set this keyword to block user interaction with all other widgets (and block the command line) until the SLICER3 exits. If SLICER3 is started from some other widget-based application, then it is usually advisable to run SLICER3 with the MODAL keyword set.

Note

SLICER3 modifies the current color table, as well as various elements of the plotting system (i.e., the "!X", "!Y", "!Z", and "!P" system variables). If the MODAL keyword is set (recommended), then SLICER3 will, upon exit, restore these system variables (and the color tables) to the values they had when SLICER3 was started.

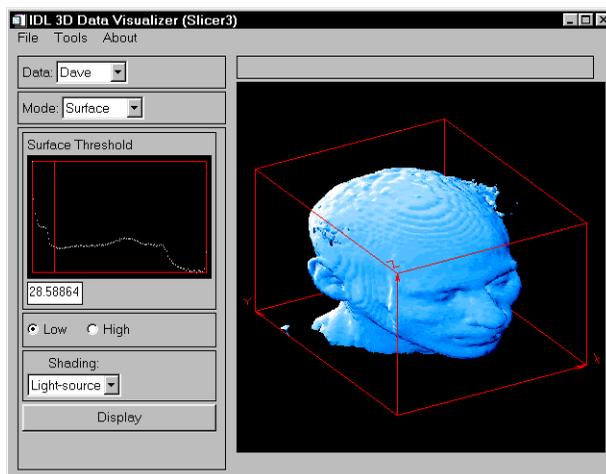
The SLICER3 Graphical User Interface


Figure 21-8: SLICER3 Graphical User Interface

The following options are available via SLICER3's graphical user interface.

File Menu

Load

Select this menu option to choose a file containing a 3-D array (or arrays) to load into SLICER3. The file must have been written in the format specified in the following table. For each data array in the file, the following values must be included.

Note that the first six values are returned by the IDL SIZE function; see "Examples" on page 2305 for an example of how to create a data file suitable for SLICER3 with just a few IDL commands.

Data item	Data Type	Number of Bytes
Number of dimension in array. **Note -** This is always 3 for valid SLICER3 data.	long	4
Size of first dimension.	long	4
Size of second dimension.	long	4
Size of third dimension.	long	4
Data type (Must be type 1 through 5. See "SIZE" on page 2277 for a list of data types.)	long	4
Total number of elements (dimX, dimY, dimZ).	long	4
Number of characters in data name. (See "STRLEN" on page 2385 for the easiest way to determine this number.)	long	4
Data name	byte	strlen()
3-D data array.	varies	varies

Table 21-9: SLICER3 Data File Structure

If multiple arrays are present in the file, they must all have the same dimensions.

Note

Files saved by the "Save Subset" operation (see below) are suitable for input via the "Load" operation.

Data files that are moved from one platform to another may not load as expected, due to byte ordering differences. See the BYTEORDER and SWAP_ENDIAN for details.

Save/Save Subset

SLICER3 must be in BLOCK mode to for this option to be available.

Select this menu option to save a subset of the 3-D data enclosed in the current block to the specified file. Subsets saved in this fashion are suitable for loading via the

"Load" menu option. If multiple 3-D arrays are available when this option is selected, multiple subsets are saved to the file.

Save/Save Tiff Image

Select this menu option to save the contents of the current SLICER3 image window as a TIFF image in the specified file. When running in 8-bit mode, a "Class P" palette color TIFF file is created. In 24-bit mode, a "Class R" (interleaved by image) TIFF file is created.

Quit

Select this menu option to exit SLICER3.

Tools Menu

Erase

Select this menu option to erase the display window and delete all the objects in the display list.

Delete/...

As graphical objects are created, they are added to the display list. Select this menu option to delete a specific object from the list. When an object is deleted, the screen is redrawn with the remaining objects.

Colors/Reset Colors

Select this menu option to restore the original color scheme.

Colors/Differential Shading

Use this menu option to change the percentage of differential shading applied to the X, Y, and Z slices.

Colors/Slice/Block

Use this menu option to launch the XLOADCT application to modify the colors used for slices and blocks

Colors/Surface

Use this menu option to launch the XLOADCT application to modify the colors used for isosurfaces.

Colors/Projection

Use this menu option to launch the XLOADCT application to modify the colors used for projections.

Note

On some platforms, the selected colors may not become visible until after you exit the "XLOADCT" application.

Options

Select this menu option to display a panel that allows you to set:

- The axis visibility.
- The wire-frame cube visibility.
- The display window size.

Main Draw Window

Operations available in the Main Draw Window are dependent on the mode selected in the Mode pulldown menu. In general, when coordinate input is required from the user, it is performed by clicking a mouse button on the "surface" of the wire-frame cube that surrounds the data. This 3-D location is then used as the basis for whatever input is needed. In most cases, the "front" side of the cube is used. In a few cases, the coordinate input is on the "back" side of the cube.

Data Pulldown Menu

If multiple datasets are currently available in SLICER3, this menu allows you to select which data will be displayed in the Main Draw Window. Slices, blocks, iso-surfaces, etc. are created from the currently selected data. If only one dataset is loaded, this menu is inactive.

Mode Pulldown Menu

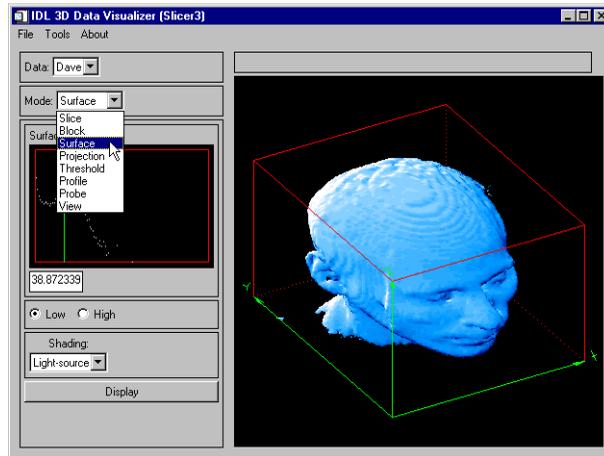
This menu is used to select the current mode of operation.


Figure 21-9: Mode Pulldown Menu

Slice Mode

To display a slice, click and drag the left mouse button on the wire-frame cube. When the button is released, a slice through the data will be drawn at that location.

Draw Radio Button

When in Draw mode, new slices will be merged into the current Z-buffer contents.

Expose Radio Button

When in Expose mode, new slices will be drawn in front of everything else.

Orthogonal Radio Button

When in Orthogonal mode, use the left mouse button in the main draw window to position and draw an orthogonal slicing plane. Clicking the right mouse button in the main draw window (or any mouse button in the small window) will toggle the slicing plane orientation.

X/Y/Z Radio Buttons

- • X: This sets the orthogonal slicing plane orientation to be perpendicular to the X axis.

- • Y: This sets the orthogonal slicing plane orientation to be perpendicular to the Y axis.

- • Z: This sets the orthogonal slicing plane orientation to be perpendicular to the Z axis.

Oblique Radio Button

Clicking any mouse button in the small window will reset the oblique slicing plane to its default orientation.

Normal Radio Button

When in this mode, click and drag the left mouse button in the big window to set the surface normal for the oblique slicing plane.

Center Radio Button

When in this mode, click and drag the left mouse button in the big window to set the center point for the surface normal.

Display Button

Clicking this button will cause an oblique slicing plane to be drawn.

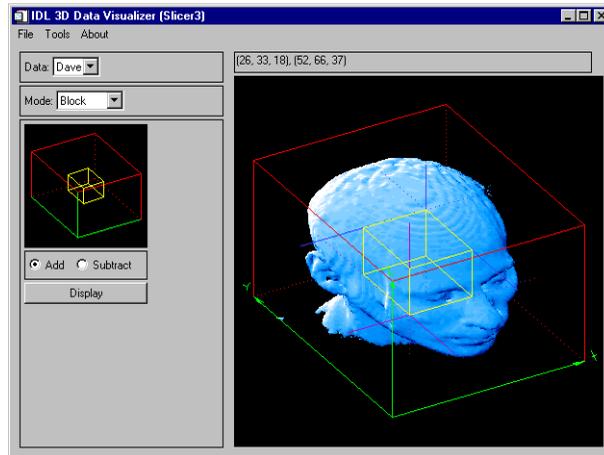
Block Mode


Figure 21-10: Block Mode

When in Block mode, use the left mouse button in the main draw window to set the location for the "purple" corner of the block. Use the right mouse button to locate the opposite "blue" corner of the block. When in Block mode, the "Save Subset" operation under the main "File" menu is available.

Add

When in this mode, the block will be "added" to the current Z-buffer contents.

Subtract

When in this mode, the block will be "subtracted" from the current Z-buffer contents. Subtract mode is only effective when the block intersects some other object in the display (such as an iso-surface).

Display Button

Clicking this button will cause the block to be drawn.

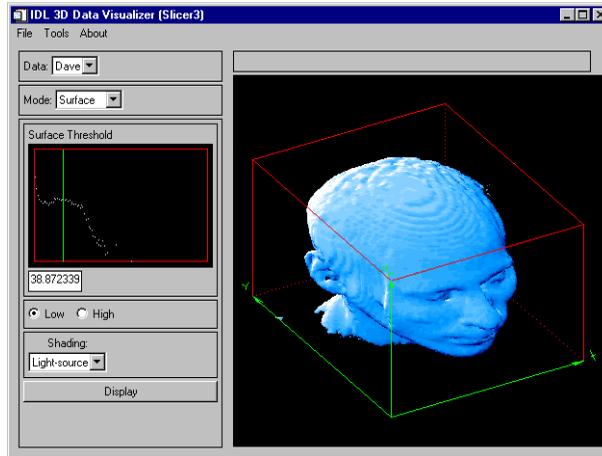
Surface Mode


Figure 21-11: Surface Mode

An iso-surface is like a contour line on a contour map. On one side of the line, the elevation is higher than the contour level, and on the other side of the line, the elevation is lower than the contour level. An iso-surface, however, is a 3-D surface that passes through the data such that the data values on one side of the surface are higher than the threshold value, and on the other side of the surface, the data values are lower than the threshold value.

When in Surface mode, a logarithmic histogram plot of the data is displayed in the small draw window. Click and drag a mouse button on this plot to set the iso-surface threshold value. This value is also shown in the text widget below the plot. The threshold value may also be set by typing a new value in this text widget. The histogram plot is affected by the current threshold settings. (See Threshold mode, below).

Low

Selecting this mode will cause the iso-surface polygon facing to face towards the lower data values. Usually, this is the mode to use when the iso-surface is desired to surround high data values.

High

Selecting this mode will cause the iso-surface polygon facing to face towards the higher data values. Usually, this is the mode to use when the iso-surface is desired to surround low data values.

Shading pulldown menu

Iso-surfaces are normally rendered with light-source shading. If multiple datasets are currently loaded, then this menu allows the selection of a different 3-D array for the source of the iso-surface shading values. If only one dataset is currently loaded, then this menu is inactive.

Display Button

Clicking this button will cause the iso-surface to be created and drawn. Iso-surfaces often consist of tens of thousands of polygons, and can sometimes take considerable time to create and render.

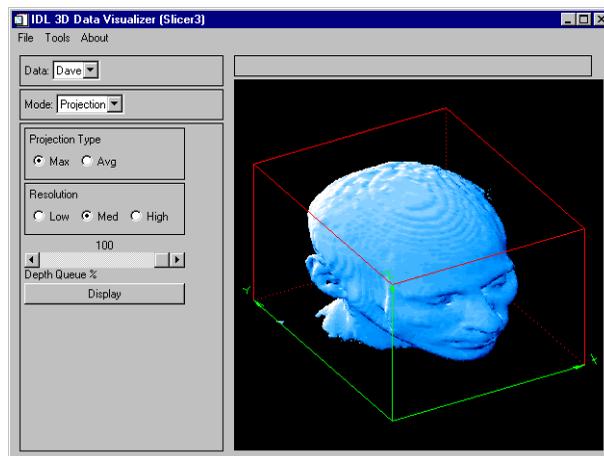
Projection Mode


Figure 21-12: Projection Mode

A "voxel" projection of a 3-D array is the projection of the data values within that array onto a viewing plane. This is similar to taking an X-ray image of a 3-D object.

Max

Select this mode for a Maximum intensity projection.

Avg

Select this mode for an Average intensity projection.

Low

Select this mode for a Low resolution projection.

Med

Select this mode for a Medium resolution projection.

High

Select this mode for a High resolution projection.

Depth Queue % Slider

Use the slider to set the depth queue percent. A value of 50, for example, indicates that the farthest part of the projection will be 50% as bright as the closest part of the projection.

Display Button

Clicking this button will cause the projection to be calculated and drawn. Projections can sometimes take considerable time to display. Higher resolution projections take more computation time.

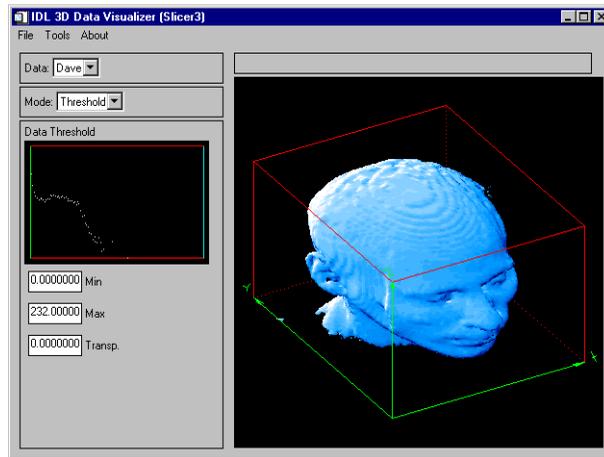
Threshold Mode


Figure 21-13: Threshold Mode

When in Threshold mode, a logarithmic histogram plot of the data is displayed in the small draw window. Click and drag the left mouse button on this plot to set the minimum and maximum threshold values. To expand a narrow range of data values into the full range of available colors, set the threshold range before displaying slices, blocks, or projections. The threshold settings also affect the histogram plot in "Surface" mode. The minimum and maximum threshold values are also shown in the text widgets below the histogram plot.

Click and drag the right mouse button on the histogram plot to set the transparency threshold. Portions of any slice, block, or projection that are less than the transparency value are not drawn (clear). Iso-surfaces are not affected by the transparency threshold. The transparency threshold value is also shown in a text widget below the histogram plot.

Min

In this text widget, a minimum threshold value can be entered.

Max

In this text widget, a maximum threshold value can be entered.

Transp.

In this text widget, a transparency threshold value can be entered.

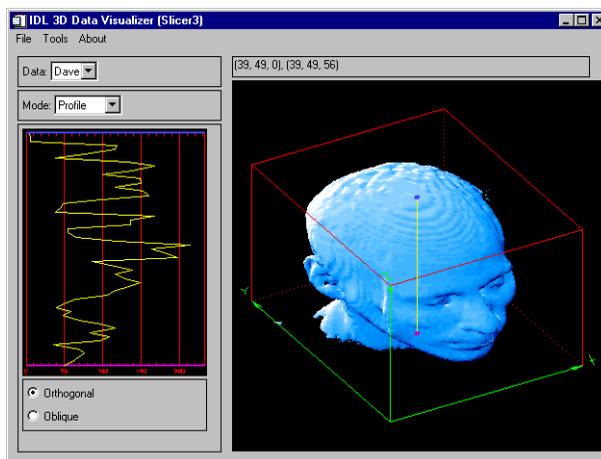
Profile Mode


Figure 21-14: Profile Mode

In Profile mode, a plot is displayed showing the data values along a line. This line is also shown superimposed on the data in the main draw window. The bottom of the plot corresponds to the "purple" end of the line, and the top of the plot corresponds to the "blue" end of the line.

Orthogonal

Click and drag the left mouse button to position the profile line, based upon a point on the "front" faces of the wire-frame cube. Click and drag the right mouse button to position the profile line, based upon a point on the "back" faces of the wire-frame cube. As the profile line is moved, The profile plot is dynamically updated.

Oblique

Click and drag the left mouse button to position the "purple" end of the profile line on one of the "front" faces of the wire-frame cube. Click and drag the right mouse button to position the "blue" end of the profile line on one of the "back" faces of the wire-frame cube. As the profile line is moved, The profile plot is dynamically updated.

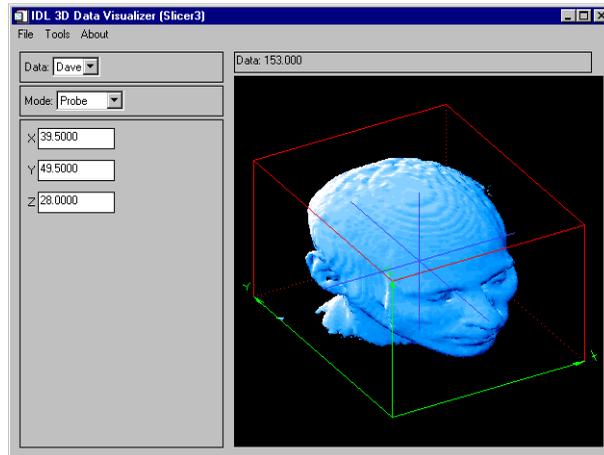
Probe Mode


Figure 21-15: Probe Mode

In Probe mode, click and drag a mouse button over an object in the main draw window. The actual X-Y-Z location within the data volume is displayed in the three text widgets. Also, the data value at that 3-D location is displayed in the status window, above the main draw window. If the cursor is inside the wire-frame cube, but not on any object, then the status window displays "No data value", and the three text widgets are empty. If the cursor is outside the wire-frame cube, then the status window and text widgets are empty.

X

Use this text widget to enter the X coordinate for the probe.

Y

Use this text widget to enter the Y coordinate for the probe.

Z

Use this text widget to enter the Z coordinate for the probe.

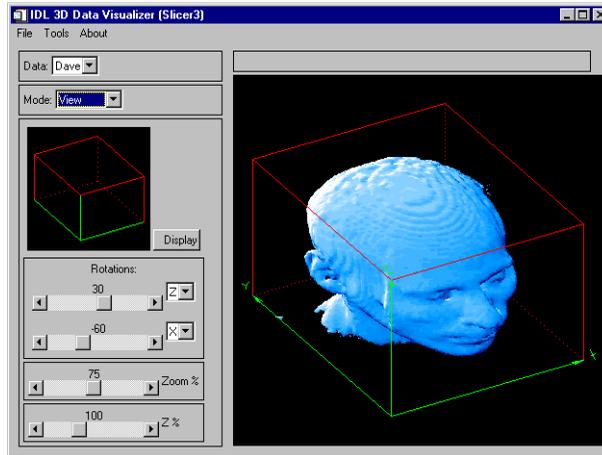
View Mode


Figure 21-16: View Mode

In view mode, a small window shows the orientation of the data cube in the current view. As view parameters are changed, this window is dynamically updated. The main draw window is then updated when the user clicks on "Display", or exits View mode.

Display

Clicking on this button will cause the objects in the main view window to be drawn in the new view. If any view parameters have been changed since the last time the main view was updated, the main view will be automatically redrawn when the user exits View mode.

1st Rotation

Use this slider to set the angle of the first view rotation (in degrees). The droplist widget adjacent to the slider indicates which axis this rotation is about.

2nd Rotation

Use this slider to set the angle of the second view rotation (in degrees). The droplist widget adjacent to the slider indicates which axis this rotation is about.

Zoom % Slider

Use this slider to set the zoom factor percent. Depending upon the view rotations, SLICER3 may override this setting to ensure that all eight corners of the data cube are within the window.

Z % Slider

Use this slider to set a scale factor for the Z axis (to compensate for the data's aspect ratio).

Operational Details

The SLICER3 procedure has the following side effects:

- SLICER3 sets the position for the light source and enables back-facing polygons to be drawn (see the IDL "SET_SHADING" command).

- SLICER3 overwrites the existing contents of the Z-buffer. Upon exiting SLICER3, the Z-buffer contents are the same as what was last displayed by SLICER3.

- On 24-bit displays, SLICER3 sets the device to non-decomposed color mode (DEVICE, DECOMPOSED=0).

- SLICER3 overwrites the existing color table. Upon exiting SLICER3, the color table (as displayed in another window, such as PLOT) is the same as what was last displayed by SLICER3.

On 24-bit displays, you can often improve performance by running SLICER3 in 8-bit mode. This can be accomplished (on some platforms) by entering the following command at the start of the IDL session (before any windows are created):

```
Device, Pseudo_Color=8
```

Examples

Note
Also see "Planar Slicing of Volumetric Data" (Chapter 2, *Image Processing in IDL*) for additional examples.

The following IDL commands open a data file from the IDL distribution and load it into SLICER3:

```
; Choose a data file:
file=FILEPATH('head.dat', SUBDIR=['examples', 'data'])
```

```
; Open the data file:
OPENR, UNIT, file, /GET_LUN

; Create an array to hold the data:
data = BYTARR(80, 100, 57, /NOZERO)

; Read the data into the array:
READU, UNIT, data

; Close the data file:
CLOSE, UNIT

; Create a pointer to the data array:
hData = PTR_NEW(data, /NO_COPY)

; Load the data into SLICER3:
SLICER3, hdata, DATA_NAMES='Dave'
```

Note

If data are loaded via the File menu after SLICER3 is launched with a pointer
argument (as shown above), the pointer becomes invalid. You can use an IDL
statement like the following to "clean up" after calling SLICER3 in this fashion:

```
if PTR_VALID(hdata) then PTR_FREE, hdata
```

Because we did not launch SLICER3 with the MODAL keyword, the last contents of
the main draw window still reside in IDL's Z-buffer. To retrieve this image after
exiting SLICER3, use the following IDL statements:

```
; Save the current graphics device:
current_device = !D.Name

; Change to the Z-buffer device:
SET_PLOT, 'Z'

; Read the image from the Z-buffer:
image_buffer = TVRD()

; Return to the original graphics device:
SET_PLOT, current_device

; Display the image:
TV, image_buffer
```

The following IDL commands manually create a data save file suitable for dynamic
loading into SLICER3. Note that if you load data into SLICER3 as shown above, you

can also create save files by switching to BLOCK mode and using the Save Subset menu option.

```
; Store some 3-D data in a variable called data_1:
data_1 = INDGEN(20,30,40)

; Store some 3-D data in a variable called data_2:
data_2 = FINDGEN(20,30,40)

; Define the names for the datasets. Their names will appear in the
; "Data" pulldown menu in SLICER3:
data_1_name ='Test Data 1'
data_2_name ='Data 2'

; Select a data file name:
dataFile = DIALOG_PICKFILE()

; Write the file:
GET_LUN, lun
OPENW, lun, dataFile
WRITEU, lun, SIZE(data_1)
WRITEU, lun, STRLEN(data_1_name)
WRITEU, lun, BYTE(data_1_name)
WRITEU, lun, data_1
WRITEU, lun, SIZE(data_2)
WRITEU, lun, STRLEN(data_2_name)
WRITEU, lun, BYTE(data_2_name)
WRITEU, lun, data_2
CLOSE, lun
FREE_LUN, lun
```

SLIDE_IMAGE

The SLIDE_IMAGE procedure creates a scrolling graphics window for examining large images. By default, 2 draw widgets are used. The draw widget on the left shows a reduced version of the complete image, while the draw widget on the right displays the actual image with scrollbars that allow sliding the visible window.

This routine is written in the IDL language. Its source code can be found in the file slide_image.pro in the lib subdirectory of the IDL distribution.

Syntax

SLIDE_IMAGE [, *Image*] [, /BLOCK] [, CONGRID=0]
    [, FULL_WINDOW=*variable*] [, GROUP=*widget_id*] [, /ORDER]
    [, /REGISTER] [, RETAIN={0 | 1 | 2}] [, SLIDE_WINDOW=*variable*]
    [, SHOW_FULL=0] [, TITLE=*string*] [, TOP_ID=*variable*] [, XSIZE=*width*]
    [, XVISIBLE=*width*] [, YSIZE=*height*] [, YVISIBLE=*height*]

Arguments

Image

A 2-D image array to be displayed. If this argument is not specified, no image is displayed. The FULL_WINDOW and SCROLL_WINDOW keywords can be used to obtain the window numbers of the two draw widgets so they can be drawn into at a later time.

Keywords

BLOCK

Set this keyword to have XMANAGER *block* when this application is registered. By default, BLOCK is set equal to zero, providing access to the command line if active command line processing is available. Note that setting BLOCK=1 will cause *all* widget applications to block, not just this application. For more information, see the documentation for the NO_BLOCK keyword to XMANAGER.

Note ───

Only the outermost call to XMANAGER can block. Therefore, to have SLIDE_IMAGE block, any earlier calls to XMANAGER must have been called with the NO_BLOCK keyword. See the documentation for the NO_BLOCK keyword to XMANAGER for an example.

───

CONGRID

Normally, the image is processed with the CONGRID procedure before it is written to the fully visible window on the left. Specifying CONGIRD=0 will force the image to be drawn as is.

FULL_WINDOW

Set this keyword to a named variable that will contain the IDL window number of the fully visible window. This window number can be used with the WSET procedure to draw to the scrolling window at a later point.

GROUP

Set this keyword to the widget ID of the widget that calls SLIDE_IMAGE. If set, the death of the caller results in the death of SLIDE_IMAGE.

ORDER

This keyword is passed directly to the TV procedure to control the order in which the images are drawn. Usually, images are drawn from the bottom up. Set this keyword to a non-zero value to draw images from the top down.

REGISTER

Set this keyword to create a "Done" button for SLIDE_IMAGE and register the widgets with the XMANAGER procedure.

The basic widgets used in this procedure do not generate widget events, so it is not necessary to process events in an event loop. The default is therefore to simply create the widgets and return. Hence, when REGISTER is not set, SLIDE_IMAGE can be displayed and the user can still type commands at the IDL command prompt.

RETAIN

This keyword is passed directly to the WIDGET_DRAW function. RETAIN specifies how backing store should be handled for the window. Valid values are:

- 0 — Specifies no backing store. In this case, it is recommended that the REGISTER keyword be set so that expose and scroll events are handled.

- 1 — Requests that the server or window system provide backing store. This is the default if RETAIN is not specified.

- 2 — Specifies that IDL provide backing store directly.

See "Backing Store" on page 5409 for details.

SLIDE_WINDOW

Set this keyword to a named variable that will contain the IDL window number of the sliding window. This window number can be used with the WSET procedure to draw to the scrolling window at a later time.

SHOW_FULL

Set this keyword to zero to show the entire image at full resolution in one scrolling graphics window. By default, SHOW_FULL is set, displaying two draw widgets.

TITLE

Set this keyword to the title to be used for the SLIDE_IMAGE widget. If this keyword is not specified, "Slide Image" is used.

TOP_ID

Set this keyword to a named variable that will contain the top widget ID of the SLIDE_IMAGE hierarchy. This ID can be used to kill the hierarchy as shown below:

```
SLIDE_IMAGE, TOP_ID=base, ...
WIDGET_CONTROL, /DESTROY, base
```

XSIZE

Set this keyword to the maximum width of the image that can be displayed by the scrolling window. This keyword should not be confused with the visible size of the image, controlled by the XVISIBLE keyword. If XSIZE is not specified, the width of *Image* is used. If *Image* is not specified, 256 is used.

XVISIBLE

Set this keyword to the width of the viewport on the scrolling window. If this keyword is not specified, 256 is used.

YSIZE

Set this keyword to the maximum height of the image that can be displayed by the scrolling window. This keyword should not be confused with the visible size of the image, controlled by the YVISIBLE keyword. If YSIZE is not present the height of *Image* is used. If *Image* is not specified, 256 is used.

YVISIBLE

Set this keyword to the height of the viewport on the scrolling window. If this keyword is not present, 256 is used.

Examples

The following example imports a grayscale image from the `nyny.dat` binary file. This grayscale image is an aerial view of New York City. The image contains byte data values and is 768 pixels by 512 pixels. You can use the SLIDE_IMAGE procedure to zoom in on the image and pan over it.

Example Code

See `panning_direct.pro` in the `examples/doc/image` subdirectory of the IDL installation directory for code that duplicates this example. Run the example procedure by entering `panning_direct` at the IDL command prompt or view the file in an IDL Editor window by entering `.EDIT panning_direct.pro`.

1. Determine the path to the `nyny.dat` file:

```
file = FILEPATH('nyny.dat', $
    SUBDIRECTORY = ['examples', 'data'])
```

2. Initialize the image size parameter:

```
imageSize = [768, 512]
```

3. Import the image from the file:

```
image = READ_BINARY(file, DATA_DIMS = imageSize)
```

4. If you are running IDL on a TrueColor display, set the DECOMPOSED keyword to the DEVICE command to zero before your first color table related routine is used within an IDL session or program.

```
DEVICE, DECOMPOSED = 0
```

5. Load a grayscale color table:

```
LOADCT, 0
```

6. Display the image with the SLIDE_IMAGE procedure:

```
SLIDE_IMAGE, image
```

Use the sliders in the display on the right side to pan over the image.

The following figure shows a possible display within the SLIDE_IMAGE application.

Figure 21-17: The SLIDE_IMAGE Application Displaying an Image of New York

SMOOTH

The SMOOTH function returns a copy of *Array* smoothed with a boxcar average of the specified width. The result has the same type and dimensions as *Array*. The algorithm used by SMOOTH is:

$$
R_i = \begin{cases} \dfrac{1}{w} \displaystyle\sum_{j=0}^{w-1} A_{i+j-w/2}, & i = \dfrac{(w-1)}{2}, ..., N - \dfrac{(w+1)}{2} \\[2em] A_i, \text{ otherwise} \end{cases}
$$

where *N* is the number of elements in A.

Syntax

Result = SMOOTH(*Array, Width* [, /EDGE_TRUNCATE] [, MISSING=*value*] [, /NAN])

Return Value

Returns the smoothed array, which has the same dimensions as the input array.

Arguments

Array

The array to be smoothed. *Array* can have any number of dimensions.

Width

The width of the smoothing window. *Width* can either be a scalar or a vector with length equal to the number of dimensions of *Array*. If *Width* is a scalar then the same width is applied for each dimension that has length greater than 1 (dimensions of length 1 are skipped). If *Width* is a vector, then each element of *Width* is used to specify the smoothing width for each dimension of *Array*. Values for *Width* must be smaller than the corresponding *Array* dimension. If a *Width* value is even, then *Width*+1 will be used instead. The value of *Width* does not affect the running time of SMOOTH to a great extent.

Note ───────────────────────────────────────

A Width value of zero or 1 implies no smoothing. However, if the NAN keyword is set, then any NaN values within the Array will be treated as missing data and will be replaced.

Tip ───────────────────────────────────────

For a multi-dimensional array, set widths to 1 within the Width vector for dimensions that you don't want smoothed.

Keywords

EDGE_TRUNCATE

Set this keyword to apply the smoothing function to all points. If the neighborhood around a point includes a point outside the array, the nearest edge point is used to compute the smoothed result. If EDGE_TRUNCATE is not set, the end points are copied from the original array to the result with no smoothing.

For example, when smoothing an *n*-element vector with a three point wide smoothing window, the first point of the result R_0 is equal to A_0 if EDGE_TRUNCATE is not set, but is equal to $(A_0+A_0+A_1)/3$ if the keyword is set. In the same manner, point R_{n-1} is set to A_{n-1} if EDGE_TRUNCATE is not set, or to $(A_{n-2}+A_{n-1}+A_{n-1})/3$ if it is.

Note ───────────────────────────────────────

Normally, two-dimensional floating-point arrays are smoothed in one pass. If the EDGE_TRUNCATE keyword is specified for a two-dimensional floating-point array, the result is obtained in two passes, first for all of the rows, and second for all of the columns. Therefore, the results for points in the interior of the array may differ slightly when the EDGE_TRUNCATE keyword is set. This difference will be most pronounced if the array contains NaN values.

MISSING

The value to return for elements that contain no valid points within the kernel. The default is the IEEE floating-point value NaN. This keyword is only used if the NAN keyword is set.

NAN

Set this keyword to cause the routine to check for occurrences of the IEEE floating-point values *NaN* or *Infinity* in the input data. Elements with the value *NaN* or *Infinity* are treated as missing data. (See "Special Floating-Point Values" (Chapter 8,

Application Programming) for more information on IEEE floating-point values.) In the *Result*, missing elements are replaced by the smoothed value of all other valid points within the smoothing window. If all points within the window are missing, then the result at that point is given by the MISSING keyword.

Note —————————————————————————————————————
SMOOTH should never be called without the NAN keyword if the input array may possibly contain *NaN* values.

Examples

Note —————————————————————————————————————
Also see "Smoothing an Image" (Chapter 8, *Image Processing in IDL*).

Create and display a simple image by entering:

```
WINDOW, XSIZE=800, YSIZE=400
D = SIN(DIST(256)/3)
TVSCL, D
```

Now display the same dataset smoothed with a width of 9 in each dimension by entering:

```
TVSCL, SMOOTH(D, 9), 256, 0
```

Now smooth only in the vertical direction with a width of 15:

```
TVSCL, SMOOTH(D, [1, 15]), 512, 0
```

This example shows the use of SMOOTH with the multidimensional width argument on an RGB image.

```
; Determine the path to the file.
file = FILEPATH('rose.jpg', $
   SUBDIRECTORY = ['examples', 'data'])
; Import in the RGB image from the file.
image = READ_IMAGE(file)
; Initialize the image size parameter.
imageSize = SIZE(image, /DIMENSIONS)
; Initialize the display.
DEVICE, DECOMPOSED = 1
WINDOW, 0, XSIZE = imageSize[1], YSIZE = imageSize[2], $
   TITLE = 'Original Rose Image'
; Display the original image on the left side.
TV, image, TRUE = 1
; Initialize another display.
WINDOW, 1, XSIZE = 3*imageSize[1], YSIZE = imageSize[2], $
```

```
   TITLE = 'Vertically Smoothed (left), Horizontally ' + $
   'Smoothed (middle), and Both (right)'
; Smooth the RGB image in just the width dimension.
smoothed = SMOOTH(image, [1, 1, 21])
; Display the results.
TV, smoothed, 0, TRUE = 1
; Smooth the RGB image in just the height dimension.
smoothed = SMOOTH(image, [1, 21, 1])
; Display the results.
TV, smoothed, 1, TRUE = 1
; Smooth the RGB image in just the width and height dimensions.
smoothed = SMOOTH(image, [1, 5, 5])
; Display the results.
TV, smoothed, 2, TRUE = 1
```

SOBEL

The SOBEL function returns an approximation to the Sobel edge enhancement operator for images,

$$G_{jk} = |G_x| + |G_y|$$

$$G_Y = F_{j-1, k-1} + 2F_{j, k-1} + F_{j+1, k-1} - (F_{j-1, k+1} + 2F_{j, k+1} + F_{j+1, k+1})$$

$$G_X = F_{j+1, k+1} + 2F_{j+1, k} + F_{j+1, k-1} - (F_{j-1, k+1} + 2F_{j-1, k} + F_{j-1, k-1})$$

where (j, k) are the coordinates of each pixel F_{jk} in the *Image*. This is equivalent to a convolution using the masks,

$$\text{X mask} = \begin{bmatrix} -1 & 0 & 1 \\ -2 & 0 & 2 \\ -1 & 0 & 1 \end{bmatrix} \qquad \text{Y mask} = \begin{bmatrix} 1 & 2 & 1 \\ 0 & 0 & 0 \\ -1 & -2 & -1 \end{bmatrix}$$

All of the edge points in the result are set to zero.

Syntax

Result = SOBEL(*Image*)

Return Value

SOBEL returns a two-dimensional array of the same size as *Image*. If *Image* is of type byte or integer then the result is of integer type, otherwise the result is of the same type as *Image*.

Note

To avoid overflow for integer types, the computation is done using the next larger signed type and the result is transformed back to the correct type. Values larger than the maximum for that integer type are truncated. For example, for integers the function is computed using type long, and on output, values larger than 32767 are set equal to 32767.

Arguments

Image

The two-dimensional array containing the image to which edge enhancement is applied.

Keywords

None.

Examples

If the variable myimage contains a two-dimensional image array, a Sobel sharpened version of myimage can be displayed with the command:

```
TVSCL, SOBEL(myimage)
```

Note

Also see "Detecting Edges" (Chapter 8, *Image Processing in IDL*).

SOCKET

The SOCKET procedure opens a client-side TCP/IP Internet socket as an IDL file unit. Such files can be used in the standard manner with any of IDL's Input/Output routines.

Tip ————————————————————————————————————

Avoid using the EOF procedure as a way to check to see if a socket is empty. Instead, structure your communication across the socket so that using EOF is not necessary to know when the communication is complete.

Syntax

SOCKET, *Unit*, *Host*, *Port* [, CONNECT_TIMEOUT=*value*] [, ERROR=*variable*]
   [, /GET_LUN] [, /RAWIO] [, READ_TIMEOUT=*value*] [, /SWAP_ENDIAN]
   [, /SWAP_IF_BIG_ENDIAN] [, /SWAP_IF_LITTLE_ENDIAN]
   [, WIDTH=*value*] [, WRITE_TIMEOUT=*value*]

UNIX-Only Keywords: [, /STDIO]

Arguments

Unit

The unit number to associate with the opened socket.

Host

The name of the host to which the socket is connected. This can be either a standard Internet host name (*e.g.* ftp.ittvis.com) or a dot-separated numeric address (*e.g.* 192.5.156.21).

Port

The port to which the socket is connected on the remote machine. If this is a well-known port (as contained in the /etc/services file on a UNIX host), then you can specify its name (*e.g.* daytime); otherwise, specify a number.

Keywords

CONNECT_TIMEOUT

Set this keyword to the number of seconds to wait before giving up and issuing an error to shorten the connect timeout from the system-supplied default. Most experts recommend that you not specify an explicit timeout, and instead use your operating system defaults.

Note ———————————————————————————————————

Although you can use CONNECT_TIMEOUT to shorten the timeout, you cannot increase it past the system-supplied default.

———

ERROR

A named variable in which to place the error status. If an error occurs in the attempt to open the socket, IDL normally takes the error handling action defined by the ON_ERROR and/or ON_IOERROR procedures. SOCKET always returns to the caller without generating an error message when ERROR is present. A nonzero error status indicates that an error occurred. The error message can then be found in the system variable !ERROR_STATE.MSG.

GET_LUN

Set this keyword to use the GET_LUN procedure to set the value of *Unit* before the file is opened. Instead of using the two statements:

```
GET_LUN, Unit
OPENR, Unit, 'data.dat'
```

you can use the single statement:

```
OPENR, Unit, 'data.dat', /GET LUN
```

RAWIO

Set this keyword to disable all use of the standard operating system I/O for the file, in favor of direct calls to the operating system. This allows direct access to devices, such as tape drives, that are difficult or impossible to use effectively through the standard I/O. Using this keyword has the following implications:

• No formatted or associated (ASSOC) I/O is allowed on the file. Only READU and WRITEU are allowed.

- Normally, attempting to read more data than is available from a file causes the unfilled space to be set to zero and an error to be issued. This does not happen with files opened with RAWIO. When using RAWIO, the programmer must check the transfer count, either via the TRANSFER_COUNT keywords to READU and WRITEU, or the FSTAT function.

- The EOF and POINT_LUN functions cannot be used with a file opened with RAWIO.

- Each call to READU or WRITEU maps directly to UNIX read(2) and write(2) system calls. The programmer must read the UNIX system documentation for these calls and documentation on the target device to determine if there are any special rules for I/O to that device. For example, the size of data that can be transferred to many cartridge tape drives is often forced to be a multiple of 512 bytes.

READ_TIMEOUT

Set this keyword to the number of seconds to wait for data to arrive before giving up and issuing an error. By default, IDL blocks indefinitely until the data arrives. Typically, this option is unnecessary on a local network, but it is useful with networks that are slow or unreliable.

STDIO

This keyword is only available on UNIX platforms.

Under UNIX, forces the file to be opened via the standard C I/O library (stdio) rather than any other more native OS API that might usually be used. This is primarily of interest to those who intend to access the file from external code, and is not necessary for most uses.

Note

Under Windows, the STDIO feature is not possible. Requesting it causes IDL to throw an error.

SWAP_ENDIAN

Set this keyword to swap byte ordering for multi-byte data when performing binary I/O on the specified file. This is useful when accessing files also used by another system with byte ordering different than that of the current host.

SWAP_IF_BIG_ENDIAN

Setting this keyword is equivalent to setting SWAP_ENDIAN; it only takes effect if the current system has big endian byte ordering. This keyword does not refer to the byte ordering of the input data, but to the computer hardware.

SWAP_IF_LITTLE_ENDIAN

Setting this keyword is equivalent to setting SWAP_ENDIAN; it only takes effect if the current system has little endian byte ordering. This keyword does not refer to the byte ordering of the input data, but to the computer hardware.

WIDTH

The desired output width. When using the defaults for formatted output, IDL uses the following rules to determine where to break lines:

- If the output file is a terminal, the terminal width is used.

- Otherwise, a default of 80 columns is used.

The WIDTH keyword allows the user to override this default.

WRITE_TIMEOUT

Set this keyword to the number of seconds to wait to send data before giving up and issuing an error. By default, IDL blocks indefinitely until it is possible to send the data. Typically, this option is unnecessary on a local network, but it is useful with networks that are slow or unreliable.

Examples

Most UNIX systems maintain a daytime server on the daytime port (port 13). These servers send a 1 line response when connected to, containing the current time of day.

```
; To obtain the current time from the host bullwinkle:
SOCKET, 1, 'bullwinkle','daytime'
date=''
READF, 1, date
CLOSE, 1
PRINT, date
```

IDL prints:

```
Wed Sep 15 17:20:27 1999
```

Version History

5.3	Introduced
5.6	Added SWAP_IF_BIG_ENDIAN and SWAP_IF_LITTLE_ENDIAN keywords

See Also

FILE_POLL_INPUT

SORT

The SORT function returns a vector of subscripts that allow access to the elements of *Array* in ascending order.

Syntax

Result = SORT(*Array* [, /L64])

Return Value

The result is always a vector of integer type with the same number of elements as *Array.*

Note ―――――――――――――――――――――――――――――――――――
If *Array* contains any identical elements, the order in which the identical elements are sorted is arbitrary and may vary between operating systems.
―――――――――――――――――――――――――――――――――――――――

Arguments

Array

The array to be sorted. *Array* can be any basic type of vector or array. String arrays are sorted using the ASCII collating sequence. Complex arrays are sorted by their magnitude. Array values which are Not A Number (NaN) are moved to the end of the resulting array.

Keywords

L64

By default, the result of SORT is 32-bit integer when possible, and 64-bit integer if the number of elements being sorted requires it. Set L64 to force 64-bit integers to be returned in all cases.

Note ―――――――――――――――――――――――――――――――――――
Only 64-bit versions of IDL are capable of creating variables requiring a 64-bit sort. Check the value of !VERSION.MEMORY_BITS to see if your IDL is 64-bit or not.
―――――――――――――――――――――――――――――――――――――――

Examples

Example 1

```
A = [4, 3, 7, 1, 2]
PRINT, 'SORT(A) = ', SORT(A)

; Display the elements of A in sorted order:
PRINT, 'Elements of A in sorted order: ', A[SORT(A)]

; Display the elements of A in descending order:
PRINT, 'Elements of A in descending order: ', A[REVERSE(SORT(A))]
```

IDL prints:

```
SORT(A) =    3    4    1    0    2
Elements of A in sorted order:    1    2    3    4    7
Elements of A in descending order:    7    4    3    2    1
```

SORT(A) returns "3 4 1 0 2" because:

$$A[3] < A[4] < A[1] < A[0] < A[2]$$

Example 2

Sorting NaN Values

When sorting data including Not A Number (NaN) values, the NaN entries are moved to the end of the resulting array. For example:

```
values = [ 500, !VALUES.F_NAN, -500 ]
PRINT, SORT(values)
```

IDL prints:

```
2           0           1
```

REVERSE, UNIQ, WHERE

SPAWN

The SPAWN procedure spawns a child process to execute a command or series of commands. The result of calling SPAWN depends on the platform on which it is being used:

- Under UNIX, the shell used (if any) is obtained from the SHELL environment variable. The NOSHELL keyword can be used to execute a command directly as a child process without starting a shell process.

- Under Windows, a Command Shell is opened. The NOSHELL keyword can be used to execute the specified command directly without starting an intermediate command interpreter shell.

Note ──

See "Using SPAWN Without a Shell Under UNIX" on page 2331 for notes on executing commands without using a shell process under UNIX. See "Execution Directory under Microsoft Windows" on page 2332 for a caution regarding Windows network paths.

──

If SPAWN is called without arguments, an interactive command interpreter process is started, in which you can enter one or more operating system commands.

By default, IDL waits for the child process started by SPAWN to finish before it continues. It is possible to have IDL instead continue execution in parallel with the child process. The syntax for this depends on the operating system on your system:

- Under UNIX, include an ampersand (&) at the end of your shell command.
- Under Windows, specify the NOWAIT keyword to SPAWN.

Note ──

For more information on using SPAWN, see Chapter 2, "Using SPAWN and Pipes" (*External Development Guide*).

──

Syntax

SPAWN [, *Command* [, *Result*] [, *ErrResult*]]

Keywords (all platforms): [, COUNT=*variable*] [, EXIT_STATUS=*variable*]
   [,/NOSHELL] [, /NULL_STDIN] [, PID=*variable*] [, /STDERR]
   [, UNIT=*variable* {*Command* required, *Result* and *ErrResult* not allowed}]

UNIX-Only Keywords: [, /NOTTYRESET] [, /SH]

Windows-Only Keywords: [, /HIDE] [, /LOG_OUTPUT] [, /NOWAIT]

Arguments

Command

A string containing the commands to be executed.

If *Command* is present, it must be specified as follows:

- On UNIX, *Command* is expected to be scalar unless used in conjunction with the NOSHELL keyword, in which case *Command* is expected to be a string array where each element is passed to the child process as a separate argument.

- On Windows, *Command* can be a scalar string or string array. If it is a string array, SPAWN glues together each element of the string array, with each element separated by whitespace.

If *Command* is not present, SPAWN starts an interactive command interpreter process, which you can use to enter one or more operating system commands. While you use the command interpreter process, IDL is suspended. Under Windows, an interactive command shell window is created for this purpose. UNIX spawn does not create a separate window, but simply runs on the user's current tty, using the default shell (as specified by the SHELL environment variable). The SH keyword can be used to force use of the Bourne shell (/bin/sh).

Note

Using SPAWN in this manner is equivalent to using the IDL $ command. The difference between these two is that $ can only be used interactively while SPAWN can be used interactively or in IDL programs

Result

A named variable in which to place the output from the child process. Each line of output becomes a single array element. If *Result* is not present, the output from the child shell process goes to the standard output (usually the terminal).

Note

Result will be a null string if the NOWAIT keyword is specified (Windows) or if *Command* ends in an ampersand (&) (UNIX).

ErrResult

A named variable in which to place the error output (stderr) from the child process. Each line of output becomes a single array element. If *ErrResult* is not present, the error output from the child shell process goes to the standard error file.

Note ———————————————————————————————

See the STDERR keyword for another error stream option.

Note ———————————————————————————————

ErrResult will be a null string if the NOWAIT keyword is specified (Windows). If *Command* ends in an ampersand (`&`) (UNIX), *ErrResult* may contain an error string generated by the shell.

Keywords

COUNT

If *Result* is present and this keyword is also specified, COUNT specifies a named variable into which the number of lines of output is placed. This value gives the number of elements placed into *Result*.

EXIT_STATUS

Set this keyword to a named variable in which the exit status for the child process is returned. The meaning of this value is operating system dependent:

- Under UNIX, it is the value passed by the child to exit(2), and is analogous to the value returned by $? under most UNIX shells.

- Under Windows, it is the value returned by the Windows GetExitCodeProcess() system function. If the NOWAIT keyword is set, EXIT_STATUS returns 0.

If the UNIT keyword is used, this keyword always returns 0. In this case, use the EXIT_STATUS keyword to FREE_LUN or CLOSE to determine the final exit status of the process.

HIDE

This keyword is only available on Windows platforms.

If HIDE is set, the command interpreter shell window is minimized to prevent the user from seeing it.

LOG_OUTPUT

This keyword is only available on Windows platforms.

Normally, IDL starts a command interpreter shell, and output from the child process is displayed in the command interpreter's window. If LOG_OUTPUT is set, the command interpreter window is minimized (as with HIDE) and all output is diverted to the workbench log window. If the *Result* or *ErrResult* arguments are present, they take precedence over LOG_OUTPUT.

NOSHELL

Set this keyword to specify that *Command* should execute directly as a child process without an intervening shell process.

- UNIX – When using the NOSHELL keyword under UNIX, you must specify *Command* as a string array in which the first element is the name of the command to execute and the following arguments are the arguments to be passed to the command. See "Using SPAWN Without a Shell Under UNIX" on page 2331 for notes on executing commands without using a shell process.

- Windows – Use this keyword to start the specified *Command* directly, without the use of an intervening command shell. This is useful for Windows programs that do not require a console, such as Notepad.

  Many common DOS commands (e.g. DIR) are not distinct programs, and are instead implemented as part of the command interpreter. Specifying NOSHELL with such commands results in the command not being found. In such cases, the HIDE keyword might be useful.

NOTTYRESET

This keyword is only available on UNIX platforms.

Some UNIX systems drop characters when the tty mode is switched between normal and raw modes. IDL switches between these modes when reading command input and when using the GET_KBRD function. On such systems, IDL avoids losing characters by delaying the switch back to normal mode until it is truly needed. This method has the benefit of avoiding the large number of mode changes that would otherwise be necessary. Routines that cause output to be sent to the standard output (e.g., I/O operations, user interaction and SPAWN) ensure that the tty is in its normal mode before performing their operations.

If the NOTTYRESET keyword is set, SPAWN does not switch the tty back to normal mode before launching the child process assuming instead that the child will not send

output to the tty. Use this keyword to avoid characters being dropped in a loop of the form:

```
WHILE (GET_KBRD(0) NE 'q') SPAWN, command
```

This keyword has no effect on systems that don't suffer from dropped characters.

NOWAIT

This keyword is only available on Windows platforms.

If this keyword is set, the IDL process continues executing in parallel with the subprocess. Normally, the IDL process suspends execution until the subprocess completes.

NULL_STDIN

If set, the null device is connected to the standard input of the child process. The null device is either /dev/null (under UNIX) or NUL (under Windows).

PID

A named variable into which the Process Identification number of the child process is stored.

SH

This keyword is only available on UNIX platforms.

Set this keyword to force the use of the Bourne shell (/bin/sh). Usually, the shell used is determined by the SHELL environment variable.

STDERR

If set, the child's error output (stderr) is combined with the standard output and returned in *Result*. STDERR and the *ErrResult* argument are mutually exclusive. You should use one or the other, but not both.

UNIT

If UNIT is present, SPAWN creates a child process in the usual manner, but instead of waiting for the specified command to finish, it attaches a bidirectional pipe between the child process and IDL. From the IDL session, the pipe appears as a logical file unit. The other end of the pipe is attached to the child process standard input and output. The UNIT keyword specifies a named variable into which the number of the file unit is stored.

Once the child process is started, the IDL session can communicate with it through the usual input/output facilities. After the child process has done its task, the CLOSE procedure can be used to kill the process and close the pipe. Since SPAWN uses GET_LUN to allocate the file unit, FREE_LUN should be used to free the unit.

If UNIT is present, *Command* must be present, and neither *Result* or *ErrResult* are allowed.

Using SPAWN Without a Shell Under UNIX

When a Unix program is run, its name and arguments are provided to it as an array of strings, one string per argument. The first string is the name of the program, and the remainder (if any) are the arguments. C programmers will recognize this as the standard (argc, argv) arguments passed to the main() function when the program is run. When you execute a command via a Unix shell, one of the operations that the shell carries out for you is to split the command and arguments apart on whitespace boundaries (blanks and tabs) to create this array of arguments. It then runs the program for you, using one of the Unix system exec() functions.

By default, SPAWN creates a shell process and passes the command to this shell instead of simply creating a child process to directly execute the command. Use of a shell is the default because the shell provides useful facilities such as wildcard expansion and argument processing (described above). Although this is usually desirable, it has the drawback of being slower than necessary, and of using an additional process for the shell.

When SPAWN is called with the NOSHELL keyword set, the command is executed as a direct child process, avoiding the extra overhead of starting a shell. This is faster, but since there is no shell, you must specify the arguments in the standard form required by Unix programs. When you specify the NOSHELL keyword, the Command argument should be a string array. The first element of the array is the name of the command to use, and the following elements contain the arguments.

For example, consider the command,

```
SPAWN, 'ps ax'
```

that uses the UNIX *ps* command to show running processes on the computer. To issue this command without a shell, you would write it as follows:

```
SPAWN, ['ps', 'ax'], /NOSHELL
```

Execution Directory under Microsoft Windows

SPAWN attempts to use IDL's current working directory as the current directory for the spawned process. However, Microsoft Windows does not support the specification of a UNC path as the current directory for a Command Shell. Issuing a SPAWN command when IDL's current working directory is set to a UNC path will cause Windows to generate an error that looks something like:

```
CMD.EXE was started with '\\host\dir' as the current directory
path. UNC paths are not supported.  Defaulting to Windows
directory.
```

If your application requires that you be able to use SPAWN when IDL's current working directory is set to a directory on a Windows network, consider mapping the UNC path to a Windows drive letter and setting that to be IDL's working directory.

If your SPAWN command contains a directory name with spaces and you are using the < or > redirect tokens in a DOS window, you may receive an error. If so, you can create a temporary environment variable containing the command as follows:

```
setenv, 'MYARG="C:\test dir\ins" <  "C:\test dir\refs" >  ^
   "C:\test dir\outs"'
SPAWN, '%MYARG%'
```

Examples

Example 1: Interactive use of SPAWN

To simply spawn a shell process from within IDL, enter the command:

```
SPAWN
```

To execute the UNIX `ls` command and return to the IDL prompt, enter:

```
SPAWN, 'ls'
```

To execute the UNIX `ls` command and store the result in the IDL string variable `listing`, enter:

```
SPAWN, 'ls', listing
```

Example 2: Noninteractive use of SPAWN

It is sometimes useful to create a temporary scratch file, removing the file when it is no longer needed. SPAWN could be used as shown below to manage the removal of the scratch file.

```
OPENW, UNIT, 'scratch.dat', /GET_LUN
```

```
;...IDL commands go here.

;Deallocate the file unit and close the file.
FREE_LUN, UNIT

;Use the !VERSION system variable to determine the proper file
;deletion command for the current operating system.
CASE !VERSION.OS OF
  'Windows': CMD = 'DEL'
  ELSE: CMD = 'rm'
ENDCASE

;Delete the file using SPAWN.
SPAWN, CMD + ' scratch.dat'

END
```

Note

The DELETE keyword to the OPENR/OPENU/OPENW procedure or the FILE_DELETE procedure more efficiently handles this job. The above example should serve only to demonstrate use of the SPAWN procedure.

SPH_4PNT

Given four 3-dimensional points, the SPH_4PNT procedure returns the center and radius necessary to define the unique sphere passing through those points.

This routine is written in the IDL language. Its source code can be found in the file `sph_4pnt.pro` in the `lib` subdirectory of the IDL distribution.

Syntax

SPH_4PNT, *X*, *Y*, *Z*, *Xc*, *Yc*, *Zc*, *R* [, /DOUBLE]

Arguments

X, Y, Z

4-element floating-point or double-precision vectors containing the X, Y, and Z coordinates of the points.

Xc, Yc, Zc

Named variables that will contain the sphere's center X, Y, and Z coordinates.

R

A named variable that will contain the sphere's radius.

Keywords

DOUBLE

Set this keyword to force computations to be done in double-precision arithmetic.

Examples

Find the center and radius of the unique sphere passing through the points: (1, 1, 0), (2, 1, 2), (1, 0, 3), (1, 0, 1):

```
; Define the floating-point vectors containing the x, y and z
; coordinates of the points:
X = [1, 2, 1, 1] + 0.0
Y = [1, 1, 0, 0] + 0.0
Z = [0, 2, 3, 1] + 0.0
```

```
; Compute sphere's center and radius:
SPH_4PNT, X, Y, Z, Xc, Yc, Zc, R

; Print the results:
PRINT, Xc, Yc, Zc, R
```

IDL prints:

```
-0.500000      2.00000      2.00000      2.69258
```

CIR_3PNT, PNT_LINE

SPH_SCAT

The SPH_SCAT function performs spherical gridding. Scattered samples on the surface of a sphere are interpolated to a regular grid. This routine is a convenient interface to the spherical gridding and interpolation provided by TRIANGULATE and TRIGRID.

This routine is written in the IDL language. Its source code can be found in the file sph_scat.pro in the lib subdirectory of the IDL distribution.

Syntax

Result = SPH_SCAT(*Lon*, *Lat*, *F* [, BOUNDS=*[lonmin, latmin, lonmax, latmax]*]
  [, BOUT=*variable*] [, GOUT=*variable*] [, GS=*[lonspacing, latspacing]*]
  [, NLON=*value*] [, NLAT=*value*])

Return Value

Returns a regularly-interpolated grid of the function.

Arguments

Lon

A vector of sample longitudes, in degrees.

Note
  Lon, Lat, and *F* must all have the same number of points.

Lat

A vector of sample latitudes, in degrees.

F

A vector of data values which are functions of Lon and Lat. F_i represents a value at (*Lon$_i$, Lat$_i$*).

Keywords

BOUNDS

Set this keyword to a four-element vector containing the grid limits in longitude and latitude of the output grid. The four elements are: [Lon_{min}, Lat_{min}, Lon_{max}, Lat_{max}]. If this keyword is not set, the grid limits are set to the extent of *Lon* and *Lat*.

Note ───

To cover all longitudes, you must explicitly specify the values for the BOUNDS keyword.

───

BOUT

Set this keyword to a named variable that, on return, contains a four-element vector (similar to BOUNDS) that describes the actual extent of the regular grid.

GOUT

Set this keyword to a named variable that, on return, contains a two-element vector (similar to GS) that describes the actual grid spacing.

GS

Set this keyword to a two-element vector that specifies the spacing between grid points in longitude (the first element) and latitude (the second element).

If this keyword is not set, the default value is based on the extents of *Lon* and *Lat*. The default longitude spacing is (Lon_{max} - Lon_{min})/(NLON-1). The default latitude spacing is (Lat_{max} - Lat_{min})/(NLAT-1). If NLON and NLAT are not set, the default grid size of 26 by 26 is used for NLON and NLAT.

NLON

The output grid size in the longitude direction. The default value is 26.

Note ───

NLON need not be specified if the size can be inferred from GS and BOUNDS.

───

NLAT

The output grid size in the latitude direction. The default value is 26.

Note

NLAT need not be specified if the size can be inferred from GS and BOUNDS.

Examples

```
; Create some random longitude points:
lon = RANDOMU(seed, 50) * 360. -180.

; Create some random latitude points:
lat = RANDOMU(seed, 50) * 180. -90.

; Make a function to fit:
z = SIN(lat*!DTOR)
c = COS(lat*!DTOR)
x = COS(lon*!DTOR) * c
y = SIN(lon*!DTOR) * c

; The finished dependent variable:
f = SIN(x+y) * SIN(x*z)
; Interpolate the data and return the result in variable r:
r = SPH_SCAT(lon, lat, f, BOUNDS=[0, -90, 350, 85], GS=[10,5])
```

TRIANGULATE, TRIGRID

SPHER_HARM

The SPHER_HARM function returns the value of the spherical harmonic $Y_{lm}(\theta,\phi)$, $-l \leq m \leq l$, $l \geq 0$, which is a function of two coordinates on a spherical surface.

The spherical harmonics are related to the associated Legendre polynomial by:

$$Y_{lm}(\theta,\phi) \;=\; \sqrt{\frac{2l+1}{4\pi}\frac{(l-m)!}{(l+m)!}}\,P_l^m(\cos\theta)e^{im\phi}$$

For negative *m* the following relation is used:

$$Y_{l,-m}(\theta,\phi) = (-1)^m Y_{lm}^*(\theta,\phi)$$

where * represents the complex conjugate.

This routine is written in the IDL language. Its source code can be found in the file spher_harm.pro in the lib subdirectory of the IDL distribution.

Syntax

Result = SPHER_HARM(*Theta*, *Phi*, *L*, *M*, [, /DOUBLE])

Return Value

SPHER_HARM returns a complex scalar or array containing the value of the spherical harmonic function. The return value has the same dimensions as the input arguments *Theta* and *Phi*. If one argument (*Theta* or *Phi*) is a scalar and the other argument is an array, the function uses the scalar value with each element of the array, and returns an array with the same dimensions as the input array.

If either *Theta* or *Phi* are double-precision or if the DOUBLE keyword is set, the result is double-precision complex, otherwise the result is single-precision complex.

Arguments

Theta

The value of the polar (colatitudinal) coordinate θ at which $Y_{lm}(\theta,\phi)$ is evaluated. *Theta* can be either a scalar or an array.

Phi

The value of the azimuthal (longitudinal) coordinate φ at which $Y_{lm}(\theta,\phi)$ is evaluated. *Phi* can be either a scalar or an array.

L

A scalar integer, L ≥ 0, specifying the order *l* of $Y_{lm}(\theta,\phi)$. If *L* is of type float, it will be truncated.

M

A scalar integer, $-L \leq M \leq L$, specifying the azimuthal order *m* of $Y_{lm}(\theta,\phi)$. If *M* is of type float, it will be truncated.

Keywords

DOUBLE

Set this keyword to force the computation to be done in double-precision arithmetic.

Examples

This example visualizes the electron probability density for the hydrogen atom in state 3d0. (Feynman, Leighton, and Sands, 1965: The Feynman Lectures on Physics, Calif. Inst. Tech, Ch. 19):

```
; Define a data cube (N x N x N)
n = 41L
a = 60*FINDGEN(n)/(n-1) - 29.999  ; [-1,+1]
x = REBIN(a, n, n, n)                     ; X-coordinates of cube
y = REBIN(REFORM(a,1,n), n, n, n)  ; Y-coordinates
z = REBIN(REFORM(a,1,1,n), n, n, n); Z-coordinates

; Convert from rectangular (x,y,z) to spherical (phi, theta, r)
spherCoord = CV_COORD(FROM_RECT= $
 TRANSPOSE([[x[*]],[y[*]],[z[*]]]), /TO_SPHERE)
phi = REFORM(spherCoord[0,*], n, n, n)
theta = REFORM(!PI/2 - spherCoord[1,*], n, n, n)
r = REFORM(spherCoord[2,*], n, n, n)

; Find electron probability density for hydrogen atom in state 3d0
; Angular component
L = 2   ; state "d" is electron spin L=2
M = 0   ; Z-component of spin is zero
angularState = SPHER_HARM(theta, phi, L, M)
```

```
; Radial component for state n=3, L=2
radialFunction = EXP(-r/2)*(r^2)
waveFunction = angularState*radialFunction
probabilityDensity = ABS(waveFunction)^2

SHADE_VOLUME, probabilityDensity, $
 0.1*MEAN(probabilityDensity), vertex, poly
oPolygon = OBJ_NEW('IDLgrPolygon', vertex, $
 POLYGON=poly, COLOR=[180,180,180])
XOBJVIEW, oPolygon
```

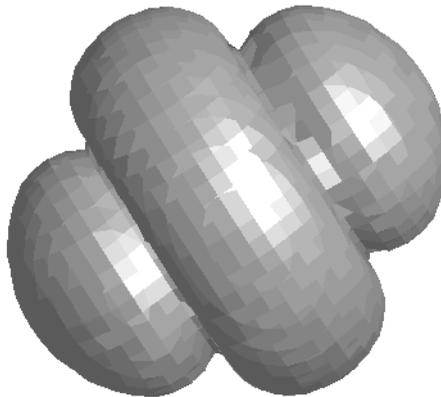
The results are shown in the following figure (rotated in XOBJVIEW for clarity):


Figure 21-18: SPHER_HARM Example of Hydrogen Atom

LEGENDRE, LAGUERRE

SPL_INIT

The SPL_INIT function is called to establish the type of interpolating spline for a tabulated set of functional values X_i, $Y_i = F(X_i)$.

It is important to realize that SPL_INIT should be called only *once* to process an entire tabulated function in arrays *X* and *Y*. Once this has been done, values of the interpolated function for any value of *X* can be obtained by calls (as many as desired) to the separate function SPL_INTERP.

SPL_INIT is based on the routine spline described in section 3.3 of *Numerical Recipes in C: The Art of Scientific Computing* (Second Edition), published by Cambridge University Press, and is used by permission.

Syntax

Result = SPL_INIT(*X*, *Y* [, /DOUBLE] [, YP0=*value*] [, YPN_1=*value*])

Return Value

Returns the values of the 2nd derivative of the interpolating function at the points X_i.

Arguments

X

An *n*-element input vector that specifies the tabulate points in ascending order.

Y

An *n*-element input vector that specifies the values of the tabulated function $F(X_i)$ corresponding to X_i.

Keywords

DOUBLE

Set this keyword to force the computation to be done in double-precision arithmetic.

YP0

The first derivative of the interpolating function at the point X_0. If YP0 is omitted, the second derivative at the boundary is set to zero, resulting in a "natural spline."

YPN_1

The first derivative of the interpolating function at the point X_{n-1}. If YPN_1 is omitted, the second derivative at the boundary is set to zero, resulting in a "natural spline."

Examples

Example 1

```
X = (FINDGEN(21)/20.) * 2.0*!PI
Y = SIN(X)
PRINT, SPL_INIT(X, Y, YP0 = -1.1, YPN_1 = 0.0)
```

IDL Prints:

```
23.1552    -6.51599    1.06983   -1.26115  -0.839544    -1.04023

SPL_INTERP, SPLINE, SPLINE_P

SPL_INTERP

Given the arrays *X* and *Y*, which tabulate a function (with the X_i in ascending order), and given the array Y_2, which is the output from SPL_INIT, and given an input value of X_2, the SPL_INTERP function returns a cubic-spline interpolated value for the given value of X_I.

SPL_INTERP is based on the routine `splint` described in section 3.3 of *Numerical Recipes in C: The Art of Scientific Computing* (Second Edition), published by Cambridge University Press, and is used by permission.

Syntax

Result = SPL_INTERP(*X*, *Y*, *Y2*, *X2* [, /DOUBLE])

Return Value

Returns either single- or double-precision floating result of the same structure as X_2.

Arguments

X

An input array that specifies the tabulated points in ascending order.

Y

An input array that specifies the values of the tabulate function corresponding to X_i.

Y2

The output from SPL_INIT for the specified *X* and *Y*.

X2

The input value for which an interpolated value is desired. *X* can be scalar or an array of values. The result of SPL_INTERP will have the same structure.

Keywords

DOUBLE

Set this keyword to force the computation to be done in double-precision arithmetic.

Examples

To create a spline interpolation over a tabulated set of data, [X_i, Y_i], first create the tabulated data. In this example, X_i will be in the range [0.0, 2π] and Y_i in the range [sin(0.0), sin(2π)].

```
X = (FINDGEN(21)/20.0) * 2.0 * !PI
Y = SIN(X)

; Calculate interpolating cubic spline:
Y2 = SPL_INIT(X, Y)

; Define the X values P at which we desire interpolated Y values:
X2= FINDGEN(11)/11.0 * !PI

; Calculate the interpolated Y values corresponding to X2[i]:
result = SPL_INTERP(X, Y, Y2, X2)

PRINT, result
```

IDL prints:

```
0.00000  0.281733  0.540638  0.755739  0.909613  0.989796
0.989796  0.909613  0.755739  0.540638  0.281733
```

The exact solution vector is sin(X_2).

To interpolate a line in the XY plane, see SPLINE_P.

SPL_INIT, SPLINE, SPLINE_P

SPLINE

The SPLINE function performs cubic spline interpolation. It accepts single- or double-precision input.

This routine is written in the IDL language. Its source code can be found in the file spline.pro in the lib subdirectory of the IDL distribution.

Syntax

Result = SPLINE(*X*, *Y*, *T* [, *Sigma*] [, /DOUBLE])

Return Value

Returns the result of the cubic spline interpolation. If *X*, *Y*, or *T* are of type double precision, then the computations will be done using double precision, and a double-precision result will be returned. Otherwise, single precision will be used, and a single-precision result will be returned.

Arguments

X

The abscissa vector. Values *must* be strictly increasing (no duplicate values). *X* must have three or more points.

Y

The vector of ordinate values corresponding to *X*. *Y* should have the same number of elements as *X*.

T

The vector of abscissa values for which the ordinate is desired. The values of *T must* be strictly increasing (no duplicate values).

Sigma

The amount of "tension" that is applied to the curve. The default value is 1.0. If sigma is close to 0, (e.g., .01), then effectively there is a cubic spline fit. If sigma is large, (e.g., greater than 10), then the fit will be like a polynomial interpolation.

Keywords

DOUBLE

Set this keyword to perform computations using double-precision arithmetic and to return a double-precision result.

Examples

The commands below show a typical use of SPLINE:

```
; X values of original function:
X = [2.,3.,4.]

; Make a quadratic
Y = (X-3)^2
;Values for interpolated points:
T = FINDGEN(20)/10.+2

; Do the interpolation:
Z = SPLINE(X,Y,T)
```

Version History

SPL_INIT, SPLINE_P

SPLINE_P

The SPLINE_P procedure performs parametric cubic spline interpolation with relaxed or clamped end conditions.

This routine is both more general and faster than the SPLINE function. One call to SPLINE_P is equivalent to two calls to SPLINE, as both the X and Y are interpolated with splines. It is suited for interpolating between randomly placed points, and the abscissa values need not be monotonic. In addition, the end conditions may be optionally specified via tangents.

This routine is written in the IDL language. Its source code can be found in the file spline_p.pro in the lib subdirectory of the IDL distribution.

Syntax

SPLINE_P, *X*, *Y*, *Xr*, *Yr* [, /DOUBLE] [, INTERVAL=*value*] [, TAN0=*[X$_0$, Y$_0$]*]
   [, TAN1=*[X$_{n-1}$, Y$_{n-1}$]*]

Arguments

X

The abscissa vector. *X* should be floating-point or double-precision.

Y

The vector of ordinate values corresponding to X. *Y* should be floating-point or double-precision.

Neither X or Y need be monotonic.

Xr

A named variable that will contain the abscissa values of the interpolated function. If X or Y is double-precision, then the computations will be done using double-precision and a double-precision result will be returned. Otherwise, single-precision will be used.

Yr

A named variable that will contain the ordinate values of the interpolated function. If X or Y is double-precision, then the computations will be done using double-precision and a double-precision result will be returned. Otherwise, single-precision will be used.

Keywords

DOUBLE

Set this keyword to perform computations using double-precision arithmetic and to return a double-precision result.

INTERVAL

Set this keyword equal to the desired interval in XY space between interpolants. If omitted, approximately 8 interpolants per XY segment will result.

TAN0

The tangent to the spline curve at X[0], Y[0]. If omitted, the tangent is calculated to make the curvature of the result zero at the beginning. TAN0 is a two element vector, containing the X and Y components of the tangent.

TAN1

The tangent to the spline curve at X[n-1], Y[n-1]. If omitted, the tangent is calculated to make the curvature of the result zero at the end. TAN1 is a two element vector, containing the X and Y components of the tangent.

Examples

The commands below show a typical use of SPLINE_P:

```
; Abscissas for square with a vertical diagonal:
X = [0.,1,0,-1,0]

; Ordinates:
Y = [0.,1,2,1,0]

; Interpolate with relaxed end conditions:
SPLINE_P, X, Y, XR, YR
```

```
; Show it:
PLOT, XR, YR
```

As above, but with setting both the beginning and end tangents:

```
SPLINE_P, X, Y, XR, YR, TAN0=[1,0], TAN1=[1,0]
```

This yields approximately 32 interpolants.

As above, but with setting the interval to 0.05, making more interpolants, closer together:

```
SPLINE_P, X, Y, XR, YR, TAN0=[1,0], TAN1=[1,0], INTERVAL=0.05
```

This yields 116 interpolants and looks close to a circle.

SPL_INIT, SPLINE

SPRSAB

The SPRSAB function performs matrix multiplication on two row-indexed sparse arrays created by SPRSIN. The routine computes all components of the matrix products, but only stores those values whose absolute magnitude exceeds the threshold value.

SPRSAB is based on the routine `sprstm` described in section 2.7 of *Numerical Recipes in C: The Art of Scientific Computing* (Second Edition), published by Cambridge University Press, and is used by permission. The difference between the two routines is that SPRSAB performs the matrix multiplication $A*B$ rather than $A*B^T$.

Syntax

Result = SPRSAB(*A*, *B* [, /DOUBLE] [, THRESHOLD=*value*])

Return Value

The result is a row-indexed sparse array.

Arguments

A, B

Row-indexed sparse arrays created by the SPRSIN function.

Note
If SPRSAB is complex then only the real part is used for the computation.

Keywords

DOUBLE

Set this keyword to force the computation to be done in double-precision arithmetic.

THRESHOLD

Use this keyword to set the criterion for deciding the absolute magnitude of the elements to be retained in sparse storage mode. For single-precision calculations, the

default value is 1.0×10^{-7}. For double-precision calculations, the default is 1.0×10^{-14}.

Examples

```
; Begin by creating two arrays:
A = [[ 5.0,  0.0, 0.0,  1.0], $
     [ 3.0, -2.0, 0.0,  1.0], $
     [ 4.0, -1.0, 0.0,  2.0], $
     [ 0.0,  3.0, 3.0,  1.0]]
B = [[ 1.0,  2.0, 3.0,  1.0], $
     [ 3.0, -3.0, 0.0,  1.0], $
     [-1.0,  3.0, 1.0,  2.0], $
     [ 0.0,  3.0, 3.0,  1.0]]

; Convert the arrays to sparse array format before multiplying.
; The variable SPARSE holds the result in sparse array form:
sparse = SPRSAB(SPRSIN(A), SPRSIN(B))

; Restore the sparse array structure to full storage mode:
result = FULSTR(sparse)

; Print the result:
PRINT, 'result:'
PRINT, result

; Check this result by multiplying the original arrays:
exact = B # A
PRINT, 'exact:'
PRINT, exact
```

IDL prints:

```
result:
 5.00000      13.0000      18.0000       6.00000
-3.00000      15.0000      12.0000       2.00000
 1.00000      17.0000      18.0000       5.00000
 6.00000       3.00000      6.00000      10.0000
exact:
 5.00000      13.0000      18.0000       6.00000
-3.00000      15.0000      12.0000       2.00000
 1.00000      17.0000      18.0000       5.00000

SPRSAX

The SPRSAX function takes a row-indexed sparse array created by the SPRSIN function and multiplies it by an *n*-element vector to its right.

SPRSAX is based on the routine `sprsax` described in section 2.7 of *Numerical Recipes in C: The Art of Scientific Computing* (Second Edition), published by Cambridge University Press, and is used by permission.

Syntax

Result = SPRSAX(*A*, *X* [, /DOUBLE])

Return Value

Returns a *n*-element vector.

Arguments

A

A row-indexed sparse array created by the SPRSIN function.

Note
If SPRSAX is complex then only the real part is used for the computation.

X

An *n*-element right hand vector.

Keywords

DOUBLE

Set this keyword to force the computation to be done in double-precision arithmetic.

Examples

```
; Begin by creating an array A:
A = [[ 5.0,  0.0, 0.0], $
     [ 3.0, -2.0, 0.0], $
     [ 4.0, -1.0, 0.0]]
```

```
; Define the right-hand vector:
X = [1.0, 2.0, -1.0]

; Convert to sparse format, then multiply by X:
result = SPRSAX(SPRSIN(A),X)

; Print the result:
PRINT, result
```

IDL prints:

```
5.00000     -1.00000      2.00000
```

FULSTR, LINBCG, SPRSAB, SPRSIN, SPRSTP, READ_SPR, WRITE_SPR

SPRSIN

The SPRSIN function converts an array, or list of subscripts and values, into a row-index sparse storage mode, retaining only elements with an absolute magnitude greater than or equal to the specified threshold. The list form is much more efficient than the array form if the density of the matrix is low.

SPRSIN is based on the routine `sprsin` described in section 2.7 of *Numerical Recipes in C: The Art of Scientific Computing* (Second Edition), published by Cambridge University Press, and is used by permission.

Syntax

Result = SPRSIN(*A* [, /COLUMN] [, /DOUBLE] [, THRESHOLD=*value*])

or

Result = SPRSIN(*Columns, Rows, Values, N* [, /DOUBLE] [, THRESHOLD=*value*])

Return Value

The result is a row-indexed sparse array contained in structure form. The structure consists of two linear sparse storage vectors: SA, a vector of array values, and IJA, a vector of subscripts to the SA vector. The length of these vectors is equal to 1 plus the number of diagonal elements of the array, plus the number of off-diagonal elements with an absolute magnitude greater that or equal to the threshold value. Diagonal elements of the array are always retained even if their absolute magnitude is less than the specified threshold.

Arguments

A

An *n* by *n* array of any type except string or complex.

Columns

A vector containing the column subscripts of the non-zero elements. Values must be in the range of 0 to (N-1).

Rows

A vector, of the same length as Column, containing the row subscripts of the non-zero elements. Values must be in the range of 0 to (N-1).

Values

A vector, of the same length as Column, containing the values of the non-zero elements.

N

The size of the resulting sparse matrix.

Keywords

COLUMN

Set this keyword if the input array *A* is in column-major format (composed of column vectors) rather than in row-major format (composed of row vectors). This keyword is not allowed in the list form of the call.

DOUBLE

Set this keyword to convert the sparse array to double-precision.

THRESHOLD

Use this keyword to set the criterion for deciding the absolute magnitude of the elements to be retained in sparse storage mode. For single-precision calculations, the default value is 1.0×10^{-7}. For double-precision values, the default is 1.0×10^{-14}.

Examples

Example1

Suppose we wish to convert the following array to sparse storage format:

```
A = [[ 5.0, -0.2, 0.1], $
     [ 3.0, -2.0, 0.3], $
     [ 4.0, -1.0, 0.0]]

; Convert to sparse storage mode. All elements of the array A that
; have absolute values less than THRESH are set to zero.
sparse = SPRSIN(A, THRESH = 0.5)
```

The variable SPARSE now contains a representation of A in structure form. See the description of FULSTR for an example that restores such a structure to full storage mode.

Example2

This example demonstrates how to use the list form of the call to SPRSIN. The following line of code creates a sparse matrix, equivalent to a 100 by 100 identity matrix, i.e. all diagonal elements are set to 1, all other elements are zero:

```
I100 = SPRSIN(LINDGEN(100), LINDGEN(100), REPLICATE(1.0,100), 100)
```

Version History

4.0	Introduced

See Also

FULSTR, LINBCG, SPRSAB, SPRSAX, SPRSTP, READ_SPR, WRITE_SPR

SPRSTP

The SPRSTP function constructs the transpose of a sparse matrix.

Syntax

Result = SPRSTP(*A*)

Return Value

Returns the sparse matrix of the given sparse array.

Arguments

A

A row-indexed sparse array created by the SPRSIN function.

Keywords

None

Examples

This example creates a 100 by 100 pseudo-random sparse matrix, with 1000 non-zero elements, and then computes the product of the matrix and its transpose:

```
n = 100                 ;Dimensions of matrix
m = 1000                ;Number of non-zero elements
a = SPRSIN(RANDOMU(seed, m)*n, RANDOMU(seed, m)*n, $
    RANDOMU(seed, m),n)
b = SPRSAB(a, SPRSTP(a))  ;Transpose and create the product
```

FULSTR, LINBCG, SPRSAB, SPRSAX, SPRSIN, READ_SPR, WRITE_SPR

SQRT

The SQRT function computes the square root of *X*.

Syntax

Result = SQRT(*X*)

Return Value

Returns the square root of *X*.

Arguments

X

The value for which the square root is desired. If *X* is double-precision floating-point or complex, the result is of the same type. All other types are converted to single-precision floating-point and yield floating-point results. When applied to complex numbers, *z = x+iy*:

$$z^{1/2} = \left[\frac{1}{2}(r + x)\right]^{1/2} \pm i\left[\frac{1}{2}(r - x)\right]^{1/2}$$

$$r = \sqrt{x^2 + y^2}$$

The ambiguous sign is taken to be the same as the sign of *y*. The result has the same structure as *X*.

Keywords

Thread Pool Keywords

This routine is written to make use of IDL's *thread pool*, which can increase execution speed on systems with multiple CPUs. The values stored in the !CPU system variable control whether IDL uses the thread pool for a given computation. In addition, you can use the thread pool keywords TPOOL_MAX_ELTS, TPOOL_MIN_ELTS, and TPOOL_NOTHREAD to override the defaults established by !CPU for a single invocation of this routine. See Appendix C, "Thread Pool Keywords" for details.

Examples

To find the square root of 145 and store the result in variable S, enter:

```
S = SQRT(145)
```

Version History

Original	Introduced

See Also

"Using Exponentiation" (Chapter 12, *Application Programming*).

STANDARDIZE

The STANDARDIZE function computes standardized variables from an array of *m* variables (columns) and *n* observations (rows).

This routine is written in the IDL language. Its source code can be found in the file standardize.pro in the lib subdirectory of the IDL distribution.

Syntax

Result = STANDARDIZE(*A* [, /DOUBLE])

Return Value

The result is an *m*-column, *n*-row array where all columns have a mean of zero and a variance of one.

Arguments

A

An *m*-column, *n*-row single- or double-precision floating-point array.

Keywords

DOUBLE

Set this keyword to force the computation to be done in double-precision arithmetic.

Examples

```
; Define an array with 4 variables and 20 observations:
array = $
          [[19.5, 43.1, 29.1, 11.9], $
           [24.7, 49.8, 28.2, 22.8], $
           [30.7, 51.9, 37.0, 18.7], $
           [29.8, 54.3, 31.1, 20.1], $
           [19.1, 42.2, 30.9, 12.9], $
           [25.6, 53.9, 23.7, 21.7], $
           [31.4, 58.5, 27.6, 27.1], $
           [27.9, 52.1, 30.6, 25.4], $
           [22.1, 49.9, 23.2, 21.3], $
           [25.5, 53.5, 24.8, 19.3], $
```

```
                [31.1, 56.6, 30.0, 25.4], $
                [30.4, 56.7, 28.3, 27.2], $
                [18.7, 46.5, 23.0, 11.7], $
                [19.7, 44.2, 28.6, 17.8], $
                [14.6, 42.7, 21.3, 12.8], $
                [29.5, 54.4, 30.1, 23.9], $
                [27.7, 55.3, 25.7, 22.6], $
                [30.2, 58.6, 24.6, 25.4], $
                [22.7, 48.2, 27.1, 14.8], $
                [25.2, 51.0, 27.5, 21.1]]

; Compute the mean and variance of each variable using the MOMENT
; function. The skewness and kurtosis are also computed:
FOR K = 0, 3 DO PRINT, MOMENT(array[K,*])

; Compute the standardized variables:
result = STANDARDIZE(array)

; Compute the mean and variance of each standardized variable using
; the MOMENT function. The skewness and kurtosis are also computed:
FOR K = 0, 3 DO PRINT, MOMENT(result[K,*])
```

IDL prints:

```
25.3050        25.2331      -0.454763       -1.10028
51.1700        27.4012      -0.356958       -1.19516

MOMENT

STDDEV

The STDDEV function computes the standard deviation of an *n*-element vector.

Syntax

Result = STDDEV(*X* [, /DOUBLE] [, /NAN])

Return Value

The result is the standard deviation of the given vector.

Arguments

X

A numeric vector.

Keywords

DOUBLE

If this keyword is set, computations are performed in double precision arithmetic.

NAN

Set this keyword to cause the routine to check for occurrences of the IEEE floating-point values *NaN* or *Infinity* in the input data. Elements with the value *NaN* or *Infinity* are treated as missing data. (See "Special Floating-Point Values" (Chapter 8, *Application Programming*) for more information on IEEE floating-point values.)

Examples

```
; Define the n-element vector of sample data:
x = [65, 63, 67, 64, 68, 62, 70, 66, 68, 67, 69, 71, 66, 65, 70]

; Compute the standard deviation:
result = STDDEV(x)

PRINT, result
```

IDL prints:

```
2.65832
```

KURTOSIS, MEAN, MEANABSDEV, MOMENT, SKEWNESS, VARIANCE

STOP

The STOP procedure stops the execution of a running program or batch file. Control reverts to the interactive mode.

Syntax

STOP [, *Expr₁*, ..., *Exprₙ*]

Arguments

Expr*ᵢ*

One or more expressions whose value is printed. If no parameters are present, a brief message describing where the STOP was encountered is printed.

Keywords

None.

Examples

Suppose that you want to stop the execution of a procedure and print the values of the variables A, B, C and NUM. At the appropriate location in your procedure include the command:

```
STOP, A, B, C, NUM
```

To continue execution of the procedure (if possible) enter the IDL executive command:

```
.CONT
```

BREAKPOINT, EXIT, WAIT

STRARR

The STRARR function returns a string array containing zero-length strings.

Syntax

Result = STRARR(D_1 [, ..., D_8])

Return Value

The result is a string array of the specified dimensions.

Arguments

D*i*

Either an array or a series of scalar expressions specifying the dimensions of the result. If a single argument is specified, it can be either a scalar expression or an array of up to eight elements. If multiple arguments are specified, they must all be scalar expressions. Up to eight dimensions can be specified.

Examples

To create S, a 20-element string vector, enter:

```
S = STRARR(20)
```

Version History

Original	Introduced

BYTARR, COMPLEXARR, DBLARR, DCOMPLEXARR, FLTARR, INTARR, LON64ARR, LONARR, MAKE_ARRAY, UINTARR, ULON64ARR, ULONARR

STRCMP

The STRCMP function performs string comparisons between its two String arguments, returning True (1) for those that match and False (0) for those that do not. Normally, the IDL equality operator (EQ) is used for such comparisons, but STRCMP can optionally perform case-insensitive comparisons and can be limited to compare only the first N characters of the two strings, both of which require extra steps using the EQ operator.

Syntax

Result = STRCMP(*String1*, *String2* [, *N*] [, /FOLD_CASE])

Return Value

If all of the arguments are scalar, the result is scalar. If one of the arguments is an array, the result is an integer with the same structure. If more than one argument is an array, the result has the structure of the smallest array. Each element of the result contains True (1) if the corresponding elements of String1 and String2 are the same, and False (0) otherwise.

Arguments

String1, String2

The strings to be compared.

N

Normally String1 and String2 are compared in their entirety. If N is specified, the comparison is made on at most the first N characters of each string.

Keywords

FOLD_CASE

String comparison is normally a case sensitive operation. Set FOLD_CASE to perform case insensitive comparisons instead.

Examples

Compare two strings in a case-insensitive manner, considering only the first 3 characters:

```
Result = STRCMP('Moose', 'moo', 3, /FOLD_CASE)
PRINT, Result
```

IDL prints:

        1

Version History

5.3	Introduced

"Non-Printing Characters" (Chapter 14, *Application Programming*)

STRCOMPRESS

The STRCOMPRESS function returns a copy of *String* with all whitespace (blanks and tabs) compressed to a single space or completely removed.

Syntax

Result = STRCOMPRESS(*String* [, /REMOVE_ALL])

Return Value

The result is a compressed string.

Arguments

String

The string to be compressed. If not of type string, it is converted using IDL's default formatting rules. If *String* is an array, the result is an array with the same structure—each element contains a compressed copy of the corresponding element of *String*.

Keywords

REMOVE_ALL

Set this keyword to remove *all* whitespace. Normally, all whitespace is compressed to a *single* space.

Examples

```
; Create a string variable S:
S = 'This is a string with spaces in it.'

; Print S with all of the whitespace removed:
PRINT, STRCOMPRESS(S, /REMOVE_ALL)
```

IDL Output

```
Thisisastringwithspacesinit.
```

STRTRIM

STREAMLINE

The STREAMLINE procedure generates the visualization graphics from a path. The output is a polygonal ribbon which is tangent to a vector field along its length. The ribbon is generated by placing a line at each vertex in the direction specified by each normal value multiplied by the anisotropy factor. The input normal array is not normalized before use, making it possible to vary the ribbon width as well.

Syntax

STREAMLINE, *Verts*, *Conn*, *Normals*, *Outverts*, *Outconn* [, ANISOTROPY=*array*] [, SIZE=*vector*] [, PROFILE=*array*]

Arguments

Verts

Input array of path vertices ([3, *n*] array).

Conn

Input path connectivity array in IDLgrPolyline POLYLINES keyword format. There is one set of line segments in this array for each streamline.

Normals

Normal estimate at each input vertex ([3, *n*] array).

Outverts

Output vertices ([3xn] float array). Useful if the routine is to be used with Direct Graphics or the user wants to manipulate the data directly.

Outconn

Output polygonal connectivity array to match the output vertices.

Keywords

ANISOTROPY

Set this input keyword to a three-element array describing the distance between grid points in each dimension. The default value is [1.0, 1.0, 1.0]

SIZE

Set this keyword to a vector of values (one for each path point). These values are used to specify the width of the ribbon or the size of profile at each point along its path. This keyword is generally used to convey additional data parameters along the streamline.

PROFILE

Set this keyword to an array of two-dimensional points which are treated as the cross section of the ribbon instead of a line segment. If the first and last points in the array are the same, a closed profile is generated. The profile is placed at each path vertex in the plane perpendicular to the line connecting each path vertex with the vertex normal defining the up direction. This allows for the generation of streamtubes and other geometries.

Version History

5.3	Introduced

STREGEX

The STREGEX function performs regular expression matching against the strings contained in StringExpression. STREGEX can perform either a simple boolean True/False evaluation of whether a match occurred, or it can return the position and offset within the strings for each match. The regular expressions accepted by this routine, which correspond to "Posix Extended Regular Expressions", are similar to those used by such UNIX tools as egrep, lex, awk, and Perl.

For more information about regular expressions, see "Learning About Regular Expressions" (Chapter 14, *Application Programming*).

STREGEX is based on the regex package written by Henry Spencer, modified by ITT Visual Information Solutions only to the extent required to integrate it into IDL. This package is freely available at `ftp://zoo.toronto.edu/pub/regex.shar`.

Syntax

Result = STREGEX(*StringExpression*, *RegularExpression* [, /BOOLEAN |
, /EXTRACT | , LENGTH=*variable* [, /SUBEXPR]] [, /FOLD_CASE])

Return Value

By default, STREGEX returns the position of the matched string within each element of *StringExpression*. If no match is found, -1 is returned. Optionally, STREGEX can return a boolean True/False result of the match or the matched strings.

Arguments

StringExpression

A string or string array in which to search for matches of *RegularExpression*.

RegularExpression

A scalar string containing the regular expression to match. See "Learning About Regular Expressions" (Chapter 14, *Application Programming*) for a description of the meta characters that can be used in a regular expression.

Keywords

BOOLEAN

Normally, STREGEX returns the position of the first character in each element of *StringExpression* that matches *RegularExpression*. Setting BOOLEAN modifies this behavior to simply return a True/False value indicating if a match occurred or not.

EXTRACT

Normally, STREGEX returns the position of the first character in each element of *StringExpression* that matches *RegularExpression*. Setting EXTRACT modifies this behavior to simply return the matched substrings. The EXTRACT keyword cannot be used with either BOOLEAN or LENGTH.

FOLD_CASE

Regular expression matching is normally a case-sensitive operation. Set FOLD_CASE to perform case-insensitive matching instead.

LENGTH

Set this keyword equal to a named variable that will contain the length of each matching string found. If no match is found in an element of *StringExpression*, the returned variable will contain -1 for that element. Together with this result of this function, which contains the starting points of the matches in *StringExpression*, LENGTH can be used with the STRMID function to extract the matched substrings. The LENGTH keyword cannot be used with either BOOLEAN or EXTRACT.

SUBEXPR

By default, STREGEX only reports the overall match. Setting SUBEXPR causes it to report the overall match as well as any subexpression matches. A subexpression is any part of a regular expression written within parentheses. For example, the regular expression '(a)(b)(c+)' has 3 subexpressions, whereas the functionally equivalent 'abc+' has none. The SUBEXPR keyword cannot be used with BOOLEAN.

If a subexpression participated in the match several times, the reported substring is the last one it matched. Note, as an example in particular, that when the regular expression '(b*)+' matches 'bbb', the parenthesized subexpression matches the three 'b's and then an infinite number of empty strings following the last 'b', so the reported substring is one of the empties. This occurs because the '*' matches *zero or more* instances of the character that precedes it.

In order to return multiple positions and lengths for each input, the result from
SUBEXPR has a new first dimension added compared to *StringExpression*.

Examples

Example 1

To match a string starting with an "a", followed by a "b", followed by 1 or more "c":

```
pos = STREGEX('aaabccc', 'abc+', length=len)
PRINT, STRMID('aaabccc', pos, len)
```

IDL Prints:

```
abccc
```

To perform the same match, and also find the locations of the three parts:

```
pos = STREGEX('aaabccc', '(a)(b)(c+)', length=len, /SUBEXPR)
print, STRMID('aaabccc', pos, len)
```

IDL Prints:

```
abccc a b ccc
```

Or more simply:

```
print,STREGEX('aaabccc','(a)(b)(c+)',/SUBEXPR,/EXTRACT)
```

IDL Prints:

```
abccc a b ccc
```

Example 2

This example searches a string array for words of any length beginning with "f" and
ending with "t" without the letter "o" in between:

```
str = ['foot', 'Feet', 'fate', 'FAST', 'ferret', 'affluent']
PRINT, STREGEX(str, '^f[^o]*t$', /EXTRACT, /FOLD_CASE)
```

This statement results in:

```
Feet FAST ferret
```

Note the following about this example:

- Unlike the * wildcard character used by STRMATCH, the * meta character used by STREGEX applies to the item directly on its left, which in this case is [^o], meaning "any character except the letter 'o' ". Therefore, [^o]* means "zero or more characters that are not 'o' ", whereas the following statement would find only words whose second character is not "o":

```
PRINT, str[WHERE(STRMATCH(str, 'f[!o]*t', /FOLD_CASE) EQ 1)]
```

- The anchors (^ and $) tell STREGEX to find only words that begin with "f" and end with "t". If we left out the ^ anchor in the above example, STREGEX would also return "ffluent" (a substring of "affluent"). Similarly, if we left out the $ anchor, STREGEX would also return "fat" (a substring of "fate").

STRETCH

The STRETCH procedure stretches the image display color tables so the full range runs from one color index to another. The modified colortable is loaded, but the COLORS common block is not changed. The original colortable can be restored by calling STRETCH with no arguments. A colortable must be loaded before STRETCH can be called.

This routine is written in the IDL language. Its source code can be found in the file stretch.pro in the lib subdirectory of the IDL distribution.

Syntax

STRETCH [, *Low*, *High* [, *Gamma*]] [, /CHOP]

Arguments

Low

The lowest pixel value to use. If this parameter is omitted, 0 is assumed. Appropriate values range from 0 to the number of available colors-1. If no parameters are supplied, the original color tables are restored.

High

The highest pixel value to use. If this parameter is omitted, the number of colors-1 is assumed. Appropriate values range from 0 to the number of available colors-1.

Gamma

An optional Gamma correction factor. If this value is omitted, 1.0 is assumed. Gamma correction works by raising the color indices to the *Gamma* power, assuming they are scaled into the range 0 to 1.

Keywords

CHOP

Set this keyword to set color indices above the upper threshold to color index 0. Normally, values above the upper threshold are set to the maximum color index.

Examples

Load the STD GAMMA-II color table by entering:

```
LOADCT, 5
```

Create and display and image by entering:

```
TVSCL, DIST(300)
```

Now adjust the color table with STRETCH. Make the entire color table fit in the range 0 to 70 by entering:

```
STRETCH, 0, 70
```

Notice that pixel values above 70 are now colored white. Restore the original color table by entering:

```
STRETCH
```

Note
The window-oriented procedures will not work without a window system.

STRING

The STRING function returns its arguments converted to string type. It is similar to the PRINT procedure, except that its output is placed in a string rather than being output to the terminal. The case in which a single expression of type byte is specified without the FORMAT keyword is special—see the "Differences Between STRING and PRINT" on page 2381 for details.

Note ————————————————————————————————————

Applying the STRING function to a byte array containing a null (zero) value will result in the resulting string being truncated at that position.

Syntax

Result = STRING(*Expression₁*, ..., *Expressionₙ* [, AM_PM=*[string*, *string]*]
  [, DAYS_OF_WEEK=*string_array*{7 names}] [, FORMAT=*value*]
  [, MONTHS=*string_array*{12 names}] [, /PRINT])

Return Value

Returns a string value or array of the same dimensions as the result of the *Expression.* If *Expression* includes complex numbers, STRING returns strings of the format
`(real, complex)`.

Arguments

Expression*ₙ*

The expressions to be converted to string type.

Note ————————————————————————————————————

If you supply a comma-separated list of expressions without specifying a FORMAT, and the combined length of the expressions is greater than the current width of your tty or command log window, STRING will create a string array with one element for each expression, rather than concatenating all expressions into a single string. In this case, you can either specify a FORMAT, or use the string concatenation operator, "+".

Keywords

AM_PM

Supplies a string array of 2 names to be used for the names of the AM and PM string when processing explicitly formatted dates (CAPA, CApA, and CapA format codes) with the FORMAT keyword.

DAYS_OF_WEEK

Supplies a string array of 7 names to be used for the names of the days of the week when processing explicitly formatted dates (CDWA, CDwA, and CdwA format codes) with the FORMAT keyword.

FORMAT

A format string to be used in formatting the expressions. See "Using Explicitly Formatted Input/Output" (Chapter 18, *Application Programming*).

MONTHS

Supplies a string array of 12 names to be used for the names of the months when processing explicitly formatted dates (CMOA, CMoA, and CmoA format codes) with the FORMAT keyword.

PRINT

Set this keyword to specify that any special case processing should be ignored and that STRING should behave exactly as the PRINT procedure would.

Differences Between STRING and PRINT

The behavior of STRING differs from the behavior of the PRINT procedure in the following ways (unless the PRINT keyword is set):

- When called with a single non-byte argument and no format specification, STRING returns a result that has the same dimensions as the original argument. For example, the statement:

```
HELP, STRING(INDGEN(5))
```

gives the result:

```
<Expression> STRING = Array[5]
```

while:

```
HELP, STRING(INDGEN(5), /PRINT)
```

results in:

```
<Expression> STRING =' 0 1 2 3 4'
```

- If called with a single argument of byte type and the FORMAT keyword is not used, STRING simply stores the unmodified values of each byte element in the result. This result is a string containing the byte values from the original argument. Thus, the result has one less dimension than the original argument. For example, a 2-dimensional byte array becomes a vector of strings, a byte vector becomes a scalar string. However, a byte scalar also becomes a string scalar. For example, the statement:

```
PRINT, STRING([72B, 101B, 108B, 108B, 111B])
```

produces the output `Hello` because the argument to STRING, is a byte vector. Its first element is a 72B which is the ASCII code for "H", the second is 101B which is an ASCII "e", and so forth.

- If both the FORMAT and PRINT keywords are not present and STRING is called with more than one argument, and the last argument is a scalar string starting with the characters "$(" or "(", this final argument is taken to be the format specification, just as if it had been specified via the FORMAT keyword. This feature is maintained for compatibility with version 1 of VMS IDL.

Examples

To convert the contents of variable A to string type and store the result in variable B, enter:

```
B = STRING(A)
```

STRJOIN

The STRJOIN function collapses a one-dimensional string array into a single merged string or two-dimensional string array into a one-dimensional array of merged strings. The strings in the removed first dimension are concatenated into a single string using the string in *Delimiter* to separate them.

Syntax

Result = STRJOIN(*String* [, *Delimiter*] [, /SINGLE])

Return Value

Returns the merged strings.

Arguments

String

A string array to be collapsed into merged strings.

Delimiter

The separator string to use between the joined strings. If Delimiter is not specified, an empty string is used.

Keywords

SINGLE

If SINGLE is set, the entire String is joined into a single scalar string result.

Examples

Replace all the blanks in a sentence with colons:

```
str = 'Out, damned spot! Out I say!'
print, (STRJOIN(STRSPLIT(str, /EXTRACT), ':'))
```

IDL prints:

```
Out,:damned:spot!:Out:I:say!
```

Version History

5.3	Introduced

STRCMP, STREGEX, STRMATCH, STRMID, STRPOS, STRSPLIT

STRLEN

The STRLEN function returns the length of its string-type argument. If the argument is not a string, it is first converted to string type.

Syntax

Result = STRLEN(*Expression*)

Return Value0

Returns the string length.

Arguments

Expression

The expression for which the string length is desired. If this parameter is not a string, it is converted using IDL's default formatting rules in order to determine the length. The result is a long integer. If *Expression* is an array, the result is a long integer array with the same structure, where each element contains the length of the corresponding *Expression* element.

Keywords

None.

Examples

To find the length of the string "IDL is fun" and print the result, enter:

```
PRINT, STRLEN('IDL is fun')
```

IDL prints:

```
10
```

Version History

Original	Introduced

STRLOWCASE

The STRLOWCASE function returns a copy of *String* converted to lowercase characters. Only uppercase characters are modified—lowercase and non-alphabetic characters are copied without change.

Syntax

Result = STRLOWCASE(*String*)

Return Value

Returns a string composed of lowercase characters.

Arguments

String

The string to be converted. If this argument is not a string, it is converted using IDL's default formatting rules. If *String* is an array, the result is an array with the same structure—each element contains a lower case copy of the corresponding element of *String*.

Keywords

None.

Examples

To convert the string "IDL is fun" to all lowercase characters and print the result, enter:

```
PRINT, STRLOWCASE('IDL is fun')
```

IDL prints:

```
idl is fun
```

Version History

Original	Introduced

STRUPCASE

STRMATCH

The STRMATCH function compares its search string, which can contain wildcard characters, against the input string expression. The result is an array with the same structure as the input string expression. Those elements that match the corresponding input string are set to True (1), and those that do not match are set to False (0).

The wildcards understood by STRMATCH are similar to those used by the standard UNIX shell:

Wildcard Character	Description
*	Matches any string, including the null string.
?	Matches any single character.
[...]	Matches any one of the enclosed characters. A pair of characters separated by "-" matches any character lexically between the pair, inclusive. If the first character following the opening [is a !, any character not enclosed is matched.

To prevent one of these characters from acting as a wildcard, precede it with a backslash character (e.g. "*" matches the asterisk character). Quoting any other (non-wildcard) character (including \ itself) is equivalent to the character (e.g. "\a" is the same as "a").

Table 21-10: Wildcard Characters used by STRMATCH

Syntax

Result = STRMATCH(*String*, *SearchString* [, /FOLD_CASE])

Return Value

Returns 1 if the pattern specified by *SearchString* exists in *String*, or 0 otherwise. If the *String* argument contains an array of strings, the result is an array of 1s and 0s with the same number of elements as *String*, indicating which elements contain *SearchString*.

Arguments

String

A scalar string or string array to be searched.

SearchString

A scalar string containing the pattern to search for in *String*. The pattern string can contain wildcard characters as discussed above.

Keywords

FOLD_CASE

The comparison is usually case sensitive. Setting the FOLD_CASE keyword causes a case insensitive match to be done instead.

Examples

Example 1

Find all 4-letter words in a string array that begin with "f" or "F" and end with "t" or "T":

```
str = ['foot', 'Feet', 'fate', 'FAST', 'ferret', 'fort']
PRINT, str[WHERE(STRMATCH(str, 'f??t', /FOLD_CASE) EQ 1)]
```

This results in:

```
foot Feet FAST fort
```

Example 2

Find words of any length that begin with "f" and end with "t":

```
str = ['foot', 'Feet', 'fate', 'FAST', 'ferret', 'fort']
PRINT, str[WHERE(STRMATCH(str, 'f*t', /FOLD_CASE) EQ 1)]
```

This results in:

```
foot Feet FAST ferret fort
```

Example 3

Find 4-letter words beginning with "f" and ending with "t", with any combination of "o" and "e" in between:

```
str = ['foot', 'Feet', 'fate', 'FAST', 'ferret', 'fort']
PRINT, str[WHERE(STRMATCH(str, 'f[eo][eo]t', /FOLD_CASE) EQ 1)]
```

This results in:

```
foot Feet
```

Example 4

Find all words beginning with "f" and ending with "t" whose second character is not the letter "o":

```
str = ['foot', 'Feet', 'fate', 'FAST', 'ferret', 'fort']
PRINT, str[WHERE(STRMATCH(str, 'f[!o]*t', /FOLD_CASE) EQ 1)]
```

This results in:

```
Feet FAST ferret
```

"Non-Printing Characters" (Chapter 14, *Application Programming*)

STRMESSAGE

The STRMESSAGE function returns the text of the error message specified by *Err*. This function is especially useful in conjunction with the CODE field of the !ERROR_STATE system variable which always contains the error number of the last error. The MSG field of the !ERROR_STATE system variable contains the text of the last error message.

Syntax

Result = STRMESSAGE(*Err* [, /BLOCK | , /CODE | , /NAME])

Return Value

Returns the error message text.

Arguments

Err

The error number or text. Programs must not make the assumption that certain error numbers are always related to certain error messages—the actual correspondence changes over time as IDL is modified.

Keywords

BLOCK

Set this keyword to return the name of the message block that defines *Err*. If this keyword is specified, *Err* must be an error code.

CODE

Set this keyword to return the error code for the error message specified in *Err*. If this keyword is specified, *Err* must be an error name.

NAME

Set this keyword to return a string containing the error message that goes with *Err*. If this keyword is specified, *Err* must be an error code.

Examples

Print the error message associated with error number 4 by entering:

```
PRINT, STRMESSAGE(4)
```

MESSAGE

STRMID

The STRMID function extracts one or more substring from a string expression. Each extracted string is the result of removing characters.

Syntax

Result = STRMID(*Expression*, *First_Character* [, *Length*] [, /REVERSE_OFFSET])

Return Value

The result of the function is a string of *Length* characters taken from *Expression*, starting at character position *First_Character.*

The form of *First_Character* and *Length* control how they are applied to *Expression*. Either argument can be a scalar or an array:

•   If a scalar value is supplied for *First_Character* and *Length*, then those values are applied to all elements of *Expression*. The result has the same structure and number of elements as *Expression*.

If *First_Character* or *Length* is an array, the size of their first dimension determines how many substrings are extracted from each element of *Expression*. We call this the "stride". If both are arrays, they must have the same stride. If *First_Character* or *Length* do not contain enough elements to process *Expression*, STRMID automatically loops back to the beginning as necessary. Excess values are ignored. If the stride is 1, the result will have the same structure and number of elements as *Expression*. If it is greater than 1, the result will have an additional dimension, with the new first dimension having the same size as the stride.

Arguments

Expression

The expression from which the substrings are to be extracted. If this argument is not a string, it is converted using IDL's default formatting rules.

First_Character

The starting position within *Expression* at which the substring starts. The first character position is 0.

Length

The length of the substring. If there are not enough characters left in the main string to obtain *Length* characters, the substring is truncated. If *Length* is not supplied, STRMID extracts all characters from the specified start position to the end of the string.

Keywords

REVERSE_OFFSET

Specifies that *First_Character* should be counted from the end of the string backwards. This allows simple extraction of strings from the end.

Examples

If the variable B contains the string "IDL is fun", the substring "is" can be extracted and stored in the variable C with the command:

```
C = STRMID(B, 4, 2)
```

STRPOS, STRPUT, STRTRIM

STRPOS

The STRPOS function finds the first occurrence of a substring within an object string.

Syntax

Result = STRPOS(*Expression*, *Search_String* [, *Pos*] [, /REVERSE_OFFSET]
   [, /REVERSE_SEARCH])

Return Value

If *Search_String* occurs in *Expression*, STRPOS returns the character position of the match, otherwise it returns -1.

Arguments

Expression

The expression in which to search for the substring. If this argument is not a string, it is converted using IDL's default formatting rules. If *Expression* is an array, the result is an array with the same structure, where each element contains the position of the substring within the corresponding element *Expression*. If *Expression* is the null string, STRPOS returns the value -1.

Search_String

The substring to be searched for within *Expression*. If this argument is not a string, it is converted using IDL's default formatting rules. If *Search_String* is the null string, STRPOS returns the smaller of *Pos* or one less than the length of *Expression*.

Pos

The character position at which the search is begun. If *Pos* is omitted and the REVERSE_SEARCH keyword is not set, the search begins at the first character (character position 0). If REVERSE_SEARCH is set, the default is to start at the last character in the string. If *Pos* is less than zero, zero is used for the starting position.

Keywords

REVERSE_OFFSET

Normally, the value of *Pos* is used as an offset from the beginning of the expression towards the end. Set REVERSE_OFFSET to use it as an offset from the last character of the string moving towards the beginning. This keyword makes it easy to position the starting point of the search at a fixed offset from the end of the string. If this keyword is set and *Pos* is not specified, STRPOS will return the value -1.

REVERSE_SEARCH

STRPOS usually starts at *Pos* and moves toward the end of the string looking for a match. If REVERSE_SEARCH is set, the search instead moves towards the beginning of the string.

Examples

Example 1

Find the position of the string "fun" within the string "IDL is fun" and print the result by entering:

```
PRINT, STRPOS('IDL is fun', 'fun')
```

IDL prints:

```
    7
```

Example 2

The REVERSE_SEARCH keyword to the STRPOS function makes it easy to find the last occurrence of a substring within a string. In the following example, we search for the last occurrence of the letter "I" (or "i") in a sentence:

```
sentence = 'IDL is fun.'
sentence = STRUPCASE(sentence)
lasti = STRPOS(sentence, 'I', /REVERSE_SEARCH)
PRINT, lasti
```

This results in:

```
4
```

Note that although REVERSE_SEARCH tells STRPOS to begin searching from the end of the string, the STRPOS function still returns the position of the search string from the beginning of the string (where 0 is the position of the first character).

STRMID, STRPUT, STRTRIM

"Non-Printing Characters" (Chapter 14, *Application Programming*)

STRPUT

The STRPUT procedure inserts the contents of one string into another. The source string, *Source*, is inserted into the destination string, *Destination*, starting at the given position, *Position*. Characters in *Destination* before the starting position and after the starting position plus the length of *Source* remain unchanged. The length of the destination string is not changed. If the insertion extends past the end of the destination, it is clipped at the end.

Syntax

STRPUT, *Destination*, *Source* [, *Position*]

Arguments

Destination

The named string variable into which *Source* is inserted. *Destination* must be a named variable of type string. If it is an array, *Source* is inserted into every element of the array.

Source

A scalar string to be inserted into *Destination*. If this argument is not a string, it is converted using IDL's default formatting rules.

Position

The character position at which the insertion is begun. If *Position* is omitted, the insertion begins at the first character (character position 0). If *Position* is less than zero, zero is used for the initial position.

Keywords

None.

Examples

If the variable A contains the string "IBM is fun", the substring "IBM" can be overwritten with the string "IDL" by entering:

```
STRPUT, A, 'IDL', 0
```

The following commands demonstrate the clipping of output that extends past the end of the destination string:

```
STRPUT, A, 'FUNNY', 7
PRINT, A
```

IDL prints:

```
IDL is FUN
```

STRMID, STRPOS, STRTRIM

STRSPLIT

The STRSPLIT function splits its input *String* argument into separate substrings, according to the specified delimiter or regular expression. By default, the position of the substrings is returned. The EXTRACT keyword can be used to cause STRSPLIT to return an array containing the substrings.

Syntax

Result = STRSPLIT(*String* [, *Pattern*] [, COUNT=*variable*] [, ESCAPE=*string* | , /REGEX [, /FOLD_CASE]] [, /EXTRACT | , LENGTH=*variable*] [, /PRESERVE_NULL])

Return Value

Returns an array containing either the positions of the substrings or the substrings themselves (if the EXTRACT keyword is specified).

Arguments

String

A scalar string to be split into substrings.

Pattern

A scalar string that can contain one of two types of information:

- One or more *single characters*, each of which is considered to be a separator. *String* will be split when any of the characters is detected. For example, if *Pattern* is " , " *String* will be split whenever *either* a space or a comma is detected. In this case, IDL performs a simple string search for the specified characters. This method is simple and fast.

- If the REGEX keyword is specified, *Pattern* is considered to be a single regular expression (as implemented by the STREGEX function). This method is slower and more complex, but can handle extremely complicated *Pattern* strings.

In either case, if the EXTRACT keyword is specified, the separator characters are *not* included in the result.

Note ───

Pattern is an optional argument. If it is not specified, STRSPLIT defaults to splitting on spans of whitespace (space or tab characters) in *String*.

───

Keywords

COUNT

Set this keyword to a named variable that will contain the number of matched substrings returned by STRSPLIT. This value will be 0 if either of the *String* or *Pattern* arguments is null. Otherwise, it will contain the number of elements in the *Result* array.

ESCAPE

When doing simple pattern matching, the ESCAPE keyword can be used to specify any characters that should be considered to be "escape" characters. Preceding any character with an escape character prevents STRSPLIT from treating it as a separator character even if it is found in *Pattern*.

Note that if the EXTRACT keyword is set, STRSPLIT will automatically remove the escape characters from the resulting substrings. If EXTRACT is not specified, STRSPLIT cannot perform this editing, and the returned position and offsets will include the escape characters.

For example:

```
print, STRSPLIT('a\,b,c', ',', ESCAPE='\', /EXTRACT)
```

IDL prints:

```
a,b c
```

ESCAPE cannot be specified with the FOLD_CASE or REGEX keywords.

EXTRACT

By default, STRSPLIT returns an array of character offsets into *String* that indicate where the substrings are located. These offsets, along with the lengths available from the LENGTH keyword can be used later with STRMID to extract the substrings. Set EXTRACT to bypass this step, and cause STRSPLIT to return the substrings. EXTRACT cannot be specified with the LENGTH keyword.

FOLD_CASE

Indicates that the regular expression matching should be done in a case-insensitive fashion. FOLD_CASE can only be specified if the REGEX keyword is set, and cannot be used with the ESCAPE keyword.

LENGTH

Set this keyword to a named variable to receive the lengths of the substrings. Together with this result of this function, LENGTH can be used with the STRMID function to extract the matched substrings. The LENGTH keyword cannot be used with the EXTRACT keyword.

PRESERVE_NULL

Normally, STRSPLIT will not return null length substrings unless there are no non-null values to report, in which case STRSPLIT will return a single null string. Set PRESERVE_NULL to cause all null substrings to be returned.

REGEX

For complex splitting tasks, the REGEX keyword can be specified. In this case, *Pattern* is taken to be a regular expression to be matched against *String* to locate the separators. If REGEX is specified and *Pattern* is not, the default *Pattern* is the regular expression:

```
'[ ' + STRING(9B) + ']+'
```

which means "any series of one or more space or tab characters" (9B is the byte value of the ASCII TAB character).

Note that the default *Pattern* contains a space after the [character.

The REGEX keyword cannot be used with the ESCAPE keyword.

Note ───

If *Pattern* specifies a single multi-character separator pattern (as contrasted with a string of two or more individual separator characters), you *must* specify the REGEX keyword.

───

Examples

Example 1

To split a string on spans of whitespace and replace them with hyphens:

```
Str = 'STRSPLIT chops up strings.'
print, STRJOIN(STRSPLIT(Str, /EXTRACT), '-')
```

IDL prints:

```
STRSPLIT-chops-up-strings.
```

Example 2

As an example of a more complex splitting task that can be handled with the simple character-matching mode of STRSPLIT, consider a sentence describing different colored ampersand characters. For unknown reasons, the author used commas to separate all the words, and used ampersands or backslashes to escape the commas that actually appear in the sentence (which therefore should not be treated as separators). The unprocessed string looks like:

```
Str = 'There,was,a,red,&&&,,a,yellow,&&\,,and,a,blue,\&.'
```

We use STRSPLIT to break this line apart, and STRJOIN to reassemble it as a standard blank-separated sentence:

```
S = STRSPLIT(Str, ',', ESCAPE='&\', /EXTRACT)
PRINT, STRJOIN(S, ' ')
```

IDL prints:

```
There was a red &, a yellow &, and a blue &.
```

Example 3

Strings separated by multi-character delimiters cannot be split using the simple character matching mode of STRSPLIT. Such delimiters require the use of a regular expression. For instance, consider splitting the following string on double ampersand boundaries.

```
str = 'red&&blue&&yellow&&odds&ends'
```

The desired result of such splitting would be four strings, with the values 'red', 'blue', 'yellow', and 'odds&ends'. You might be tempted to use STRSPLIT as follows:

```
PRINT, STRSPLIT(str,'&&',/EXTRACT)
```

which causes IDL to print:

```
red blue yellow odds ends
```

IDL split the string on single ampersand boundaries, yielding 5 strings instead of the desired 4. When using the simple character matching mode of STRSPLIT, the characters in the Pattern argument specify a set of possible single character delimiters. The order of these characters is unimportant, and specifying a character more than once has no effect (the extras are ignored).

To properly split the above string using a regular expression:

```
print, strsplit(str,'&&',/EXTRACT, /REGEX)
```

producing the desired IDL output:

```
red blue yellow odds&ends
```

Example 4

Finally, suppose you had a complicated string, in which every token was preceded by the count of characters in that token, with the count enclosed in angle brackets:

```
str = '<4>What<1>a<7>tangled<3>web<2>we<6>weave.'
```

This is too complex to handle with simple character matching, but can be easily handled using the regular expression '<[0-9]+>' to match the separators. This regular expression can be read as "an opening angle bracket, followed by one or more numeric characters between 0 and 9, followed by a closing angle bracket." The STRJOIN function is used to glue the resulting substrings back together:

```
S = STRSPLIT(str,'<[0-9]+>',/EXTRACT,/REGEX)
PRINT, STRJOIN(S, ' ')
```

IDL prints:

```
What a tangled web we weave.
```

5.3	Introduced
6.0	Added COUNT keyword

See Also

STRCMP, STRJOIN, STRMATCH, STREGEX, STRMID, STRPOS

STRTRIM

The STRTRIM function removes leading and/or trailing blank from the input *String*.

Syntax

Result = STRTRIM(*String* [, *Flag*])

Return Value

Returns a copy of string with the specified blank spaces removed.

Arguments

String

The string to have leading and/or trailing blanks removed. If this argument is not a string, it is converted using IDL's default formatting rules. If it is an array, the result is an array with the same structure where each element contains a trimmed copy of the corresponding element of *String*.

Flag

A value that controls the action of STRTRIM. If *Flag* is zero or not present, trailing blanks are removed. Leading blanks are removed if it is equal to 1. Both are removed if it is equal to 2.

Examples

Converting variables to string type often results in undesirable leading blanks. For example, the following command converts the integer 56 to string type:

```
C = STRING(56)
```

Entering the command:

```
HELP, C
```

IDL prints:

```
C               STRING = '        56'
```

which shows that there are six leading spaces before the characters 5 and 6. To remove these leading blanks, enter the command:

```
C = STRTRIM(C, 1)
```

To confirm that the blanks were removed, enter:

```
HELP, C
```

IDL prints:

```
C          STRING = '56'
```

STRUCT_ASSIGN

The IDL "=" operator is unable to assign a structure value to a structure of a different type. The STRUCT_ASSIGN procedure performs "relaxed structure assignment," which is a field-by-field copy of a structure to another structure. Fields are copied according to the following rules:

1. Any fields found in the destination structure that are not found in the source structure are "zeroed" (set to zero, the empty string, or a null pointer or object reference depending on the type of field).

2. Any fields in the source structure that are not found in the destination structure are quietly ignored.

3. Any fields that are found in both the source and destination structures are copied one at a time. If necessary, type conversion is done to make their types agree. If a field in the source structure has fewer data elements than the corresponding field in the destination structure, then the "extra" elements in the field in the destination structure are zeroed. If a field in the source structure has more elements than the corresponding field in the destination structure, the extra elements are quietly ignored.

Relaxed structure assignment is especially useful when restoring structures from disk files into an environment where the structure definition has changed. See the description o f the RELAXED_STRUCTURE_ASSIGNMENT keyword to the RESTORE procedure for additional details. "Relaxed Structure Assignment" (Chapter 16, *Application Programming*) provides a more in-depth discussion of the structure-definition process.

Syntax

STRUCT_ASSIGN, *Source*, *Destination* [, /NOZERO] [, /VERBOSE]

Arguments

Source

A named variable or element of an array containing a structure, the contents of which will be assigned to the structure specified by the *Destination* argument. *Source* can be an object reference if STRUCT_ASSIGN is called inside an object method.

Destination

A named variable containing a structure into which the contents of the structure specified by the *Source* argument will be inserted. *Destination* can be an object reference if STRUCT_ASSIGN is called inside an object method.

Keywords

NOZERO

Normally, any fields found in the destination structure that are not found in the source structure are zeroed. Set NOZERO to prevent this action and leave the original contents of such fields unchanged.

VERBOSE

Set this keyword to cause STRUCT_ASSIGN to issue informational messages about any incompatibilities that prevent data from being copied.

Examples

The following example creates two anonymous structures, then uses STRUCT_ASSIGN to insert the contents of the first into the second:

```
source = { a:FINDGEN(4), b:12 }
dest = { a:INDGEN(2), c:20 }
STRUCT_ASSIGN, /VERBOSE, source, dest
```

IDL prints:

```
% STRUCT_ASSIGN: <Anonymous> tag A is longer than destination.
                 The end will be clipped.
% STRUCT_ASSIGN: Destination lacks <Anonymous> tag B. Not copied.
```

After assignment, dest contains a two-element integer array [0, 1] in its field A and the integer 0 in its field C. Since dest does not have a field B, field B from source is not copied.

Version History

5.1	Introduced

STRUCT_HIDE

The IDL HELP procedure displays information on all known structures or object classes when used with the STRUCTURES or OBJECTS keywords. Although this is usually the desired behavior, authors of large vertical applications or library routines may wish to prevent IDL from displaying information on structures or objects that are not part of their public interface, but which exist solely in support of the internal implementation. The STRUCT_HIDE procedure is used to mark such structures or objects as hidden. Items so marked are not displayed by HELP, /STRUCTURE unless the user sets the FULL keyword, but are otherwise unaltered.

Note ──
STRUCT_HIDE is primarily intended for use with named structures or objects. Although it can be safely used with anonymous structures, there is no visible benefit to doing so as anonymous structures are hidden by default.
──

Tip ───
Authors of objects will often place a call to STRUCT_HIDE in the _ _DEFINE procedure that defines the structure.
──

Syntax

STRUCT_HIDE, Arg_1 [, Arg_2, ..., Arg_n]

Arguments

Arg$_1$, ..., Arg$_n$

If an argument is a variable of one of the following types, its underlying structure and/or object definition is marked as being hidden from the HELP procedure's default output:

- Structure

- Pointer that refers to a heap variable of structure type

- Object Reference

Any arguments that are not one of these types are quietly ignored. No change is made to the value of any argument.

Keywords

None

Examples

This example shows how a structure can be hidden if an application designer doesn't want end-users to be able to see it, but variables are not hidden. To create a named structure called bullwinkle and prevent it from appearing in the HELP procedure's default output, do the following.

```
; Define a variable containing the named structure:
tmp = { bullwinkle, moose:1, squirrel:0 }
; IDL returns BULLWINKLE in addition to the other system variables.
HELP, /STRUCTURE, /BRIEF
; Next, specifically hide the structure using
; the STRUCT_HIDE procedure.
STRUCT_HIDE, tmp
; This time IDL returns the system variables but
; not the BULLWINKLE structure.
HELP, /STRUCTURE, /BRIEF
; IDL returns the variable tmp showing that it is
; a named structure called BULLWINKLE.
HELP, tmp
```

COMPILE_OPT

STRUPCASE

The STRUPCASE function returns a copy of *String* converted to upper case. Only lowercase characters are modified—uppercase and non-alphabetic characters are copied without change.

Syntax

Result = STRUPCASE(*String*)

Return Value

Returns a string composed of uppercase characters.

Arguments

String

The string to be converted. If this argument is not a string, it is converted using IDL's default formatting rules. If it is an array, the result is an array with the same structure where each element contains an uppercase copy of the corresponding element of *String*.

Keywords

None.

Examples

To print an uppercase version of the string "IDL is fun", enter:

```
PRINT, STRUPCASE('IDL is fun')
```

IDL prints:

```
IDL IS FUN
```

STRLOWCASE

SURFACE

The SURFACE procedure draws a wire-mesh representation of a two-dimensional array projected into two dimensions, with hidden lines removed. SURFACE accepts a two-dimensional array of *z* (elevation) values, and optionally *x* and *y* parameters indicating the location of each *z* element. SURFACE depicts the surface created by interpreting each element value as an elevation. These three-dimensional, wire-mesh surface plots can have almost any rotation about the *x*- and *z*-axes (the data *z*-axis must project parallel to the device's *y*-axis).

SURFACE projects the three-dimensional array of points into two dimensions after rotating about the *z*- and then the *x*-axes. Each point is connected to its neighbors by lines. Hidden lines are suppressed. The rotation about the *x*- and *z*-axes can be specified with keywords or a complete three-dimensional transformation matrix can be stored in the field !P.T for use by SURFACE. Details concerning the mechanics of three-dimensional projection and rotation are covered in "Coordinates of 3-D Graphics" (Chapter 5, *Using IDL*).

Restrictions

If the *(X, Y)* grid is not regular or nearly regular, errors in hidden line removal occur. The TRIGRID and TRIANGULATE routines can be used to interpolate irregularly-gridded data points to a regular grid before plotting.

If the T3D keyword is set, the 3-D to 2-D transformation matrix contained in !P.T must project the Z axis to a line parallel to the device Y axis, or errors will occur.

The surface lines may blend together when drawing large arrays, especially on low or medium resolution displays. Use the REBIN or CONGRID procedure to resample the array to a lower resolution before plotting.

Syntax

SURFACE, *Z* [, *X*, *Y*] [, AX=*degrees*] [, AZ=*degrees*] [, BOTTOM=*index*]
   [, /HORIZONTAL] [, /LEGO] [, /LOWER_ONLY | , /UPPER_ONLY]
   [, MAX_VALUE=*value*] [, MIN_VALUE=*value*] [, /SAVE] [, SHADES=*array*]
   [, SKIRT=*value*] [, /XLOG] [, /YLOG] [, ZAXIS={1 | 2 | 3 | 4}] [, /ZLOG]

Graphics Keywords: Accepts all graphics keywords accepted by PLOT except for: PSYM, SYMSIZE. See "Graphics Keywords Accepted" on page 2418.

Note ——————————————————————————————

Many of the graphic keyword parameters correspond directly to fields in the system variables !P, !X, !Y, or !Z. When specifying a keyword parameter name and value in a call that value affects only the current call, the corresponding system-variable field is not changed. Changing the value of a system-variable field changes the default for that particular parameter and remains in effect until explicitly changed. The system variables involving graphics and their corresponding keywords are detailed in "!P" in Appendix D.

———

Arguments

Z

The two-dimensional array to be displayed. If *X* and *Y* are provided, the surface is plotted as a function of the (*X*, *Y*) locations specified by their contents. Otherwise, the surface is generated as a function of the array index of each element of *Z*.

This argument is converted to double-precision floating-point before plotting. Plots created with SURFACE are limited to the range and precision of double-precision floating-point values.

X

A vector or two-dimensional array specifying the X coordinates of the grid. If this argument is a vector, each element of *X* specifies the X coordinate for a column of *Z* (e.g., X[0] specifies the X coordinate for Z[0,*]). If *X* is a two-dimensional array, each element of *X* specifies the X coordinate of the corresponding point in *Z* (X_{ij} specifies the X coordinate for Z_{ij}).

This argument is converted to double-precision floating-point before plotting.

Y

A vector or two-dimensional array specifying the Y coordinates of the grid. If this argument is a vector, each element of *Y* specifies the Y coordinate for a row of *Z* (e.g., Y[0] specifies the Y coordinate for Z[*,0]). If *Y* is a two-dimensional array, each element of *Y* specifies the Y coordinate of the corresponding point in *Z* (Y_{ij} specifies the Y coordinate for Z_{ij}).

This argument is converted to double-precision floating-point before plotting.

Keywords

AX

This keyword specifies the angle of rotation, about the X axis, in degrees towards the viewer. This keyword is effective only if !P.T3D is not set. If !P.T3D is set, the three-dimensional to two-dimensional transformation used by SURFACE is taken from the 4 by 4 array !P.T.

The surface represented by the two-dimensional array is first rotated, AZ (see below) degrees about the Z axis, then by AX degrees about the X axis, tilting the surface towards the viewer (AX > 0), or away from the viewer.

The AX and AZ keyword parameters default to +30 degrees if omitted and !P.T3D is 0.

The three-dimensional to two-dimensional transformation represented by AX and AZ, can be saved in !P.T by including the SAVE keyword.

AZ

This keyword specifies the counterclockwise angle of rotation about the Z axis. This keyword is effective only if !P.T3D is not set. The order of rotation is AZ first, then AX.

BOTTOM

The color index used to draw the bottom surface. If not specified, the bottom is drawn with the same color as the top.

HORIZONTAL

A keyword flag which if set causes SURFACE to only draw lines across the plot perpendicular to the line of sight. The default is for SURFACE to draw both across the plot and from front to back.

LEGO

Set this keyword to produce stacked histogram-style plots. Each data value is rendered as a box covering the XY extent of the cell and with a height proportional to the Z value.

If the *X* and *Y* arguments are specified, only N_x-1 columns and N_y-1 rows are drawn. (This means that the last row and column of array data are not displayed.) The rectangular area covered by *Z*[*i*, *j*] is given by *X*[*i*], *X*[*i*+1], *Y*[*j*], and *Y*[*j*+1].

LOWER_ONLY

Set this keyword to draw only the lower surface of the object. By default, both surfaces are drawn.

MAX_VALUE

The maximum value to be plotted. If this keyword is present, data values greater than the value of MAX_VALUE are treated as missing and are not plotted. Note that the IEEE floating-point value NaN is also treated as missing data. (See "Special Floating-Point Values" (Chapter 8, *Application Programming*) for more information on IEEE floating-point values.)

MIN_VALUE

The minimum value to be plotted. If this keyword is present, data values less than the value of MIN_VALUE are treated as missing and are not plotted. Note that the IEEE floating-point value NaN is also treated as missing data. (See "Special Floating-Point Values" (Chapter 8, *Application Programming*) for more information on IEEE floating-point values.)

SAVE

Set this keyword to save the 3-D to 2-D transformation matrix established by SURFACE in the system variable field !P.T. Use this keyword when combining the output of SURFACE with additional output from other routines in the same plot.

When used with AXIS, the SAVE keyword parameter saves the scaling parameters established by the call in the appropriate axis system variable, !X, !Y, or !Z. This causes subsequent overplots to be scaled to the new axis.

For example, to display a two-dimensional array using SURFACE, and to then superimpose contours over the surface (this example assumes that !P.T3D is zero, its default value.), enter the following commands:

```
; Make a surface plot and save the transformation:
SURFACE, Z, /SAVE

; Make contours, don't erase, use the 3-D to 2-D transform placed
; in !P.T by SURFACE:
CONTOUR, Z, /NOERASE, /T3D
```

To display a surface and to then display a flat contour plot, registered above the surface:

```
; Make the surface, save transform:
SURFACE, Z, /SAVE
```

```
; Now display a flat contour plot, at the maximum Z value
; (normalized coordinates):
CONTOUR, Z, /NOERASE, /T3D, ZVALUE=1.0
```

You can display the contour plot below the surface with by using a ZVALUE of 0.0.

SHADES

This keyword allows user-specified coloring of the mesh surfaces. Set this keyword to an array that specifies the color index of the lines emanating from each data point toward the top and right.

Warning

When using the SHADES keyword on True Color devices, we recommend that decomposed color support be turned off, by setting DEVICE, DECOMPOSED=0. See "DEVICE" on page 612 and "DECOMPOSED" on page 5378.

SKIRT

This keyword represents a Z-value at which to draw a skirt around the array. The Z value is expressed in data units. The default is no skirt.

If the skirt is drawn, each point on the four edges of the surface is connected to a point on the skirt which has the given Z value, and the same X and Y values as the edge point. In addition, each point on the skirt is connected to its neighbor.

UPPER_ONLY

Set this keyword to draw only the upper surface of the object. By default, both surfaces are drawn.

XLOG

Set this keyword to specify a logarithmic X axis.

YLOG

Set this keyword to specify a logarithmic Y axis.

ZAXIS

This keyword specifies the placement of the Z axis for the SURFACE plot.

By default, SURFACE draws the Z axis at the upper left corner of the axis box. To suppress the Z axis, use ZAXIS=-1 in the call. The position of the Z axis is

determined from the value of ZAXIS as follows: 1 = lower right, 2 = lower left, 3 = upper left, and 4 = upper right.

ZLOG

Set this keyword to specify a logarithmic Z axis.

Graphics Keywords Accepted

See Appendix B, "Graphics Keywords" for the description of the following graphics and plotting keywords:

BACKGROUND, CHARSIZE, CHARTHICK, CLIP, COLOR, DATA, DEVICE, FONT, LINESTYLE, NOCLIP, NODATA, NOERASE, NORMAL, POSITION, SUBTITLE, T3D, THICK, TICKLEN, TITLE, [XYZ]CHARSIZE, [XYZ]GRIDSTYLE, [XYZ]MARGIN, [XYZ]MINOR, [XYZ]RANGE, [XYZ]STYLE, [XYZ]THICK, [XYZ]TICKFORMAT, [XYZ]TICKINTERVAL, [XYZ]TICKLAYOUT, [XYZ]TICKLEN, [XYZ]TICKNAME, [XYZ]TICKS, [XYZ]TICKUNITS, [XYZ]TICKV, [XYZ]TICK_GET, [XYZ]TITLE, ZVALUE

Examples

Note ——

Also see the PLOT routine "Examples" on page 1796 for examples that control plot position, configure axes and position multiple plots on a page.

———

Surface of a Gaussian Function

The following IDL code illustrates the most basic call to SURFACE. ; Create a 40 by 40 array in which each element is

```
; equal to the Euclidean distance from the center:
Z = SHIFT(DIST(40), 20, 20)
; Make Gaussian with a 1/e width of 10:
Z = EXP(-(Z/10)^2)
; Call SURFACE to display plot:
SURFACE, Z
```

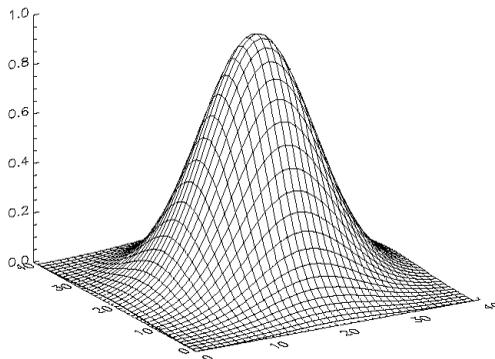
In the example above, the DIST function creates an (*n*, *n*) array in which each
element is set to its Euclidean distance from the origin. It produces a two-dimensional
Gaussian function, then calls SURFACE to produce the figure below.


Figure 21-19: Simple SURFACE Plot of a Gaussian

Another simple example is created with the following statements:

```
; Create a simple dataset to display:
D = DIST(30)

; Plot a simple wire-mesh surface representation of D:
SURFACE, D

; Create a wire-mesh plot of D with a title and a "skirt" around
; the edges of the dataset at Z=0:
SURFACE, D, SKIRT=0.0, TITLE = 'Surface Plot', CHARSIZE = 2
```

Surface of Elevation Data

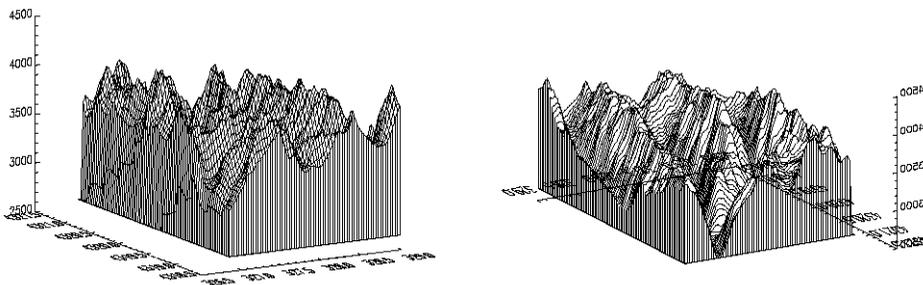
The figures below illustrate the application of the SURFACE procedure to the
Maroon Bells elevation data. As with CONTOUR, it is often useful to reduce the
number of individual data values, so that the surface is not obscured by excessive
detail.


Figure 21-20: Maroon Bells Surface Plots

The left illustration in the figure above was produced by the following statements:

```
; Restore variables.
@cntour01
; Resize the original data into a 72 x 92 array, setting
; all data values which are less than 2650 (the lowest
; elevation we wish to show) to 2650.
surf = REBIN(elev > 2650, 360/5, 460/5)
; Display the surface, drawing a skirt down to 2650 meters:
SURFACE, surf, X, Y, SKIRT = 2650
```

Example Code

Alternatively, run the batch file surf01 with the following command at the IDL prompt:

```
@surf01
```

The right illustration in the figure shows the Maroon Peaks area looking from the back row to the front row (north to the south) of the Maroon Peaks area. This perspective on the data is created by setting the angle of rotation around the *z*-axis to 210 degrees (setting AZ = 210), and increasing the azimuth from the default 30 degrees to 45 (setting AX = 45). Also, only the horizontal lines are drawn because the /HORIZONTAL keyword is present in the following call:

```
SURFACE, surf, X, Y, SKIRT = 2650, /HORIZ, AZ = 210, AX = 45
```

Because the axes are rotated 210 degrees about the original *z*-axis, the annotation is reversed and the *x*-axis is behind and obscured by the surface. This undesirable effect can be eliminated by reversing the minimum and maximum values of the X and Y ranges used when drawing the surface:

```
; As above, but reverse the data rather than the axes:
SURFACE, surf, X, Y, SKIRT = 2650, /HORIZONTAL, AX = 45, $
   YRANGE = [MAX(Y), MIN(Y)], XRANGE=[MAX(X), MIN(X)]
```

Transformation Created by SURFACE

The SURFACE procedure creates a transformation matrix from its keyword parameters AX and AZ as follows:

1. Starting with the identity transformation, SURFACE translates the center of the normalized cube to the origin.

2. SURFACE rotates 90 degrees about the *x*-axis to make the + *z*-axis of the data the +*y* axis of the display. The +*y* data axis extends from the front of the display to the rear.

3. SURFACE rotates AZ degrees about the *y*-axis. This rotates the result counter-clockwise, as seen from above the page.

4. SURFACE rotates AX degrees about the *x*-axis, tilting the data towards the viewer.

5. The procedure then removes the translation applied in the first step and scales the data so that the data are still contained within the normal coordinate unit cube after transformation.

These transformations can be created using T3D as shown below. The SCALE3 procedure, mimics the transformation matrix created by SURFACE using the following method:

```
; Translate to move center of cube to origin.
T3D, /RESET, TRANSLATE = [-.5, -.5, -.5]
; Rotate 90 degrees about x-axis, so +z axis is now +y.
; Then rotate AZ degrees about y-axis.
T3D, ROTATE = [-90, AZ, 0]
; Rotate AX about x axis:
T3D, ROTATE = [AX, 0, 0]
; Restore origin.
T3D, TRANSLATE = [0.5, 0.5, 0.5]
```

The SCALE3 procedure, scales the unit cube by a fixed factor, 1/SQRT(3) to ensure that the corners of the rotated cube fit within the drawing area. If requested, it also will set the data scaling. Animations involving rotations or the SURFACE procedure

should have their scaling and viewing transformation set by SCALE3 rather than the obsolete SURFR procedure, so that the scaling does not vary between frames.

Combining CONTOUR and SURFACE

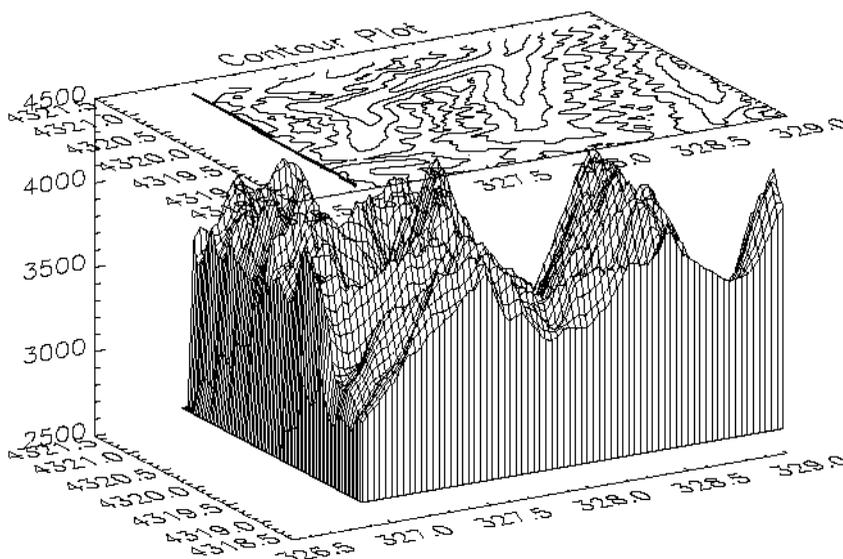
It is easy to combine the results of SURFACE with the other IDL graphics procedures. The keyword parameter SAVE causes SURFACE to save the graphic transformation it used in !P.T. Then, when either CONTOUR or PLOT is called with the keyword parameter T3D, its output is transformed with the same projection. For example, the figure below illustrates how SURFACE and CONTOUR can be combined. In essence, this is a combination of figures from 2 previous sections.


Figure 21-21: Combining CONTOUR with SURFACE, Maroon Bells Data

Using the same variables as in the earlier sections of this section, the figure was produced with the following statements:

```
; Restore variables.
@cntour01

; Resize the original data into a 72 x 92 array,
; setting all data values which are less than
; 2650 (the lowest elevation we wish to show) to 2650.
surf = REBIN(elev > 2650, 360/5, 460/5)
```

```
; Make the mesh.
SURFACE, surf, X, Y, SKIRT=2650, /SAVE

; Specify T3D to align with SURFACE, at ZVALUE of 1.0.
; Suppress clipping as the plot is outside the normal plot window.
CONTOUR, surf, X, Y, /T3D, /NOERASE, TITLE = 'Contour Plot', $
   MAX_VAL = 5000., ZVALUE = 1.0, /NOCLIP, $
   LEVELS = 2750. + FINDGEN(6) * 250
```

CONTOUR, ISURFACE, SHADE_SURF

SURFR

The SURFR procedure sets up 3-D transformations. This procedure duplicates the rotation, translation, and scaling features of the SURFACE routine, but does not display any data. The resulting transformations are stored in the !P.T system variable.

This routine is written in the IDL language. Its source code can be found in the file surfr.pro in the lib subdirectory of the IDL distribution.

Syntax

SURFR [, AX=*degrees*] [, AZ=*degrees*]

Arguments

None.

Keywords

AX

This keyword specifies the angle of rotation about the X axis in degrees towards the viewer. The default is 30 degrees.

First rotated, AZ (see below) degrees about the Z axis, then by AX degrees about the X axis, tilting the surface towards the viewer (AX > 0), or away from the viewer.

AZ

This keyword specifies the counterclockwise angle of rotation about the Z axis. The default is 30 degrees.

SCALE3, SCALE3D, T3D

SVDC

The SVDC procedure computes the Singular Value Decomposition (SVD) of a square (*n* x *n*) or non-square (*n* x *m*) array as the product of orthogonal and diagonal arrays. SVD is a very powerful tool for the solution of linear systems, and is often used when a solution cannot be determined by other numerical algorithms.

The SVD of an (*n* x *m*) non-square array *A* is computed as the product of an (*n* x *m*) column orthogonal array *U*, an (*n* x *n*) diagonal array *SV*, composed of the singular values, and the transpose of an (*n* x *n*) orthogonal array V: $A = U \ SV \ V^T$

SVDC is based on the routine `svdcmp` described in section 2.6 of *Numerical Recipes in C: The Art of Scientific Computing* (Second Edition), published by Cambridge University Press, and is used by permission.

Note

If you are working with complex inputs, use the LA_SVD procedure instead.

Syntax

SVDC, *A*, *W*, *U*, *V* [, /COLUMN] [, /DOUBLE] [, ITMAX=*value*]

Arguments

A

The square (*n* x *n*) or non-square (*n* x *m*) single- or double-precision floating-point array to decompose.

W

On output, *W* is an *n*-element output vector containing the "singular values."

U

On output, *U* is an *n*-column, *m*-row orthogonal array used in the decomposition of *A*.

V

On output, *V* is an *n*-column, *n*-row orthogonal array used in the decomposition of *A*.

Keywords

COLUMN

Set this keyword if the input array *A* is in column-major format (composed of column vectors) rather than in row-major format (composed of row vectors).

DOUBLE

Set this keyword to force the computation to be done in double-precision arithmetic.

ITMAX

Set this keyword to specify the maximum number of iterations. The default value is 30.

Examples

To find the singular values of an array A:

```
; Define the array A:
A = [[1.0, 2.0, -1.0, 2.5], $
     [1.5, 3.3, -0.5, 2.0], $
     [3.1, 0.7,  2.2, 0.0], $
     [0.0, 0.3, -2.0, 5.3], $
     [2.1, 1.0,  4.3, 2.2], $
     [0.0, 5.5,  3.8, 0.2]]

; Compute the Singular Value Decomposition:
SVDC, A, W, U, V

; Print the singular values:
PRINT, W
```

IDL prints:

```
8.81973     2.65502     4.30598     6.84484
```

To verify the decomposition, use the relationship A = U ## SV ## TRANSPOSE(V), where SV is a diagonal array created from the output vector W:

```
sv = FLTARR(4, 4)
FOR K = 0, 3 DO sv[K,K] = W[K]
result = U ## sv ## TRANSPOSE(V)
PRINT, result
```

IDL prints:

```
        1.00000        2.00000       -1.00000        2.50000
        1.50000        3.30000       -0.500001       2.00000
        3.10000        0.700000       2.20000        0.00000
    2.23517e-08        0.300000      -2.00000        5.30000
        2.10000        0.999999       4.30000        2.20000
   -3.91155e-07        5.50000        3.80000        0.200000
```

This is the input array, to within machine precision.

See Also

CHOLDC, LA_SVD, LUDC, SVSOL, "Linear Systems" (Chapter 9, *Using IDL*).

SVDFIT

The SVDFIT function performs a least squares fit with optional error estimates. Either a user-supplied function written in the IDL language or a built-in polynomial can be used to fit the data.

Note ───

SVDFIT only works for functions whose parameters are linearly independent. To perform a fit for a function whose parameters are linearly dependent, use either CURVEFIT or LMFIT.

───

SVDFIT is based on the routine svdfit described in section 15.4 of *Numerical Recipes in C: The Art of Scientific Computing* (Second Edition), published by Cambridge University Press, and is used by permission.

Syntax

Result = SVDFIT(*X*, *Y* [, *M*] [, A=*vector*] [, CHISQ=*variable*] [, COVAR=*variable*]
   [, /DOUBLE] [, FUNCTION_NAME=*string*] [, /LEGENDRE]
   [, MEASURE_ERRORS=*vector*] [, SIGMA=*variable*]
   [, SING_VALUES=*variable*] [, SINGULAR=*variable*] [, STATUS=*variable*]
   [, TOL=*value*] [, VARIANCE=*variable*] [, YFIT=*variable*])

Return Value

Returns a vector of coefficients.

Arguments

X

An n-element vector of independent variables.

Y

A vector of dependent variables, the same length as *X*.

M

The number of coefficients in the fitting function. For polynomials, *M* is equal to the degree of the polynomial + 1. If the *M* argument is not specified, you must supply

initial coefficient estimates using the A keyword. In this case, *M* is set equal to the number of elements of the array specified by the A keyword.

Keywords

A

This keyword is both an input and output keyword. Set this keyword equal to a variable containing a vector of initial estimates for the fitted function parameters. On exit, SVDFIT returns in this variable a vector of coefficients that are improvements of the initial estimates. If A is supplied, the *M* argument will be set equal to the number of elements in the vector specified by A.

CHISQ

Set this keyword equal to a named variable that will contain the value of the unreduced chi-square goodness-of-fit.

COVAR

Set this keyword equal to a named variable that will contain the covariance matrix of the fitted coefficients.

Note

The COVAR matrix depends only upon the independent variable X and (optionally) the MEASURE_ERRORS. The values do not depend upon Y. See section 15.4 of *Numerical Recipes in C* (Second Edition) for details.

DOUBLE

Set this keyword to force the computation to be done in double-precision arithmetic.

FUNCTION_NAME

Set this keyword equal to a string containing the name of a user-supplied IDL basis function with *M* coefficients. If this keyword is omitted, and the LEGENDRE keyword is not set, IDL assumes that the IDL procedure SVDFUNCT, found in the file svdfunct.pro, located in the lib subdirectory of the IDL distribution, is to be used. SVDFUNCT uses the basis functions for the fitting polynomial:

$$y = \sum_{i=0}^{M} A(i)x^i$$

The function to be fit must be written as an IDL function and compiled prior to calling SVDFIT. The function must accept values of *X* (a scalar), and *M* (a scalar). It must return an *M*-element vector containing the basis functions.

See the "Examples" section below for an example function.

LEGENDRE

Set this keyword to use Legendre polynomials instead of the function specified by the FUNCTION_NAME keyword. If the LEGENDRE keyword is set, the IDL uses the function SVDLEG found in the file svdleg.pro, located in the lib subdirectory of the IDL distribution.

MEASURE_ERRORS

Set this keyword to a vector containing standard measurement errors for each point *Y*[*i*]. This vector must be the same length as *X* and *Y*.

Note ───

For Gaussian errors (e.g., instrumental uncertainties), MEASURE_ERRORS should be set to the standard deviations of each point in *Y*. For Poisson or statistical weighting, MEASURE_ERRORS should be set to SQRT(*Y*).

───

SIGMA

Set this keyword to a named variable that will contain the 1-sigma uncertainty estimates for the returned parameters.

Note ───

If MEASURE_ERRORS is omitted, then you are assuming that the polynomial (or your user-supplied model) is the correct model for your data, and therefore, no independent goodness-of-fit test is possible. In this case, the values returned in SIGMA are multiplied by SQRT(CHISQ/(*N*–*M*)), where *N* is the number of points in *X*, and *M* is the number of coefficients. See section 15.2 of *Numerical Recipes in C* (Second Edition) for details.

───

SING_VALUES

Set this keyword to a named variable in which to return the singular values from the SVD. Singular values which have been removed will be set to zero.

SINGULAR

Set this keyword equal to a named variable that will contain the number of singular values returned. This value should be 0. If not, the basis functions do not accurately characterize the data.

STATUS

Set this keyword to a named variable that will contain the status of the computation. Possible values are:

- STATUS = 0: The computation was successful.

- STATUS > 0: Singular values were found and were removed. STATUS contains the number of singular values.

Note ———————————————————————————————————

If STATUS is not specified, any error messages will be output to the screen.

___

TOL

Set this keyword to the tolerance used when removing singular values. The default is 10^{-5} for single precision, and $2x10^{-12}$ for double precision (these defaults are approximately 100 and 10000 times the machine precisions for single and double precision, respectively).

Setting TOL to a larger value may remove coefficients that do not contribute to the solution, which may reduce the errors on the remaining coefficients.

VARIANCE

Set this keyword equal to a named variable that will contain the variance (sigma squared) of each coefficient *M*.

YFIT

Set this keyword equal to a named variable that will contain the vector of calculated *Y* values.

Examples

This example fits a function of the following form:

$$F(x) \,=\, A(0) + A(1)\sin\frac{(2x)}{x} + A(2)\cos(4x)^2$$

First, create the function in IDL, then create a procedure to perform the fit. Create the following file called `example_svdfit.pro`:

```
PRO example_svdfit

; Provide an array of coefficients:
C = [7.77, 8.88, -9.99]
X = FINDGEN(100)/15.0 + 0.1
Y = C[0] + C[1] * SIN(2*X)/X + C[2] * COS(4.*X)^2.

; Set uncertainties to 5%:
measure_errors = 0.05 * Y

; Provide an initial guess:
A=[1,1,1]
result_a = SVDFIT(X, Y, A=A, MEASURE_ERRORS=measure_errors, $
   FUNCTION_NAME='myfunct', SIGMA=SIGMA, YFIT=YFIT)

; Plot the results:
PLOT, X, YFIT
FOR I = 0, N_ELEMENTS(A)-1 DO $
   PRINT, I, result_a[I], SIGMA[I], C[I],$
   FORMAT = $
   '(" result_a ( ",I1," ) = ",F7.4," +- ",F7.4," VS. ",F7.4)'
END

FUNCTION myfunct, X ,M
   RETURN,[ [1.0], [SIN(2*X)/X], [COS(4.*X)^2.] ]
END
```

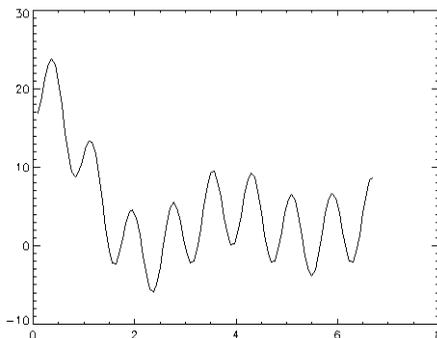
Place the file example_svdfit.pro in a directory in the IDL search path, and enter
example_svdfit at the command prompt to create the plot.


Figure 21-22: Example Plot

In addition to creating the above plot, IDL prints:

```
result_a ( 0 ) =  7.7700 +-  0.0390 VS.  7.7700
result_a ( 1 ) =  8.8800 +-  0.0468 VS.  8.8800
result_a ( 2 ) = -9.9900 +-  0.0506 VS. -9.9900
```

SVSOL

The SVSOL function uses "back-substitution" to solve a set of simultaneous linear equations Ax = b, given the *U*, *W*, and *V* arrays returned by the SVDC procedure. None of the input arguments are modified, making it possible to call SVSOL multiple times with different right hand vectors, *B*.

SVSOL is based on the routine svbksb described in section 2.6 of *Numerical Recipes in C: The Art of Scientific Computing* (Second Edition), published by Cambridge University Press, and is used by permission.

Syntax

Result = SVSOL(*U*, *W*, *V*, *B* [, /COLUMN] [, /DOUBLE])

Return Value

Returns the solution to the linear system using decomposition and back substitution.

Arguments

U

An *n*-column, *m*-row orthogonal array used in the decomposition of *A*. Normally, *U* is returned from the SVDC procedure.

W

An *n*-element vector containing "singular values." Normally, *W* is returned from the SVDC procedure. Small values (close to machine floating-point precision) should be set to zero prior to calling SVSOL.

V

An *n*-column, *n*-row orthogonal array used in the decomposition of *A*. Normally, *V* is returned from the SVDC procedure.

B

An *m*-element vector containing the right hand side of the linear system Ax = b.

Keywords

COLUMN

Set this keyword if the input arrays *U* and *V* are in column-major format (composed of column vectors) rather than in row-major format (composed of row vectors).

DOUBLE

Set this keyword to force the computation to be done in double-precision arithmetic.

Examples

To solve the linear system Ax = b using Singular-value decomposition and back substitution, begin with an array A which serves as the coefficient array:

```
; Define the array A:
A = [[1.0, 2.0, -1.0, 2.5], $
     [1.5, 3.3, -0.5, 2.0], $
     [3.1, 0.7,  2.2, 0.0], $
     [0.0, 0.3, -2.0, 5.3], $
     [2.1, 1.0,  4.3, 2.2], $
     [0.0, 5.5,  3.8, 0.2]]

; Define the right-hand side vector B:
B = [0.0, 1.0, 5.3, -2.0, 6.3, 3.8]

; Decompose A:
SVDC, A, W, U, V

; Compute the solution and print the result:
PRINT, SVSOL(U, W, V, B)
```

IDL prints:

```
   1.00095    0.00881170     0.984176    -0.0100954
```

This is the correct solution.

SWAP_ENDIAN

The SWAP_ENDIAN function reverses the byte ordering of arbitrary scalars, arrays or structures. It can make "big endian" number "little endian" and vice-versa.

Note ───

The BYTEORDER procedure can be used to reverse the byte ordering of *scalars and arrays* (SWAP_ENDIAN also allows structures).

──

This routine is written in the IDL language. Its source code can be found in the file swap_endian.pro in the lib subdirectory of the IDL distribution.

Syntax

Result = SWAP_ENDIAN(*Variable* [, /SWAP_IF_BIG_ENDIAN]
   [, /SWAP_IF_LITTLE_ENDIAN])

Return Value

SWAP_ENDIAN returns values of the same type and structure as the input value, with the pertinent bytes reversed.

Arguments

Variable

The named variable—scalar, array, or structure—to be swapped.

Keywords

SWAP_IF_BIG_ENDIAN

If this keyword is set, the swap request will only be performed if the platform running IDL uses "big endian" byte ordering. On little endian machines, the SWAP_ENDIAN request quietly returns without doing anything. Note that this keyword does not refer to the byte ordering of the input data, but to the computer hardware.

SWAP_IF_LITTLE_ENDIAN

If this keyword is set, the swap request will only be performed if the platform running IDL uses "little endian" byte ordering. On big endian machines, the SWAP_ENDIAN request quietly returns without doing anything. Note that this keyword does not refer to the byte ordering of the input data, but to the computer hardware.

Examples

```
; Reverse the byte order of A:
A = SWAP_ENDIAN(A)
```

BYTEORDER, SWAP_ENDIAN_INPLACE

SWAP_ENDIAN_INPLACE

The SWAP_ENDIAN_INPLACE procedure reverses the byte ordering of arbitrary scalars, arrays or structures. It can make "big endian" number "little endian" and vice-versa.

Note ———————————————————————————————

The BYTEORDER procedure can be used to reverse the byte ordering of *scalars and arrays* (SWAP_ENDIAN_INPLACE also allows structures).

———————————————————————————————————————

SWAP_ENDIAN_INPLACE differs from the SWAP_ENDIAN function in that it alters the input data in place rather than making a copy as does SWAP_ENDIAN. SWAP_ENDIAN_INPLACE can therefore be more efficient, if a copy of the data is not needed. The pertinent bytes in the input variable are reversed.

This routine is written in the IDL language. Its source code can be found in the file swap_endian_inplace.pro in the lib subdirectory of the IDL distribution.

Syntax

SWAP_ENDIAN_INPLACE, *Variable* [, /SWAP_IF_BIG_ENDIAN]
   [, /SWAP_IF_LITTLE_ENDIAN]

Arguments

Variable

The named variable—scalar, array, or structure—to be swapped.

Keywords

SWAP_IF_BIG_ENDIAN

If this keyword is set, the swap request will only be performed if the platform running IDL uses "big endian" byte ordering. On little endian machines, the SWAP_ENDIAN_INPLACE request quietly returns without doing anything. Note that this keyword does not refer to the byte ordering of the input data, but to the computer hardware.

SWAP_IF_LITTLE_ENDIAN

If this keyword is set, the swap request will only be performed if the platform running IDL uses "little endian" byte ordering. On big endian machines, the SWAP_ENDIAN_INPLACE request quietly returns without doing anything. Note that this keyword does not refer to the byte ordering of the input data, but to the computer hardware.

Examples

Reverse the byte order of A:

```
SWAP_ENDIAN_INPLACE, A
```

SWITCH

The SWITCH statement is used to select one statement for execution from multiple choices, depending upon the value of the expression following the word SWITCH.

Each statement that is part of a SWITCH statement is preceded by an expression that is compared to the value of the SWITCH expression. SWITCH executes by comparing the SWITCH expression with each selector expression in the order written. If a match is found, program execution jumps to that statement and execution continues from that point. Whereas CASE executes at most one statement within the CASE block, SWITCH executes the first matching statement and any following statements in the SWITCH block. Once a match is found in the SWITCH block, execution falls through to any remaining statements. For this reason, the BREAK statement is commonly used within SWITCH statements to force an immediate exit from the SWITCH block.

The ELSE clause of the SWITCH statement is optional. If included, it matches any selector expression, causing its code to be executed. For this reason, it is usually written as the last clause in the switch statement. The ELSE statement is executed only if none of the preceding statement expressions match. If an ELSE clause is not included and none of the values match the selector, program execution continues immediately below the SWITCH without executing any of the SWITCH statements.

SWITCH is similar to the CASE statement. For more information on using SWITCH and other IDL program control statements, as well as the differences between SWITCH and CASE, see Chapter 7, "Program Control" (*Application Programming*).

Syntax

SWITCH *expression* OF

  expression: *statement*

  ...

  expression: *statement*

ELSE: *statement*

ENDSWITCH

Examples

This example illustrates how, unlike CASE, SWITCH executes the first matching statement and any following statements in the SWITCH block:

```
x=2

SWITCH x OF
   1: PRINT, 'one'
   2: PRINT, 'two'
   3: PRINT, 'three'
   4: PRINT, 'four'
ENDSWITCH
```

IDL Prints:

```
two
three
four
```

SYSTIME

The SYSTIME function returns the current time as either a date/time string, as the number of seconds elapsed since 1 January 1970, or as a Julian date/time value.

Syntax

String = SYSTIME([0 [, *ElapsedSeconds*]] [, /UTC])

or

Seconds = SYSTIME(1 | /SECONDS)

or

Julian = SYSTIME(/JULIAN [, /UTC])

Return Value

Returns the specified time.

Arguments

SecondsFlag

If *SecondsFlag* is present and nonzero, the number of seconds elapsed since 1 January 1970 UTC is returned as a double-precision, floating-point value.

Note ————————————————————————————————————

The precision of the returned value depends on your platform:
  On Windows platforms, the value is expressed as *seconds.milliseconds*.
  On UNIX platforms, the value is expressed as *seconds.microseconds*.

——

Otherwise, if *SecondsFlag* is not present or zero, a scalar string containing the date/time is returned in standard 24-character system format as follows:

```
DOW MON DD HH:MM:SS YEAR
```

where DOW is the day of the week, MON is the month, DD is the day of the month, HH is the hour, MM is the minute, SS is the second, and YEAR is the year. By default, the date/time string is adjusted for the local time zone; use the UTC keyword to override this default.

> **Note** ───
> If the JULIAN or SECONDS keyword is set, the *SecondsFlag* argument is ignored.

ElapsedSeconds

If the *SecondsFlag* argument is zero, the *ElapsedSeconds* argument may be set to the number of seconds past 1 January 1970 UTC. In this case, SYSTIME returns the corresponding date/time string (rather than the string for the current time). The returned date/time string is adjusted for the local time zone, unless the UTC keyword is set. If this argument is present, the JULIAN keyword is not allowed.

Keywords

JULIAN

Set this keyword to specify that the current time is to be returned as a a double precision floating value containing the current Julian date/time. By default, the current time is adjusted for the local time zone; use the UTC keyword to override this default. This keyword is not allowed if the *ElapsedSeconds* argument is present.

> **Note** ───
> If the JULIAN keyword is set, a small offset is added to the returned Julian date to eliminate roundoff errors when calculating the day fraction from hours, minutes, and seconds. This offset is given by the larger of EPS and EPS*Julian, where Julian is the integer portion of the Julian date, and EPS is the EPS field from MACHAR. For typical Julian dates, this offset is approximately $6x10^{-10}$ (which corresponds to $5x10^{-5}$ seconds). This offset ensures that if the Julian date is converted back to hour, minute, and second, then the hour, minute, and second will have the same integer values as were originally input.

SECONDS

Set this keyword to specify that the current time is to be returned as the number of seconds elapsed since 1 January 1970 UTC. This option is equivalent to setting the *SecondsFlag* argument to a non-zero value.

UTC

Set this keyword to specify that the value returned by SYSTIME is to be returned in Universal Time Coordinated (UTC) rather than being adjusted for the current time zone. UTC time is defined as Greenwich Mean Time updated with leap seconds.

Examples

Print today's date as a string:

```
PRINT, SYSTIME()
```

Print today's date as a string in UTC (rather than local time zone):

```
PRINT, SYSTIME(/UTC)
```

Print today's date as a Julian date/time value in UTC:

```
PRINT, SYSTIME(/JULIAN, /UTC), FORMAT='(f12.2)'
```

Compute and display the seconds elapsed since 1 January 1970 UTC, showing milliseconds (Windows) or microseconds (UNIX):

```
seconds = SYSTIME(1) ; or seconds = SYSTIME(/SECONDS)
PRINT, seconds, FORMAT='(D0.0)'
```

Verify that the seconds from the previous example are correct:

```
PRINT, SYSTIME(0, seconds)
```

Print the day of the week:

```
PRINT, STRMID(SYSTIME(0), 0, 3)
```

Compute the time required to perform a 16,384 point FFT:

```
T = SYSTIME(1)
A = FFT(FINDGEN(16384), -1)
PRINT, SYSTIME(1) - T, 'Seconds'
```

Routines: T

T_CVF

The T_CVF function computes the cutoff value *V* in a Student's *t* distribution with *Df* degrees of freedom such that the probability that a random variable *X* is greater than *V* is equal to a user-supplied probability *P*.

Note ─────────────────────────────

T_CVF computes the cutoff value using the one-tailed probability. The cutoff value for the two-tailed probability, which is the probability that the absolute value of *X* is greater than *V*), can be computed as T_CVF(*P*/2, *Df*).

─────────────────────────────

This routine is written in the IDL language. Its source code can be found in the file t_cvf.pro in the lib subdirectory of the IDL distribution.

Syntax

Result = T_CVF(*P*, *Df*)

Return Value

Returns the cutoff value.

Arguments

P

A non-negative single- or double-precision floating-point scalar, in the interval [0.0, 1.0], that specifies the probability of occurrence or success.

Df

A positive integer, single- or double-precision floating-point scalar that specifies the number of degrees of freedom of the Student's t distribution.

Keywords

None

Examples

Use the following command to compute the cutoff value in a Student's t distribution with five degrees of freedom such that the probability that a random variable X is greater than the cutoff value is 0.025.

```
result = T_CVF(0.025, 5)
PRINT, result
```

IDL prints:

```
2.57058
```

T_PDF

The T_PDF function computes the probability *P* that, in a Student's t distribution with *Df* degrees of freedom, a random variable *X* is less than or equal to a user-specified cutoff value *V*.

Note ──

T_PDF computes the one-tailed probability. The two-tailed probability, which is the probability that the absolute value of *X* is less than or equal to *V*, can be computed as 1 - 2×(1 - T_PDF(*V*, *Df*)).

───

This routine is written in the IDL language. Its source code can be found in the file t_pdf.pro in the lib subdirectory of the IDL distribution.

Syntax

Result = T_PDF(*V*, *Df*)

Return Value

If both arguments are scalar, the function returns a scalar. If both arguments are arrays, the function matches up the corresponding elements of *V* and *Df*, returning an array with the same dimensions as the smallest array. If one argument is a scalar and the other argument is an array, the function uses the scalar value with each element of the array, and returns an array with the same dimensions as the input array.

If any of the arguments are double-precision, the result is double-precision, otherwise the result is single-precision.

Arguments

V

A scalar or array that specifies the cutoff value(s).

Df

A scalar or array that specifies the number of degrees of freedom of the Student's t distribution.

Keywords

None.

Examples

Use the following command to compute the probability that a random variable X, from the Student's t distribution with 15 degrees of freedom, is less than or equal to 0.691:

```
PRINT, T_PDF(0.691, 15)
```

IDL prints:

```
0.749940
```

T3D

The T3D procedure implements three-dimensional transforms.

This routine accumulates one or more sequences of translation, scaling, rotation, perspective, and oblique transformations and stores the result in !P.T, the 3D transformation system variable. All the IDL graphic routines use this (4,4) matrix for output. Note that !P.T3D is *not* set, so for the transformations to have effect you must set !P.T3D = 1 (or set the T3D keyword in subsequent calls to graphics routines).

This procedure is based on that of Foley & Van Dam, Chapter 8, "Viewing in Three Dimensions" (Foley, J.D., and A. Van Dam (1982), *Fundamentals of Interactive Computer Graphics*, Addison-Wesley Publishing Co.).

Transformations are applied in the order of the following keywords: 1)RESET, 2) TRANSLATE, 3) SCALE, 4) ROTATE, 5) PERSPECTIVE, 6) OBLIQUE, 7) XYEXCH, 8) XZEXCH, 9) YZEXCH.

A right-handed system is used. Positive rotations are counterclockwise when looking from a positive axis position towards the origin.

This routine is written in the IDL language. Its source code can be found in the file t3d.pro in the lib subdirectory of the IDL distribution.

Syntax

T3D [, *Array*][, /RESET] [, MATRIX=*variable*] [, OBLIQUE=*vector*]
   [, PERSPECTIVE=*p*{eye at 0,0,*p*}] [, ROTATE=*[x, y, z]*] [, SCALE=*[x, y, z]*]
   [, TRANSLATE=*[x, y, z]*] [, /XYEXCH | , /XZEXCH | , /YZEXCH]

Arguments

Array

An optional 4 x 4 matrix used as the starting transformation. If *Array* is missing, the current !P.T transformation is used. *Array* is ignored if /RESET is set.

Keywords

The transformation specified by each keyword is performed in the order of their descriptions below (e.g., if both TRANSLATE and SCALE are specified, the translation is done first).

MATRIX

Set this keyword to a named variable that will contain the result. If this keyword is specified, !P.T is not modified.

OBLIQUE

A two-element vector of oblique projection parameters. Points are projected onto the XY plane at Z=0 as follows:

```
x' = x + z(d * COS(a))
y' = y + z(d * SIN(a))
```

where OBLIQUE[0] = d and OBLIQUE[1] = a. An oblique projection is a parallel projection in which the normal to the projection plane is the *z*-axis, and the unit vector (0, 0, 1) is projected to (*d* cos α, *d* sin α) where α is expressed in degrees.

PERSPECTIVE

Perspective transformation. This parameter is a scalar (p) that indicates the Z distance of the center of the projection. Objects are projected into the XY plane at Z=0, and the "eye" is at point (0,0,p).

RESET

Set this keyword to reset the transformation to the default identity matrix. Set this keyword to begin a new accumulation of transformations. If this keyword is not present, the current transformation matrix !P.T is post-multiplied by the new transformation. The final transformation matrix is always stored back in !P.T. If this keyword is set, the *Array* argument is ignored.

ROTATE

A three-element vector of the rotations, in DEGREES, about the X, Y, and Z axes. The viewing area is rotated about each axis by the amount [θ_x, θ_y, θ_z], in degrees. Rotations are performed in the order of X, Y, and then Z.

SCALE

A three-element vector of scale factors for the X, Y, and Z axes. The viewing area is scaled by factor [S_x, S_y, S_z].

TRANSLATE

A three-element vector of the translations in the X, Y, and Z directions. The viewpoint is translated by the three-element vector [T_x, T_y, T_z].

XYEXCH

Set this keyword to exchange the X and Y axes.

XZEXCH

Set this keyword to exchange the X and Z axes.

YZEXCH

Set this keyword to exchange the Y and Z axes.

Examples

To reset the transformation, rotate 30 degs about the X axis and do perspective transformation with the center of the projection at Z = -1, X=0, and Y=0, enter:

```
T3D, /RESET, ROT = [ 30,0,0], PERS = 1.
```

Transformations may be cascaded, for example:

```
T3D, /RESET, TRANS = [-.5,-.5,0], ROT = [0,0,45]
T3D, TRANS = [.5,.5,0]
```

The first command resets, translates the point (.5,.5,0) to the center of the viewport, then rotates 45 degrees counterclockwise about the Z axis. The second call to T3D moves the origin back to the center of the viewport.

Also see "Transformation Created by SURFACE" on page 2421.

Establishing a Three-Dimensional Coordinate System

Usually, scaling parameters for coordinate conversion are set up by the higher-level procedures. To set up your own three-dimensional coordinate system with a given transformation matrix and *x*, *y*, *z* data range, follow these steps:

- Establish the scaling from your data coordinates to normalized coordinates—the (0, 1) cube. Assuming your data are contained in the range (X_{min}, Y_{min}, Z_{min}) to (X_{max}, Y_{max}, Z_{max}), set the data scaling system variables as follows:

    ```
    !X.S = [ -Xmin, 1 ] / (Xmax - Xmin)
    !Y.S = [ -Ymin, 1 ] / (Ymax - Ymin)
    !Z.S = [ -Zmin, 1 ] / (Zmax - Zmin)
    ```

- Establish the transformation matrix that determines the view of the unit cube. This can be done by either calling T3D, as explained above or by directly manipulating !P.T yourself. If you wish to simply mimic the rotations provided

by the SURFACE procedure, call the SCALE3 procedure (which can also be used to perform the previous step).

House Example

This example draws four views of a simple house. The procedure HOUSE defines the coordinates of the front and back faces of the house. The data-to-normal coordinate scaling is set, as shown above, to a volume about 25 percent larger than that enclosing the house. The PLOTS procedure is called to draw lines describing and connecting the front and back faces. XYOUTS is called to label the front and back faces.

The commands shown after the definition of the HOUSE procedure contain four sequences of calls to T3D to establish the coordinate transformation, each followed by a call to HOUSE.

Example Code

If you prefer not to enter the IDL code by hand, run the batch file showhaus with the following command at the IDL prompt:

```
@showhaus
```

```
PRO HOUSE
   ; X coordinates of 10 vertices. First 5 are front face,
   ; second 5 are back face. The range is 0 to 16.
   house_x = [0, 16, 16, 8, 0, 0, 16, 16, 8, 0]
   ; The corresponding y values range from 0 to 16.
   house_y = [0, 0, 10, 16, 10, 0, 0, 10, 16, 10]
   ; The z values range from 30 to 54.
   house_z = [54, 54, 54, 54, 54, 30, 30, 30, 30, 30]
   ; Define max and min xy values to scale.
   ; Slightly larger than data range.
   min_x = -4 & max_x = 20.
   ; Set x data scale to range from -4 to 20.
   !X.S = [-(-4), 1.]/(20 - (-4))
   ; Same for y.
   !Y.S = !X.S
   ; The z range is from 10 to 70.
   !Z.S = [-10, 1.]/(70 - 10)
   ; Indices of front face.
   face = [INDGEN(5), 0]
   ; Draw front face.
   PLOTS, house_x[face], house_y[face], $
      house_z[face], /T3D, /DATA
   ; Draw back face.
   PLOTS, house_x[face + 5], house_y[face + 5], $
      house_z[face + 5], /T3D, /DATA
```

```
                ; Connecting lines from front to back.
                FOR I = 0, 4 DO PLOTS, [house_x[i], house_x[i + 5]], $
                   [house_y[i], house_y[i + 5]], $
                   [house_z[i], house_z[i + 5]], /T3D, /DATA
                ; Annotate front peak.
                XYOUTS, house_x[3], house_y[3], Z = house_z[3], 'Front', $
                   /T3D, /DATA, SIZE = 2
                ; Annotate back.
                XYOUTS, house_x[8], house_y[8], Z = house_z[8], 'Back', $
                   /T3D, /DATA, SIZE = 2
             END
```

The HOUSE procedure could be called from the IDL command line to produce a number of different plots. For example:

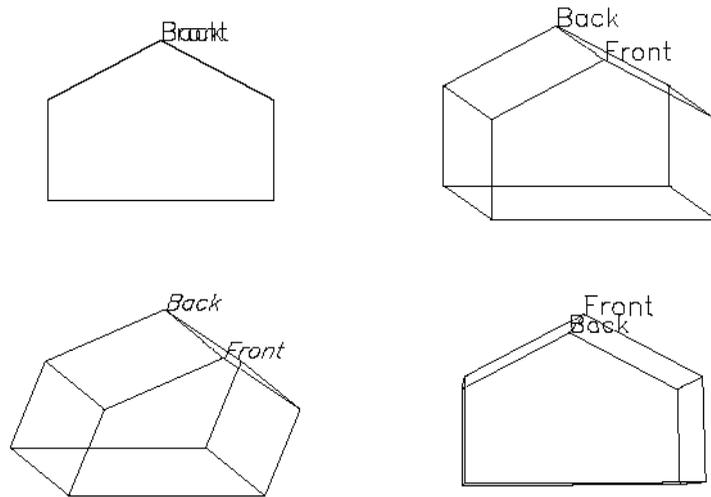
```
     ; Set up no rotation, scale, and draw house.
     T3D, /RESET & HOUSE
     ; Create a handy constant.
     H = [0.5, 0.5, 0.5]
     ; Straight projection after rotating 30 degrees about x and y axes.
     T3D, /RESET, TRANS = -H, ROT = [30, 30, 0] & $
        T3D, TR = H & HOUSE
     ; No rotation, oblique projection, z factor = 0.5, angle = 45.
     T3D, /RESET, TRANS = -H, ROT=[0, 0, 0], OBLIQUE=[.5, -45] & $
        T3D, TR = H & HOUSE
     ; Rotate 6 degrees about x and y, then apply perspective.
     T3D, /RESET, TR=-H, ROT=[-6, 6, 0], PERS=4 & $
        T3D, TR=H & HOUSE
```


Figure 22-1: Illustration of Different Three-Dimensional Transformations

The figure illustrates the different transformations. The four rotations are:

- Upper left: no rotation, plain projection

- Upper right: oblique projection, factor = 0.5, angle = –45

- Bottom left: rotation of 30 degrees about both the *x*-and *y*-axes, plain projection

- Bottom right: rotation of –6 degrees about the *x*-axis and +6 degrees about the *y*-axis, and perspective projection with the eye at 4.

See "Rotating the Shaded Volume" on page 2226 for another T3D example.

Rotating the House

A common procedure for visualizing three-dimensional data is to animate the data by rotating it about one or more axes. To make an animation of the house in the preceding example ("House Example" on page 2454), use the XINTERANIMATE procedure as follows:

```
; Initialize animation: set frame size and number of frames.
sizx = 300
sizy = 300
```

```
nframes = 16
XINTERANIMATE, SET=[sizx, sizy, nframes]
; Rotate about the z axis. Draw the house.Save the window.
FOR i = 0, nframes - 1 DO BEGIN $
   SCALE3, AX = 75, AZ = i * 360. / nframes & $
   ERASE & $
   HOUSE & $
   SCALE3, AX = 75, AZ = i * 360. / nframes & $
   XINTERANIMATE, FRAME=i, WINDOW=!D.WINDOW & $
ENDFOR
; Show the animation.
XINTERANIMATE
```

In the above example, SCALE3 rather than SCALE3D is used to maintain the same scaling in all rotations.

Example Code

If you prefer not to enter the IDL code by hand, run the batch file animhaus with the following command at the IDL prompt:

```
@animhaus
```

Positioning Contours and Plots Three-Dimensions

The CONTOUR and PLOT procedures output their results using the three-dimensional coordinate transformation contained in !P.T when the keyword T3D is specified. Note that !P.T must contain a valid transformation matrix prior to using the T3D keyword.

PLOT and its variants output graphs in the *xy*-plane at the normal coordinate *z* value given by the keyword ZVALUE. If this keyword is not specified, the plot is drawn at the bottom of the unit cube at $z = 0$.

CONTOUR draws its axes at $z = 0$ and its contours at their *z* data value if ZVALUE is not specified. If ZVALUE is present, CONTOUR draws both the axes and contours in the *xy*-plane at the given *z* value. See the following for examples:

- "Combining CONTOUR and SURFACE" on page 2422
- "SCALE3 and More Complicated Transformations" on page 2164
- "Combining Images with Three-Dimensional Graphics" on page 2261

SCALE3, SCALE3D, SURFR

TAG_NAMES

The TAG_NAMES function returns a string array containing the names of the tags in a structure expression. It can also be used to determine the expression's structure name (if the structure has a name).

Syntax

Result = TAG_NAMES(*Expression* [, /STRUCTURE_NAME])

Return Value

Returns structure tag names or the expression's structure name.

Arguments

Expression

The structure expression for which the tag names are returned. This argument must be of structure type. TAG_NAMES does not search for tags recursively, so if *Expression* is a structure containing nested structures, only the names of tags in the outermost structure are returned.

Keywords

STRUCTURE_NAME

Set this keyword to return a scalar string that contains the name of the structure instead of the names of the tags in the structure. If the structure is "anonymous", a null string is returned.

Examples

Print the names of the tags in the system variable !P by entering:

```
PRINT, TAG_NAMES(!P)
```

IDL prints:

```
BACKGROUND CHARSIZE CHARTHICK CLIP COLOR FONT LINESTYLE MULTI
NOCLIP NOERASE NSUM POSITION PSYM REGION SUBTITLE SYMSIZE T
T3D THICK TITLE TICKLEN CHANNEL
```

Print the name of the structure in the system variable !P:

```
PRINT, TAG_NAMES(!P, /STRUCTURE_NAME)

CREATE_STRUCT, N_TAGS

TAN

The TAN function computes the tangent of *X*.

Syntax

Result = TAN(*X*)

Return Value

Returns the tangent of the specified angle.

Arguments

X

The angle for which the tangent is desired, specified in radians. If *X* is double-precision floating or complex, the result is of the same type. All other types are converted to single-precision floating-point and yield floating-point results. If *X* is an array, the result has the same structure, with each element containing the tangent of the corresponding element of *X*.

Keywords

Thread Pool Keywords

This routine is written to make use of IDL's *thread pool*, which can increase execution speed on systems with multiple CPUs. The values stored in the !CPU system variable control whether IDL uses the thread pool for a given computation. In addition, you can use the thread pool keywords TPOOL_MAX_ELTS, TPOOL_MIN_ELTS, and TPOOL_NOTHREAD to override the defaults established by !CPU for a single invocation of this routine. See Appendix C, "Thread Pool Keywords" for details.

Examples

```
; Find the tangent of 0.5 radians and store the result in
; the variable T:
T = TAN(0.5)
```

ATAN, TANH

TANH

The TANH function returns the hyperbolic tangent of X.

Syntax

Result = TANH(*X*)

Return Value

Returns the single- or double-precision hyperbolic tangent.

Arguments

X

The value for which the hyperbolic tangent is desired, specified in radians. If *X* is double-precision floating or complex, the result is of the same type. All other types are converted to single-precision floating-point and yield floating-point results. TANH is defined as:

$$\tanh(x) \ = \ \frac{e^x - e^{-x}}{e^x + e^{-x}}$$

If *X* is an array, the result has the same structure, with each element containing the hyperbolic tangent of the corresponding element of *X*.

Keywords

Thread Pool Keywords

This routine is written to make use of IDL's *thread pool*, which can increase execution speed on systems with multiple CPUs. The values stored in the !CPU system variable control whether IDL uses the thread pool for a given computation. In addition, you can use the thread pool keywords TPOOL_MAX_ELTS, TPOOL_MIN_ELTS, and TPOOL_NOTHREAD to override the defaults established by !CPU for a single invocation of this routine. See Appendix C, "Thread Pool Keywords" for details.

Examples

```
; Find the hyperbolic tangent of 1 radian and print the result:
PRINT, TANH(1)

; Plot the hyperbolic tangent from -5 to +5 with an increment
; of 0.1:
PLOT, TANH(FINDGEN(101)/10. - 5)
```

TEK_COLOR

The TEK_COLOR procedure loads a 32-color colortable similar to the default Tektronix 4115 colortable. This colortable is useful because of its distinct colors.

By default, this palette consists of 32 colors. The first 9 colors are: Index 0=black, 1=white, 2=red, 3=green, 4=blue, 5=cyan, 6=magenta, 8=orange.

This routine is written in the IDL language. Its source code can be found in the file `tek_color.pro` in the `lib` subdirectory of the IDL distribution.

Syntax

TEK_COLOR [, *Start_Index*, *Colors*]

Arguments

Start_Index

An optional starting index for the palette. The default is 0. If this argument is included, the colors are loaded into the current colortable starting at the specified index.

Colors

The number of colors to load. The default is 32, which is also the maximum.

Keywords

None.

Version History

Pre-4.0	Introduced

LOADCT, XLOADCT

TEMPORARY

The TEMPORARY function returns a temporary copy of a variable, and sets the original variable to "undefined". This function can be used to conserve memory when performing operations on large arrays, as it avoids making a new copy of results that are only temporary. In general, the TEMPORARY routine can be used to advantage whenever a variable containing an array on the left hand side of an assignment statement is also referenced on the right hand side.

Syntax

Result = TEMPORARY(*Variable*)

Return Value

Returns a copy of a specified variable.

Arguments

Variable

The variable to be referenced and deleted.

Keywords

None.

Examples

Assume the variable A is a large array of integers. The statement:

```
A = A + 1
```

creates a new array for the result of the addition, places the sum into the new array, assigns it to A, and then frees the old allocation of A. Total storage required is twice the size of A. The statement:

```
A = TEMPORARY(A) + 1
```

requires no additional space.

Note

> If the operation performed on *Variable* requires that *Variable* be converted to another data type, there is no benefit to using TEMPORARY. For instance, if the array A in the above example contained byte data rather than integer data, the array would have to be converted to integer type before the addition could be performed. In such a case, memory could not be re-used.

DELVAR

TETRA_CLIP

The TETRA_CLIP function clips a tetrahedral mesh to an arbitrary plane in space and returns a tetrahedral mesh of the remaining portion. An auxiliary array of data may also be passed and clipped. This array can have multiple values for each vertex (the trailing array dimension must match the number of vertices in the Vertsin array).

A tetrahedral connectivity array consists of groups of four vertex index values. Each set of four index values specifies four vertices which define a single tetrahedron.

Syntax

Result = TETRA_CLIP (*Plane*, *Vertsin*, *Connin*, *Vertsout*, *Connout*
   [, AUXDATA_IN=*array*, AUXDATA_OUT=*variable*]
   [, CUT_VERTS=*variable*])

Return Value

The return value is the number of tetrahedra returned.

Arguments

Plane

Input four-element array describing the equation of the plane to be clipped to. The elements are the coefficients (*a,b,c,d*) of the equation *ax+by+cz+d=0*.

Vertsin

Input array of tetrahedral vertices [3, *n*].

Connin

Input tetrahedral mesh connectivity array.

Vertsout

Output array of tetrahedral vertices [3, *n*].

Connout

Output tetrahedral mesh connectivity array.

Keywords

AUXDATA_IN

Input array of auxiliary data. If present, these values are interpolated and returned through AUXDATA_OUT. The trailing array dimension must match the number of vertices in the Vertsin array.

AUXDATA_OUT

Set this keyword to a named variable to contain an output array of interpolated auxiliary data.

CUT_VERTS

Set this keyword to a named variable to contain an output array of vertex indices (into Vertsout) of the vertices which are considered to be 'on' the clipped surface.

Version History

5.5	Introduced

TETRA_SURFACE

The TETRA_SURFACE function extracts a polygonal mesh as the exterior surface of a tetrahedral mesh. The output of this function is a polygonal mesh connectivity array that can be used with the input Verts array to display the outer surface of the tetrahedral mesh.

Syntax

Result = TETRA_SURFACE (*Verts*, *Connin*)

Return Value

Returns a polygonal mesh connectivity array. When used with the input vertex array, this function yields the exposed tetrahedral mesh surface.

Arguments

Verts

Array of vertices [3, *n*].

Connin

Tetrahedral connectivity array.

Keywords

None.

Version History

5.5	Introduced

TETRA_VOLUME

The TETRA_VOLUME function computes properties of a tetrahedral mesh array. The basic property is the volume. An auxiliary data array may be supplied which specifies weights at each vertex which are interpolated through the volume during integration. Higher order moments (with respect to the X, Y, and Z axis) may be computed as well (with or without weights).

Syntax

Result = TETRA_VOLUME (*Verts*, *Conn* [, AUXDATA=*array*]
   [, MOMENT=*variable*])

Return Value

Returns the cumulative (weighted) volume of the tetrahedrons in the mesh.

Arguments

Verts

Array of vertices [3, *n*].

Conn

Tetrahedral connectivity array.

Keywords

AUXDATA

Array of input auxiliary data (one value per vertex). If present, these values are used to weight a vertex. The volume area integral will linearly interpolate these values. The volume integral will linearly interpolate these values within each tetrahedra. The default weight is 1.0 which results in a basic volume.

MOMENT

Set this keyword to a named variable that will contain a three-element float vector which corresponds to the first order moments computed with respect to the X, Y and Z axis. The computation is:

$$\vec{m} \;=\; \sum_{ntetras} v_i \vec{c}_i$$

where v is the (weighted) volume of the tetrahedron and c is the centroid of the tetrahedron, thus

$$\vec{m}/volume$$

yields the (weighted) centroid of the tetrahedral mesh.

Version History

5.5	Introduced

THIN

The THIN function returns the "skeleton" of a bi-level image. The skeleton of an object in an image is a set of lines that reflect the shape of the object. The set of skeletal pixels can be considered to be the medial axis of the object. For a much more extensive discussion of skeletons and thinning algorithms, see *Algorithms for Graphics and Image Processing*, Theo Pavlidis, Computer Science Press, 1982. The THIN function is adapted from Algorithm 9.1 (the classical thinning algorithm).

On input, the bi-level image is a rectangular array in which pixels that compose the object have a nonzero value. All other pixels are zero. The result is a byte type image in which skeletal pixels are set to 2 and all other pixels are zero.

Syntax

Result = THIN(*Image* [, /NEIGHBOR_COUNT] [, /PRUNE])

Return Value

Returns the thinned, two-dimensional byte array.

Arguments

Image

The two-dimensional image (array) to be thinned.

Keywords

NEIGHBOR_COUNT

Set this keyword to select an alternate form of output. In this form, output pixel values count the number of neighbors an individual skeletal pixel has (including itself). For example, a pixel that is part of a line will have the value 3 (two neighbors and itself). Terminal pixels will have the value 2, while isolated pixels have the value 1.

PRUNE

If the PRUNE keyword is set, pixels with single neighbors are removed iteratively until only pixels with 2 or more neighbors exist. This effectively removes (or "prunes") skeleton branches, leaving only closed paths.

Examples

The following commands display the "thinned" edges of a Sobel filtered image:

```
; Open a file for reading:
OPENR, 1, FILEPATH('people.dat', SUBDIR = ['examples','data'])

; Create a byte array in which to store the image:
A = BYTARR(192, 192, /NOZERO)

; Read first 192 by 192 image:
READU, 1, A

; Close the file:
CLOSE, 1

; Display the image:
TV, A, 0

; Apply the Sobel filter, threshold the image at value 75, and
; display the thinned edges:
TVSCL, THIN(SOBEL(A) GT 75), 1
```

THREED

The THREED procedure plots a 2-D array as a pseudo 3-D plot. The orientation of the data is fixed. This routine is written in the IDL language. Its source code can be found in the file threed.pro in the lib subdirectory of the IDL distribution.

Syntax

THREED, *A* [, *Sp*] [, TITLE=*string*] [, XTITLE=*string*] [, YTITLE=*string*]

Arguments

A

The two-dimensional array to plot.

Sp

The spacing between plot lines. If *Sp* is omitted, the spacing is set to: (MAX(*A*)-MIN(*A*))/ROWS. If *Sp* is negative, hidden lines are not removed.

Keywords

TITLE

Set this keyword to the main plot title.

XTITLE

Set this keyword to the X axis title.

YTITLE

Set this keyword to the Y axis title.

Examples

```
; Create a 2-D dataset:
A = -SHIFT(DIST(30), 15, 15)
; Make a THREED plot:
THREED, A
; Compare to SURFACE:
SURFACE, A
```

TIME_TEST2

The TIME_TEST2 procedure is a general-purpose IDL benchmark program that performs approximately 20 common operations and prints the time required.

This routine is written in the IDL language. Its source code can be found in the file time_test.pro in the lib subdirectory of the IDL distribution. This file also contains the procedure GRAPHICS_TIMES, used to time graphical operations.

Syntax

TIME_TEST2 [, *Filename*]

Arguments

Filename

An optional string that contains the name of output file for the results of the time test.

Keywords

None.

Examples

```
; Run the computational tests:
TIME_TEST2

; Run the graphics tests. Note that TIME_TEST2 must be compiled
; before GRAPHICS_TIMES will run:
GRAPHICS_TIMES
```

SYSTIME

TIMEGEN

The TIMEGEN function returns an array, with specified dimensions, of double-precision floating-point values that represent times in terms of Julian dates.

The Julian date is the number of days elapsed since Jan. 1, 4713 B.C.E., plus the time expressed as a day fraction. Following the astronomical convention, the day is defined to start at 12 PM (noon). Julian date 0.0d is therefore Jan. 1, 4713 B.C.E. at 12:00:00.

The first value of the returned array corresponds to a Julian date start time, and each subsequent value corresponds to the next Julian date in the sequence. The sequence is determined by specifying the time unit (such as months or seconds) and the step size, or spacing, between the units. You can also construct more complicated arrays by including smaller time units within each major time interval.

A small offset is added to each Julian date to eliminate roundoff errors when calculating the day fraction from the hour, minute, second. This offset is given by the larger of EPS and EPS*Julian, where Julian is the integer portion of the Julian date and EPS is the double-precision floating-point precision parameter from MACHAR. For typical Julian dates the offset is approximately 6×10^{-10} (which corresponds to 5×10^{-5} seconds). This offset ensures that when the Julian date is converted back to the hour, minute, and second, the hour, minute, and second will have the same integer values.

Tip ————————————————————————————————————

Because of the large magnitude of the Julian date (1 Jan 2000 is Julian day 2451545), the precision of most Julian dates is limited to 1 millisecond (0.001 seconds). If you are not interested in the date itself, you can improve the precision by subtracting a large offset or setting the START keyword to zero.

——

Note ————————————————————————————————————

Julian values must be in the range -1095 to 1827933925, which corresponds to calendar dates 1 Jan 4716 B.C.E. and 31 Dec 5000000, respectively.

——

Syntax

Result = TIMEGEN([D_1,...,D_8] [, FINAL=*value*] [, DAYS=*vector*]
    [, HOURS=*vector*] [, MINUTES=*vector*] [, MONTHS=*vector*]
    [, SECONDS=*vector*] [, START=*value*] [, STEP_SIZE=*value*] [, UNITS=*string*]
    [, YEAR=*value*])

Return Value

Returns the specified time values.

Arguments

D*ᵢ*

The dimensions of the result. The dimension parameters may be any scalar expression. Up to eight dimensions may be specified. If the dimension arguments are not integer values, IDL will truncate them to integer values before creating the new array. The dimension arguments are required unless keyword FINAL is set, in which case they are ignored.

Keywords

DAYS

Set this keyword to a scalar or a vector giving the day values that should be included within each month. This keyword is ignored if the UNITS keyword is set to "Days", "Hours", "Minutes", or "Seconds".

Note

Day values that are beyond the end of the month will be set equal to the last day for that month. For example, setting DAY=[31] will automatically return the last day in each month.

FINAL

Set this keyword to a double-precision value representing the Julian date/time to use as the last value in the returned array. In this case, the dimension arguments are ignored and *Result* is a one-dimensional array, with the number of elements depending upon the step size. The FINAL time may be less than the START time, in which case STEP_SIZE should be negative.

Note

If the step size is not an integer then the last element may not be equal to the FINAL time. In this case, TIMEGEN will return enough elements such that the last element is less than or equal to FINAL.

HOURS

Set this keyword to a scalar or a vector giving the hour values that should be included within each day. This keyword is ignored if UNITS is set to "Hours", "Minutes", or "Seconds".

MINUTES

Set this keyword to a scalar or a vector giving the minute values that should be included within each hour. This keyword is ignored if UNITS is set to "Minutes" or "Seconds".

MONTHS

Set this keyword to a scalar or a vector giving the month values that should be included within each year. This keyword is ignored if UNITS is set to "Months", "Days", "Hours", "Minutes", or "Seconds".

SECONDS

Set this keyword to a scalar or a vector giving the second values that should be included within each minute. This keyword is ignored if UNITS is set to "Seconds".

START

Set this keyword to a double-precision value representing the Julian date/time to use as the first value in the returned array. The default is 0.0d [corresponding to January 1, 4713 B.C.E. at 12 pm (noon)].

Note

If subintervals are provided by MONTHS, DAYS, HOURS, MINUTES, or SECONDS, then the first element may not be equal to the START time. In this case the first element in the returned array will be greater than or equal to START.

Tip —————————————————————————————————————

Other array generation routines in IDL (such as FINDGEN) do not allow you to specify a starting value because the resulting array can be added to a scalar representing the start value. For TIMEGEN it is correct to add a scalar to the array if the units are days, hours, minutes, seconds, or sub-seconds. For example:

```
MyTimes = TIMEGEN(365, UNITS="Days") + SYSTIME(/JULIAN)
```

However, if the units are months or years, the start value is necessary because the number of days in a month or year can vary depending upon the year in which they fall (for instance, consider leap years). For example:

```
MyTimes = TIMEGEN(12, UNITS="Months", START=JULDAY(1,1,2000))
```

———

STEP_SIZE

Set this keyword to a scalar value representing the step size between the major intervals of the returned array. The step size may be negative. The default step size is 1. When the UNITS keyword is set to "Years" or "Months", the STEP_SIZE value is rounded to the nearest integer.

UNITS

Set this keyword to a scalar string indicating the time units to be used for the major intervals for the generated array. Valid values include:

- "Years" or "Y"
- "Months" or "M"
- "Days" or "D"
- "Hours" or "H"
- "Minutes" or "I"
- "Seconds" or "S"

The case (upper or lower) is ignored. If this keyword is not specified, then the default for UNITS is the time unit that is larger than the largest keyword present:

Largest Keyword Present	Default UNITS
SECONDS=*vector*	"Minutes"
MINUTES=*vector*	"Hours"
HOURS=*vector*	"Days"
DAYS=*vector*	"Months"
MONTHS=*vector*	"Years"
YEAR=*value*	"Years"

Table 22-1: Defaults for the UNITS keyword

If none of the above keywords are present, the default is UNITS="Days".

YEAR

Set this keyword to a scalar giving the starting year. If YEAR is specified then the starting year from START is ignored.

Examples

Generate an array of 366 time values that are one day apart starting with January 1, 2000:

```
MyDates = TIMEGEN(366, START=JULDAY(1,1,2000))
```

Generate an array of 20 time values that are 12 hours apart starting with the current time:

```
MyTimes = TIMEGEN(20, UNITS='Hours', STEP_SIZE=12, $
    START=SYSTIME(/JULIAN))
```

Generate an array of time values that are 1 hour apart from 1 January 2000 until the current time:

```
MyTimes = TIMEGEN(START=JULDAY(1,1,2000), $
    FINAL=SYSTIME(/JULIAN), UNITS='Hours')
```

Generate an array of time values composed of seconds, minutes, and hours that start from the current hour:

```
MyTimes = TIMEGEN(60, 60, 24, $
    START=FLOOR(SYSTIME(/JULIAN)*24)/24d, UNITS='S')
```

Generate an array of 24 time values with monthly intervals, but with subintervals at 5 PM on the first and fifteenth of each month:

```
MyTimes = TIMEGEN(24, START=FLOOR(SYSTIME(/JULIAN)), $
    DAYS=[1,15], HOURS=17)
```

TM_TEST

The TM_TEST function computes the Student's T-statistic and the probability that two sample populations *X* and *Y* have significantly different means. *X* and *Y* may be of different lengths. The default assumption is that the data is drawn from populations with the same true variance. This type of test is often referred to as the t-means test.

The T-statistic for sample populations *x* and *y* with means $\bar{x}$ and $\bar{y}$ is defined as:

$$T = \frac{\bar{x} - \bar{y}}{\sqrt{\dfrac{\displaystyle\sum_{i=0}^{N-1}(x_i - \bar{x})^2 + \sum_{i=0}^{M-1}(y_i - \bar{y})^2}{(N+M-2)}} \left(\dfrac{1}{N} + \dfrac{1}{M}\right)}$$

where $x = (x_0, x_1, x_2, ..., x_{N-1})$ and $y = (y_0, y_1, y_2 ..., y_{M-1})$

This routine is written in the IDL language. Its source code can be found in the file `tm_test.pro` in the `lib` subdirectory of the IDL distribution.

Syntax

Result = TM_TEST(*X*, *Y* [, /PAIRED] [, /UNEQUAL])

Return Value

The result is a two-element vector containing the T-statistic and its significance. The significance is a value in the interval [0.0, 1.0]; a small value (0.05 or 0.01) indicates that *X* and *Y* have significantly different means.

Arguments

X

An *n*-element integer, single-, or double-precision floating-point vector.

Y

An *m*-element integer, single-, or double-precision floating-point vector. If the PAIRED keyword is set, *X* and *Y* must have the same number of elements.

Keywords

PAIRED

If this keyword is set, *X* and *Y* are assumed to be paired samples and must have the same number of elements.

UNEQUAL

If this keyword is set, *X* and *Y* are assumed to be from populations with unequal variances.

Examples

```
; Define two n-element sample populations.
X = [257, 208, 296, 324, 240, 246, 267, 311, 324, 323, 263, $
     305, 270, 260, 251, 275, 288, 242, 304, 267]
Y = [201, 56, 185, 221, 165, 161, 182, 239, 278, 243, 197, $
     271, 214, 216, 175, 192, 208, 150, 281, 196]

; Compute the Student's t-statistic and its significance assuming
; that X and Y belong to populations with the same true variance:
PRINT, TM_TEST(X, Y)
```

IDL prints:

```
5.52839  2.52455e-06
```

The result indicates that *X* and *Y* have significantly different means.

FV_TEST, KW_TEST, RS_TEST, S_TEST

TOTAL

The TOTAL function returns the sum of the elements of *Array*. The sum of the array elements over a given dimension is returned if the *Dimension* argument is present.

Syntax

Result = TOTAL(*Array* [, *Dimension*] [, /CUMULATIVE] [, /DOUBLE]
    [, /INTEGER] [, /NAN] [, /PRESERVE_TYPE])

Return Value

Returns the array sum for the specified dimensions.

Arguments

Array

The array to be summed. This array can be of any basic type except string. If *Array* is double-precision floating-point, complex, or double-precision complex, the result is of the same type. Otherwise, the result is single-precision floating-point.

Dimension

The dimension over which to sum, starting at one. If this argument is not present or zero, the scalar sum of all the array elements is returned. If this argument is present, the result is an array with one less dimension than *Array*. For example, if the dimensions of *Array* are N_1, N_2, N_3, and *Dimension* is 2, the dimensions of the result are (N_1, N_3), and element *(i,j)* of the result contains the sum:

$$\sum_{k=0}^{N_2-1} A_{i,k,j}$$

Keywords

CUMULATIVE

If this keyword is set, the result is an array of the same size as the input, with each element, *i*, containing the sum of the input array elements 0 to *i*. This keyword also works with the Dimension parameter, in which case the sum is performed over the given dimension.

Tip ———————————————————————————————————

If the input array is a temporary variable or an expression, and the result type matches the input type (for example by using the PRESERVE_TYPE keyword), then TOTAL will perform the cumulative sum in place and no additional memory will be used.

DOUBLE

Set this keyword to force the summation to be done using double-precision arithmetic. By default, if the input is of type DOUBLE, DCOMPLEX, LONG64, or ULONG64, IDL does the summation using double precision; otherwise IDL does the summation using single precision. If this keyword is set to zero, IDL still does the summation using the default precision, but the result is converted to single precision before returning.

INTEGER

Set this keyword to perform the TOTAL using integer arithmetic, and to return an integer result. If *Array* is of type ULONG64 then unsigned 64-bit integers are used for the computation and the Result is of type ULONG64, otherwise signed 64-bit integers are used and the Result is of type LONG64. If *Array* is complex and INTEGER is set, then only the real part of each value is used for the computation. The DOUBLE keyword is ignored if INTEGER is set.

Note ———————————————————————————————————

If *Array* has a large number of values or the values themselves are large, then the TOTAL with the INTEGER keyword may easily overflow the largest 64-bit integer and return an incorrect result. In this case you may want to avoid using the INTEGER keyword.

NAN

Set this keyword to cause the routine to check for occurrences of the IEEE floating-point values *NaN* or *Infinity* in the input data. Elements with the value *NaN* or *Infinity* are treated as missing data. (See "Special Floating-Point Values" (Chapter 8, *Application Programming*) for more information on IEEE floating-point values.)

Note ———————————————————————————————————

Since the value NaN is treated as missing data, if *Array* contains only NaN values the TOTAL routine will return 0.

PRESERVE_TYPE

Set this keyword to perform the TOTAL using the input type, and to return a result of the same type. The DOUBLE and INTEGER keywords are ignored if PRESERVE_TYPE is set.

Note

For byte or integer data the TOTAL with PRESERVE_TYPE may easily overflow the largest value for that type. The PRESERVE_TYPE keyword is only useful if you know that your values will not overflow, or you want to exploit the overflow, for example in computing a checksum. Otherwise, you may want to use the INTEGER keyword instead.

Thread Pool Keywords

This routine is written to make use of IDL's *thread pool*, which can increase execution speed on systems with multiple CPUs. The values stored in the !CPU system variable control whether IDL uses the thread pool for a given computation. In addition, you can use the thread pool keywords TPOOL_MAX_ELTS, TPOOL_MIN_ELTS, and TPOOL_NOTHREAD to override the defaults established by !CPU for a single invocation of this routine. See Appendix C, "Thread Pool Keywords" for details.

The thread pool is used for non-cumulative sums, and is not used if the CUMULATIVE keyword is specified. In a cumulative sum, each result value depends on all of the previous results, so overlapped execution is not possible.

You should be aware that when summing a large number of values, the result from TOTAL can depend heavily upon the order in which the numbers are added. Since the thread pool will add values in a different order, you may obtain a different — but equally correct — result than that obtained using the standard non-threaded implementation. This effect occurs because TOTAL uses floating point arithmetic, and the mantissa of a floating point value has a fixed number of significant digits. The effect is especially obvious when using single precision arithmetic, but can also affect double precision computations. Such differences do not mean that the sums are incorrect. Rather, they mean that they are equal within the ability of the floating point representation used to represent them. For more information on floating-point numbers, see "Accuracy and Floating Point Operations" (Chapter 13, *Application Programming*).

It is also worth noting that this effect, while illustrated by the use of the thread pool, is not caused by the use of threading. It is simply caused by the different order in which the numbers are summed, as can be illustrated by the following non-threaded example:

```
vec = FINDGEN(100000)
PRINT, TOTAL(vec, /TPOOL_NO) - TOTAL(REVERSE(vec), /TPOOL_NO)
```

IDL prints:

```
-96768.0
```

As you can see, the small floating-point errors can accumulate across the sum of a large number of values.

Note ——————————————————————————————————————

The computation above was done on a Sun Sparc workstation. Your result will depend on the architecture of your CPU; it may be slightly different, and in the notable case of Intel-compatible X86 CPUs may actually be zero due to the use of internal 80-bit floating point registers on that CPU which give it better than double precision accuracy for some computations. Nonetheless, you should be aware of the fact that the order of operations can influence the result.

Examples

Example 1

This example sums the elements of a one-dimensional array:

```
; Define a one-dimensional array:
A = [20, 10, 5, 5, 3]

; Sum the elements of the array:
SUMA = TOTAL([20, 10, 5, 5, 3])

; Print the results:
PRINT, 'A = ', A
PRINT, 'Sum of A = ', SUMA
```

IDL prints:

```
A =   20   10   5   5   3
Sum of A =   43.0000
```

Example 2

The results are different when a multi-dimensional array is used:

```
; Define a multi-dimensional array:
A = FINDGEN(5,5)

; Sum each of the rows in A:
SUMROWS = TOTAL(A, 1)

; Sum each of the columns in A:
SUMCOLS = TOTAL(A, 2)

; Print the results:
PRINT, 'A = ', A
PRINT, 'Sum of each row:', SUMROWS
PRINT, 'Sum of each column:', SUMCOLS
```

IDL prints:

```
A = 0.000000    1.00000    2.00000    3.00000    4.00000
    5.00000     6.00000    7.00000    8.00000    9.00000
    10.0000     11.0000    12.0000    13.0000    14.0000
    15.0000     16.0000    17.0000    18.0000    19.0000
    20.0000     21.0000    22.0000    23.0000    24.0000

Sum of each row:  10.0000  35.0000  60.0000  85.0000  110.000

Sum of each column:  50.0000  55.0000  60.0000  65.0000  70.0000
```

TRACE

The TRACE function computes the trace of an *n* by *n* array.

This routine is written in the IDL language. Its source code can be found in the file trace.pro in the lib subdirectory of the IDL distribution.

Syntax

Result = TRACE(*A* [, /DOUBLE])

Return Value

Returns the sum of the values along the array diagonal.

Arguments

A

An *n* by *n* real or complex array.

Keywords

DOUBLE

Set this keyword to force the computation to be done in double-precision arithmetic.

Examples

```
; Define an array:
A = [[ 2.0,1.0,  1.0, 1.5], $
     [ 4.0, -6.0,  0.0, 0.0], $
     [-2.0,  7.0,  2.0, 2.5], $
     [ 1.0,  0.5,  0.0, 5.0]]

; Compute the trace of A:
result = TRACE(A)

;Print the result:
PRINT, 'TRACE(A) = ', result
```

IDL prints:

```
TRACE(A) =   3.00000
```

TrackBall Object

See "TrackBall" on page 5348.

TRANSPOSE

The TRANSPOSE function returns the transpose of *Array*. If an optional permutation vector is provided, the dimensions of *Array* are rearranged as well.

Syntax

Result = TRANSPOSE(*Array* [, *P*])

Return Value

Returns the reflection of the array along a diagonal.

Arguments

Array

The array to be transposed.

P

A vector specifying how the dimensions of *Array* will be permuted. The elements of *P* correspond to the dimensions of *Array*; the *i*th dimension of the output array is dimension *P*[*i*] of the input array. Each element of the vector *P* must be unique. Dimensions start at zero and can not be repeated.

If *P* is not present, the order of the dimensions of *Array* is reversed.

Keywords

None.

Examples

Note

Also see "Transposing Images" (Chapter 2, *Image Processing in IDL*) for a more extensive example.

Example 1

Print a simple array and its transpose by entering:

```
; Create an array:
A = INDGEN(3,3)
TRANSA = TRANSPOSE(A)

; Print the array and its transpose:
PRINT, 'A:'
PRINT, A
PRINT, 'Transpose of A:'
PRINT, TRANSA
```

IDL prints:

```
A:
   0  1  2
   3  4  5
   6  7  8

Transpose of A:
   0  3  6
   1  4  7
   2  5  8
```

Example 2

This example demonstrates multi-dimensional transposition:

```
; Create the array:
A = INDGEN(2, 3, 4)

; Take the transpose, reversing the order of the indices:
B = TRANSPOSE(A)

; Re-order the dimensions of A, so that the second dimension
; becomes the first, the third becomes the second, and the first
; becomes the third:
C = TRANSPOSE(A, [1, 2, 0])

; View the sizes of the three arrays:
HELP, A, B, C
```

IDL prints:

```
A    INT  = Array[2, 3, 4]
B    INT  = Array[4, 3, 2]
C    INT  = Array[3, 4, 2]
```

TRI_SURF

The TRI_SURF function interpolates a regularly- or irregularly-gridded set of points with a smooth quintic surface.

TRI_SURF is similar to MIN_CURVE_SURF but the surface fitted is a smooth surface, not a minimum curvature surface. TRI_SURF has the advantage of being much more efficient for larger numbers of points.

Note
The TRI_SURF function is designed to interpolate low resolution data. Large arrays may cause TRI_SURF to issue the following error message:
`Partial Derivative Approximation Failed to Converge`"
In such cases, interpolation is most likely unnecessary.

This routine is written in the IDL language. Its source code can be found in the file `tri_surf.pro` in the `lib` subdirectory of the IDL distribution.

Syntax

Result = TRI_SURF(*Z* [, *X*, *Y*] [, /EXTRAPOLATE] [, /LINEAR]
   [, MISSING=*value*] [, /REGULAR] [, XGRID=*[xstart, xspacing]* |
   [, XVALUES=*array*]] [, YGRID=*[yxstart, yspacing]* | [, YVALUES=*array*]]
   [, GS=*[xspacing, yspacing]*] [, BOUNDS=*[xmin, ymin, xmax, ymax]*]
   [, NX=*value*] [, NY=*value*])

Return Value

The result is s a two-dimensional floating-point array containing the interpolated surface, sampled at the grid points.

Arguments

X, Y, Z

arrays containing the X, Y, and Z coordinates of the data points on the surface. Points need not be regularly gridded. For regularly gridded input data, X and Y are not used: the grid spacing is specified via the XGRID and YGRID (or XVALUES and YVALUES) keywords, and Z must be a two dimensional array. For irregular grids, all three parameters must be present and have the same number of elements.

Keywords

EXTRAPOLATE

Set this keyword to cause TRI_SURF to extrapolate the surface to points outside the convex hull of input points. This keyword has no effect if the input points are regularly gridded.

LINEAR

Set this keyword to use linear interpolation, without gradient estimates, instead of quintic interpolation. Linear interpolation does not extrapolate, although it is faster and more numerically stable.

MISSING

Set this keyword equal to the value to which points outside the convex hull of input points should be set. The default is 0. This keyword has no effect if the input points are regularly gridded.

Input Grid Description:

REGULAR

If set, the *Z* parameter is a two-dimensional array of dimensions (*n,m*), containing measurements over a regular grid. If any of XGRID, YGRID, XVALUES, or YVALUES are specified, REGULAR is implied. REGULAR is also implied if there is only one parameter, *Z*. If REGULAR is set, and no grid specifications are present, the grid is set to (0, 1, 2, ...).

XGRID

A two-element array, [*xstart, xspacing*], defining the input grid in the *x* direction. Do not specify both XGRID and XVALUES.

XVALUES

An *n*-element array defining the *x* locations of Z[*i,j*]. Do not specify both XGRID and XVALUES.

YGRID

A two-element array, [*ystart, yspacing*], defining the input grid in the *y* direction. Do not specify both YGRID and YVALUES.

YVALUES

An *n*-element array defining the *y* locations of Z[*i,j*]. Do not specify both YGRID and YVALUES.

Output Grid Description:

Note —————————————————————————————————————

The output grid must enclose the convex hull of the input points.

GS

The output grid spacing. If present, GS must be a two-element vector [*xs, ys*], where *xs* is the horizontal spacing between grid points and *ys* is the vertical spacing. The default is based on the extents of *x* and *y*. If the grid starts at *x* value *xmin* and ends at *xmax*, then the default horizontal spacing is (*xmax - xmin*)/(NX-1). YS is computed in the same way. The default grid size, if neither NX or NY are specified, is 26 by 26.

BOUNDS

If present, BOUNDS must be a four-element array containing the grid limits in *x* and *y* of the output grid: [*xmin, ymin, xmax, ymax*]. If not specified, the grid limits are set to the extent of *x* and *y*.

NX

The output grid size in the *x* direction. NX need not be specified if the size can be inferred from GS and BOUNDS. The default value is 26.

NY

The output grid size in the *y* direction. NY need not be specified if the size can be inferred from GS and BOUNDS. The default value is 26.

Examples

Example 1

Regularly gridded case:

```
; Make some random data
Z = randomu(seed, 5, 6)

; Interpolate to a 26 x 26 grid:
CONTOUR, TRI_SURF(Z, /REGULAR)
```

Example 2

Irregularly gridded case:

```
; Make a random set of points that lie on a Gaussian:
N = 15
X = RANDOMU(seed, N)
Y = RANDOMU(seed, N)

; The Gaussian:
Z = EXP(-2 * ((X-.5)^2 + (Y-.5)^2))

; Use a 26 by 26 grid over the rectangle bounding x and y.
; Get the surface:
R = TRI_SURF(Z, X, Y)

; Alternatively, get a surface over the unit square, with spacing
; of 0.05:
R = TRI_SURF(z, x, y, GS=[0.05, 0.05], BOUNDS=[0,0,1,1])

; Alternatively, get a 10 by 10 surface over the rectangle bounding
; x and y:
R = TRI_SURF(z, x, y, NX=10, NY=10)
```

CONTOUR, MIN_CURVE_SURF

TRIANGULATE

The TRIANGULATE procedure constructs a Delaunay triangulation of a planar set of points. Delaunay triangulations are very useful for the interpolation, analysis, and visual display of irregularly-gridded data. In most applications, after the irregularly gridded data points have been triangulated, the function TRIGRID is invoked to interpolate surface values to a regular grid. TRIANGULATE uses double precision for all computations.

Since Delaunay triangulations have the property that the circumcircle of any triangle in the triangulation contains no other vertices in its interior, interpolated values are only computed from nearby points.

TRIANGULATE can, optionally, return the adjacency list that describes, for each node, the adjacent nodes in the Delaunay triangulation. With this list, the Voronoi polygon (the polygon described by the set of points which are closer to that node than to any other node) can be computed for each node. This polygon contains the area influenced by its associated node. Tiling of the region in this manner is also called Dirichlet, Wigner-Seithz, or Thiessen tessellation.

The grid returned by the TRIGRID function can be input to various routines such as SURFACE, TV, and CONTOUR. See the description of TRIGRID for an example.

TRIANGULATE and TRIGRID can also be used to perform gridding and interpolation over the surface of a sphere. The interpolation is C_1 continuous, meaning that the result is continuous over both the function value and its first derivative. This feature is ideal for interpolating an irregularly-sampled dataset over part or all of the surface of the earth (or other (spherical) celestial bodies). Extrapolation outside the convex hull of sample points is also supported. To perform spherical gridding, you must include the FVALUE and SPHERE keywords described below. The spherical gridding technique used in IDL is based on the paper "Interpolation of Data on the Surface of a Sphere", R. Renka, *Oak Ridge National Laboratory Report ORNL/CSD-108*, 1982.

The TRIANGULATE procedure uses the divide-and-conquer method described in "Two Algorithms for Constructing a Delaunay Triangulation," D.T. Lee and B.J. Schachter, *Int. J. of Computer and Information Sci.*, Vol. 9, 1980, pp. 219-242.

Syntax

TRIANGULATE, *X*, *Y*, *Triangles* [, *B*] [, CONNECTIVITY=*variable*]
   [, SPHERE=*variable* [, /DEGREES]] [, FVALUE=*variable*]
   [, REPEATS=*variable*] [, TOLERANCE=*value*]

Arguments

X

An array that contains the X coordinates of the points to be triangulated.

Y

An array that contains the Y coordinates of the points to be triangulated. Parameters *X* and *Y* must have the same number of elements.

Triangles

A named variable that, on exit, contains the list of triangles in the Delaunay triangulation of the points specified by the X and Y arguments. Triangles is a longword array dimensioned (3, *number of triangles*), where `Triangles[0, i]`, `Triangles[1, i]`, and `Triangles[2, i]` contain the indices of the vertices of the *i*-th triangle (i.e., `X[Tr[*, i]]` and `Y[Triangles[*, i]]` are the X and Y coordinates of the vertices of the *i*-th triangle).

B

An optional, named variable that, upon return, contains a list of the indices of the boundary points in counterclockwise order.

Keywords

CONNECTIVITY

Set this keyword to a named variable in which the adjacency list for each of the *N* nodes (xy point) is returned. The list has the following form:

Each element *i*, $0 \leq i < N$, contains the starting index of the connectivity list for node *i* within the list array. To obtain the adjacency list for node *i*, extract the list elements from LIST[*i*] to LIST[*i*+1]-1.

The adjacency list is ordered in the counter-clockwise direction. The first item on the list of boundary nodes is the subscript of the node itself. For interior nodes, the list contains the subscripts of the adjacent nodes in counter-clockwise order.

For example, the call:

```
TRIANGULATE, X, Y, CONNECTIVITY = LIST
```

returns the adjacency list in the variable LIST.

The subscripts of the nodes adjacent to X[*i*] and Y[*i*] are contained in the array:

```
LIST[LIST[i] : LIST[i+1]-1]
```

DEGREES

Set this keyword to indicate that the *X* and *Y* arguments contain longitude and latitude coordinates specified in degrees. This keyword is only effective if the SPHERE keyword is specified. If DEGREES is not set, *X* and *Y* are assumed to be specified in radians when a spherical triangulation is performed.

FVALUE

Set this keyword to a named variable that contains sample values for each longitude/latitude point in a spherical triangulation. On output, the elements of FVALUE are rearranged to correspond to the new ordering of *X* and *Y* (as described in the SPHERE keyword, below). This reordered array can be passed to TRIGRID to complete the interpolation.

REPEATS

Set this keyword to a named variable to return a (2, *n*) list of the indices of duplicated points. That is, for each *i*,

```
X[REPEATS[0,i]] = X[REPEATS[1,i]]
```

and

```
Y[REPEATS[0,i]] = Y[REPEATS[1,i]]
```

Note

Use the GRID_INPUT procedure to handle repeated points (duplicate locations).

SPHERE

Set this keyword to a named variable in which the results from a spherical triangulation are returned. This result is a structure that can be passed to TRIGRID to perform spherical gridding. The structure contains the 3D Cartesian locations sample points and the adjacency list that describes the triangulation.

When spherical triangulation is performed, *X* and *Y* are interpreted as longitude and latitude, in either degrees or radians (see the DEGREES keyword, above). The *X* and *Y* parameters are converted to double precision and are rearranged to match the spherical triangulation.

TOLERANCE

Set this keyword to the tolerance to be used when determining whether points are colinear. If *X* and *Y* are double-precision values, the default is $10^{-12} * Max(X,Y)$; otherwise the default is $10^{-6} * Max(X,Y)$, where *Max(X,Y)* is the maximum absolute value of the *X* and *Y* arrays. If three points are colinear within the given tolerance, a triangle will not be constructed for those points. The default is zero, which assumes that none of the points are colinear.

Tip ──

TRIANGULATE is typically used for irregular grids, where none of the points are colinear. For regular or semi-regular grids, you can use the TOLERANCE value to avoid creating artificial triangles along the boundary, and to triangulate the appropriate points within the grid. In this case, an appropriate tolerance value might be $10^{-6} * Max(X,Y)$, where *Max(X,Y)* is the maximum absolute value of the *X* and *Y* arrays.

──

Examples

For some examples using the TRIANGULATE routine, see the TRIGRID function.

SPH_SCAT, TRIGRID

TRIGRID

For non-spherical data, given data points defined by the parameters *X, Y,* and *Z* and a triangulation of the planar set of points determined by *X* and *Y,* the TRIGRID function returns a regular grid of interpolated *Z* values. Linear or smooth quintic polynomial interpolation can be selected. Extrapolation for gridpoints outside of the triangulation area is also an option. An input triangulation can be constructed using the procedure TRIANGULATE. TRIGRID uses double precision for all computations.

For spherical data, given the data values *F* and the spherical triangulation, the TRIGRID function returns a regular grid of interpolated *F* values using quadratic polynomial interpolation.

Syntax

Result = TRIGRID(*X*, *Y*, *Z*, *Triangles* [, *GS*, *Limits*])

For spherical gridding:

Result = TRIGRID(*F* , *GS*, *Limits*, SPHERE=*S*)

Keywords: [, /DEGREES] [, EXTRAPOLATE=*array*] [, INPUT=*variable*]
   [, MAX_VALUE=*value*] [, MIN_VALUE=*value*] [, MISSING=*value*]
   [, NX=*value*] [, NY=*value*] [, /QUINTIC] [, SPHERE=*variable*]
   [, XGRID=*variable*] [, XOUT=*vector*] [, YGRID=*variable*] [, YOUT=*vector*]

Return Value

If any of *X*, *Y*, or *Z* are double precision, *Result* is double precision; otherwise, *Result* is single precision. If SPHERE is present, *Result* is always double precision.

Arguments

X, Y, Z

Input arrays of *X*, *Y*, and *Z* coordinates of data points. Integer, long, double-precision and floating-point values are allowed. In addition, *Z* can be a complex array. All three arrays must have the same number of elements.

F

When performing a spherical gridding, this argument should be the named variable that contains the rearranged sample values that were returned by TRIANGULATE's FVALUE keyword.

Triangles

A longword array of the form output by TRIANGULATE. That is, *Triangles* has the dimensions (3, *number of triangles*) and, for each *i*, `Triangles[0,i]`, `Triangles[1,i]`, and `Triangles[2,i]` are the indices of the vertices of the *i*-th triangle.

GS

If present, *GS* should be a two-element vector [*XS, YS*], where *XS* is the horizontal spacing between grid points and *YS* is the vertical spacing. The default is based on the extents of *X* and *Y*. If the grid starts at *X* value x_0 and ends at x_1, then the horizontal spacing is

$(x_1 - x_0)/50$

The default for *YS* is computed in the same way. Since the default grid spacing divides each axis into 50 intervals and produces 51 samples, TRIGRID returns a grid with dimensions (51, 51).

If the NX or NY keywords are set to specify the output grid dimensions, either or both of the values of *GS* may be set to 0. In this case, the grid spacing is computed as the respective range divided by the dimension minus one:

$(x_1 - x_0)/(NX-1)$ and $(y_1 - y_0)/(NY-1)$

For spherical gridding, *GS* is assumed to be specified in radians, unless the DEGREES keyword is set.

Limits

If present, *Limits* should be a four-element vector [x_0, y_0, x_1, y_1] that specifies the data range to be gridded (x_0 and y_0 are the lower X and Y data limits, and x_1 and y_1 are the upper limits). The default for *Limits* is:

```
[MIN(X), MIN(Y), MAX(X), MAX(Y)]
```

If the NX or NY keywords are not specified, the size of the grid produced is specified by the value of *Limits*. If the NX or NY keywords are set to specify the output grid dimensions, a grid of the specified size will be used regardless of the value of *Limits*.

Keywords

DEGREES

For a spherical gridding, set this keyword to indicate that the grid spacing (the *GS* argument) is specified in degrees rather than radians.

EXTRAPOLATE

Set this keyword equal to an array of boundary node indices (as returned by the optional parameter B of the TRIANGULATE procedure) to extrapolate to grid points outside the triangulation. The extrapolation is not smooth, but should give acceptable results in most cases.

Setting this keyword sets the quintic interpolation mode, as if the QUINTIC keyword has been specified.

This keyword is ignored for spherical gridding.

INPUT

Set this keyword to a named variable (which must be an array of the appropriate size to hold the output from TRIGRID) in which the results of the gridding are returned. This keyword is provided to make it easy and memory-efficient to perform multiple calls to TRIGRID. The interpolates within each triangle overwrite the array and the array is not initialized.

MAX_VALUE

Set this keyword to a value that represents the maximum *Z* value to be gridded. Data larger than this value are treated as missing data and are not gridded.

This keyword is ignored for spherical gridding.

MIN_VALUE

Set this keyword to a value that represents the minimum *Z* value to be gridded. Data smaller than this value are treated as missing data and are not gridded.

This keyword is ignored for spherical gridding.

MISSING

The *Z* value to be used for grid points that lie outside the triangles in *Triangles*. The default is 0. This keyword also applies to data points outside the range specified by MIN_VALUE and MAX_VALUE.

Note ──

Letting MISSING default to 0 does not always produce the same result as explicitly setting it to 0. For example, if you specify INPUT and not EXTRAPOLATE, letting MISSING default to 0 will result in the INPUT values being used for data outside the Triangles; explicitly setting MISSSING to 0 will result in 0 being used for the data outside the Triangles.

──

NX

The output grid size in the *x* direction. The default value is 51.

NY

The output grid size in the *y* direction. The default value is 51.

QUINTIC

If QUINTIC is set, smooth interpolation is performed using Akima's quintic polynomials from "A Method of Bivariate Interpolation and Smooth Surface Fitting for Irregularly Distributed Data Points" in *ACM Transactions on Mathematical Software*, 4, 148-159. For non-spherical data, the default method is linear interpolation. For spherical data, the default method is quadratic interpolation, and the QUINTIC keyword is ignored.

Derivatives are estimated by Renka's global method in "A Triangle-Based C1 Interpolation Method" in *Rocky Mountain Journal of Mathematics*, vol. 14, no. 1, 1984.

QUINTIC is not available for complex data values. Setting the EXTRAPOLATE keyword implies the use of quintic interpolation; it is not necessary to specify both.

SPHERE

For a spherical gridding, set this keyword to the named variable that contains the results of the spherical triangulation returned by TRIANGULATE's SPHERE keyword.

XGRID

Set this keyword to a named variable that will contain a vector of *X* values for the output grid.

XOUT

Set this keyword to a vector specifying the output grid *X* values. If this keyword is supplied, the *GS* and *Limits* arguments are ignored. Use this keyword to specify irregularly spaced rectangular output grids. If XOUT is specified, YOUT must also be specified. If keyword NX is also supplied then only the first NX points of XOUT will be used.

Note ──

The XOUT keyword cannot be used with the SPHERE keyword.

──

YGRID

Set this keyword to a named variable that will contain a vector of *Y* values for the output grid.

YOUT

Set this keyword to a vector specifying the output grid *Y* values. If this keyword is supplied, the *GS* and *Limits* arguments are ignored. Use this keyword to specify irregularly spaced rectangular output grids. If keyword NY is also supplied then only the first NY points of YOUT will be used.

Table 22-2 shows the interrelationships between the keywords EXATRAPOLATE, INPUT, MAX_VALUE, MIN_VALUE, and MISSING.

Note ──

The YOUT keyword cannot be used with the SPHERE keyword.

            in=' '
            READ,"Press enter",in

            ; Output grid size is 20 x 11. The X grid is
            ; [0, .1, .2, ..., 19 * .1 = 1.9].  The Y grid goes from 0 to 1:
            SURFACE, TRIGRID(X, Y, Z, Tr, [.1, .1], NX=20)
            in=' '
            READ,"Press enter",in

            ; Output size is 20 x 40.  The range of the grid in X and Y is
            ; specified by the Limits parameter.  Grid spacing in X is
            ; [5-0]/(20-1) = 0.263.  Grid spacing in Y is (4-0)/(40-1) = 0.128:
            SURFACE, TRIGRID(X, Y, Z, Tr, [0,0], [0,0,5,4],NX=20, NY=40)
            in=' '
            READ,"Press enter",in

            WDELETE

            END
```

Example 2

This example shows how to perform spherical gridding:

```
            PRO SphericalGrid
            ; Create some random longitude points:
            lon = RANDOMU(seed, 50) * 360. - 180.

            ; Create some random latitude points:
            lat = RANDOMU(seed, 50) * 180. - 90.
```

```
; Make a fake function value to be passed to FVALUE. The system
; variable !DTOR contains the conversion value for degrees to
; radians.
f = SIN(lon * !DTOR)^2 * COS(lat * !DTOR)

; Perform a spherical triangulation:
TRIANGULATE, lon, lat, tr, $
    SPHERE=s, FVALUE=f, /DEGREES

; Perform a spherical triangulation using the values returned from
; TRIANGULATE. The result, r, is a 180 by 91 element array:
r=TRIGRID(f, SPHERE=s, [2.,2.],$
   [-180.,-90.,178.,90.], /DEGREES)

; Display the surface
SURFACE, r
END
```

Example 3

This example demonstrates the use of the INPUT keyword:

```
PRO TrigridInputKeyword

; Make 50 normal x, y points:
x = RANDOMN(seed, 50)
y = RANDOMN(seed, 50)

; Make the Gaussian:
z = EXP(-(x^2 + y^2))

; Show points:
PLOT, x, y, psym=1

; Obtain triangulation:
TRIANGULATE, x, y, tr, b

;Show the triangles.
FOR i=0, N_ELEMENTS(tr)/3-1 DO BEGIN $
   ; Subscripts of vertices [0,1,2,0]:
   t = [tr[*,i], tr[0,i]] & $
   ; Connect triangles:
   PLOTS, x[t], y[t]
ENDFOR

; The default size for the return value of trigrid. xtemp should be
; the same type as Z. xtemp provides temporary space for trigrid:
xtemp=FLTARR(51,51)
xtemp = TRIGRID(x, y, z, INPUT = xtemp, tr)
```

```
; Show linear surface:
SURFACE, xtemp, TITLE='Linear surface', CHARSIZE=2
in=' '
READ,"Press enter",in
xtemp = TRIGRID(x, y, z, tr, INPUT = xtemp, /QUINTIC)

; Show smooth quintic surface:
SURFACE, xtemp, TITLE='Smooth Quintic surface', CHARSIZE=2
in=' '
READ,"Press enter",in
xtemp = TRIGRID(x, y, z, tr, INPUT = xtemp, EXTRA = b)

; Show smooth extrapolated surface:
SURFACE, xtemp, TITLE='Smooth Extrapolated surface', CHARSIZE=2
in=' '
READ,"Press enter",in
END
```

Example 4

The XOUT and YOUT keywords allow you to obtain an irregular interval from the
TRIGRID routine. This example creates an irregularly-gridded dataset of a Gaussian
surface. A grid is formed from these points with the TRIANGULATE and TRIGRID
routines. The inputs to the XOUT and YOUT keywords are determined at random to
produce an irregular interval. These inputs are sorted before setting them to XOUT
and YOUT because these keywords require monotonically ascending or descending
values. The lines of the resulting surface are spaced at the irregular intervals provided
by the settings of the XOUT and YOUT keywords.

```
PRO GriddingIrregularIntervals

; Make 100 normal x, y points:
x = RANDOMN(seed, 100)
y = RANDOMN(seed, 100)
PRINT, MIN(x), MAX(x)
PRINT, MIN(y), MAX(y)

; Make a Gaussian surface:
z = EXP(-(x^2 + y^2))

; Obtain triangulation:
TRIANGULATE, x, y, triangles, boundary

; Create random x values.  These values will be used to
; form the x locations of the resulting grid.
gridX = RANDOMN(seed, 30)
; Sort x values. Sorted values are required for the XOUT
```

```
; keyword.
sortX = UNIQ(gridX, SORT(gridX))
gridX = gridX[sortX]
; Output sorted x values to be used with the XOUT
; keyword.
PRINT, 'gridX:'
PRINT, gridX

; Create random y values.  These values will be used to
; form the y locations of the resulting grid.
gridY = RANDOMN(seed, 30)
; Sort y values. Sorted values are required for the YOUT
; keyword.
sortY = UNIQ(gridY, SORT(gridY))
gridY = gridY[sortY]
; Output sorted y values to be used with the YOUT
; keyword.
PRINT, 'gridY:'
PRINT, gridY

; Derive grid of initial values.  The location of the
; resulting grid points are the inputs to the XOUT and
; YOUT keywords.
grid = TRIGRID(x, y, z, triangles, XOUT = gridX, $
   YOUT = gridY, EXTRAPOLATE = boundary)

; Display resulting grid.  The grid lines are not
; at regular intervals because of the randomness of the
; inputs to the XOUT and YOUT keywords.
SURFACE, grid, gridX, gridY, /XSTYLE, /YSTYLE

END
```

TRIQL

The TRIQL procedure uses the QL algorithm with implicit shifts to determine the eigenvalues and eigenvectors of a real, symmetric, tridiagonal array. The routine TRIRED can be used to reduce a real, symmetric array to the tridiagonal form suitable for input to this procedure.

TRIQL is based on the routine `tqli` described in section 11.3 of *Numerical Recipes in C: The Art of Scientific Computing* (Second Edition), published by Cambridge University Press, and is used by permission.

Note ————————————————————————————————————

If you are working with complex inputs, use the LA_TRIQL procedure instead.

——

Syntax

TRIQL, *D*, *E*, *A* [, /DOUBLE]

Arguments

D

On input, this argument should be an *n*-element vector containing the diagonal elements of the array being analyzed. On output, *D* contains the eigenvalues.

E

An *n*-element vector containing the off-diagonal elements of the array. E_0 is arbitrary. On output, this parameter is destroyed.

A

A named variable that returns the *n* eigenvectors. If the eigenvectors of a tridiagonal array are desired, *A* should be input as an identity array. If the eigenvectors of an array that has been reduced by TRIRED are desired, *A* is input as the array *Q* output by TRIRED.

Keywords

DOUBLE

Set this keyword to force the computation to be done in double-precision arithmetic.

Examples

To compute eigenvalues and eigenvectors of a real, symmetric, tridiagonal array, begin with an array A representing a symmetric array:

```
; Create the array A:
A = [[ 3.0,  1.0, -4.0], $
     [ 1.0,  3.0, -4.0], $
     [-4.0, -4.0,  8.0]]

; Compute the tridiagonal form of A:
TRIRED, A, D, E

; Compute the eigenvalues (returned in vector D) and the
; eigenvectors (returned in the rows of the array A):
TRIQL, D, E, A

; Print eigenvalues:
PRINT, 'Eigenvalues:'
PRINT, D

; Print eigenvectors:
PRINT, 'Eigenvectors:'
PRINT, A
```

IDL prints:

```
Eigenvalues:
  2.00000  4.76837e-7  12.0000

Eigenvectors:
  0.707107  -0.707107   0.00000
 -0.577350  -0.577350  -0.577350
 -0.408248  -0.408248   0.816497
```

The exact eigenvalues are:

```
   [2.0, 0.0, 12.0]
```

The exact eigenvectors are:

```
[ 1.0/sqrt(2.0), -1.0/sqrt(2.0), 0.0/sqrt(2.0)],
[-1.0/sqrt(3.0), -1.0/sqrt(3.0), -1.0/sqrt(3.0)],
[-1.0/sqrt(6.0), -1.0/sqrt(6.0), 2.0/sqrt(6.0)]
```

TRIRED

The TRIRED procedure uses Householder's method to reduce a real, symmetric array to tridiagonal form.

TRIRED is based on the routine `tred2` described in section 11.2 of *Numerical Recipes in C: The Art of Scientific Computing* (Second Edition), published by Cambridge University Press, and is used by permission.

Note

If you are working with complex inputs, use the LA_TRIRED procedure instead.

Syntax

TRIRED, *A*, *D*, *E* [, /DOUBLE]

Arguments

A

An *n* by *n* real, symmetric array that is replaced, on exit, by the orthogonal array *Q* effecting the transformation. The routine TRIQL can use this result to find the eigenvectors of the array *A*.

D

An *n*-element output vector containing the diagonal elements of the tridiagonal array.

E

An *n*-element output vector containing the off-diagonal elements.

Keywords

DOUBLE

Set this keyword to force the computation to be done in double-precision arithmetic.

Examples

See the description of TRIQL for an example using this function.

TRISOL

The TRISOL function solves tridiagonal systems of linear equations that have the form: $A^T U = R$

Note ──

Because IDL subscripts are in column-row order, the equation above is written $A^T U = R$ rather than $AU = R$. The result *U* is a vector of length *n* whose type is identical to *A*.

──

TRISOL is based on the routine `tridag` described in section 2.4 of *Numerical Recipes in C: The Art of Scientific Computing* (Second Edition), published by Cambridge University Press, and is used by permission.

Note ──

If you are working with complex inputs, use the LA_TRISOL procedure instead.

──

Syntax

Result = TRISOL(*A*, *B*, *C*, *R* [, /DOUBLE])

Return Value

Returns a vector containing the solutions.

Arguments

A

A vector of length *n* containing the *n*-1 sub-diagonal elements of A^T. The first element of *A*, A_0, is ignored.

B

An *n*-element vector containing the main diagonal elements of A^T.

C

An *n*-element vector containing the *n*-1 super-diagonal elements of A^T. The last element of *C*, C_{n-1}, is ignored.

R

An *n*-element vector containing the right hand side of the linear system $A^T U = R$.

Keywords

DOUBLE

Set this keyword to force the computation to be done in double-precision arithmetic.

Example

To solve a tridiagonal linear system, begin with an array representing a real tridiagonal linear system. (Note that only three vectors need be specified; there is no need to enter the entire array shown.)

$$\begin{bmatrix} -4.0 & 1.0 & 0.0 & 0.0 \\ 2.0 & -4.0 & 1.0 & 0.0 \\ 0.0 & 2.0 & -4.0 & 1.0 \\ 0.0 & 0.0 & 2.0 & -4.0 \end{bmatrix}$$

```
; Define a vector A containing the sub-diagonal elements with a
; leading 0.0 element:
A = [0.0, 2.0, 2.0, 2.0]

; Define B containing the main diagonal elements:
B = [-4.0, -4.0, -4.0, -4.0]

; Define C containing the super-diagonal elements with a trailing
; 0.0 element:
C = [1.0, 1.0, 1.0, 0.0]

; Define the right-hand side vector:
R = [6.0, -8.0, -5.0, 8.0]

; Compute the solution and print:
result = TRISOL(A, B, C, R)
PRINT, result
```

IDL prints:

```
-1.00000  2.00000  2.00000  -1.00000
```

The exact solution vector is [-1.0, 2.0, 2.0, -1.0].

TRUNCATE_LUN

The TRUNCATE_LUN procedure truncates the contents of a file (which must be open for write access) at the current position of the file pointer. After this operation, all data before the current file pointer remains intact, and all data following the file pointer are gone. The position of the current file pointer is not altered.

Syntax

TRUNCATE_LUN, *Unit₁*, ..., *Unitₙ*

TRUNCATE_LUN, $Unit_1$, ..., $Unit_n$

Arguments

Unit$_n$

Scalar or array variables containing the logical file unit numbers of the open files to be truncated.

Keywords

None.

Examples

Example 1

Truncate the entire contents of an existing file:

```
OPENU, unit, 'baddata.dat', /GET_LUN
TRUNCATE_LUN, unit
FREE_LUN, unit
```

Example 2

Given an existing file of 10,000 bytes, throw away the final 5,000 bytes, and then write an additional 2,000 byte array in their place. The resulting file will be 7,000 bytes in length.

```
OPENU, unit, 'mydata.dat', /GET_LUN
POINT_LUN, unit, 5000
TRUNCATE_LUN, unit
WRITEU, unit, BYTARR(2000)
FREE_LUN, unit
```

TS_COEF

The TS_COEF function computes the coefficients ϕ_1, ϕ_2, ... , ϕ_P used in a *P*-th order autoregressive time-series forecasting model. This routine is written in the IDL language. Its source code can be found in the file ts_coef.pro in the lib subdirectory of the IDL distribution.

Syntax

Result = TS_COEF(*X*, *P* [, /DOUBLE] [, MSE=*variable*])

Return Value

Returns a *P*-element vector whose type is identical to *X*.

Arguments

X

An *n*-element single- or double-precision floating-point vector containing time-series samples.

P

An integer or long integer scalar that specifies the number of coefficients to be computed.

Keywords

DOUBLE

Set this keyword to force the computation to be done in double-precision arithmetic.

MSE

Set this keyword to a named variable that will contain the mean square error of the *P*-th order autoregressive model.

Examples

```
; Define an n-element vector of time-series samples:
X = [6.63, 6.59, 6.46, 6.49, 6.45, 6.41, 6.38, 6.26, 6.09, 5.99, $
     5.92, 5.93, 5.83, 5.82, 5.95, 5.91, 5.81, 5.64, 5.51, 5.31, $
     5.36, 5.17, 5.07, 4.97, 5.00, 5.01, 4.85, 4.79, 4.73, 4.76]
; Compute the coefficients of a 5th order autoregressive model:
PRINT, TS_COEF(X, 5)
```

IDL prints:

```
1.30168    -0.111783    -0.224527     0.267629    -0.233363

TS_FCAST

TS_DIFF

The TS_DIFF function recursively computes the forward differences of an *n*-element time-series *k* times. This routine is written in the IDL language. Its source code can be found in the file ts_diff.pro in the lib subdirectory of the IDL distribution.

Syntax

Result = TS_DIFF(*X*, *K* [, /DOUBLE])

Return Value

The result is an *n*-element differenced time-series with its last *k* elements as zeros.

Arguments

X

An *n*-element integer, single- or double-precision floating-point vector containing time-series samples.

K

A positive integer or long integer scalar that specifies the number of times *X* is to be differenced. *K* must be in the interval [1, N_ELEMENTS(*X*) - 1].

Keywords

DOUBLE

Set this keyword to force the computation to be done in double-precision arithmetic.

Examples

```
; Define an n-element vector of time-series samples:
X = [389, 345, 303, 362, 412, 356, 325, 375, $
     410, 350, 310, 388, 399, 362, 325, 382, $
     399, 382, 318, 385, 437, 357, 310, 391]
; Compute the second forward differences of X:
PRINT, TS_DIFF(X, 2)
```

IDL prints:

```
   2  101   -9 -106   25   81  -15  -95   20
 118  -67  -48    0   94  -40  -34  -47  131
 -15 -132   33  128    0    0
```

SMOOTH, TS_FCAST

TS_FCAST

The TS_FCAST function computes future or past values of a stationary time-series using a *P*-th order autoregressive model.

A *P*-th order autoregressive model relates a forecasted value x_t of the time series $X = [x_0, x_1, x_2, \ldots, x_{t-1}]$, as a linear combination of *P* past values.

$$x_t = \phi_1 x_{t-1} + \phi_2 x_{t-2} + \ldots + \phi_P x_{t-P} + w_t$$

The coefficients $\phi_1, \phi_2, \ldots, \phi_P$ are calculated such that they minimize the uncorrelated random error terms, *wt*.

This routine is written in the IDL language. Its source code can be found in the file ts_fcast.pro in the lib subdirectory of the IDL distribution.

Syntax

Result = TS_FCAST(*X*, *P*, *Nvalues* [, /BACKCAST] [, /DOUBLE])

Return Value

The result is an *Nvalues*-element vector whose type is identical to *X*.

Arguments

X

An *n*-element single- or double-precision floating-point vector containing time-series samples.

P

An integer or long integer scalar that specifies the number of actual time-series values to be used in the forecast. In general, a larger number of values results in a more accurate forecast.

Nvalues

An integer or long integer scalar that specifies the number of future or past values to be computed.

Keywords

BACKCAST

Set this keyword to produce past values (backward forecasts or "backcasts")

DOUBLE

Set this keyword to force the computation to be done in double-precision arithmetic.

Examples

```
; Define an n-element vector of time-series samples:
X = [6.63, 6.59, 6.46, 6.49, 6.45, 6.41, 6.38, 6.26, 6.09, 5.99, $
     5.92, 5.93, 5.83, 5.82, 5.95, 5.91, 5.81, 5.64, 5.51, 5.31, $
     5.36, 5.17, 5.07, 4.97, 5.00, 5.01, 4.85, 4.79, 4.73, 4.76]

; Compute and print five future values of the time-series using ten
; time-series values:
PRINT, TS_FCAST(X, 10, 5)

; Compute five past values of the time-series using ten time-series
;values:
PRINT, TS_FCAST(X, 10, 5, /BACKCAST)
```

IDL prints:

```
4.65870      4.58380      4.50030      4.48828      4.46971
6.94862      6.91103      6.86297      6.77826      6.70282
```

A_CORRELATE, COMFIT, CURVEFIT, SMOOTH, TS_COEF, TS_DIFF

TS_SMOOTH

The TS_SMOOTH function computes central, backward, or forward moving averages of an *n*-element time-series. Autoregressive forecasting and backcasting are used to extrapolate the time-series and compute a moving average for each point.

Note ───

Central moving averages require *Nvalues*/2 forecasts and *Nvalues*/2 backcasts. Backward moving averages require *Nvalues*-1 backcasts. Forward moving averages require *Nvalues*-1 forecasts.

───

This routine is written in the IDL language. Its source code can be found in the file ts_smooth.pro in the lib subdirectory of the IDL distribution.

Syntax

Result = TS_SMOOTH(*X*, *Nvalues* [, /BACKWARD] [, /DOUBLE] [, /FORWARD] [, ORDER=*value*])

Return Value

The result is an *n*-element vector of the same data type as the input vector.

Arguments

X

An *n*-element single- or double-precision floating-point vector containing time-series samples. Note that *n* must be greater than or equal to 11.

Nvalues

A scalar of type integer or long integer that specifies the number of time-series values used to compute each moving-average. If central-moving averages are computed (the default), this parameter must be an odd integer greater than or equal to three.

Keywords

BACKWARD

Set this keyword to compute backward-moving averages. If BACKWARD is set, the *Nvalues* argument must be an integer greater than one.

DOUBLE

Set this keyword to force the computation to be done in double-precision arithmetic.

FORWARD

Set this keyword to compute forward-moving averages. If FORWARD is set, the *Nvalues* argument must be an integer greater than one.

ORDER

An integer or long-integer scalar that specifies the order of the autoregressive model used to compute the forecasts and backcasts of the time-series. By default, a time-series with a length between 11 and 219 elements will use an autoregressive model with an order of 10. A time-series with a length greater than 219 will use an autoregressive model with an order equal to 5% of its length. The ORDER keyword is used to override this default.

Examples

```
; Define an n-element vector of time-series samples:
X = [6.63, 6.59, 6.46, 6.49, 6.45, 6.41, 6.38, 6.26, 6.09, 5.99,$
     5.92, 5.93, 5.83, 5.82, 5.95, 5.91, 5.81, 5.64, 5.51, 5.31,$
     5.36, 5.17, 5.07, 4.97, 5.00, 5.01, 4.85, 4.79, 4.73, 4.76]

; Compute the 11-point central-moving-averages of the time-series:
PRINT, TS_SMOOTH(X, 11)
```

IDL prints:

```
6.65761 6.60592 6.54673 6.47646 6.40480 6.33364
6.27000 6.20091 6.14273 6.09364 6.04455 5.99000
5.92273 5.85455 5.78364 5.72636 5.65818 5.58000
5.50182 5.42727 5.34182 5.24545 5.15273 5.07000
5.00182 4.94261 4.87205 4.81116 4.75828 4.71280
```

SMOOTH, TS_DIFF, TS_FCAST

TV

The TV procedure displays images in a Direct Graphics window without scaling the intensity. To display an image with scaling, use the TVSCL procedure.

Note

The TV procedure displays an image in its original form. The TVSCL procedure displays an image scaled to range from 0 up to 255 depending on the colors available to IDL.

RGB images are displayed with the TV procedure. To display a TrueColor image (an image with 16, 24, or 32 bits per pixel) you must use the TRUE keyword.

While the TV procedure does not *scale* the intensity of an image, it does convert the input image data to byte type. Values outside the range [0,255] are "wrapped" during the conversion. In addition, for displays with less than 256 colors, elements of the input image with values between !D.TABLE_SIZE and 255 will be displayed using the color index !D.TABLE_SIZE-1.

If no optional parameters are present, IMAGE is output to the display with its lower-left corner at coordinate (0, 0). The optional parameters can be used to specify the screen position of the image in a variety of ways.

Syntax

TV, *Image* [, *Position*] [, /CENTIMETERS | , /INCHES] [, /ORDER]
    [, TRUE={1 | 2 | 3}] [, /WORDS] [, XSIZE=*value*] [, YSIZE=*value*]

or

TV, *Image* [, *X*, *Y* [, *Channel*]] [, /CENTIMETERS | , /INCHES] [, /ORDER]
    [, TRUE={1 | 2 | 3}] [, /WORDS] [, XSIZE=*value*] [, YSIZE=*value*]

Graphics Keywords: [, CHANNEL=*value*] [, /DATA | , /DEVICE | , /NORMAL]
[, /T3D] [, Z=*value*]

Arguments

Image

A vector or two-dimensional, or three-dimensional array to be displayed as an image. If this argument is not already of byte type, it is converted prior to use.

X, Y

If *X* and *Y* are present, they specify the lower-left coordinate of the displayed image, relative to the lower-left corner of the screen.

Position

An integer specifying the position for *Image* within the graphics window. Image positions run from the top left of the screen to the bottom right. If a position number is used instead of *X* and *Y*, the position of the image is calculated from the dimensions of the image as follows (integer arithmetic is used).

$$\text{Xsize, Ysize} = \text{Size of display or window}$$

$$\text{Xdim, Ydim} = \text{Dimensions of image to be displayed}$$

$$N_x = \frac{\text{Xsize}}{\text{Xdim}} = \text{Images across screen}$$

$$X = \text{Xdim Position}_{\text{modulo} N_x} = \text{Starting X}$$

$$Y = \text{Ysize} - \text{Ydim} \left[1 + \frac{\text{Position}}{N_x} \right] = \text{Starting Y}$$

For example, when displaying 128 by 128 images on a 512 by 512 display, the position numbers run from 0 to 15 as follows:

0	1	2	3
4	5	6	7
8	9	10	11
12	13	14	15

Note ───

When using a device with scalable pixels (e.g., PostScript), the XSIZE and YSIZE keywords should also be used.

───

Channel

Some image display devices are capable of storing more than a single image or can combine three single color images to form a TrueColor image. CHANNEL specifies the memory channel to be written. It is assumed to be zero if not specified. This parameter is ignored on display systems that have only one memory channel. The *Channel* argument is identical to the CHANNEL graphics keyword.

Keywords

CENTIMETERS

Set this keyword to indicate that the *X*, *Y*, *Xsize*, *Ysize*, and *Z* arguments are given in centimeters from the origin. This system is useful when dealing with devices, such as PostScript printers, that do not provide a direct relationship between image pixels and the size of the resulting image.

INCHES

Set this keyword to indicate that all position and size values are given in inches from the origin. This system is useful when dealing with devices, such as PostScript printers, that do not provide a direct relationship between image pixels and the size of the resulting image.

ORDER

If specified, ORDER overrides the current setting of the !ORDER system variable for the current image only. If set, the image is drawn from the top down instead of the normal bottom up.

TRUE

Set this keyword to a nonzero value to indicate that a TrueColor (16-, 24-, or 32-bit) image is to be displayed. The value assigned to TRUE specifies the index of the dimension over which color is interleaved. The image parameter must have three dimensions, one of which must be equal to three. For example, set TRUE to 1 to display an image that is pixel interleaved and has dimensions of (3, *m, n*). Specify 2 for row-interleaved images, of size (*m*, 3, *n*), and 3 for band-interleaved images of the form (*m*, *n*, 3).

See "TrueColor Images" on page 5427 for an example using this keyword to write 24-bit images to the PostScript device.

Note ───

When a TrueColor image is specified, the image is displayed using decomposed color, regardless of the setting of the DECOMPOSED keyword for the current graphics device.

──

WORDS

Set this keyword to indicate that words (short integers) instead of 8-bit bytes are to be transferred to the device. This keyword is valid only when using devices that can transfer 16-bit pixels. The normal transfer uses 8-bit pixels. If this keyword is set, the *Image* parameter is converted to short integer type, if necessary, and then written to the display.

XSIZE

The width of the resulting image. On devices with scalable pixel size (such as PostScript), if XSIZE is specified the image will be scaled to fit the specified width. If neither XSIZE nor YSIZE is specified, the image will be scaled to fill the plotting area, while preserving the image's aspect ratio. This keyword is ignored by pixel-based devices that are unable to change the size of their pixels.

YSIZE

The height of the resulting image. On devices with scalable pixel size (such as PostScript), if YSIZE is specified the image will be scaled to fit the specified height. If neither XSIZE nor YSIZE is specified, the image will be scaled to fill the plotting area, while preserving the image's aspect ratio. This keyword is ignored by pixel-based devices that are unable to change the size of their pixels.

Graphics Keywords Accepted

See Appendix B, "Graphics Keywords" for the description of the following graphics and plotting keywords:

CHANNEL, DATA, DEVICE, NORMAL, T3D, Z

Note ───

The T3D and Z keywords are only honored when the DATA keyword is also set. Note also that when the T3D keyword is set, the X and Y arguments and the Z keyword position the lower left corner of the image displayed by TV, but do not change its orientation. Use the POLY_2D routine to warp the image into 3D space.

──

Examples

In addition to the following basic example, this section also includes :

```
; Create and display a simple image:
D = BYTSCL(DIST(256)) & TV, D

; Erase the screen:
ERASE

; Use the position parameter to display a number of images in the
; same window.
; Display the image in the upper left corner.
TV, D, 0

; Display another copy of the image in the next position:
TV, D, 1
```

Positioning Multiple Images in Direct Graphics

The following example imports an RGB image from the rose.jpg image file. This RGB image is a close-up photograph of a red rose and is pixel interleaved. This example extracts the three color channels of this image, and displays them as grayscale images in various locations within the same window. Complete the following steps for a detailed description of the process.

Example Code

See displaymultiples_direct.pro in the examples/doc/image subdirectory of the IDL installation directory for code that duplicates this example. Run the example procedure by entering displaymultiples_direct at the IDL command prompt or view the file in an IDL Editor window by entering .EDIT displaymultiples_direct.pro.

1. Determine the path to the rose.jpg file:

```
file = FILEPATH('rose.jpg', $
   SUBDIRECTORY = ['examples', 'data'])
```

2. Use QUERY_IMAGE to query the file to determine image parameters:

```
queryStatus = QUERY_IMAGE(file, imageInfo)
```

3. Set the image size parameter from the query information:

   ```
   imageSize = imageInfo.dimensions
   ```

4. Use READ_IMAGE to import the image from the file:

   ```
   image = READ_IMAGE(file)
   ```

5. Extract the channels (as images) from the pixel interleaved RGB image:

   ```
   redChannel = REFORM(image[0, *, *])
   greenChannel = REFORM(image[1, *, *])
   blueChannel = REFORM(image[2, *, *])
   ```

6. If you are running IDL on a TrueColor display, set the DECOMPOSED keyword to the DEVICE command to zero before your first color table related routine is used within an IDL session or program.

   ```
   DEVICE, DECOMPOSED = 0
   ```

7. Since the channels are grayscale images, load a grayscale color table:

   ```
   LOADCT, 0
   ```

   The TV procedure can be used to display the channels (grayscale images). The TV procedure has two different location input arguments. One argument is *position*. This argument arranges the image in a calculated location based on the size of the display and the dimension sizes of the image.

8. Create a window and horizontally display the three channels with the *position* argument:

   ```
   WINDOW, 0, XSIZE = 3*imageSize[0], YSIZE = imageSize[1], $
      TITLE = 'The Channels of an RGB Image'
   TV, redChannel, 0
   TV, greenChannel, 1
   TV, blueChannel, 2
   ```

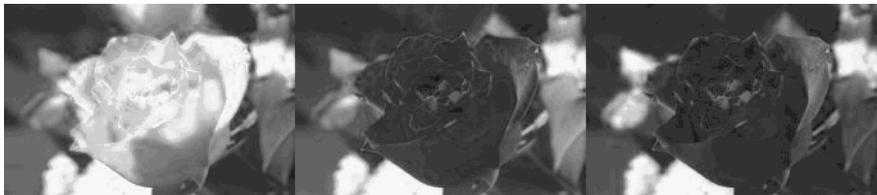
   The following figure shows the resulting grayscale images.


Figure 22-2: Horizontal Display of RGB Channels in Direct Graphics

The TV procedure can also be used with its *x* and *y* input arguments. These arguments define the location of the lower left corner of the image. The values of these arguments are in device coordinates by default. However, you can provide data or normalized coordinates when the DATA or NORMAL keyword is set.

9. Create a window and vertically display the three channels with the *x* and *y* arguments:

```
WINDOW, 0, XSIZE = imageSize[0], YSIZE = 3*imageSize[1], $
   TITLE = 'The Channels of an RGB Image'
TV, redChannel, 0, 0
TV, greenChannel, 0, imageSize[1]
TV, blueChannel, 0, 2*imageSize[1]
```

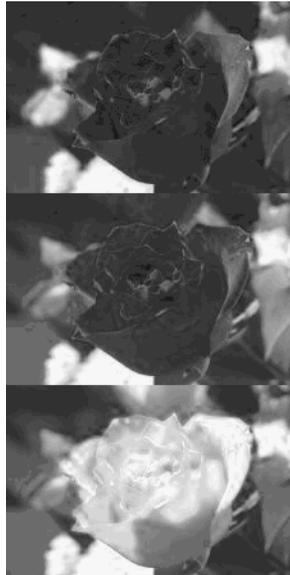
The following figure shows the resulting grayscale images.


Figure 22-3: Vertical Display of RGB Channels in Direct Graphics

The *x* and *y* arguments can also be used to create a display of overlapping images. When overlapping images in Direct Graphics, you must remember the last image placed in the window will be in front of the previous images. So if you want to bring a display from the back of the window to the front, you must redisplay it after all the other displays.

10. Create another window:

```
WINDOW, 2, XSIZE = 2*imageSize[0], YSIZE = 2*imageSize[1], $
   TITLE = 'The Channels of an RGB Image'
```

11. Make a white background to distinguish the edges of the images:

```
ERASE, !P.COLOR
```

12. Diagonally display the three channels with the *x* and *y* arguments:

```
TV, redChannel, 0, 0
TV, greenChannel, imageSize[0]/2, imageSize[1]/2
TV, blueChannel, imageSize[0], imageSize[1]
```

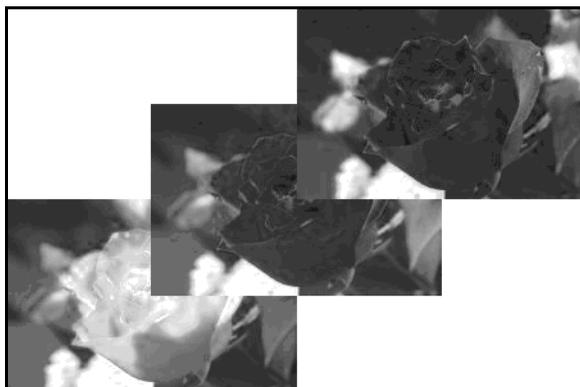
The following figure shows the resulting grayscale images.


Figure 22-4: Diagonal Display of RGB Channels in Direct Graphics

Displaying RGB Images with Direct Graphics

RGB images are three-dimensional arrays made up of width, height, and three channels of color information. In Direct Graphics, these images are displayed with the TV procedure. The TRUE keyword to TV is set according to the interleaving of the RGB image. With RGB images, the interleaving, or arrangement of the channels within the image file, dictates the setting of the TRUE keyword. If the image is:

- pixel interleaved (3, w, h), TRUE is set to 1.

- line interleaved (w, 3, h), TRUE is set to 2.

- planar interleaved (w, h, 3), TRUE is set to 3.

You can determine if an image file contains an RGB image by querying the file. The CHANNELS tag of the resulting query structure will equal 3 if the file's image is RGB. The query does not determine which interleaving is used in the image, but the array returned in DIMENSIONS tag of the query structure can be used to determine the type of interleaving.

If you are using a PseudoColor display, your RGB images must be converted to indexed images to be displayed within IDL.

The following example queries and imports a pixel-interleaved RGB image from the rose.jpg image file. This pixel interleaved RGB image is a close-up photograph of a red rose. Complete the following steps for a detailed description of the process.

Example Code

See displayrgbimage_direct.pro in the examples/doc/image subdirectory of the IDL installation directory for code that duplicates this example. Run the example procedure by entering displayrgbimage_direct at the IDL command prompt or view the file in an IDL Editor window by entering .EDIT displayrgbimage_direct.pro.

1. Determine the path to the rose.jpg file:

```
file = FILEPATH('rose.jpg', $
    SUBDIRECTORY = ['examples', 'data'])
```

2. Use QUERY_IMAGE to query the file to determine image parameters:

```
queryStatus = QUERY_IMAGE(file, imageInfo)
```

3. Output the results of the file query:

```
PRINT, 'Query Status = ', queryStatus
HELP, imageInfo, /STRUCTURE
```

The following text appears in the Output Log:

```
Query Status =           1
** Structure <14055f0>, 7 tags, length=36, refs=1:
    CHANNELS     LONG      3
    DIMENSIONS   LONG      Array[2]
    HAS_PALETTE  INT       0
    IMAGE_INDEX  LONG      0
    NUM_IMAGES   LONG      1
    PIXEL_TYPE   INT       1
    TYPE         STRING    'JPEG'
```

The CHANNELS tag has a value of 3. Thus, the image is an RGB image.

4. Set the image size parameter from the query information:

```
imageSize = imageInfo.dimensions
```

The type of interleaving can be determined from the image size parameter and actual size of each dimension of the image. To determine the size of each dimension, you must first import the image.

5. Use READ_IMAGE to import the image from the file:

```
image = READ_IMAGE(file)
```

6. Determine the size of each dimension within the image:

    ```
    imageDims = SIZE(image, /DIMENSIONS)
    ```

7. Determine the type of interleaving by comparing the dimension sizes to the image size parameter from the file query:

    ```
    interleaving = WHERE((imageDims NE imageSize[0]) AND $
       (imageDims NE imageSize[1])) + 1
    ```

8. Output the results of the interleaving computation:

    ```
    PRINT, 'Type of Interleaving = ', interleaving
    ```

    The following text appears in the Output Log:

    ```
    Type of Interleaving = 1
    ```

    The image is pixel interleaved. If the resulting value was 2, the image would have been line interleaved. If the resulting value was 3, the image would have been planar interleaved.

9. If you are running IDL on a TrueColor display, set the DECOMPOSED keyword to the DEVICE command to one before your first RGB image is displayed within an IDL session or program.

    ```
    DEVICE, DECOMPOSED = 1
    ```

10. Create a window and display the image with the TV procedure:

    ```
    WINDOW, 0, XSIZE = imageSize[0], YSIZE = imageSize[1], $
       TITLE = 'An RGB Image'
    TV, image, TRUE = interleaving[0]
    ```

    The following figure shows the resulting RGB image display.

Figure 22-5: RGB Image in Direct Graphics

Displaying RGB Images and Converting to Grayscale

The following example displays an RGB image, extracts the three channels contained in the glowing_gas.jpg file, which is in the examples/data directory. This file is provided by the Hubble Heritage Team, which is made of AURA, STScI, and NASA.

This example uses REFORM t o extract individual channels as grayscale (intensity) images from the original RGB image. These images are converted to floating-point data and then added together to form a single image, which is a grayscale version of the original RGB image. Complete the following steps for a detailed description of the process.

Example Code

See rgbtograyscale.pro in the examples/doc/image subdirectory of the IDL installation directory for code that duplicates this example. Run the example procedure by entering rgbtograyscale at the IDL command prompt or view the file in an IDL Editor window by entering .EDIT rgbtograyscale.pro.

1. Determine the path to the file:

   ```
   file = FILEPATH('glowing_gas.jpg', $
      SUBDIRECTORY = ['examples', 'data'])
   ```

2. Query the file to determine the image parameters:

   ```
   queryStatus = QUERY_JPEG(file, imageInfo)
   ```

3. Set the image size parameter from the query information:

   ```
   imageSize = imageInfo.dimensions
   ```

4. Import the image from the file:

   ```
   READ_JPEG, file, image
   ```

5. If you are running IDL on a TrueColor display, set the DECOMPOSED keyword to the DEVICE command to one before your first RGB image is displayed within an IDL session or program.

   ```
   DEVICE, DECOMPOSED = 1
   ```

6. Create a window and display the image:

   ```
   WINDOW, 0, XSIZE = imageSize[0], YSIZE = imageSize[1], $
      TITLE = 'Glowing Gas RGB Image'
   TV, image, TRUE = 1
   ```

The following figure shows the original RGB image.

Figure 22-6: The Glowing Gas RGB Image

7. Extract the channels (as images) from the RGB image:

```
redChannel = REFORM(image[0, *, *])
greenChannel = REFORM(image[1, *, *])
blueChannel = REFORM(image[2, *, *])
```

8. Initialize the grayscale display:

```
DEVICE, DECOMPOSED = 0
LOADCT, 0
```

9. Create another window and display each channel of the RGB image:

```
WINDOW, 1, XSIZE = 3*imageSize[0], YSIZE = imageSize[1], $
   TITLE = 'Red (left), Green (middle), ' + $
   'and Blue (right) Channels of the RGB Image'
TV, redChannel, 0
TV, greenChannel, 1
TV, blueChannel, 2
```

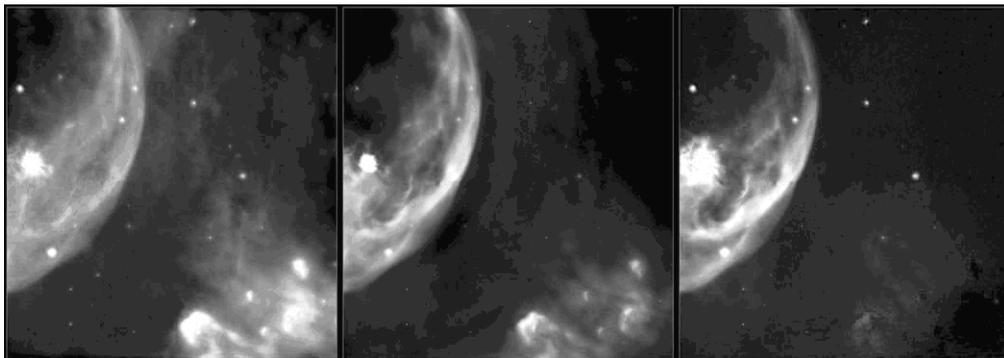
The following figure shows the RGB channels. The red channel is on the left, the green channel is in the middle, and the blue channel is on the right.


Figure 22-7: The Channels of the Glowing Gas RGB Image

10. Convert the channels into a single grayscale image.

```
grayscaleImage = BYTE(0.299*FLOAT(redChannel) + $
    0.587*FLOAT(redChannel) + 0.114*FLOAT(blueChannel))
```

The pixel values of the channels are converted from byte values to floating-point values because byte values cannot exceed 255. The adjustment factors (0.299, 0.587, and 0.114) are used to enhance visual perception and to scale the results to a range from 0 to 255. The BYTE function is used to restore the pixel values back to their original data type.

11. Create another window and display the grayscale image:

```
WINDOW, 2, XSIZE = 2*imageSize[0], YSIZE = imageSize[1], $
    TITLE = 'Resulting Grayscale Image' + $
TV, grayscaleImage
```

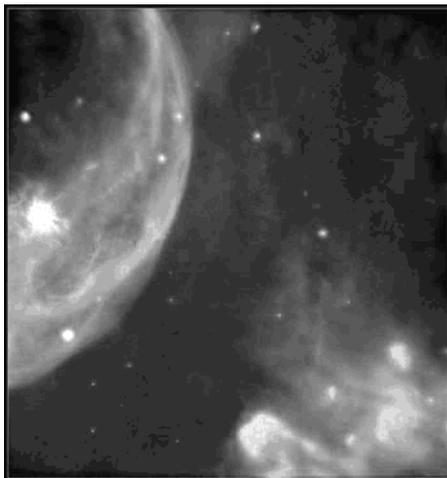
The following figure shows the result of creating a grayscale image from the individual channels of an RGB image.


Figure 22-8: Resulting Grayscale Image

ERASE, IIMAGE, SLIDE_IMAGE, TVRD, TVSCL, WIDGET_DRAW, WINDOW, and the DECOMPOSED keyword to the DEVICE routine

TVCRS

The TVCRS procedure manipulates the display device cursor. The initial state of the cursor is device dependent. Call TVCRS with one argument to enable or disable the cursor. Call TVCRS with two parameters to enable the cursor and place it on pixel location *(X, Y)*.

Syntax

TVCRS [, *ON_OFF*] [, /CENTIMETERS | , /INCHES] [, /HIDE_CURSOR]

or

TVCRS [, *X*, *Y*] [, /CENTIMETERS | , /INCHES] [, /HIDE_CURSOR]

Graphics Keywords: [, /DATA | , /DEVICE | , /NORMAL] [, /T3D | Z=*value*]

Arguments

ON_OFF

This argument specifies whether the cursor should be on or off. If this argument is present and nonzero, the cursor is enabled. If *ON_OFF* is zero or no parameters are specified, the cursor is turned off.

X

The column to which the cursor is set.

Y

The row to which the cursor is set.

Keywords

CENTIMETERS

Set this keyword to cause X and Y to be interpreted as centimeters, based on the current device resolution.

INCHES

Set this keyword to cause X and Y to be interpreted as inches, based on the current device resolution.

HIDE_CURSOR

By default, disabling the cursor works differently for window systems than for other devices. For window systems, the cursor is restored to the standard cursor used for non-IDL windows (and remains visible), while for other devices it is completely blanked out. If the HIDE keyword is set, disabling the cursor causes it to always be blanked out.

Graphics Keywords Accepted

See Appendix B, "Graphics Keywords" for the description of the following graphics and plotting keywords:

DATA, DEVICE, NORMAL, T3D, Z

Examples

To enable the graphics cursor and position it at device coordinate (100, 100), enter:

```
TVCRS, 100, 100
```

To position the cursor at data coordinate (0.5, 3.2), enter:

```
TVCRS, 0.5, 3.2, /DATA
```

Version History

CURSOR, RDPIX

TVLCT

The TVLCT procedure loads the display color translation tables from the specified variables. Although IDL uses the RGB color system internally, color tables can be specified to TVLCT using any of the following color systems: RGB (Red, Green, Blue), HLS (Hue, Lightness, Saturation), and HSV (Hue, Saturation, Value). Alpha values may also be used when using the second form of the command. The type and meaning of each argument is dependent upon the color system selected, as described below. Color arguments can be either scalar or vector expressions. If no color-system keywords are present, the RGB color system is used.

Syntax

TVLCT, V_1, V_2, V_3 [, *Start*] [, /GET] [, /HLS | , /HSV]

or

TVLCT, V [, *Start*] [, /GET] [, /HLS | , /HSV]

Arguments

TVLCT will accept either three *n*-element vectors (V_1, V_2, and V_3) or a single *n*-by-3 array (*V*) as an argument. The vectors (or rows of the array) have different meanings depending on the color system chosen. If an array *V* is specified, *V*[*,0] is the same as V_1, *V*[*,1] is the same as V_2, *V*[*,2] is the same as V_3. In the description below, we assume that three vectors, V_1, V_2, and V_3 are specified.

V_1, V_2, and V_3

The V_1, V_2, and V_3 arguments have different meanings depending upon which color system they represent.

If the GET keyword is specified, V_1, V_2, and V_3 should be set to named variables.

R, G, B Color System

The parameters V_1, V_2, and V_3 contain the red, green, and blue values, respectively. Values are interpreted as integers in the range 0 (lowest intensity) to 255 (highest intensity). The parameters can be scalars or vectors of up to 256 elements. By default, the three arguments are assumed to be R, G, and B values.

H, L, S Color System

Parameters V_1, V_2, and V_3 contain the Hue, Lightness, and Saturation values respectively. All parameters are floating-point. Hue is expressed in degrees and is reduced modulo 360. V_2 (lightness) and V_3 (saturation) and can range from 0 to 1.0. Set the HLS keyword to have the arguments interpreted this way.

H, S, V Color System

Parameters V_1, V_2, and V_3 contain values for Hue, Saturation, and Value (similar to intensity). All parameters are floating-point. Hue is in degrees. The Saturation and Value can range from 0 to 1.0. Set the HSV keyword to have the arguments interpreted this way.

Start

An integer value that specifies the starting point in the color translation table into which the color intensities (V_1, V_2, and V_3) are loaded. If this argument is not specified, a value of zero is used, causing the tables to be loaded starting at the first element of the translation tables. The *Start* argument can be used to change only part of the color table.

Keywords

GET

Set this keyword to return the RGB values from the internal color tables into the V_1, V_2, and V_3 parameters. For example, the statements:

```
TVLCT, H, S, V, /HSV
TVLCT, R, G, B, /GET
```

load a color table based in the HSV system, and then read the equivalent RGB values into the variables R, G, and B.

If GET is specified, either *V* (for the single argument form), or V_1, V_2, and V_3 (for the three argument form) must be set to named variables.

HLS

Set this keyword to indicate that the parameters specify color using the HLS color system. The plain argument parameters are in the order H-L-S. Hue is expressed in degrees, and the lightness and saturation range from 0 to 1.

HSV

Set this keyword to indicate that the parameters specify color using the HSV color system. The plain argument parameters are in the order H-S-V. As above, hue is in degrees, and the saturation and value range from 0 to 1.

Examples

This section includes the following simple example as well as the following, more extensive examples:

- "Highlighting Features with Color in Direct Graphics" on page 2553

- "Converting Indexed Images to RGB Images" on page 2557

```
; Initialize display.
DEVICE, DECOMPOSED = 0

; Create a set of R, G, and B colormap vectors:
R = BYTSCL(SIN(FINDGEN(256)))
G = BYTSCL(COS(FINDGEN(256)))
B = BINDGEN(256)

; Load these vectors into the color table:
TVLCT, R, G, B

; Display an image to see the effect of the new color table:
TVSCL, DIST(400)
```

Highlighting Features with Color in Direct Graphics

The data in the mineral.png file in the examples/data directory comes with its own color table. The following example will apply this related color table, then a pre-defined color table, and finally derive a new color table to highlight specific features. Complete the following steps for a detailed description of the process.

Example Code

See highlightfeatures_direct.pro in the examples/doc/image subdirectory of the IDL installation directory for code that duplicates this example. Run the example procedure by entering highlightfeatures_direct at the IDL command prompt or view the file in an IDL Editor window by entering .EDIT highlightfeatures_direct.pro.

1. Determine the path to the mineral.png file:

```
mineralFile = FILEPATH('mineral.png', $
```

```
SUBDIRECTORY = ['examples', 'data'])
```

2. Import the image from the `mineral.png` file into IDL:

```
mineralImage = READ_PNG(mineralFile, red, green, blue)
```

The image's associated color table is contained within the resulting red, green, and blue vectors.

3. Determine the size of the imported image:

```
mineralSize = SIZE(mineralImage, /DIMENSIONS)
```

4. If you are running IDL on a TrueColor display, set the DECOMPOSED keyword to the DEVICE command to zero before your first color table related routine is used within an IDL session or program.

```
DEVICE, DECOMPOSED = 0
```

5. Load the image's associated color table with the TVLCT routine:

```
TVLCT, red, green, blue
```

6. Initialize the display:

```
WINDOW, 0, XSIZE = mineralSize[0], YSIZE = mineralSize[1], $
    TITLE = 'mineral.png'
```

7. Display the imported image:

```
TV, mineralImage
```

This scanning electron microscope image shows mineral deposits in a sample of polished granite and gneiss. The associated color table is a reverse grayscale.

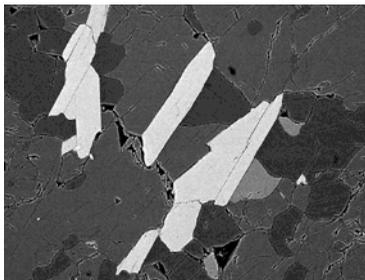
The following figure shows that the associated color table highlights the gneiss very well, but the other features are not very clear. The other features can be defined with IDL's pre-defined color table, RAINBOW.


Figure 22-9: Mineral Image and Default Color Table (Direct Graphics)

8. Load the RAINBOW color table and redisplay the image in another window:

```
LOADCT, 13
WINDOW, 1, XSIZE = mineralSize[0], YSIZE = mineralSize[1], $
   TITLE = 'RAINBOW Color'
TV, mineralImage
```

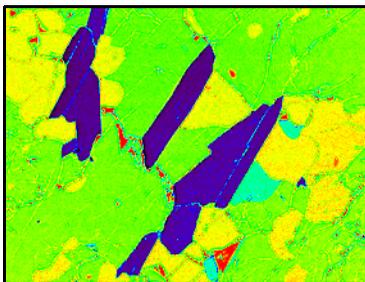
The following figure shows that the yellow, cyan, and red sections are now apparent, but the cracks are no longer visible. Details within the yellow areas and the green background are also difficult to distinguish. These features can be highlighted by designing your own color table.


Figure 22-10: Mineral Image and RAINBOW Color Table (Direct Graphics)

The features within the image are at specific ranges in between 0 and 255. Instead of a progressive color table, specific colors can be defined to be

constant over these ranges. Any contrasting colors can be used, but it is easiest to derive the additive and subtractive primary colors used in the previous section.

9. Define the colors for a new color table:

```
colorLevel = [[0, 0, 0], $ ; black
   [255, 0, 0], $ ; red
   [255, 255, 0], $ ; yellow
   [0, 255, 0], $ ; green
   [0, 255, 255], $ ; cyan
   [0, 0, 255], $ ; blue
   [255, 0, 255], $ ; magenta
   [255, 255, 255]] ; white
```

10. Create a new color table that contains eight levels, including the highest end boundary by first deriving levels for each color in the new color table:

```
numberOfLevels = CEIL(!D.TABLE_SIZE/8.)
level = INDGEN(!D.TABLE_SIZE)/numberOfLevels
```

11. Place each color level into its appropriate range.

```
newRed = colorLevel[0, level]
newGreen = colorLevel[1, level]
newBlue = colorLevel[2, level]
```

12. Include the last color in the last level:

```
newRed[!D.TABLE_SIZE - 1] = 255
newGreen[!D.TABLE_SIZE - 1] = 255
newBlue[!D.TABLE_SIZE - 1] = 255
```

13. Make the new color table current:

```
TVLCT, newRed, newGreen, newBlue
```

14. Display the image with this new color table in another window:

```
WINDOW, 2, XSIZE = mineralSize[0], $
   YSIZE = mineralSize[1], TITLE = 'Cube Corner Colors'
TV, mineralImage
```

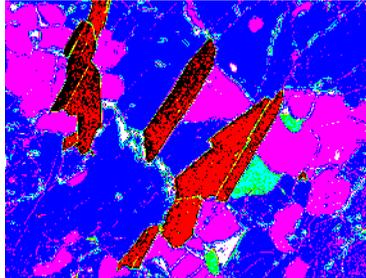
The following figure shows that each feature is now highlighted including the cracks. The color table also highlights at least three different types of cracks.


Figure 22-11: Mineral Image and Derived Color Table (Direct Graphics)

Converting Indexed Images to RGB Images

The convec.dat file is a binary file that contains an indexed image (a two-dimensional image and its associated color table) of the convection of the earth's mantle. This file does not contain a related color table. The following example applies a color table to this image and then converts the image and table to an RGB image (which contains its own color information) and writes it to a JPEG file. Complete the following steps for a detailed description of the process.

Example Code

See indexedtorgb.pro in the examples/doc/image subdirectory of the IDL installation directory for code that duplicates this example. Run the example procedure by entering indexedtorgb at the IDL command prompt or view the file in an IDL Editor window by entering .EDIT indexedtorgb.pro.

1. Determine the path to the convec.dat binary file:

```
convecFile = FILEPATH('convec.dat', $
   SUBDIRECTORY = ['examples', 'data'])
```

2. Initialize the image size parameter:

```
convecSize = [248, 248]
```

3. Import the image from the file:

```
convecImage = READ_BINARY(convecFile, $
   DATA_DIMS = convecSize)
```

4. If you are running IDL on a TrueColor display, set the DECOMPOSED
    keyword to the DEVICE command to zero before your first color table related
    routine is used within an IDL session or program.

    ```
    DEVICE, DECOMPOSED = 0
    ```

5. Load the EOS B color table (index number 27) to highlight the image's
    features and initialize the display:

    ```
    LOADCT, 27
    WINDOW, 0, TITLE = 'convec.dat', $
       XSIZE = convecSize[0], YSIZE = convecSize[1]
    ```

6. Now display the image with this color table.

    ```
    TV, convecImage
    ```

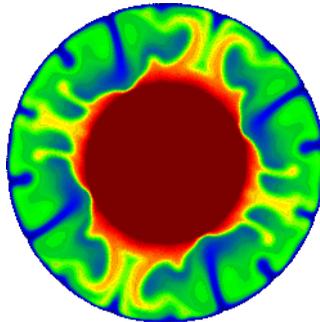

Figure 22-12: Example of an Indexed Image With Associated Color Table

A color table is formed from three vectors (the red vector, the green vector, and
the blue vector). The same element of each vector together form an RGB
triplet to create a color. For example, the *i-th* element of the red vector may be
255, the *ith* element of the green vector may be 255, and the *ith* element of the
blue vector maybe 0. The RGB triplet of the *ith* element would then be (255,
255, 0), which is the color yellow. Since a color table contains 256 indices, its
three vectors have 256 elements each. You can access these vectors with the
TVLCT routine using the GET keyword.

Note ——————————————————————————————

On some PseudoColor displays, fewer than 256 entries will be available.

7. Access the values of the color table by setting the GET keyword to the TVLCT
    routine.

```
TVLCT, red, green, blue, /GET
```

This color table (color information) can be stored within the image by converting it to an RGB image. For this example, the RGB image will be pixel interleaved in order to be exported to a JPEG file.

Tip ───────────────────────────────────────
If the original indexed image contains values of a data type other than byte, you should byte-scale the image (with the BYTSCL routine) before using the following method.
──

8. Before converting the indexed image into an RGB image, the resulting three-dimensional array must be initialized. Initialize the data type and the dimensions of the resulting RGB image:

   ```
   imageRGB = BYTARR(3, convecSize[0], convecSize[1], /NOZERO)
   ```

9. Use the red, green, and blue vectors of the color table and the original indexed image to form a single image composed of these channels:

   ```
   imageRGB[0, *, *] = red[convecImage]
   imageRGB[1, *, *] = green[convecImage]
   imageRGB[2, *, *] = blue[convecImage]
   ```

10. Export the resulting RGB image to a JPEG file:

   ```
   WRITE_JPEG, 'convecImage.jpg', imageRGB, TRUE = 1, $
      QUALITY = 100.
   ```

The TRUE keyword is set to 1 because the resulting RGB image is pixel interleaved. See WRITE_JPEG for more information.

TVRD

The TVRD function returns the contents of the specified rectangular portion of the current Direct Graphics window or device. (X_0, Y_0) is the coordinate of the lower left corner of the area to be read and N_x, N_y is the size of the rectangle in columns and rows. The result is a byte array of dimensions N_x by N_y. All parameters are optional. If no arguments are supplied, the entire display device area is read.

Important Note about TVRD and Backing Store

On some systems, when backing store is provided by the window system (the RETAIN keyword to DEVICE or WINDOW is set to 1), reading data from a window using TVRD may cause unexpected results. For example, data may be improperly read from the window even when the image displayed on screen is correct. Having IDL provide the backing store (set the RETAIN keyword to 2) ensures that the window contents will be read properly. More detailed notes about TVRD and the X Window system can be found below in "Unexpected Results Using TVRD with X Windows" on page 2562.

Syntax

Result = TVRD([X_0 [, Y_0 [, N_x [, N_y [, *Channel*]]]]] [, CHANNEL=*value*]
   [, /ORDER] [, TRUE={1 | 2 | 3}] [, /WORDS])

Return Value

Returns a byte array of the specified dimensions.

Arguments

X*₀*

The starting column of data to read. The default is 0.

Y*₀*

The starting row of data to read. The default is 0.

N*ₓ*

The number of columns to read. The default is the width of the display device or window less X_0.

N*y*

The number of rows to read. The default is the height of the display device or window less Y_0.

Channel

The memory channel to be read. If not specified, this argument is assumed to be zero. This parameter is ignored on display systems that have only one memory channel.

Keywords

CHANNEL

The memory channel to be read. The CHANNEL keyword is identical to the optional *Channel* argument.

Note

If the display is a 24-bit display, and both the CHANNEL and TRUE parameters are absent, the maximum RGB value in each pixel is returned.

ORDER

Set this keyword to override the current setting of the !ORDER system variable for the current image only. If set, it causes the image to be read from the top down instead of the normal bottom up.

TRUE

If this keyword is present, it indicates that a TrueColor image is to be read, if the display is capable. The value assigned to TRUE specifies the index of the dimension over which color is interleaved. The result is an $(3, n_x, n_y)$ pixel-interleaved array if TRUE is 1; or an $(n_x, 3, n_y)$ line-interleaved array if TRUE is 2; or an $(n_x, n_y, 3)$ image-interleaved array if TRUE is 3.

Note

IDL simply returns the MAX of the three channels when you do TVRD without setting TRUE on a TrueColor system.

WORDS

Set this keyword to indicate that words are to be transferred from the device. This keyword is valid only when using devices that can transfer 16-bit pixels. The normal transfer uses 8-bit pixels. If this keyword is set, the function result is an integer array.

Unexpected Results Using TVRD with X Windows

When using TVRD with the X Windows graphics device, there are two unexpected behaviors that can be confusing to users:

- When reading from a window that is obscured by another window (i.e., the target window has another window "on top" or "in front" of it), TVRD may return the contents of the window in front as part of the image contained in the target window.

- When reading from an iconified window, the X server may return a stream of "BadMatch" protocol events.

IDL uses the Xlib function `XGetSubImage()` to implement TVRD. The following quote is from the documentation for XGetSubImage() found in *The X Window System* by Robert W. Scheifler and James Gettys, Second Edition, page 174. It explains the reasons for the behaviors described above:

"If the drawable is a window, the window must be viewable, and it must be the case that if there were no... overlapping windows, the specified rectangle of the window would be fully visible on the screen, ... or a BadMatch error results. If the window has backing-store, then the backing-store contents are returned for regions of the window that are obscured... If the window does not have backing-store, the returned contents of such obscured regions are undefined."

Hence, the first behavior is caused by attempting to use TVRD on an obscured window that does not have backing store provided by the X server. The result in this case is undefined, meaning that the different servers can produce entirely different results. Many servers simply return the image of the obscuring window.

The second behavior is caused by attempting to read from a non-viewable (i.e., unmapped) window. Although IDL could refuse to allow TVRD to work with unmapped windows, some X servers return valid and useful results. Therefore, TVRD is allowed to attempt to read from unmapped windows.

Both of these behavior problems can be solved by using one of the following methods:

- Always make sure that your target window is mapped and is not obscured before using TVRD on it. The following IDL command can be used:

    ```
    WSET, Window_Index
    ```

- Make IDL provide backing store (rather than the window system) by setting the RETAIN keyword to DEVICE or WINDOW equal to 2.

For a full description of backing store, see "Backing Store" on page 5409. Note that under X Windows, backing store is a request that may or may not be honored by the X server. Many servers will honor backing store for 8-bit visuals but ignore them for 24-bit visuals because they require three times as much memory.

Examples

```
; Read the entire contents of the current display device into the
; variable T:
T = TVRD()
```

To read from the display to an IDL variable or expression, use the TVRD function with either the CHANNEL parameter or TRUE keyword parameter. The calling sequence for TVRD is:

$Result$ = TVRD($[X_0, Y_0, N_x, N_y, Channel]$)

where (X_0, Y_0) specifies the window coordinate of the lower-left corner of the rectangle to be read, and (N_x, N_y) contains the number of columns and rows to read. Note that all parameters to TVRD are optional. If no arguments are supplied, the entire area of the display device is returned.

When used without the TRUE parameter, TVRD returns an (N_x, N_y) byte image read from the indicated channel. If the channel number is not specified or is zero, the maximum RGB value of each pixel is returned, approximating the luminance.

If present and nonzero, the TRUE keyword indicates that a TrueColor image is to be read and specifies the index of the dimension over which color is interleaved. The result is a $(3, N_x, N_y)$ pixel interleaved array if TRUE is 1; or an $(N_x, 3, N_y)$ line interleaved array if TRUE is 2; or an $(N_x, N_y, 3)$ image interleaved array if TRUE is 3.

Some examples of TVRD follow.

```
; Read a 512 × 512 image, starting at (0, 0),
; from the red channel into R:
R = TVRD(0, 0, 512, 512, 1)
; Read a TrueColor 512 × 512, line interleaved image,
; starting at (0, 0) into T. The variable T is
```

```
; now dimensioned (512, 3, 512):
T = TVRD(0, 0, 512, 512, TRUE = 2)
; Read the maximum RGB value of each pixel into L:
L = TVRD(0, 0, 512, 512)
```

RDPIX, TV, WINDOW

TVSCL

The TVSCL procedure scales the intensity values of *Image* into the range of the Direct Graphics image display device and outputs the data to the image display at the specified location. The array is scaled so the minimum data value becomes 0 and the maximum value becomes the maximum number of available colors (held in the system variable !D.TABLE_SIZE) as follows:

$$\text{Output} = (\text{!D.TABLE\_SIZE - 1})\frac{\text{Data} - \text{Data}_{min}}{\text{Data}_{max} - \text{Data}_{min}}$$

where the maximum and minimum are found by scanning the array. The parameters and keywords of the TVSCL procedure are identical to those accepted by the TV procedure. For additional information about each parameter, consult the description of TV.

Syntax

TVSCL, *Image* [, *Position*] [, /CENTIMETERS] [, /INCHES] [, /NAN] [, /ORDER]
   [, TOP=*value*] [, TRUE={1 | 2 | 3}] [, /WORDS] [, XSIZE=*value*]
   [, YSIZE=*value*]

or

TVSCL, *Image* [, *X*, *Y* [, *Channel*] [, /CENTIMETERS] [, /INCHES] [, /NAN]
   [, /ORDER] [, TOP=*value*] [, TRUE={1 | 2 | 3}] [, /WORDS] [, XSIZE=*value*]
   [, YSIZE=*value*]]

Graphics Keywords: [, CHANNEL=*value*] [, /DATA | , /DEVICE | , /NORMAL]
[, /T3D] [, Z=*value*]

Arguments

Image

A two-dimensional array to be displayed as an image. If this argument is not already of byte type, it is converted prior to use.

X, Y

If *X* and *Y* are present, they specify the lower left coordinate of the displayed image.

Position

Image position. See the discussion of "Position" on page 2535 under TV for a full description.

Channel

Some image display devices are capable of storing more than a single image or can combine three single color images to form a TrueColor image. *Channel* specifies the memory channel to be written. It is assumed to be zero if not specified. This parameter is ignored on display systems that have only one memory channel. The *Channel* argument is identical to the CHANNEL graphics keyword.

Keywords

CENTIMETERS

Set this keyword to indicate that the *X*, *Y*, *Xsize*, *Ysize*, and *Z* arguments are given in centimeters from the origin. This system is useful when dealing with devices, such as PostScript printers, that do not provide a direct relationship between image pixels and the size of the resulting image.

INCHES

Set this keyword to indicate that all position and size values are given in inches from the origin. This system is useful when dealing with devices, such as PostScript printers, that do not provide a direct relationship between image pixels and the size of the resulting image.

NAN

Set this keyword to cause TVSCL to treat elements of *Image* that are not numbers (that is, elements that have the special IEEE floating-point values *Infinity* or *NaN*) as missing data, and display them using color index 0 (zero). Note that color index 0 is also used to display elements that have the minimum value in the *Image* array. (See "Special Floating-Point Values" (Chapter 8, *Application Programming*) for more information on IEEE floating-point values.)

ORDER

If specified, ORDER overrides the current setting of the !ORDER system variable for the current image only. If set, the image is drawn from the top down instead of the normal bottom up.

TOP

The maximum value of the scaled result. If TOP is not specified, !D.TABLE_SIZE-1 is used. Note that the minimum value of the scaled result is always 0.

TRUE

Set this keyword to a nonzero value to indicate that a TrueColor (16-, 24-, or 32-bit) image is to be displayed. The value assigned to TRUE specifies the index of the dimension over which color is interleaved. The image parameter must have three dimensions, one of which must be equal to three. For example, set TRUE to 1 to display an image that is pixel interleaved and has dimensions of (3, *m, n*). Specify 2 for row-interleaved images, of size (*m*, 3, *n*), and 3 for band-interleaved images of the form (*m*, *n*, 3).

See "TrueColor Images" on page 5427 for an example using this keyword to write 24-bit images to the PostScript device.

WORDS

Set this keyword to indicate that words (short integers) instead of 8-bit bytes are to be transferred to the device. This keyword is valid only when using devices that can transfer 16-bit pixels. The normal transfer uses 8-bit pixels. If this keyword is set, the *Image* parameter is converted to short integer type, if necessary, and then written to the display.

XSIZE

The width of the resulting image. On devices with scalable pixel size (such as PostScript), if XSIZE is specified the image will be scaled to fit the specified width. If neither XSIZE nor YSIZE is specified, the image will be scaled to fill the plotting area, while preserving the image's aspect ratio. This keyword is ignored by pixel-based devices that are unable to change the size of their pixels.

YSIZE

The height of the resulting image. On devices with scalable pixel size (such as PostScript), if YSIZE is specified the image will be scaled to fit the specified height. If neither XSIZE nor YSIZE is specified, the image will be scaled to fill the plotting area, while preserving the image's aspect ratio. This keyword is ignored by pixel-based devices that are unable to change the size of their pixels.

Graphics Keywords Accepted

See Appendix B, "Graphics Keywords" for the description of the following graphics and plotting keywords:

CHANNEL, DATA, DEVICE, NORMAL, T3D, Z

Note ──
The T3D and Z keywords are only honored when the DATA keyword is also set. Note also that when the T3D keyword is set, the X and Y arguments and the Z keyword position the lower left corner of the image displayed by TVSCL, but do not change its orientation. Use the POLY_2D routine to warp the image into 3D space.
──

Thread Pool Keywords

This routine is written to make use of IDL's *thread pool*, which can increase execution speed on systems with multiple CPUs. The values stored in the !CPU system variable control whether IDL uses the thread pool for a given computation. In addition, you can use the thread pool keywords TPOOL_MAX_ELTS, TPOOL_MIN_ELTS, and TPOOL_NOTHREAD to override the defaults established by !CPU for a single invocation of this routine. See Appendix C, "Thread Pool Keywords" for details.

Examples

Display a floating-point array as an image using the TV command:

```
TV, DIST(200)
```

Note that the image is not easily visible because the values in the array have not been scaled into the full range of display values. Now display the image with the TVSCL command by entering:

```
TVSCL, DIST(200)
```

Notice how much brighter the image appears.

Routines: U

UINDGEN

The UINDGEN function creates an unsigned integer array. Each element of the array is set to the value of its one-dimensional subscript.

Syntax

Result = UINDGEN(D_1 [, ..., D_8])

Return Value

Returns an unsigned integer array of the specified dimensions.

Arguments

D$_i$

Either an array or a series of scalar expressions specifying the dimensions of the result. If a single argument is specified, it can be either a scalar expression or an array of up to eight elements. If multiple arguments are specified, they must all be scalar expressions. Up to eight dimensions can be specified. If the dimension arguments are not integer values, IDL will convert them to integer values before creating the new array.

Keywords

Thread Pool Keywords

This routine is written to make use of IDL's *thread pool*, which can increase execution speed on systems with multiple CPUs. The values stored in the !CPU system variable control whether IDL uses the thread pool for a given computation. In addition, you can use the thread pool keywords TPOOL_MAX_ELTS, TPOOL_MIN_ELTS, and TPOOL_NOTHREAD to override the defaults established by !CPU for a single invocation of this routine. See Appendix C, "Thread Pool Keywords" for details.

Examples

To create UI, a 10-element by 10-element 16-bit array where each element is set to the value of its one-dimensional subscript, enter:

```
UI = UINDGEN(10, 10)
```

UINT

The UINT function returns a result equal to *Expression* converted to unsigned integer type.

Syntax

Result = UINT(*Expression[*, *Offset [*, *D_1 [*, ..., *D_8]]]*)

Return Value

Returns an unsigned integer value or array of the same dimensions as the result of the *Expression.* If *Expression* is a complex number, UINT returns the real part.

Arguments

Expression

The expression to be converted to unsigned integer.

Offset

Offset from beginning of the *Expression* data area. Specifying this argument allows fields of data extracted from *Expression* to be treated as unsigned integer data. See the description in Chapter 13, "Working with Data in IDL" (*Application Programming*) for details.

D_i

When extracting fields of data, the D_i arguments specify the dimensions of the result. If no dimension arguments are given, the result is taken to be scalar.

The D_i arguments can be either an array or a series of scalar expressions specifying the dimensions of the result. If a single argument is specified, it can be either a scalar expression or an array of up to eight elements. If multiple arguments are specified, they must all be scalar expressions. Up to eight dimensions can be specified.

When converting from a string argument, it is possible that the string does not contain a valid integer and no conversion is possible. The default action in such cases is to print a warning message and return 0. The ON_IOERROR procedure can be used to establish a statement to be jumped to in case of such errors.

Keywords

Thread Pool Keywords

This routine is written to make use of IDL's *thread pool*, which can increase execution speed on systems with multiple CPUs. The values stored in the !CPU system variable control whether IDL uses the thread pool for a given computation. In addition, you can use the thread pool keywords TPOOL_MAX_ELTS, TPOOL_MIN_ELTS, and TPOOL_NOTHREAD to override the defaults established by !CPU for a single invocation of this routine. See Appendix C, "Thread Pool Keywords" for details.

Examples

If A contains the floating-point value 32000.0, it can converted to an unsigned integer and stored in the variable B by entering:

```
B = UINT(A)
```

UINTARR

The UINTARR function creates an unsigned integer vector or array.

Syntax

Result = UINTARR(D_1 *[, ..., D_8]* [, /NOZERO])

Return Value

Returns an unsigned integer vector or array of the specified dimensions.

Arguments

D*i*

Either an array or a series of scalar expressions specifying the dimensions of the result. If a single argument is specified, it can be either a scalar expression or an array of up to eight elements. If multiple arguments are specified, they must all be scalar expressions. Up to eight dimensions can be specified.

Keywords

NOZERO

Normally, UINTARR sets every element of the result to zero. If NOZERO is set, this zeroing is not performed and UINTARR executes faster.

Examples

To create L, a 100-element, unsigned integer vector with each element set to 0, enter:

```
L = UINTARR(100)
```

UL64INDGEN

The UL64INDGEN function returns an unsigned 64-bit integer array with the specified dimensions. Each element of the array is set to the value of its one-dimensional subscript.

Syntax

Result = UL64INDGEN(D_1 [, ..., D_8])

Return Value

Returns the specified unsigned integer array.

Arguments

D$_i$

Either an array or a series of scalar expressions specifying the dimensions of the result. If a single argument is specified, it can be either a scalar expression or an array of up to eight elements. If multiple arguments are specified, they must all be scalar expressions. Up to eight dimensions can be specified. If the dimension arguments are not integer values, IDL will convert them to integer values before creating the new array.

Keywords

Thread Pool Keywords

ULINDGEN

The ULINDGEN function returns an unsigned longword array with the specified dimensions. Each element of the array is set to the value of its one-dimensional subscript.

Syntax

Result = ULINDGEN(D_1 [, ..., D_8])

Return Value

Returns the specified unsigned longword array.

Arguments

D$_i$

Either an array or a series of scalar expressions specifying the dimensions of the result. If a single argument is specified, it can be either a scalar expression or an array of up to eight elements. If multiple arguments are specified, they must all be scalar expressions. Up to eight dimensions can be specified. If the dimension arguments are not integer values, IDL will convert them to integer values before creating the new array.

ULON64ARR

The ULON64ARR function returns an unsigned 64-bit integer vector or array.

Syntax

Result = ULON64ARR(*D₁ [, ..., D₈]* [, /NOZERO])

Return Value

Returns a vector or array of the specified dimensions.

Arguments

D*ᵢ*

Either an array or a series of scalar expressions specifying the dimensions of the result. If a single argument is specified, it can be either a scalar expression or an array of up to eight elements. If multiple arguments are specified, they must all be scalar expressions. Up to eight dimensions can be specified.

Keywords

NOZERO

Normally, ULON64ARR sets every element of the result to zero. If NOZERO is set, this zeroing is not performed and ULON64ARR executes faster.

Examples

To create L, a 100-element, unsigned 64-bit vector with each element set to 0, enter:

```
L = ULON64ARR(100)
```

ULONARR

The ULONARR function returns an unsigned longword integer vector or array.

Syntax

Result = ULONARR(D_1 *[, ..., D_8]* [, /NOZERO])

Return Value

Returns an unsigned longword integer array of the specified dimensions.

Arguments

D*i*

Either an array or a series of scalar expressions specifying the dimensions of the result. If a single argument is specified, it can be either a scalar expression or an array of up to eight elements. If multiple arguments are specified, they must all be scalar expressions. Up to eight dimensions can be specified.

Keywords

NOZERO

Normally, ULONARR sets every element of the result to zero. If NOZERO is set, this zeroing is not performed and ULONARR executes more quickly.

Examples

To create L, a 100-element, unsigned longword vector with each element set to 0, enter:

```
L = ULONARR(100)
```

ULONG

The ULONG function returns a result equal to *Expression* converted to the unsigned longword integer type.

Syntax

Result = ULONG(*Expression[*, *Offset [*, *D₁ [*, ..., *D₈]]]*)

Return Value

Returns an unsigned longword integer value or array of the same dimensions as the result of the *Expression.* If *Expression* is a complex number, ULONG returns the real part.

Arguments

Expression

The expression to be converted to unsigned longword integer.

Offset

Offset from beginning of the *Expression* data area. Specifying this argument allows fields of data extracted from *Expression* to be treated as unsigned longword integer data. See the description in Chapter 13, "Working with Data in IDL" (*Application Programming*) for details.

D$_i$

When extracting fields of data, the D_i arguments specify the dimensions of the result. If no dimension arguments are given, the result is taken to be scalar.

The D_i arguments can be either an array or a series of scalar expressions specifying the dimensions of the result. If a single argument is specified, it can be either a scalar expression or an array of up to eight elements. If multiple arguments are specified, they must all be scalar expressions. Up to eight dimensions can be specified.

When converting from a string argument, it is possible that the string does not contain a valid integer and no conversion is possible. The default action in such cases is to print a warning message and return 0. The ON_IOERROR procedure can be used to establish a statement to be jumped to in case of such errors.

Keywords

Thread Pool Keywords

This routine is written to make use of IDL's *thread pool*, which can increase execution speed on systems with multiple CPUs. The values stored in the !CPU system variable control whether IDL uses the thread pool for a given computation. In addition, you can use the thread pool keywords TPOOL_MAX_ELTS, TPOOL_MIN_ELTS, and TPOOL_NOTHREAD to override the defaults established by !CPU for a single invocation of this routine. See Appendix C, "Thread Pool Keywords" for details.

Examples

If A contains the floating-point value 32000.0, it can converted to an unsigned longword integer and stored in the variable B by entering:

```
B = ULONG(A)
```

Version History

5.2	Introduced

ULONG64

The ULONG64 function returns a result equal to *Expression* converted to the unsigned 64-bit integer type.

Syntax

Result = ULONG64(*Expression[, Offset [, D_1 [, ..., D_8]]]*)

Return Value

Returns an unsigned 64-bit longword integer value or array of the same dimensions as the result of the *Expression.* If *Expression* is a complex number, ULONG64 returns the real part.

Arguments

Expression

The expression to be converted to unsigned 64-bit integer.

Offset

Offset from beginning of the *Expression* data area. Specifying this argument allows fields of data extracted from *Expression* to be treated as unsigned 64-bit integer data. See the description in Chapter 13, "Working with Data in IDL" (*Application Programming*) for details.

D_i

When extracting fields of data, the D_i arguments specify the dimensions of the result. If no dimension arguments are given, the result is taken to be scalar.

The D_i arguments can be either an array or a series of scalar expressions specifying the dimensions of the result. If a single argument is specified, it can be either a scalar expression or an array of up to eight elements. If multiple arguments are specified, they must all be scalar expressions. Up to eight dimensions can be specified.

When converting from a string argument, it is possible that the string does not contain a valid integer and no conversion is possible. The default action in such cases is to print a warning message and return 0. The ON_IOERROR procedure can be used to establish a statement to be jumped to in case of such errors.

UNIQ

The UNIQ function returns the subscripts of the unique elements in an array. Note that repeated elements must be adjacent in order to be found. This routine is intended to be used with the SORT function: see the examples below. This function was inspired by the UNIX `uniq(1)` command.

This routine is written in the IDL language. Its source code can be found in the file `uniq.pro` in the `lib` subdirectory of the IDL distribution.

Syntax

Result = UNIQ(*Array* [, *Index*])

Return Value

UNIQ returns an array of indices into the original array. Note that the index of the last element in each set of non-unique elements is returned. If the optional *Index* argument is supplied, then the last index in the order provided by the *Index* array is returned.

The following expression returns a copy of the sorted array with duplicate adjacent elements removed:

```
Array[UNIQ(Array)]
```

UNIQ returns 0 (zero) if the argument supplied is a scalar rather than an array.

Arguments

Array

The array to be scanned. For UNIQ to work properly, the array must be sorted into monotonic order unless the optional parameter *Index* is supplied.

Index

This optional parameter is an array of indices into *Array* that order the elements into monotonic order. That is, the expression:

```
Array[Index]
```

yields an array in which the elements of *Array* are rearranged into monotonic order.

The *Index* array can be generated from *Array* using the SORT function:

```
Index = SORT(Array)
```

If *Array* is not already in monotonic order, use the command:

```
UNIQ(Array, SORT(Array))
```

Examples

Find the unique elements of an unsorted array:

```
; Create an array:
array = [1, 2, 1, 2, 3, 4, 5, 6, 6, 5]

; Variable B holds an array containing the sorted, unique values in
; array:
b = array[UNIQ(array, SORT(array))]
PRINT, b
```

IDL prints

```
1    2    3    4    5    6
```

SORT, WHERE

UNSHARP_MASK

The UNSHARP_MASK function performs an unsharp-mask sharpening filter on a two-dimensional array or a TrueColor image. For TrueColor images the unsharp mask is applied to each channel.

The unsharp mask algorithm works by enhancing the contrast between neighboring pixels in an image, and is widely used for astronomical images and for digital photographs.

The algorithm involves the following steps:

1. Smooth the original image with a Gaussian filter, with the width controlled by the RADIUS keyword.

2. Subtract the smoothed image from the original to create a high-pass filtered image.

3. Apply any clipping needed on the high-pass image, as controlled by the THRESHOLD keyword.

4. Add a certain percentage of the high-pass filtered image to the original image, with the percentage controlled by the AMOUNT keyword.

In pseudocode this algorithm can be written as:

```
HighPass = Image - Convol ( Image, Gaussian )
Result = Image + A * HighPass * ( |HighPass| ≥ T )
```

where A is the amount, T is the threshold, and ≥ indicates a Boolean operation, 1 if true, or 0 otherwise.

Note

To avoid overflow for byte or integer data, the computations are performed using a larger integer type, the result is clipped to the minimum and maximum values for the original type, and the result is then converted back to the original type.

This routine is written in the IDL language. Its source code can be found in the file `unsharp_mask.pro` in the `lib` subdirectory of the IDL distribution.

Syntax

Result = UNSHARP_MASK(*Image* [, AMOUNT=*value*] [, RADIUS=*value*]
   [, THRESHOLD=*value*] [, TRUE={1|2|3}])

Return Value

The *Result* is an array with the same dimensions and type as *Image* that contains the filtered image.

Arguments

Image

The two-dimensional array or multichannel image to be filtered. If *Image* is a multichannel image, then the TRUE keyword may be used to indicate which dimension represents the channels.

Keywords

AMOUNT

Set this keyword to a floating-point value giving the amount (or strength) of filtering to be applied. The default is AMOUNT=1.0, which implies that 100% of the filter difference will be applied to the *Image*. AMOUNT may be negative, which will have the effect of blurring the image instead of sharpening.

RADIUS

Set this keyword to a floating-point value giving the radius in pixels of the Gaussian smoothing filter. The default is RADIUS=3. The Gaussian filter is designed to fall to $1/e$ (~0.367) at a distance of RADIUS/sqrt(2). The total width of the Gaussian filter is given by ceil(2 * RADIUS)/2 * 2 + 1 (if RADIUS is an integer then this is just 2 * RADIUS + 1).

Note
The value of RADIUS must be smaller than one-half of the largest array dimension.

Tip
Use small RADIUS values (such as 3) for small images or images with fine details. Use larger RADIUS values for large images with larger details.

THRESHOLD

Set this keyword to a non-negative integer (or a floating-point if *Image* is floating point) giving the clipping threshold. For each element, if the absolute value of the difference between the original image and the low-pass filtered array is greater than

or equal to THRESHOLD then the filter is applied to that point. The default is THRESHOLD=0, which implies that every point will be filtered.

Tip ————————————————————————————————————

Lower values of THRESHOLD will provide greater sharpening but may cause more speckling, while higher values of THRESHOLD will exclude regions of low contrast and cause less speckling.

TRUE

If *Image* is a three-dimensional array (a multichannel image), set this keyword to 1, 2, or 3 to indicate which dimension represents the channels. The default is 1, for pixel interleaving, (3, *m*, *n*). A value of 2 indicates line interleaving (*m*, 3, *n*), and 3 indicates band interleaving, (*m*, *n*, 3).

Example

```
file = FILEPATH('marsglobe.jpg', SUBDIR=['examples','data'])
READ_JPEG, file, image
; Display the original image.
iImage, image, VIEW_GRID=[2,1], DIMENSIONS = [800, 500]
; Display the unsharp-mask-filtered image.
result = UNSHARP_MASK(image, RADIUS=4)
iImage, result, /VIEW_NEXT
```

USERSYM

The USERSYM procedure is used to define the plotting symbol that marks points when the PSYM keyword symbol is set to plus or minus 8. Symbols can be drawn with vectors or can be filled. Symbols can be of any size and can have up to 49 vertices.

The symbol you define can be drawn using lines or it can be filled using the polygon filling operator. USERSYM accepts two vector parameters: a vector of *x* values and a vector of *y* values. The coordinate system you use to define the symbol's shape is centered on each data point, and each unit is approximately the size of a character. The color and line thickness used to draw the symbols are also optional keyword parameters of USERSYM.

Syntax

USERSYM, *X* [, *Y*] [, COLOR=*value*] [, /FILL] [, THICK=*value*]

Arguments

X, Y

The *X* and/or *Y* parameters define the vertices of the symbol as offsets from the data point in units of approximately the size of a character. In the case of a vector drawn symbol, the symbol is formed by connecting the vertices in order. If only one argument is specified, it must be a (2, *N*) array of vertices, with element [0, *i*] containing the X coordinate of the vertex, and element [1, *i*] containing the Y. If both arguments are provided, *X* contains only the X coordinates.

Keywords

COLOR

The color used to draw the symbols, or used to fill the polygon. The default color is the same as the line color.

FILL

Set this keyword to fill the polygon defined by the vertices. If FILL is not set, lines are drawn connecting the vertices.

THICK

The thickness of the lines used in drawing the symbol. The default thickness is 1.0.

Examples

To define the simplest symbol, use a one character-wide dash centered over the data point:

```
USERSYM, [-.5, .5], [0, 0]
```

Make a large, diamond-shaped plotting symbol. Define the vectors of X values by entering:

```
X = [-6, 0, 6, 0, -6]
```

Define the vectors of Y values by entering:

```
Y = [0, 6, 0, -6, 0]
```

Now call USERSYM to create the new plotting symbol 8. Enter:

```
USERSYM, X, Y
```

Generate a simple plot to test the plotting symbol by entering:

```
PLOT, FINDGEN(20), PSYM = 8
```

Creating a Filled Circle Symbol

The following code illustrates the use of USERSYM to define a new symbol—a filled circle:

```
; Make a vector of 16 points, A[i] = 2pi/16:
A = FINDGEN(17) * (!PI*2/16.)
; Define the symbol to be a unit circle with 16 points,
; and set the filled flag:
USERSYM, COS(A), SIN(A), /FILL
```

Using the variables defined in a batch file, we then create the plot, specifying 8 (user-defined) for the PSYM keyword to PLOT:

```
; Define variables.
@plot01
; Use the LINFIT function to fit the data to a line:
coeff = LINFIT(YEAR, SOCKEYE)
;YFIT is the fitted line:
YFIT = coeff[0] + coeff[1]*YEAR
```

```
PLOT, YEAR, SOCKEYE, /YNOZERO, PSYM = 8, $
   TITLE = 'Quadratic Fit', XTITLE = 'Year', $
   YTITLE = 'Sockeye Population'
; Overplot the smooth curve using a plain line:
OPLOT, YEAR, YFIT
```

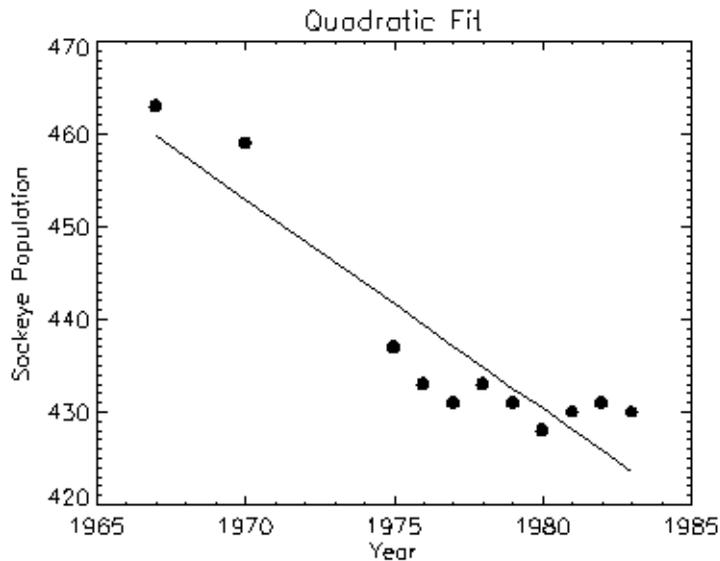
The following figure shows the result of this code:


Figure 23-2: Plotting with User-defined Plotting Symbols

Note ───

If IDL does not find the batch file, the required directory may not be in your IDL search path. All of the files mentioned are located in the examples/doc subdirectory of the IDL distribution. By default, this directory is part of IDL's path; if you have not changed your path, you will be able to run the examples as described here. See !PATH for information on modifying IDL's path.

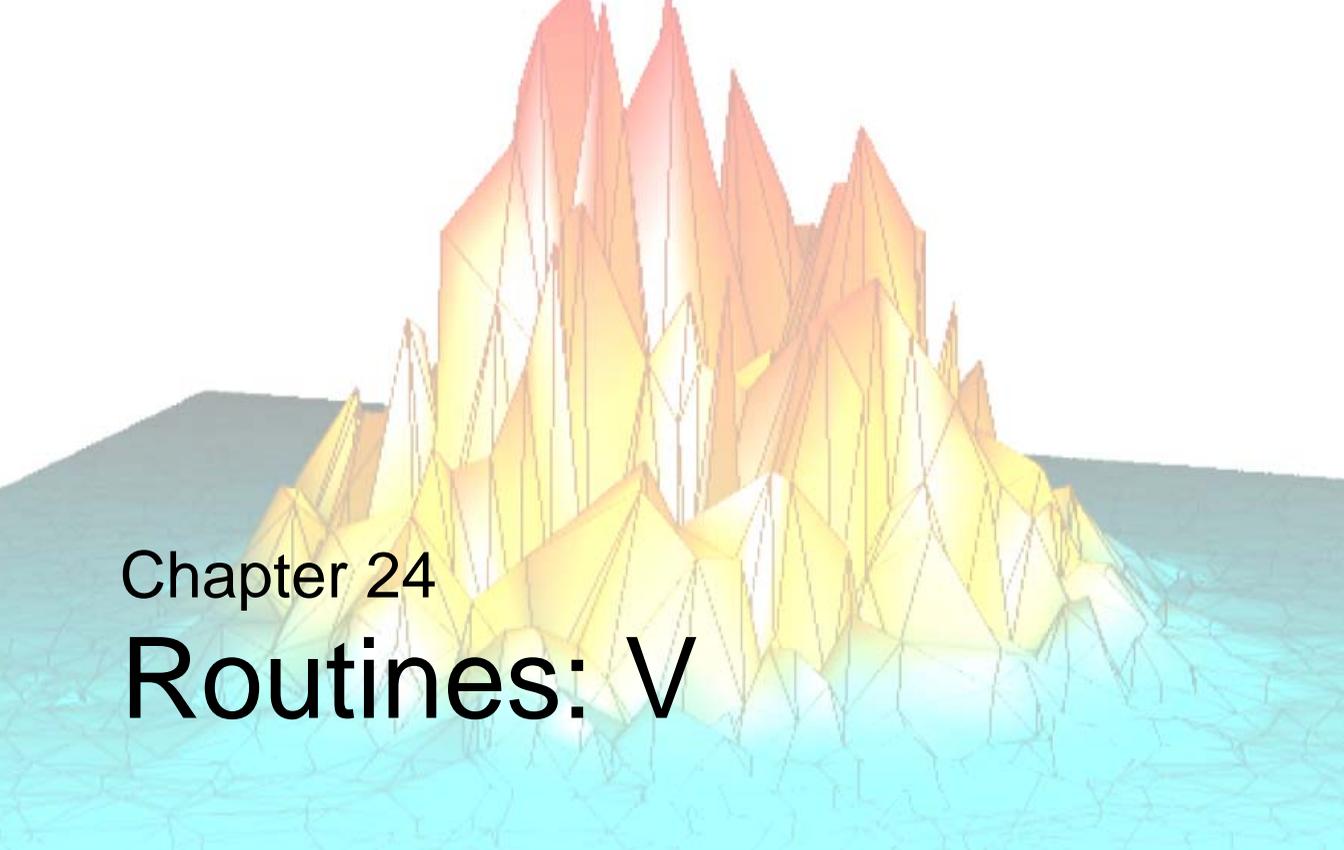
PLOT


Chapter 24
Routines: V

VALUE_LOCATE

The VALUE_LOCATE function finds the intervals within a given monotonic vector that brackets a given set of one or more search values. This function is useful for interpolation and table-lookup, and is an adaptation of the locate() routine in Numerical Recipes. VALUE_LOCATE uses the bisection method to locate the interval.

Syntax

Result = VALUE_LOCATE (*Vector*, *Value* [, /L64])

Return Value

Each return value, *Result* [*i*], is an index, *j*, into *Vector*, corresponding to the interval into which the given *Value* [*i*] falls. The returned values are in the range $-1 \leq j \leq N-1$, where *N* is the number of elements in the input vector.

If *Vector* is monotonically increasing, the result *j* is:

if $j = -1$ *Value* [*i*] < *Vector* [0]

if $0 \leq j < N-1$ *Vector* [*j*] $\leq$ *Value* [*i*] < *Vector* [*j*+1]

if $j = N-1$ *Vector* [*N*–1] $\leq$ *Value* [*i*]

If *Vector* is monotonically decreasing

if $j = -1$ *Vector* [*0*] $\leq$ *Value* [*i*]

if $0 \leq j < N-1$ *Vector* [*j*+1] $\leq$ *Value* [*i*] < *Vector* [*j*]

if $j = N-1$ *Value* [*i*] < *Vector* [*N*–1]

Arguments

Vector

A vector of monotonically increasing or decreasing values. *Vector* may be of type string, or any numeric type except complex, and may not contain the value NaN (not-a-number).

Value

The value for which the location of the intervals is to be computed. *Value* may be either a scalar or an array. The return value will contain the same number of elements as this parameter.

Keywords

L64

By default, the result of VALUE_LOCATE is 32-bit integer when possible, and 64-bit integer if the number of elements being processed requires it. Set L64 to force 64-bit integers to be returned in all cases.

Note ————————————————————————————————

Only 64-bit versions of IDL are capable of creating variables requiring a 64-bit result. Check the value of !VERSION.MEMORY_BITS to see if your IDL is 64-bit or not.

Examples

```
; Define a vector of values.
vec = [2,5,8,10]

; Compute location of other values within that vector.
loc = VALUE_LOCATE(vec, [0,3,5,6,12])
PRINT, loc
```

IDL prints:

```
-1   0   1   1   3
```

VARIANCE

The VARIANCE function computes the statistical variance of an *n*-element vector.

Syntax

Result = VARIANCE(*X* [, /DOUBLE] [, /NAN])

Return Value

Returns the floating-point or double-precision statistical variance of the input vector.

Arguments

X

An *n*-element, floating-point or double-precision vector.

Keywords

DOUBLE

If this keyword is set, VARIANCE performs its computations in double precision arithmetic and returns a double precision result. If this keyword is not set, the computations and result depend upon the type of the input data (integer and float data return float results, while double data returns double results).

NAN

Set this keyword to cause the routine to check for occurrences of the IEEE floating-point values *NaN* or *Infinity* in the input data. Elements with the value *NaN* or *Infinity* are treated as missing data. (See "Special Floating-Point Values" (Chapter 8, *Application Programming*) for more information on IEEE floating-point values.)

Examples

```
; Define the n-element vector of sample data:
x = [1, 1, 1, 2, 5]
; Compute the variance:
result = VARIANCE(x)
PRINT, result
```

IDL prints:

```
3.00000
```

VECTOR_FIELD

The VECTOR_FIELD procedure is used to place colored, oriented vectors of specified length at each vertex in an input vertex array. The output can be sent directly to an IDLgrPolyline object. The generated display is generally referred to as a hedgehog display and is used to convey various aspects of a vector field.

Syntax

VECTOR_FIELD, *Field*, *Outverts*, *Outconn* [, ANISOTROPY=*array*]
    [, SCALE=*value*] [, VERTICES=*array*]

Arguments

Field

Input vector field array. This can be a [3, *x*, *y*, *z*] array or a [2, *x*, *y*] array. The leading dimension is the vector quantity to be displayed.

Outverts

Output vertex array ([3, *N*] or [2, *N*] array of floats). Useful if the routine is to be used with Direct Graphics or the user wants to manipulate the data directly.

Outconn

Output polyline connectivity array to be applied to the output vertices.

Keywords

ANISOTROPY

Set this keyword to a two- or three-element array describing the distance between grid points in each dimension. The default value is [1.0, 1.0, 1.0] for three-dimensional data and [1.0, 1.0] for two-dimensional data.

SCALE

Set this keyword to a scalar scaling factor. All vector lengths are multiplied by this value. The default is 1.0.

VERTICES

Set this keyword to a [3, *n*] or [2, *n*] array of points. If this keyword is set, the vector field is interpolated at these points. The resulting interpolated vectors are displayed as line segments at these locations. If the keyword is not set, each spatial sample point in the input Field grid is used as the base point for a line segment.

Version History

5.3	Introduced

VEL

The VEL procedure draws a velocity (flow) field with arrows following the field proportional in length to the field strength. Arrows are composed of a number of small segments that follow the streamlines.

This routine is written in the IDL language. Its source code can be found in the file `vel.pro` in the `lib` subdirectory of the IDL distribution.

Syntax

VEL, *U*, *V* [, NVECS=*value*] [, XMAX= *value*{*xsize/ysize*}]
   [, LENGTH=*value*{*longest/steps*}] [, NSTEPS=*value*] [, TITLE=*string*]

Arguments

U

The X component at each point of the vector field. *U* must be a 2-D array.

V

The Y component at each point of the vector field. *V* must have the same dimensions as *U*.

Keywords

LENGTH

The length of each arrow line segment expressed as a fraction of the longest vector divided by the number of steps. The default is 0.1.

NSTEPS

The number of shoots or line segments for each arrow. The default is 10.

NVECS

The number of vectors (arrows) to draw. If this keyword is omitted, 200 vectors are drawn.

TITLE

A string containing the title for the plot.

XMAX

X axis size as a fraction of Y axis size. The default is 1.0. This argument is ignored when !P.MULTI is set.

Examples

```
; Create a vector of X values:
X = DIST(20)

; Create a vector of Y values:
Y = SIN(X)*100

; Plot the vector field:
VEL, X, Y
```

FLOW3, PLOT_FIELD, VELOVECT

VELOVECT

The VELOVECT procedure produces a two-dimensional velocity field plot. A directed arrow is drawn at each point showing the direction and magnitude of the field.

This routine is written in the IDL language. Its source code can be found in the file velovect.pro in the lib subdirectory of the IDL distribution.

Syntax

VELOVECT, *U*, *V* [, *X*, *Y*] [, COLOR=*index*] [, MISSING=*value* [, /DOTS]]
    [, LENGTH=*value*] [, /OVERPLOT] [Also accepts all PLOT keywords]

Arguments

U

The X component of the two-dimensional field. *U* must be a two-dimensional array.

V

The Y component of the two dimensional field. *V* must have the same dimensions as *U*.

X

Optional abscissae values. *X* must be a vector with a length equal to the first dimension of *U* and *V*.

Y

Optional ordinate values. *Y* must be a vector with a length equal to the second dimension of *U* and *V*.

Keywords

Note

Keywords not described here are passed directly to the PLOT procedure and may be used to set options such as TITLE, POSITION, NOERASE, etc.

COLOR

Set this keyword equal to the color index used for the plot.

DOTS

Set this keyword to 1 to place a dot at each missing point. Set this keyword to 0 or omit it to draw nothing for missing points. Has effect only if MISSING is specified.

LENGTH

Set this keyword equal to the length factor. The default of 1.0 makes the longest (*U*,*V*) vector the length of a cell.

MISSING

Set this keyword equal to the missing data value. Vectors with a length greater than MISSING are ignored.

OVERPLOT

Set this keyword to make VELOVECT "overplot". That is, the current graphics screen is not erased, no axes are drawn, and the previously established scaling remains in effect.

PLOT Keywords Accepted

See PLOT for the description of the following plotting keywords:

ISOTROPIC, MAX_VALUE, MIN_VALUE, NSUM, POLAR, THICK, XLOG, YLOG, YNOZERO

Examples

```
; Create some random data:
U = RANDOMN(S, 20, 20)
V = RANDOMN(S, 20, 20)

; Plot the vector field:
VELOVECT, U, V

; Plot the field, using dots to represent vectors with values
; greater than 18:
VELOVECT, U, V, MISSING=18, /DOTS
```

```
; Plot with a title. Note that the XTITLE keyword is passed
; directly to the PLOT procedure:
VELOVECT, U, V, MISSING=18, /DOTS, XTITLE='Random Vectors'
```

FLOW3, PLOT, PLOT_FIELD, VEL

VERT_T3D

The VERT_T3D function transforms a 3-D array by a 4x4 transformation matrix. The 3-D points are typically an array of polygon vertices that were generated by SHADE_VOLUME or MESH_OBJ.

This routine is written in the IDL language. Its source code can be found in the file vert_t3d.pro in the lib subdirectory of the IDL distribution.

Syntax

Result = VERT_T3D(*Vertex_List* [, DOUBLE=*value*] [, MATRIX=*4x4_array*] [, /NO_COPY] [, /NO_DIVIDE [, SAVE_DIVIDE=*variable*]])

Return Value

Returns the single- or double-precision coordinates of the transformed array.

Arguments

Vertex_List

A 3 x *n* array of 3-D coordinates to transform.

Keywords

DOUBLE

Set this keyword to a nonzero value to indicate that the returned coordinates should be double-precision. If this keyword is not set, the default is to return single-precision coordinates (unless double-precision arguments are input, in which case the DOUBLE keyword is implied to be non-zero).

MATRIX

The 4x4 transformation matrix to use. The default is to use the system viewing matrix (!P.T).

NO_COPY

Normally, a copy of *Vertex_list* is transformed and the original *Vertex_list* is preserved. If NO_COPY is set, however, then the original *Vertex_List* will be undefined after the call to VERT_T3D. Using the NO_COPY requires less memory.

NO_DIVIDE

Normally, when a [*x*, *y*, *z*, 1] vector is transformed by a 4x4 matrix, the final homogeneous coordinates are obtained by dividing the *x*, *y*, and *z* components of the result vector by the fourth element in the result vector. Setting the NO_DIVIDE keyword will prevent VERT_T3D from performing this division. In some cases (usually when a perspective transformation is involved) the fourth element in the result vector can be very close to (or equal to) zero.

SAVE_DIVIDE

Set this keyword to a named variable that will hold receive the fourth element of the transformed vector(s). If *Vertex_list* is a vector then SAVE_DIVIDE is a scalar. If *Vertex_list* is an array then SAVE_DIVIDE is an array of *n* elements. This keyword only has effect when the NO_DIVIDE keyword is set.

Examples

Transform four points representing a square in the x-y plane by first translating +2.0 in the positive X direction, and then rotating 60.0 degrees about the Y axis.

```
points = [[0.0, 0.0, 0.0], [1.0, 0.0, 0.0], $
          [1.0, 1.0, 0.0], [0.0, 1.0, 0.0]]
T3D, /RESET
T3D, TRANSLATE=[2.0, 0.0, 0.0]
T3D, ROTATE=[0.0, 60.0, 0.0]
points = VERT_T3D(points)
```

T3D

VOIGT

The VOIGT function returns the value of the classical Voigt function, H(a, u), defined in terms of the Voigt damping parameter a and the frequency offset u:

$$H(a, u) = \frac{a}{\pi} \int_{-\infty}^{\infty} \frac{e^{-y^2}dy}{a^2 + (u - y)^2}$$

The dimensionless frequency offset u and the damping parameter a are determined by:

$$u = \frac{\nu - \nu_0}{\Delta\nu_D}$$

$$a = \frac{\Gamma}{4\pi\Delta\nu_D}$$

where ν_0 is the line center frequency and the Doppler width $\Delta\nu_D$ (assuming no turbulence), is defined as:

$$\Delta\nu_D = \frac{\nu_0}{c}b = \frac{\nu_0}{c}\sqrt{2kT/m}$$

and, Γ is the transition rate:

$$\Gamma = \gamma + 2\nu_{col}$$

where γ is the spontaneous decay rate, and ν_{col} is the atomic collision rate. (See *Radiative Processes in Astrophysics* by G. B. Rybicki and A. P. Lightman (1979) p. 291 for more information.)

The Voigt function can be used to compute the intensity of an atomic absorption line profile (also known as a VOIGT profile). The line profile $\phi(a, u)$ is defined as:

$$\phi(a, u) \equiv \frac{H(a, u)}{\Delta\nu_D\sqrt{\pi}}$$

The algorithm is from Armstrong, *JQSRT 7*, 85. (1967). The definition of the classical Voigt function H(*a*,*u*) can be found in Equation 7.4.13 of Abramowitz, M. and Stegun, I.A., 1964, *Handbook of Mathematical Functions* (Washington:National Bureau of Standards).

Syntax

Result = VOIGT(*A*, *U*)

Return Value

If both arguments are scalars, the function returns a scalar. If both arguments are arrays, the function matches up the corresponding elements of A and U, returning an array with the same dimensions as the smallest array. If one argument is a scalar and the other argument is an array, the function uses the scalar value with each element of the array, and returns an array with the same dimensions as the smallest input array. If A is double-precision, the result is double-precision, otherwise the result is single-precision.

Arguments

A

A scalar or array specifying the values for the Voigt damping parameter.

U

A scalar or array specifying the values for the dimensionless frequency offset in Doppler widths.

Keywords

Thread Pool Keywords

This routine is written to make use of IDL's *thread pool*, which can increase execution speed on systems with multiple CPUs. The values stored in the !CPU system variable control whether IDL uses the thread pool for a given computation. In addition, you can use the thread pool keywords TPOOL_MAX_ELTS, TPOOL_MIN_ELTS, and TPOOL_NOTHREAD to override the defaults established by !CPU for a single invocation of this routine. See Appendix C, "Thread Pool Keywords" for details.

LEEFILT, ROBERTS, SOBEL

VORONOI

The VORONOI procedure computes the Voronoi polygon of a point within an irregular grid of points, given the Delaunay triangulation. The Voronoi polygon of a point contains the region closer to that point than to any other point.

For interior points, the polygon is constructed by connecting the midpoints of the lines connecting the point with its Delaunay neighbors. Polygons are traversed in a counterclockwise direction.

For exterior points, the set is described by the midpoints of the connecting lines, plus the circumcenters of the two triangles that connect the point to the two adjacent exterior points.

This routine is written in the IDL language. Its source code can be found in the file `voronoi.pro` in the `lib` subdirectory of the IDL distribution.

Syntax

VORONOI, *X*, *Y*, *I0*, *C*, *Xp*, *Yp*, *Rect*

Arguments

X

An array containing the X locations of the points.

Y

An array containing the Y locations of the points.

I0

An array containing the indices of the points.

C

A connectivity list from the Delaunay triangulation. This list is produced with the CONNECTIVITY keyword of the TRIANGULATE procedure.

Xp, Yp

Named variables that will contain the X and Y vertices of Voronoi polygon.

Rect

The bounding rectangle: [Xmin, Ymin, Xmax, Ymax]. Because the Voronoi polygon (VP) for points on the convex hull extends to infinity, a clipping rectangle must be supplied to close the polygon. This rectangle has no effect on the VP of interior points. If this rectangle does not enclose all the Voronoi vertices, the results will be incorrect. If this parameter, which must be a named variable, is undefined or set to a scalar value, it will be calculated.

Examples

To draw the Voronoi polygons of each point of an irregular grid:

```
N = 20

; Create a random grid of N points:
X = RANDOMU(seed, N)
Y = RANDOMU(seed, N)

; Triangulate it:
TRIANGULATE, X, Y, tr, CONN=C

FOR I=0, N-1 DO BEGIN & $
   ; Get the ith polygon:
   VORONOI, X, Y, I, C, Xp, Yp & $
      ; Draw it:
      POLYFILL, Xp, Yp, COLOR = (I MOD 10) + 2 & $
ENDFOR
```

TRIANGULATE

VOXEL_PROJ

The VOXEL_PROJ function generates visualizations of volumetric data by computing 2-D projections of a colored, semi-transparent volume. Parallel rays from any given direction are cast through the volume, onto the viewing plane. User-selected colors and opacities can be assigned to arbitrary data ranges, simulating the appearance of the materials contained within the volume.

The VOXEL_PROJ function can be combined with the Z-buffer to render volume data over objects. Cutting planes can also be specified to view selected portions of the volume. Other options include: selectable resolution to allow quick "preview" renderings, and average and maximum projections.

VOXEL_PROJ renders volumes using an algorithm similar to the one described by Drebin, Carpenter, and Hanrahan, in "Volume Rendering", *Computer Graphics*, Volume 22, Number 4, August 1988, pp. 125-134, but without the surface extraction and enhancement step.

Voxel rendering can be quite time consuming. The time required to render a volume is proportional to the viewing areas size, in pixels, times the thickness of the volume cube in the viewing direction, divided by the product of the user-specified X, Y, and Z steps.

Note ───

It is necessary to use SCALE3 to initialize a display before calling VOXEL_PROJ as shown in the following Examples section.

──

Syntax

Result = VOXEL_PROJ(*V* [, *RGBO*] [, BACKGROUND=*array*]
   [, CUTTING_PLANE=*array*] [, /INTERPOLATE]
   [, /MAXIMUM_INTENSITY] [, STEP=*[Sx, Sy, Sz]*] [, XSIZE=*pixels*]
   [, YSIZE=*pixels*] [, ZBUFFER=*int_array*] [, ZPIXELS=*byte_array*])

Return Value

Returns the specified voxel projection results.

Arguments

V

A three-dimensional array containing the volume to be rendered. This array is converted to byte type if necessary.

RGBO

This optional parameter is used to specify the look-up tables that indicate the color and opacity of each voxel value. This argument can be one of the following types:

- A (256, 4) byte array for TrueColor rendering. This array represents 256 sets of red, green, blue, and opacity (RGBO) components for each voxel value, scaled into the range of bytes (0 to 255). The R, G, and B components should already be scaled by the opacity. For example, if a voxel value of 100 contains a material that is red, and 35% opaque, the RGBO values should be, respectively: [89, 0, 0, 89] because $255 * 0.35 = 89$. If more than one material is present, the RGBO arrays contain the sum of the individual RGBO arrays. The content and shape of the RGBO curves is highly dependent upon the volume data and experimentation is often required to obtain the best display.

- A (256, 2) byte array for volumes with only one material or monochrome rendering. This array represents 256 sets of pixel values and their corresponding opacities for each voxel value.

- If this argument is omitted, the average projection method, or maximum intensity method (if the MAXIMUM_INTENSITY keyword is set) is used.

Keywords

BACKGROUND

A one- or three-element array containing the background color indices. The default is (0,0,0), yielding a black background with most color tables.

CUTTING_PLANE

A floating-point array specifying the coefficients of additional cutting planes. The array has dimensions of (4, N), where N is the number of additional cutting planes from 1 to 6. Cutting planes are constraints in the form of:

$$C[0] * X + C[1] * Y + C[2] * Z + D > 0$$

The X, Y, and Z coordinates are specified in voxel coordinates. For example, to specify a cutting plane that excludes all voxels with an X value greater than 10:

CUTTING_PLANE = [-1.0, 0, 0, 10.], for the constraint: -X + 10 > 0.

INTERPOLATE

Set this keyword to use tri-linear interpolation to determine the data value for each step on a ray. Otherwise, the nearest-neighbor method is used. Setting this keyword improves the quality of images produced, especially when the volume has low resolution in relation to the size of the viewing plane, at the cost of more computing time.

MAXIMUM_INTENSITY

Set this keyword to make the value of each pixel in the viewing plane the maximum data value along the corresponding ray. The *RGBO* argument is ignored if present.

STEP

Set this keyword to a three-element vector, [*Sx*, *Sy*, *Sz*], that controls the resolution of the resulting projection. The first two elements contain the step size in the X and Y view plane, in pixels. The third element is the sampling step size in the Z direction, given in voxels. *Sx* and *Sy* must be integers equal to or greater than one, while *Sz* can contain a fractional part. If *Sx* or *Sy* are greater than one, the values of intermediate pixels in the output image are linearly interpolated. Higher step sizes require less time because fewer rays are cast, at the expense of lower resolution in the output image.

XSIZE

The width, in pixels, of the output image. If this keyword is omitted, the output image is as wide as the currently-selected output device.

YSIZE

The height, in pixels, of the output image. If this keyword is omitted, the output image is as tall as the currently selected output device.

ZBUFFER

An integer array, with the same width and height as the output image, that contains the depth portion of the Z-buffer. Include this parameter to combine the previously-read contents of a Z-buffer with a voxel rendering. See the third example, below, for details.

ZPIXELS

A byte array, with the same width and height as the output image, that contains the image portion of the Z-buffer. Include this parameter to combine the contents of a Z-buffer with a voxel rendering. See the third example, below, for details.

Examples

Example 1

In the following example, assume that variable V contains a volume of data, with dimensions Vx by Vy by Vz. The volume contains two materials, muscle tissue represented by a voxel range of 50 to 70, that we want to render with red color, and an opacity of 20; and bone tissue represented by a voxel range of 220-255, that we want to render with white color, and an opacity of 50:

```
; Create the opacity vector:
rgbo = BYTARR(256,4, /NOZERO)

; Red and opacity for muscle:
rgbo[50:70, [0,3]] = 20

; White and opacity for bone:
rgbo[220:255, *] = 50
```

Example 2

Although it is common to use trapezoidal or Gaussian functions when forming the RGBO arrays, this example uses rectangular functions for simplicity.

```
; Set up the axis scaling and default rotation:
SCALE3, XRANGE=[0, Vx-1], YRANGE=[0, Vy-1], ZRANGE=[0, Vz-1]

; Compute projected image:
C = VOXEL_PROJ(V, rgbo)

; Convert from 24-bit to 8-bit image and display:
TV, COLOR_QUAN(C, 3, R, G, B)

; Load quantized color tables:
TVLCT, R, G, B
```

This example required approximately 27 seconds on a typical workstation to compute the view in a 640- by 512-pixel viewing window. Adding the keyword STEP=[2,2,1] in the call to VOXEL_PROJ decreased the computing time to about 8 seconds, at the expense of slightly poorer resolution.

When viewing a volume with only one constituent, the RGBO array should contain only an intensity/opacity value pair. To illustrate, if in the above example, only muscle was of interest we create the RGBO argument as follows:

```
; Create an empty 256 x 2 array:
rgbo = BYTARR(256,2, /NOZERO)

; Intensity and opacity for muscle:
rgbo[50:70, *] = 20
SCALE3, XRANGE=[0, Vx-1], YRANGE=[0, Vy-1], ZRANGE=[0, Vz-1]

; Compute and display the projected image:
TV, VOXEL_PROJ(V, rgbo)

; Create color table array for red:
C = (FINDGEN(256)/255.) # [255., 0., 0]

; Load colors:
TVLCT, C[*,0], C[*,1], C[*,2]
```

Example 3

This example demonstrates combining a volume with the contents of the Z-buffer:

```
; Set plotting to Z-buffer:
SET_PLOT, 'Z'

; Turn on Z buffering:
DEVICE, /Z_BUFFER

; Set scaling:
SCALE3, XRANGE=[0, Vx-1], YRANGE=[0, Vy-1], ZRANGE=[0, Vz-1]

; Draw a polygon at z equal to half the depth:
POLYFILL, [0, Vx-1, Vx-1, 0], [0, 0, Vy-1, Vy-1], Vz/2., /T3D

; Read pixel values from the Z-buffer:
zpix = TVRD()

; Read depth values from the Z-buffer:
zbuff = TVRD(/WORDS,/CHAN)

; Back to display window:
SET_PLOT, 'X'

; Compute the voxel projection and use the ZPIXELS and ZBUFFER
; keywords to combine the volume with the previously-read contents
; of the Z-buffer:
C = VOXEL_PROJ(V, rgbo, ZPIX=zpix, ZBUFF=zbuff)
```

```
; Convert from 24-bit to 8-bit image.
IMAGE = COLOR_QUAN(C, 3, R, G, B)

; Load the quantized color tables:
TVLCT, R, G, B

; Display
TV, IMAGE
```

Routines: W

WAIT

The WAIT procedure suspends execution of an IDL program for a specified period. Note that because of other activity on the system, the duration of program suspension may be longer than requested.

Syntax

WAIT, *Seconds*

Arguments

Seconds

The duration of the wait, specified in seconds. This parameter can be a floating-point value to specify a fractional number of seconds.

Keywords

None.

Examples

To make an IDL program suspend execution for about five and one half seconds, use the command:

```
WAIT, 5.5
```

EXIT, STOP

WARP_TRI

The WARP_TRI function returns an image array with a specified geometric correction applied. Images are warped using control (tie) points such that locations (*Xi, Yi*) are shifted to (*Xo*, *Yo*).

The irregular grid defined by (*Xo, Yo*) is triangulated using TRIANGULATE. Then the surfaces defined by (*Xo, Yo, Xi*) and (*Xo, Yo, Yi*) are interpolated using TRIGRID to get the locations in the input image of each pixel in the output image. Finally, INTERPOLATE is called to obtain the result. Linear interpolation is used by default. Smooth quintic interpolation is used if the QUINTIC keyword is set.

This routine is written in the IDL language. Its source code can be found in the file `warp_tri.pro` in the `lib` subdirectory of the IDL distribution.

Syntax

Result = WARP_TRI(*Xo*, *Yo*, *Xi*, *Yi*, *Image* [, OUTPUT_SIZE=*vector*] [, /QUINTIC]
   [, /EXTRAPOLATE] [, /TPS])

Return Value

Returns the warped image array.

Arguments

Xo, Yo

Vectors containing the locations of the control (tie) points in the output image.

Xi, Yi

Vectors containing the location of the control (tie) points in the input image. *Xi* and *Yi* must be the same length as *Xo* and *Yo*.

Image

The image to be warped. Can be any type of data.

Keywords

OUTPUT_SIZE

Set this keyword equal to a 2-element vector containing the size of the output image. If omitted, the output image is the same size as *Image*.

QUINTIC

Set this keyword to use smooth quintic interpolation. Quintic interpolation is slower, but the derivatives are continuous across triangles, giving a more pleasing result than the default linear interpolation.

EXTRAPOLATE

Set this keyword to extrapolate outside the convex hull of the tie points. Setting this keyword implies the use of QUINTIC interpolation.

TPS

Set this keyword to use Thin Plate Spline interpolation, which interpolates a set of irregularly sampled data value over a regular two dimensional grid. Thin plate splines are ideal for modeling functions with complex local distortions, such as warping functions, which are too complex to be fit with polynomials.

Examples

This example produces a warped image of the world, where the irregular grid has been created using smooth quintic interpolation. The displayed image is in black and white.

INTERPOLATE, TRIANGULATE, TRIGRID

WATERSHED

The WATERSHED function applies the morphological watershed operator to a grayscale image. This operator segments images into watershed regions and their boundaries. Considering the gray scale image as a surface, each local minimum can be thought of as the point to which water falling on the surrounding region drains. The boundaries of the watersheds lie on the tops of the ridges. This operator labels each watershed region with a unique index, and sets the boundaries to zero.

Typically, morphological gradients, or images containing extracted edges are used for input to the watershed operator. Noise and small unimportant fluctuations in the original image can produce spurious minima in the gradients, which leads to oversegmentation. Smoothing, or manually marking the seed points are two approaches to overcoming this problem. For further reading, see Dougherty, "An Introduction to Morphological Image Processing", SPIE Optical Engineering Press, 1992.

Syntax

Result = WATERSHED (*Image* [, CONNECTIVITY={4 | 8}] [, /LONG]
   [, NREGIONS=*variable*])

Return Value

Returns an integer array of the same dimensions as the input image. An element of the *Result* array contains the integer identifier of the watershed region in which the corresponding pixel falls, or a zero if the corresponding pixel falls along the separation between regions.

Note

If the LONG keyword is set, *Result* is an array of long integers; otherwise it is an array of short integers. If the LONG keyword is *not* set, *Result* will be clipped to a maximum of 65530 regions. (Regions above 32767 will have negative values; if you have more than 32767 regions you may want to convert your *Result* to unsigned integers using UINT). Use the NREGIONS keyword to determine the actual number of regions.

Arguments

Image

The two-dimensional image to be segmented. *Image* is converted to byte type if necessary.

Keywords

CONNECTIVITY

Set this keyword to either 4 (to select 4-neighbor connectivity) or 8 (to select 8-neighbor connectivity). Connectivity indicates which pixels in the neighborhood of a given pixel are sampled during the segmentation process. 4-neighbor connectivity samples only the pixels that are immediately adjacent horizontally and vertically. 8-neighbor connectivity samples the diagonally adjacent neighbors in addition to the immediate horizontal and vertical neighbors. The default is 4-neighbor connectivity.

LONG

Set this keyword to return an array of long integers, instead of short integers. This keyword is useful if your image contains more than 32766 regions.

NREGIONS

Set this keyword to a named variable that will contain the total number of regions within *Image*. In most cases, this will be equal to the maximum value of *Result*.

Tip
If the LONG keyword is *not* set, and NREGIONS is greater than 32766, then the *Result* overflowed the maximum. If this occurs, you may wish to re-run WATERSHED with the LONG keyword set.

Examples

Note
Also see "Creating Image Object Boundaries" (Chapter 9, *Image Processing in IDL*).

The following code crudely segments the grains in the data file in the IDL Demo data directory containing a magnified image of grains of pollen. Note that the IDL Demos must be installed in order to read the image used in this example.

It inverts the image, because the watershed operator finds holes, brightening the grains of pollen. Next, the morphological closing operator is applied with a disc of radius 9, contained within a 19 by 19 kernel, to eliminate holes in the image smaller than the disc. The watershed operator is then applied to segment this image. The borders of the watershed images, which have pixel values of zero, are then merged with the original image and displayed as white.

```
;Radius of disc...
r = 9

;Create a disc of radius r
disc = SHIFT(DIST(2*r+1), r, r) LE r

;Read the image
READ_JPEG, FILEPATH('pollens.jpg', $
   SUBDIR=['examples','demo','demodata']), a

;Invert the image
b = MAX(a) - a

TVSCL, b, 0

;Remove holes of radii less than r
c = MORPH_CLOSE(b, disc, /GRAY)

TVSCL, c, 1

;Create watershed image
d = WATERSHED(c)

;Display it, showing the watershed regions
TVSCL, d, 2

;Merge original image with boundaries of watershed regions
e = a > (MAX(a) * (d EQ 0b))

TVSCL, e, 3
```

6.1	Added LONG and NREGIONS keywords

Wavelet Toolkit

For information, see the *Chapter 1, "Introduction to the IDL Wavelet Toolkit"* (*IDL Wavelet Toolkit*).

WDELETE

The WDELETE procedure deletes IDL windows.

Syntax

WDELETE [, *Window_Index* [, ...]]

Arguments

Window_Index

A list of one or more window indices to delete. If this argument is not specified, the current window (as specified by the system variable !D.WINDOW) is deleted. If the window being deleted is not the active window, the value of !D.WINDOW remains unchanged. If the window being deleted is the active window, !D.WINDOW is set to the highest numbered window index or to -1 if no windows remain open.

If this window index is the widget ID of a draw widget, that widget is deleted.

Keywords

None.

Examples

Create IDL graphics window number 5 by entering:

```
WINDOW, 5
```

Delete window 5 by entering:

```
WDELETE, 5
```

WF_DRAW

The WF_DRAW procedure draws weather fronts of various types using parametric spline interpolation to smooth the lines. WF_DRAW uses the POLYFILL routine to make the annotations on the front lines.

This routine is written in the IDL language. Its source code can be found in the file `wf_draw.pro` in the `lib` subdirectory of the IDL distribution.

Syntax

WF_DRAW, *X*, *Y* [[, /COLD | , FRONT_TYPE=1] | [, /WARM | , FRONT_TYPE=2] | [, /OCCLUDED | , FRONT_TYPE=3] | [, /STATIONARY | , FRONT_TYPE=4] | [, /CONVERGENCE | , FRONT_TYPE=5]] [, COLOR=*value*] [, /DATA | , /DEVICE | , /NORMAL] [, INTERVAL=*value*] [, PSYM=*value*] [, SYM_HT=*value*] [, SYM_LEN=*value*] [, THICK=*value*]

Arguments

X, Y

Vectors of abscissae and ordinates defining the front to be drawn.

Keywords

COLD

Set this keyword to draw a cold front. The default is a plain line with no annotations. A cold front can also be specified by setting the keyword FRONT_TYPE = 1.

COLOR

Use this keyword to specify the color to use. The default = !P.COLOR.

CONVERGENCE

Set this keyword to draw a convergence line. A convergence line can also be specified by setting the keyword FRONT_TYPE = 5.

DATA

Set this keyword if X and Y are specified in data coordinates.

DEVICE

Set this keyword if X and Y are specified in device coordinates.

FRONT_TYPE

Set this keyword equal to the numeric index of type of front to draw. Front type indices are as follows: COLD=1, WARM=2, OCCLUDED=3, STATIONARY=4, CONVERGENCE = 5. Not required if plain line is desired or if an explicit front type keyword is specified.

INTERVAL

Use this keyword to specify the spline interpolation interval, in normalized units. The default = 0.01. Larger values give coarser approximations to curves, smaller values make more interpolated points.

NORMAL

Set this keyword if X and Y are specified in normalized coordinates. This is the default.

OCCLUDED

Set this keyword to draw an occluded front. An occluded front can also be specified by setting the keyword FRONT_TYPE = 3.

PSYM

Set this keyword a standard PSYM value to draw a marker on each actual (*X*, *Y*) data point. See "PSYM" on page 5471 for a list of the symbol types.

STATIONARY

Set this keyword to draw a stationary front. A stationary front can also be specified by setting the keyword FRONT_TYPE = 4.

SYM_HT

Use this keyword to specify the height of front symbols, in normalized units. The default = 0.02.

SYM_LEN

Use this keyword to specify the length and spacing factor for front symbols, in normalized units. The default = 0.15.

THICK

Use this keyword to specify the line thickness. The default = 1.0.

WARM

Set this keyword to draw a warm front. A warm front can also be specified by setting the keyword FRONT_TYPE = 2.

Examples

This example draws various fronts on a map of the United States.

Note that this example code is in `wf_draw.pro` in the `lib` subdirectory of the IDL installation directory, and can be run by entering `test_wf_draw` at the IDL command line.

```
PRO test_wf_draw

 MAP_SET, LIMIT = [25, -125, 50, -70], /GRID, /USA

ANNOTATE, XYOUTS

WHERE

The WHERE function returns a vector that contains the one-dimensional subscripts of the nonzero elements of *Array_Expression*. The length of the resulting vector is equal to the number of nonzero elements in *Array_Expression*. Frequently the result of WHERE is used as a vector subscript to select elements of an array using given criteria.

Note: When WHERE Returns –1

If all the elements of *Array_Expression* are zero, WHERE returns a scalar integer with a value of –1. Attempting to use this result as an index into another array results in a "subscripts out of bounds" error. In situations where this is possible, code similar to the following can be used to avoid errors:

```
; Use Count to get the number of nonzero elements:
index = WHERE(array, count)

; Only subscript the array if it's safe:
IF count NE 0 THEN result = array[index]
```

Syntax

Result = WHERE(*Array_Expression* [, *Count*] [, COMPLEMENT=*variable*]
    [, /L64] [, NCOMPLEMENT=*variable*])

Return Value

Returns a longword vector containing the subscripts of non-zero array elements matching the specified conditions.

Arguments

Array_Expression

The array to be searched. Both the real and imaginary parts of a complex number must be zero for the number to be considered zero.

Count

A named variable that will receive the number of nonzero elements found in *Array_Expression*. This value is returned as a longword integer.

Note ———————————————————————————————————

The system variable !ERR is set to the number of nonzero elements. This effect is for compatibility with previous versions of IDL and should *not* be used in new code. Use the COUNT argument to return this value instead.

———

Keywords

COMPLEMENT

Set this keyword to a named variable that receives the subscripts of the zero elements of *Array_Expression*. These are the subscripts that are not returned in *Result*. Together, *Result* and COMPLEMENT specify every subscript in *Array_Expression*. If there are no zero elements in *Array_Expression*, COMPLEMENT returns a scalar integer with the value -1.

L64

By default, the result of WHERE is 32-bit integer when possible, and 64-bit integer if the number of elements being processed requires it. Set L64 to force 64-bit integers to be returned in all cases.

Note ———————————————————————————————————

Only 64-bit versions of IDL are capable of creating variables requiring a 64-bit result. Check the value of !VERSION.MEMORY_BITS to see if your IDL is 64-bit or not.

———

NCOMPLEMENT

Set this keyword to a named variable that receives the number of zero elements found in *Array_Expression*. This value is the number of subscripts that will be returned via the COMPLEMENT keyword if it is specified.

Thread Pool Keywords

This routine is written to make use of IDL's *thread pool*, which can increase execution speed on systems with multiple CPUs. The values stored in the !CPU system variable control whether IDL uses the thread pool for a given computation. In addition, you can use the thread pool keywords TPOOL_MAX_ELTS, TPOOL_MIN_ELTS, and TPOOL_NOTHREAD to override the defaults established by !CPU for a single invocation of this routine. See Appendix C, "Thread Pool Keywords" for details.

Examples

> **Note** ───────────────────────────────────
> Also see "Locating Pixel Values in an Image" (Chapter 4, *Image Processing in IDL*).

Example 1

```
; Create a 10-element integer array where each element is
; set to the value of its subscript:
array = INDGEN(10)
PRINT, 'array = ', array

; Find the subscripts of all the elements in the array that have
; a value greater than 5:
B = WHERE(array GT 5, count, COMPLEMENT=B_C, NCOMPLEMENT=count_c)

; Print how many and which elements met the search criteria:
PRINT, 'Number of elements > 5: ', count
PRINT, 'Subscripts of elements > 5: ', B
PRINT, 'Number of elements <= 5: ', count_c
PRINT, 'Subscripts of elements <= 5: ', B_C
```

IDL prints:

```
array = 0  1  2  3  4  5  6  7  8  9
Number of elements > 5:  4
Subscripts of elements > 5:  6  7  8  9
Number of elements <= 5:  6
Subscripts of elements <= 5:  0  1  2  3  4  5
```

Example 2

The WHERE function behaves differently with different kinds of array expressions. For instance, if a relational operator is used to compare an array, A, with a scalar, B, then every element of A is searched for B. However, if a relational operator is used to compare two arrays, C and D, then a comparison is made between each corresponding element (i.e. C_i & D_i, C_{i+1} & D_{i+1}, etc) of the two arrays. If the two arrays have different lengths then a comparison is only made up to the number of elements for the shorter array. The following example illustrates this behavior:

```
; Compare array, a, and scalar, b:
a = [1,2,3,4,5,5,4,3,2,1]
b = 5
PRINT, 'a = ', a
PRINT, 'b = ', b
```

```
result=WHERE(a EQ b)
PRINT,'Subscripts of a that equal b: ', result

; Now compare two arrays of different lengths:
c = [1,2,3,4,5,5,4,3,2,1]
d = [0,2,4]
PRINT, 'c = ', c
PRINT, 'd = ', d

result=WHERE(c EQ d)
PRINT, 'Subscripts of c that equal d: ', result
```

IDL prints:

```
a = 1  2  3  4  5  5  4  3  2  1
b = 5
Subscripts of a that equal b:  4  5

c = 1  2  3  4  5  5  4  3  2  1
d = 0  2  4
Subscripts of c that equal d: 1
```

Note that WHERE found only one element in the array d that equals an element in array c. This is because only the first three elements of c were searched, since d has only three elements.

ARRAY_INDICES, UNIQ, "Conditionally Altering Array Elements" (Chapter 15, *Application Programming*)

WHILE...DO

The WHILE...DO statement performs its subject statement(s) as long as the expression evaluates to true. The subject is never executed if the condition is initially false.

Note

For information on using WHILE...DO and other IDL program control statements, see Chapter 7, "Program Control" (*Application Programming*).

Syntax

WHILE *expression* DO *statement*

or

WHILE *expression* DO BEGIN

  statements

ENDWHILE

Examples

```
i = 0
WHILE (i EQ 1) DO PRINT, i
```

Because the expression (which is false in this case) is evaluated before the subject statement is executed, this code yields no output.

BEGIN...END, BREAK, CASE, CONTINUE, FOR, GOTO, IF...THEN...ELSE, REPEAT...UNTIL, SWITCH, Chapter 7, "Program Control" (*Application Programming*)

WIDGET_ACTIVEX

The WIDGET_ACTIVEX function is used to incorporate an ActiveX control into an IDL widget hierarchy. It is available on 32-bit Microsoft Windows installations of IDL. (This function is not currently supported by 64-bit IDL for Windows.) An ActiveX widget instantiates an ActiveX control within an IDL widget hierarchy.

IDL provides the same object method and property manipulation facilities for ActiveX controls as it does for COM objects incorporated using the IDLcomIDispatch object interface, but adds the ability to process events generated by the ActiveX control using IDL's widget event handling mechanisms.

Note

IDL can only incorporate ActiveX controls on Windows 2000/XP (and later) platforms.

When you use the WIDGET_ACTIVEX routine, IDL automatically creates an IDLcomActiveX object that encapsulates the ActiveX control. You can then call the ActiveX control's methods using IDL object syntax, as discussed in Chapter 4, "Using ActiveX Controls in IDL" (*IDL Connectivity Bridges*). You should be familiar with the material in that chapter before attempting to incorporate ActiveX controls in your IDL programs.

Note

If the COM object you want to use in your IDL application is *not* an ActiveX control, use the IDLcomIDispatch object class.

Warning

When displaying an ActiveX form or dialog box, it is the responsibility of the COM object to pump messages. Modal dialogs pump messages themselves, but modeless dialogs do not. IDL's COM subsystem does not provide the ability to pump messages explicitly, giving IDL no way to pump messages while a modeless dialog is displayed. As a result, calling a modeless dialog from IDL will result in an error.

Syntax

Result = WIDGET_ACTIVEX(*Parent*, *COM_ID,* [, /ALIGN_BOTTOM | ,
   /ALIGN_CENTER | , /ALIGN_LEFT | , /ALIGN_RIGHT | , /ALIGN_TOP]
   [, EVENT_FUNC=*string*] [, EVENT_PRO=*string*]
   [, FUNC_GET_VALUE=*string*] [ID_TYPE=*value*] [, KILL_NOTIFY=*string*]
   [, /NO_COPY] [, NOTIFY_REALIZE=*string*] [, PRO_SET_VALUE=*string*]

[, SCR_XSIZE=*width*] [, SCR_YSIZE=*height*] [, /SENSITIVE]
[, UNAME=*string*] [, UNITS={0 | 1 | 2}] [, UVALUE=*value*]
[, XOFFSET=*value*] [, XSIZE=*value*] [, YOFFSET=*value*] [, YSIZE=*value*])

Return Value

The returned value is the widget ID of the ActiveX widget. Note that the *widget value* of the ActiveX widget is an object reference to the IDLcomActiveX object that encapsulates the specified ActiveX control. The value cannot be set, and cannot be retrieved before the widget is realized.

Arguments

Parent

The widget ID of the parent widget of the new ActiveX control.

COM_ID

A string value specifying the class or program ID of the COM object to create. Note that if you specify a COM program ID via this argument, you must also set the ID_TYPE keyword.

Note

The class or program ID must follow the standard Microsoft naming convention. See Chapter 4, "Using ActiveX Controls in IDL" (*IDL Connectivity Bridges*) for more on class and program IDs, and their use with WIDGET_ACTIVEX.

Keywords

ALIGN_BOTTOM

Set this keyword to align the new widget with the bottom of its parent base. To take effect, the parent must be a ROW base.

ALIGN_CENTER

Set this keyword to align the new widget with the center of its parent base. To take effect, the parent must be a ROW or COLUMN base. In ROW bases, the new widget will be vertically centered. In COLUMN bases, the new widget will be horizontally centered.

ALIGN_LEFT

Set this keyword to align the new widget with the left side of its parent base. To take effect, the parent must be a COLUMN base.

ALIGN_RIGHT

Set this keyword to align the new widget with the right side of its parent base. To take effect, the parent must be a COLUMN base.

ALIGN_TOP

Set this keyword to align the new widget with the top of its parent base. To take effect, the parent must be a ROW base.

EVENT_FUNC

A string containing the name of a function to be called by the WIDGET_EVENT function when an event arrives from a widget in the widget hierarchy rooted at the newly-created widget.

EVENT_PRO

A string containing the name of a procedure to be called by the WIDGET_EVENT function when an event arrives from a widget in the widget hierarchy rooted at the newly-created widget.

FUNC_GET_VALUE

A string containing the name of a function to be called when the GET_VALUE keyword to the WIDGET_CONTROL procedure is called for this widget. Using this technique allows you to change the value that should be returned for a widget. Compound widgets use this ability to define their values transparently to the user.

ID_TYPE

The type of COM object ID specified by the *COM_ID* parameter (class or program). If set to 0 (zero), the value is a class ID (the default). If set to 1 (one), the value is a program ID.

KILL_NOTIFY

Set this keyword to a string that contains the name of a procedure to be called automatically when the specified widget dies. Each widget is allowed a single such callback procedure. It can be removed by setting the routine to the null string (`' '`).

The callback routine is called with the widget identifier as its only argument. At that point, the widget identifier can only be used with the WIDGET_CONTROL procedure to get or set the user value. All other requests that require a widget ID are disallowed for the target widget. The callback is not issued until the WIDGET_EVENT function is called.

NO_COPY

Usually, when setting or getting widget user values, either at widget creation or using the SET_UVALUE and GET_UVALUE keywords to WIDGET_CONTROL, IDL makes a second copy of the data being transferred. Although this technique is fine for small data, it can have a significant memory cost when the data being copied is large.

If the NO_COPY keyword is set, IDL handles these operations differently. Rather than copy the source data, it takes the data away from the source and attaches it directly to the destination. This feature can be used by compound widgets to obtain state information from a UVALUE without all the memory copying that would otherwise occur. However, it has the side effect of causing the source variable to become undefined. On a "set" operation (using the UVALUE keyword to WIDGET_BASE or the SET_UVALUE keyword to WIDGET_CONTROL), the variable passed as value becomes undefined. On a "get" operation (GET_UVALUE keyword to WIDGET_CONTROL), the user value of the widget in question becomes undefined.

NOTIFY_REALIZE

Set this keyword to a string that contains the name of a procedure to be called automatically when the specified widget is realized. This callback occurs just once (because widgets are realized only once). Each widget is allowed a single such callback procedure. It can be removed by setting the routine to the null string (' '). The callback routine is called with the widget ID as its only argument.

PRO_SET_VALUE

A string containing the name of a procedure to be called when the SET_VALUE keyword to the WIDGET_CONTROL procedure is called for this widget. See the description of the PRO_SET_VALUE keyword to WIDGET_CONTROL for information on using this keyword.

SCR_XSIZE

Set this keyword to the desired "screen" width of the widget, in units specified by the UNITS keyword (pixels are the default). In many cases, setting this keyword is the same as setting the XSIZE keyword.

SCR_YSIZE

Set this keyword to the desired "screen" height of the widget, in units specified by the UNITS keyword (pixels are the default). In many cases, setting this keyword is the same as setting the YSIZE keyword.

SENSITIVE

Set this keyword to control the initial sensitivity state of the widget.

If SENSITIVE is zero, the widget becomes insensitive. If nonzero, it becomes sensitive. When a widget is sensitive, it has normal appearance and can receive user input. For example, a sensitive button widget can be activated by moving the mouse cursor over it and pressing a mouse button. When a widget is insensitive, it indicates the fact by changing its appearance, looking disabled, and it ignores any input.

Sensitivity can be used to control when a user is allowed to manipulate the widget. Note that some widgets do not change their appearance when they are made insensitive, but they cease generating events.

After creating the widget hierarchy, you can change the sensitivity state using the SENSITIVE keyword with the WIDGET_CONTROL procedure.

UNAME

Set this keyword to a string that can be used to identify the widget in your code. You can associate a name with each widget in a specific hierarchy, and then use that name to query the widget hierarchy and get the correct widget ID.

To query the widget hierarchy, use the WIDGET_INFO function with the FIND_BY_UNAME keyword. The UNAME should be unique to the widget hierarchy because the FIND_BY_UNAME keyword returns the ID of the widget with the specified name.

UNITS

Set this keyword to specify the units used when *supplying* measurements or position values. Set UNITS equal to 0 (zero) to specify that all measurements are in pixels (this is the default), to 1 (one) to specify that all measurements are in inches, or to 2 (two) to specify that all measurements are in centimeters. This keyword does not change the units used in a widget event structure or in most of the fields of the geometry structure returned by WIDGET_INFO.

UVALUE

The "user value" to be assigned to the widget.

Each widget can contain a user-specified value of any data type and organization. This value is not used by the widget in any way, but exists entirely for the convenience of the IDL programmer. This keyword allows you to set this value when the widget is first created.

If UVALUE is not present, the widget's initial user value is undefined.

The user value for a widget can be accessed and modified at any time by using the GET_UVALUE and SET_UVALUE keywords to the WIDGET_CONTROL procedure.

XOFFSET

The horizontal offset of the widget in units specified by the UNITS keyword (pixels are the default) relative to its parent.

Specifying an offset relative to a row or column major base widget does not work because those widgets enforce their own layout policies. This keyword is primarily of use relative to a plain base widget. Note that it is best to avoid using this style of widget layout.

XSIZE

The width of the widget in units specified by the UNITS keyword (pixels are the default). Most widgets attempt to size themselves to fit the situation. However, if the desired effect is not produced, use this keyword to override it. This keyword is only a "hint" to the toolkit and may be ignored in some situations.

YOFFSET

The vertical offset of the widget in units specified by the UNITS keyword (pixels are the default) relative to its parent. This offset is specified relative to the *upper left* corner of the parent widget.

Specifying an offset relative to a row or column major base widget does not work because those widgets enforce their own layout policies. This keyword is primarily of use relative to a plain base widget. Note that it is best to avoid using this style of widget layout.

YSIZE

The height of the widget in units specified by the UNITS keyword (pixels are the default). Most widgets attempt to size themselves to fit the situation. However, if the desired effect is not produced, use this keyword to override it. This keyword is only a "hint" to the toolkit and may be ignored in some situations.

Keywords to WIDGET_CONTROL

ActiveX widgets are controlled using the object methods of the underlying ActiveX control rather than via the WIDGET_CONTROL and WIDGET_INFO routines. The GET_VALUE keyword to the WIDGET_CONTROL procedure is used to retrieve an object reference to the IDLcomActiveX object that underlies the ActiveX widget. The object reference returned in this manner can be used to call the ActiveX control's native methods.

ActiveX Widget Events

ActiveX widgets return a basic widget event structure augmented by fields that are specific to the ActiveX control. See "ActiveX Widget Events" (Chapter 4, *IDL Connectivity Bridges*) for details.

Examples

For examples using WIDGET_ACTIVEX, see Chapter 4, "Using ActiveX Controls in IDL" (*IDL Connectivity Bridges*).

Version History

5.5	Introduced

WIDGET_BASE

The WIDGET_BASE function is used to create base widgets. Base widgets serve as containers for other widgets, including other base widgets. Base widgets can optionally contain scroll bars that allow the base to be larger than the space on the screen. In this case, only part of the base is visible at any given time, and the scroll bars are used to control which part is visible.

Note

In most cases, you will want to let IDL determine the placement of widgets within the base widget. Do this by specifying either the COLUMN keyword or the ROW keyword. See "Positioning Child Widgets Within a Base" in the following section for details.

Exclusive And Non-Exclusive Bases

If the EXCLUSIVE or NONEXCLUSIVE keywords are specified, the base only allows button widget children.

Positioning Child Widgets Within a Base

The standard base widget does not impose any placement constraints on its child widgets. Children of a "bulletin board" base (a base that was created without setting the COLUMN or ROW keywords) have an offset of (0,0) unless an offset is explicitly specified via the XOFFSET or YOFFSET keywords. This means that if you do not specify any of COLUMN, ROW, XOFFSET, or YOFFSET keywords, child widgets will be placed one on top of the other in the upper left corner of the base.

However, laying out widgets using the XSIZE, YSIZE, XOFFSET, and YOFFSET keywords can be both tedious and error-prone. Also, if you want your widget application to display properly on different platforms, you should use the COLUMN and ROW keywords to influence child widget layouts instead of explicitly formatting your interfaces.

When the ROW or COLUMN keywords are specified, the base decides how to lay out its children, and any XOFFSET and YOFFSET keywords specified for such children are ignored.

Positioning Top-Level Bases

Top-level bases are a special class of base widget created without a parent widget ID. Every widget hierarchy has exactly one top-level base. (Multiple widget hierarchies, represented by their top-level bases, can be organized into an application hierarchy by specifying the GROUP_LEADER keyword. (See "Using Multiple Widget Hierarchies" (Chapter 3, *Widget Application Programming*) for additional discussion of widget applications with multiple widget hierarchies.)

When locating a new top level window, some window managers ignore the program's positioning requests and either choose a position or allow the user to choose. In such cases, the XOFFSET and YOFFSET keywords to WIDGET_BASE will not have an effect. The window manager may provide a way to disable this positioning style. The Motif window manager (mwm) can be told to honor positioning requests by placing the following lines in your .Xdefaults file:

```
Mwm*clientAutoPlace: False
Mwm*interactivePlacement: False
```

Top-Level Base Positioning in Multi-Monitor Situations

In multi-monitor environments you can place your widget on any desired monitor. To do this, use the XOFFSET and YOFFSET keywords to WIDGET_BASE to position the widget on the desired monitor. If the monitors are configured as an extended desktop, XOFFSET and YOFFSET will be sufficient for locating the widget base on any monitor. In X Multi-Screen environments, you must also use the DISPLAY_NAME keyword to select the desired monitor. For more details, see IDLsysMonitorInfo.

If position is *not* specified, the top-level base widget is placed at [0,0] on the primary monitor.

If a position *is* specified that does not exist on any available monitor, or if a position selected would cause the widget to be partly off-screen, the widget will be positioned so that it is completely on the monitor that is closest to the specified position.

To move a widget off-screen, use the WIDGET_CONTROL function.

Note ───

Direct Graphics draw widgets cannot be used on the non-default DISPLAY in the X Multi-Screen environment. See "The X Windows Device" in Appendix A for details.

───

Iconizing, Layering, and Destroying Groups of Top-Level Bases

Group membership (defined via the GROUP_LEADER keyword) controls the way top-level base widgets are iconized, layered, and destroyed.

Note

A group can contain sub-groups. Group behavior affects all members of a group and its sub-groups. For example, suppose we create three top-level base widgets with the following group hierarchy:

```
base1 = WIDGET_BASE()
base2 = WIDGET_BASE(GROUP_LEADER=base1)
base3 = WIDGET_BASE(GROUP_LEADER=base2)
```

Effectively, two groups are created. One group has base2 as its leader and base3 as its member. The other group has base1 as its leader and both base2 and base3 as members. If base1 is iconized, both base2 and base3 are iconized as well. If base2 is iconized, base3 is iconized but base1 is not.

Widgets behave slightly differently when displayed on different platforms, and depending on whether they are floating or modal bases. The following rules apply to groups of widgets within a group leader/member hierarchy. Widgets that do not belong to the same group hierarchy cannot influence each other.

Iconization and Mapping

Bases and groups of bases can be *iconized* (or *minimized*) by clicking the system minimize control. Bases and groups of bases can also be *mapped* (made visible) and *unmapped* (made invisible).

Mapping or unmapping a group leader has no effect on the mapped state of the group members. Iconifying or mapping a group member has no effect on the group leader. Modal bases cannot be unmapped.

Bases and groups of bases can be iconized (or minimized) by clicking the system minimize control. When a group leader is iconized, all members of the group are iconized as well. Similarly, when a group leader is restored, all members of the group are restored.

Layering

Layering is the process by which groups of widgets seem to share the same plane on the display screen. Within a layer on the screen, widgets have a *Z-order*, or front-to-back order, that defines which widgets appear to be on top of other widgets.

Motif — All elements on the screen—widgets, the workbench, other Motif applications—share a single layer and have an arbitrary Z-order. There is no special layering of IDL widgets.

Windows — All non-floating and non-modal widgets within a group hierarchy share the same layer—that is, when one group member has the input focus, all members of the group hierarchy are displayed in a layer that appears in front of all other groups or applications. Within the layer, the widgets can have an arbitrary Z-order.

Widgets that are floating or modal always float above their group leaders.

Destruction

When a group leader widget is destroyed, either programmatically or by clicking on the system "close" button, all members of the group and all sub-groups are destroyed as well.

If a modal base is on the display, it must be dismissed before any widget can be destroyed.

Syntax

Result = WIDGET_BASE([*Parent*] [, /ALIGN_BOTTOM | , /ALIGN_CENTER | , /ALIGN_LEFT | , /ALIGN_RIGHT | , /ALIGN_TOP]
[, /BASE_ALIGN_BOTTOM | , /BASE_ALIGN_CENTER | , /BASE_ALIGN_LEFT | , /BASE_ALIGN_RIGHT | , /BASE_ALIGN_TOP]
[, BITMAP=*value*] [, COLUMN=*ncols* | , ROW=*nrows*]
[, /CONTEXT_EVENTS] [, /CONTEXT_MENU] [, EVENT_FUNC=*string*]
[, EVENT_PRO=*string*] [, /EXCLUSIVE | , /NONEXCLUSIVE] [, /FLOATING]
[, FRAME=*width*] [, FUNC_GET_VALUE=*string*] [, /GRID_LAYOUT]
[, GROUP_LEADER=*widget_id*{must specify for modal dialogs}]
[, /KBRD_FOCUS_EVENTS] [, KILL_NOTIFY=*string*]
[, /MAP{not for modal bases}] [, /MASK] [, MBAR=*variable* | , /MODAL]
[, /NO_COPY] [, NOTIFY_REALIZE=*string*] [, PRO_SET_VALUE=*string*]
[, SCR_XSIZE=*width*] [, SCR_YSIZE=*height*] [, /SCROLL{not for modal bases}] [, /SENSITIVE] [, SPACE=*value*{ignored if exclusive or nonexclusive}]
[, TAB_MODE=*value*] [, TITLE=*string*] [, TLB_FRAME_ATTR=*value*{top-level bases only}] [, /TLB_ICONIFY_EVENTS{top-level bases only}]
[, /TLB_KILL_REQUEST_EVENTS{top-level bases only}]
[, /TLB_MOVE_EVENTS{top-level bases only}] [, /TLB_SIZE_EVENTS{top-level bases only}] [, /TOOLBAR] [, /TRACKING_EVENTS] [, UNAME=*string*]
[, UNITS={0 | 1 | 2}] [, UVALUE=*value*] [, XOFFSET=*value*]
[, XPAD=*value*{ignored if exclusive or nonexclusive}] [, XSIZE=*value*]

[, X_SCROLL_SIZE=*value*] [, YOFFSET=*value*] [, YPAD=*value*{ignored if exclusive or nonexclusive}] [, YSIZE=*value*] [, Y_SCROLL_SIZE=*value*])

X Windows Keywords: [, DISPLAY_NAME=*string*]
[, RESOURCE_NAME=*string*] [, RNAME_MBAR=*string*]

Return Value

The returned value of this function is the widget ID of the newly-created base.

Arguments

Parent

The widget ID of the parent widget. To create a *top-level* base, omit the *Parent* argument.

Keywords

ALIGN_BOTTOM

Set this keyword to align the new widget with the bottom of its parent base. To take effect, the parent must be a ROW base.

ALIGN_CENTER

Set this keyword to align the new widget with the center of its parent base. To take effect, the parent must be a ROW or COLUMN base. In ROW bases, the new widget will be vertically centered. In COLUMN bases, the new widget will be horizontally centered.

ALIGN_LEFT

Set this keyword to align the new widget with the left side of its parent base. To take effect, the parent must be a COLUMN base.

ALIGN_RIGHT

Set this keyword to align the new widget with the right side of its parent base. To take effect, the parent must be a COLUMN base.

ALIGN_TOP

Set this keyword to align the new widget with the top of its parent base. To take effect, the parent must be a ROW base.

To apply actions triggered by menu items to widgets other than the base that includes the menubar, use the KBRD_FOCUS_EVENTS keyword to keep track of which widget has (or last had) the keyboard focus.

BASE_ALIGN_BOTTOM

Set this keyword to make all children of the new base align themselves with the bottom of the base by default. To take effect, you must also set the ROW keyword for the new base. The default can be overridden for individual child widgets by setting a different ALIGN_XXX keyword when the child widget is created.

BASE_ALIGN_CENTER

Set this keyword to make all children of the new base align themselves with the center of the base by default. To take effect, you must also set the COLUMN or ROW keyword for the new base. The default can be overridden for individual child widgets by setting a different ALIGN_XXX keyword when the child widget is created. In ROW bases, child widgets will be vertically centered. In COLUMN bases, child widgets will be horizontally centered.

BASE_ALIGN_LEFT

Set this keyword to make all children of the new base align themselves with the left side of the base by default. To take effect, you must also set the COLUMN keyword for the new base. The default can be overridden for individual child widgets by setting a different ALIGN_XXX keyword when the child widget is created.

BASE_ALIGN_RIGHT

Set this keyword to make all children of the new base align themselves with the right side of the base by default. To take effect, you must also set the COLUMN keyword for the new base. The default can be overridden for individual child widgets by setting a different ALIGN_XXX keyword when the child widget is created.

BASE_ALIGN_TOP

Set this keyword to make all children of the new base align themselves with the top of the base by default. To take effect, you must also set the ROW keyword for the new base. The default can be overridden for individual child widgets by setting a different ALIGN_XXX keyword when the child widget is created.

BITMAP

Set this keyword to specify a custom top level base icon that will be used in the title bar, the task bar and the Windows task switching window (accessed using `Alt+Tab`).

There are three allowed value types:

Value Type	Description
String	The full path to a bitmap or icon file (BMP or ICO)
String Array	The full paths to one or more bitmap files
Byte Array	An [*n*, *n*, 3] byte array containing the red, green, and blue values for the icon.

Specifying an icon file or an array of bitmap files allows the top level base icon to be legible at a wide range of sizes. IDL chooses the image whose size best matches the needed use (title bar, task switcher, etc.). It is recommended that ICO files and arrays of bitmap files include both 16x16 pixel and 32x32 pixel images. In rare cases a 48x48 pixel image might be useful because users can customize window properties, such as the height of title bars. When there is no exact match the image is automatically scaled.

When the keyword is not set, the top level base inherits the icon of its group leader. An application-wide icon can be specified by applying the icon to just the group leaders.

To enable transparency in BMP files and byte arrays, set the MASK keyword. Icon files (.ICO) define their own transparency.

Note

The base widget icon functionality is only available on the Microsoft Windows platform. On Motif platforms the BITMAP and MASK keywords are quietly ignored.

COLUMN

If this keyword is included, the base lays out its children in columns. The value of this keyword specifies the number of columns to be used. The number of child widgets in

each column is determined by distributing the children as evenly as possible across the columns.

Specifying both the COLUMN and ROW keywords causes an error.

Column Width

The width of each column is determined by the width of the widest widget in that column. If the GRID_LAYOUT keyword is set, all columns are as wide as the widest widget in the base.

Horizontal Size of Widgets

If any of the BASE_ALIGN_* keywords to WIDGET_BASE is set, each widget has its "natural" width, determined either by the value of the widget or by the XSIZE keyword. Similarly, if any of the child widgets specifies one of the ALIGN_* keywords, that widget will have its "natural" width. If none of the BASE_ALIGN_* or (ALIGN_*) keywords are set, all widgets in the base are as wide as their column.

Vertical Placement

Child widgets are placed vertically one below the other, with no extra space. If the GRID_LAYOUT keyword is set, each row is as high as its tallest member.

CONTEXT_EVENTS

Set this keyword to cause context menu events (or simply context events) to be issued when the user clicks the right mouse button over the widget. Set the keyword to 0 (zero) to disable such events. Context events are intended for use with context-sensitive menus (also known as pop-up or shortcut menus); pass the context event ID to the WIDGET_DISPLAYCONTEXTMENU procedure within your widget program's event handler to display the context menu.

For more on detecting and handling context menu events, see "Context-Sensitive Menus" (Chapter 3, *Widget Application Programming*).

CONTEXT_MENU

Set this keyword to create a base widget that can be used as the base for a context-sensitive menu (also known as a pop-up or shortcut menu). A context menu base must have as its parent one of the following types of widgets: WIDGET_BASE, WIDGET_DRAW, WIDGET_TEXT, WIDGET_LIST, WIDGET_PROPERTYSHEET, WIDGET_TABLE, WIDGET_TEXT or WIDGET_TREE.

For more on creating context menus, see "Context-Sensitive Menus" (Chapter 3, *Widget Application Programming*).

DISPLAY_NAME

Set this keyword equal to a string that specifies the name of the X Windows display on which the base should be displayed. This keyword has no effect on Microsoft Windows platforms.

EVENT_FUNC

A string containing the name of a function to be called by the WIDGET_EVENT function when an event arrives from a widget in the widget hierarchy rooted at the newly-created widget.

Note

If you are using XMANAGER to manage events for your widget application, you should not specify an event processing routine for the top-level base of the application using this keyword. Instead, specify the event processing routine using the EVENT_HANDLER keyword to XMANAGER.

EVENT_PRO

A string containing the name of a procedure to be called by the WIDGET_EVENT function when an event arrives from a widget in the widget hierarchy rooted at the newly-created widget.

Note

If you are using XMANAGER to manage events for your widget application, you should not specify an event processing routine for the top-level base of the application using this keyword. Instead, specify the event processing routine using the EVENT_HANDLER keyword to XMANAGER.

EXCLUSIVE

Set this keyword to specify that the base can have only button-widget children and that only one button can be set at a time. These buttons, unlike normal button widgets, have two states—set and unset.

When one exclusive button is pressed, any other exclusive buttons (in the same base) that are currently set are automatically released. Hence, only one button can ever be set at one time.

This keyword can be used to create exclusive button menus. See the CW_BGROUP and CW_PDMENU functions for high-level menu-creation utilities.

Note ───

If this keyword is set, the XOFFSET and YOFFSET keywords are ignored for any widgets in this base. Exclusive bases are always laid out in columns or rows. If neither the COLUMN nor ROW keyword is specified for an exclusive base, the base defaults to COLUMN layout.

──

FLOATING

Set this keyword—along with the GROUP_LEADER keyword—to create a "floating" top-level base widget. If the windowing system provides Z-order control, floating base widgets appear above the base specified as their group leader. If the windowing system does not provide Z-order control, the FLOATING keyword has no effect.

The iconizing, layering, and destruction behavior of floating bases and their group leaders is discussed in "Iconizing, Layering, and Destroying Groups of Top-Level Bases" on page 2653.

FRAME

The value of this keyword specifies the width of a frame (in pixels) to be drawn around the borders of the widget. Note that this keyword is only a hint to the toolkit, and may be ignored in some instances.

FUNC_GET_VALUE

A string containing the name of a function to be called when the GET_VALUE keyword to the WIDGET_CONTROL procedure is called for this widget. Using this technique allows you to change the value that should be returned for a widget. Compound widgets use this ability to define their values transparently to the user.

GRID_LAYOUT

Set this keyword to force the base to have a grid layout, in which all rows have the same height, and all columns have the same width. The row heights and column widths are taken from the largest child widget.

GROUP_LEADER

The widget ID of an existing widget that serves as "group leader" for the newly-created widget. Widget application hierarchies are defined by group membership relationships between top-level widget bases. When a group leader is killed, for any reason, all widgets in the group are also destroyed. Iconizing and layering behavior is

discussed in "Iconizing, Layering, and Destroying Groups of Top-Level Bases" on page 2653.

Note ───────────────────────────────────

If you specify a floating base (created with the FLOATING keyword) as a group leader, all member bases must also have either the FLOATING or MODAL keywords set. If you specify a modal base (created with the MODAL keyword) as a group leader, all member bases must have the MODAL keyword set as well.

───────────────────────────────────

A given widget can be in more than one group. The WIDGET_CONTROL procedure can be used to add additional group associations to a widget. It is not possible to remove a widget from an existing group.

If the group leader specified by this keyword uses a custom title bar icon (as specified by the BITMAP keyword), the same icon will be used in the title bar of a new top-level base widget. If a top-level base has more than one group leader, the icon associated with the *first* group leader assigned is used.

On multi-monitor configurations, the widget will appear at the upper-left corner [0,0] of the monitor that contains the group leader if no explicit offset was specified.

KBRD_FOCUS_EVENTS

Set this keyword to make the base return keyboard focus events whenever the keyboard focus of the base changes. See the "Events Returned by Base Widgets" section below for more information.

KILL_NOTIFY

Set this keyword to a string that contains the name of a procedure to be called automatically when the specified widget dies. Each widget is allowed a single such "callback" procedure. It can be removed by setting the routine to the null string (' ').

The callback routine is called with the widget identifier as its only argument. At that point, the widget identifier can only be used with the WIDGET_CONTROL procedure to get or set the user value. All other requests that require a widget ID are disallowed for the target widget. The callback is not issued until the WIDGET_EVENT function is called.

Note ───────────────────────────────────

A procedure specified via the CLEANUP keyword to XMANAGER will override a procedure specified for your application's top-level base with WIDGET_BASE, KILL_NOTIFY.

───────────────────────────────────

MAP

Once a widget hierarchy has been realized, it can be mapped (visible) or unmapped (invisible). This keyword specifies the initial map state for the given base and its descendants. Specifying a non-zero value indicates that the base should be mapped when realized (the default). A zero value indicates that the base should be unmapped initially.

After the base is realized, its map state can be altered using the MAP keyword to the WIDGET_CONTROL procedure.

Note ———

Modal bases cannot be mapped and unmapped.

Warning ——

Under Microsoft Windows, when a hidden base is realized, then mapped, a Windows resize message is sent by the windowing system. This "extra" resize event is generated before any manipulation of the base widget by the user.

MASK

Set this keyword along with the BITMAP keyword to create a top level base icon that has transparency. When set to 1 (one), all bitmap pixels that match the lower left pixel are treated as transparent, allowing the background color to show through. The default value is 0. The MASK keyword has no effect when the BITMAP keyword references an icon file (.ico) because images in icon files define their own transparency.

Note ———

The base widget icon functionality is only available on the Microsoft Windows platform. On Motif platforms the BITMAP and MASK keywords are quietly ignored.

MBAR

Set this keyword to a named variable to cause a menubar to be placed at the top of the base (the base must be a top-level base). The menubar is itself a special kind of base widget that can only have buttons as children. Upon return, the named variable contains the widget ID of the new menubar base. This widget ID can then be used to fill the menubar with pulldown menus. For example, the following widget creation commands first create a base with a menubar, then populate the menubar with a

simple pulldown menu (CW_PDMENU could also have been used to construct the pulldown menu):

```
base = WIDGET_BASE(TITLE = 'Example', MBAR=bar)
file_menu = WIDGET_BUTTON(bar, VALUE='File', /MENU)
file_bttn1=WIDGET_BUTTON(file_menu, VALUE='Item 1',$
   UVALUE='FILE1')
file_bttn2=WIDGET_BUTTON(file_menu, VALUE='Item 2',$
   UVALUE='FILE2')
```

Note that to set X Window System resources for menubars created with this keyword, you must use the RNAME_MBAR keyword rather than the RESOURCE_NAME keyword.

If you use CW_PDMENU to create a menu for the menubar, be sure to set the MBAR keyword to that function as well.

Note also that the size returned by the GEOMETRY keyword to WIDGET_INFO does not include the size of the menubar.

Warning ———————————————————————————————
You cannot specify both the MBAR and MODAL keywords for the same widget. Doing so will cause an error.

———

Warning ———————————————————————————————
You cannot specify both an APP_MBAR and an MBAR for the same top-level base widget. Doing so will cause an error.

———

To apply actions triggered by menu items to widgets other than the base that includes the menubar, use the KBRD_FOCUS_EVENTS keyword to keep track of which widget has (or last had) the keyboard focus.

MODAL

Set this keyword to create a modal dialog. While a modal dialog is displayed, IDL blocks event processing.

Note ———————————————————————————————————
Modal dialogs must have a group leader. Specify the group leader for a modal top-level base via the GROUP_LEADER keyword.

———

Modal dialogs cannot be scrollable, nor can they support menubars. Setting the SCROLL, MBAR, or APP_MBAR keywords in conjunction with the MODAL keyword will cause an error. Modal dialogs cannot be mapped or unmapped. Setting

the MAP keyword on a modal base will cause an error. Modal dialogs cannot be resized, regardless of the setting of the TLB_SIZE_EVENTS keyword.

Note ───

On Windows platforms, the group leader of a modal base must be realized before the modal base itself can be realized. If the group leader has not been realized, it will be realized automatically.

───

The iconizing, layering, and destruction behavior of modal bases and their group leaders is discussed in "Iconizing, Layering, and Destroying Groups of Top-Level Bases" on page 2653.

NO_COPY

Usually, when setting or getting widget user values, either at widget creation or using the SET_UVALUE and GET_UVALUE keywords to WIDGET_CONTROL, IDL makes a second copy of the data being transferred. Although this technique is fine for small data, it can have a significant memory cost when the data being copied is large.

If the NO_COPY keyword is set, IDL handles these operations differently. Rather than copy the source data, it takes the data away from the source and attaches it directly to the destination. This feature can be used by compound widgets to obtain state information from a UVALUE without all the memory copying that would otherwise occur. However, it has the side effect of causing the source variable to become undefined. On a "set" operation (using the UVALUE keyword to WIDGET_BASE or the SET_UVALUE keyword to WIDGET_CONTROL), the variable passed as value becomes undefined. On a "get" operation (GET_UVALUE keyword to WIDGET_CONTROL), the user value of the widget in question becomes undefined.

NONEXCLUSIVE

Set this keyword to specify that the base can only have button widget children. These buttons, unlike normal button widgets, have two states—set and unset. Non-exclusive bases allow any number of the toggle buttons to be set at one time.

Note ───

If this keyword is set, the XOFFSET and YOFFSET keywords are ignored for any widgets in this base. Non-exclusive bases are always laid out in columns or rows. If neither the COLUMN nor ROW keyword is specified for a non-exclusive base, the base defaults to COLUMN layout.

───

NOTIFY_REALIZE

Set this keyword to a string that contains the name of a procedure to be called automatically when the specified widget is realized. This callback occurs just once (because widgets are realized only once). Each widget is allowed a single such "callback" procedure. It can be removed by setting the routine to the null string (`' '`). The callback routine is called with the widget ID as its only argument.

PRO_SET_VALUE

A string containing the name of a procedure to be called when the SET_VALUE keyword to the WIDGET_CONTROL procedure is called for this widget. See the description of the PRO_SET_VALUE keyword to WIDGET_CONTROL for information on using this keyword.

RESOURCE_NAME

A string containing an X Window System resource name to be applied to the widget. Once defined, this name can be used in the user's .Xdefaults file to customize widget resources not directly supported via the IDL widget routines. This keyword is accepted by all widget creation routines. This keyword only works with the "X" device and is ignored on Microsoft Windows platforms.

RESOURCE_NAME allows unrestricted access to the underlying Motif widgets within the following limitations:

- Users must have the appropriate resources defined in their .Xdefaults or application default resource file, or IDL will not see the definitions and they will not take effect.

- Motif resources are documented in the *OSF/Motif Programmer's Reference Manual*. To use them with RESOURCE_NAME, the IDL programmer must determine the type of widget being used by IDL, and then look up the resources that apply to them. Hence, RESOURCE_NAME requires some programmer-level familiarity with Motif.

- Only resources that are not set within IDL can be modified using this mechanism. Although it is not an error to set resources also set by IDL, the IDL settings will silently override user settings. These IDL resources are not documented since the actual resources used may differ from release to release as the IDL widgets evolve. Therefore, you should set only those resources that are obviously not being set by IDL. Among the resources that are not being set by IDL are those that control colors, menu mnemonics, and accelerator keys.

Example

The sample code below produces a pulldown menu named "Menu" with 2 entries named "Item 1" and "Item 2".

Using the RESOURCE_NAME keyword in conjunction with X resource definitions, we can alter "Item 1" in several ways not possible through the standard IDL widgets interface. We'll give Item 1 a red background color. We'll also assign "I" as the keyboard mnemonic. Note that Motif automatically underlines the "I" in the title to indicate this. We'll also select Meta-F4 as the keyboard accelerator for selecting "Item 1". If Meta-F4 is pressed while the pointer is anywhere over this application, the effect will be as if the menu was pulled down and "Item 1" was selected with the mouse.

```
; Simple event handler:
PRO test_event, ev
   HELP, /STRUCTURE, ev
END

; Simple widget creation routine:
PRO test

   ; The base gets the resource name "test":
   a = WIDGET_BASE(RESOURCE_NAME = 'test')
   b = WIDGET_BUTTON(a, VALUE='Menu', /MENU)

   ; Assign the Item 1 button the resource name "item1":
   c = WIDGET_BUTTON(b, VALUE='Item 1', $
      RESOURCE_NAME='item1')
   c = WIDGET_BUTTON(b, VALUE='Item 2')
   WIDGET_CONTROL, /REALIZE, a
   XMANAGER, 'test', a
END
```

Note that we gave the overall application the resource name "test", and the "Item 1" button the resource name "item1". Now we can use these names in the following .Xdefaults file entries:

```
Idl*test*item1*mnemonic: I
Idl*test*item1*accelerator: Meta<Key>F4
Idl*test*item1*acceleratorText: Meta-F4
Idl*test*item1*background: red
```

Note on Specifying Color Resources

If you wish to specify unique colors for your widgets, it is generally a good idea to use a color name ("red" or "lightblue", for example) rather than specifying an exact color match with a color string (such as "#b1b122222020"). If IDL is not able to

allocate an exact color, the entire operation may fail. Specifying a named color implies "closest color match," an operation that rarely fails.

If you need an exact color match and IDL fails to allocate the color, try modifying the `Idl.colors` resource in the `$IDL_DIR/resource/X11/lib/app-defaults/Idl` file.

RNAME_MBAR

A string containing an X Window System resource name to be applied to the menubar created by the MBAR keyword. This keyword is identical to the RESOURCE_NAME keyword except that the resource it specifies applies only to the menubar.

ROW

If this keyword is included, the base lays out its children in rows. The value of this keyword specifies the number of rows to be used. The number of child widgets in each row is determined by distributing the children as evenly as possible across the rows.

Specifying both the COLUMN and ROW keywords causes an error.

Row Height

The height of each row is determined by the height of the tallest widget in that row. If the GRID_LAYOUT keyword is set, all rows are as tall as the tallest widget in the base.

Vertical Size of Widgets

If any of the BASE_ALIGN_* keywords to WIDGET_BASE is set, each widget has its "natural" height, determined either by the value of the widget or by the YSIZE keyword. Similarly, if any of the child widgets specifies one of the ALIGN_* keywords, that widget will have its "natural" height. If none of the BASE_ALIGN_* or (ALIGN_*) keywords are set, all widgets in the base are as tall as their row.

Horizontal Placement

Child widgets are placed horizontally one next to the other, with no extra space. If the GRID_LAYOUT keyword is set, each column is as wide as its widest member.

SCR_XSIZE

Set this keyword to the desired "screen" width of the widget, in units specified by the UNITS keyword (pixels are the default). In many cases, setting this keyword is the same as setting the XSIZE keyword.

SCR_YSIZE

Set this keyword to the desired "screen" height of the widget, in units specified by the UNITS keyword (pixels are the default). In many cases, setting this keyword is the same as setting the YSIZE keyword.

SCROLL

Set this keyword to give the widget scroll bars that allow viewing portions of the widget contents that are not currently on the screen. You must also set X_SCROLL_SIZE and Y_SCROLL_SIZE to set the viewport size.

Note ───

Under UNIX, base widgets with scroll bars do not automatically size themselves to fit their contents. Use the XSIZE and YSIZE keywords to explicitly specify the size of the base widget.

───

Warning ──

You cannot specify both the SCROLL and MODAL keywords for the same widget. Doing so will cause an error.

───

SENSITIVE

Set this keyword to control the initial sensitivity state of the widget.

If SENSITIVE is zero, the widget becomes insensitive. If nonzero, it becomes sensitive. When a widget is sensitive, it has normal appearance and can receive user input. For example, a sensitive button widget can be activated by moving the mouse cursor over it and pressing a mouse button. When a widget is insensitive, it indicates the fact by changing its appearance, looking disabled, and it ignores any input.

Sensitivity can be used to control when a user is allowed to manipulate the widget. Note that some widgets do not change their appearance when they are made insensitive, but they cease generating events.

Warning ──

Under Microsoft Windows, a top-level base that is insensitive does not allow the user to control the window using the system close or minimize/maximize buttons.

───

After creating the widget hierarchy, you can change the sensitivity state using the SENSITIVE keyword with the WIDGET_CONTROL procedure.

SPACE

The space, in units specified by the UNITS keyword (pixels are the default), between children of a row or column major base. This keyword is ignored if either the EXCLUSIVE or NONEXCLUSIVE keyword is present.

TAB_MODE

Set this keyword to one of the values shown in the table below to determine how the widget hierarchy can be navigated using the **Tab** key. The TAB_MODE setting is inherited by lower-level bases and child widgets unless it is explicitly set on an individual widget.

Note
It is not possible to tab to disabled (SENSITIVE=0) or hidden (MAP=0) widgets.

Valid settings are:

0	Disable navigation onto or off of the widget. This is the default. Child widgets automatically inherit the tab mode of the parent base as described in "Inheriting the TAB_MODE Value" (Chapter 3, *Widget Application Programming*).
1	Enable navigation onto and off of the widget.
2	Navigate only onto the widget.
3	Navigate only off of the widget.

Note
In widget applications on the UNIX platform, the Motif library controls what widgets are brought into and released from focus using tabbing. The TAB_MODE keyword value is always zero, and any attempt to change it is ignored when running a widget application on the UNIX platform. Tabbing behavior may vary significantly between UNIX platforms; do not rely on a particular behavior being duplicated on all UNIX systems.

After creating the widget hierarchy, you can change tabbing support using the WIDGET_CONTROL procedure's TAB_MODE keyword, or query a widget's support for tabbing using the WIDGET_INFO procedure's TAB_MODE keyword.

See "Tabbing in Widget Applications" (Chapter 3, *Widget Application Programming*) for usage details and examples.

TITLE

A string containing the title to be used for the widget. Base widgets use the title only if they are top-level widgets or if they are children of a tab widget. For top-level base widgets, the title appears in the "window dressing" at the top of the base widget; the appearance is platform-specific. For base widgets that have a tab widget as their parent widget, the title is used as the text of the tab.

Note that if the widget base is not wide enough to contain the specified title, the title may appear truncated. If you must be able to see the full title, you have several alternatives:

- Rearrange the widgets in the base so that the base becomes naturally wide enough. This is the best solution.

- Don't worry about this issue. If the user needs to see the entire label, they can resize the window using the mouse.

- Create the base without using the COLUMN or ROW keywords. Instead, use the XSIZE keyword to explicitly set a usable width. This is an undesirable solution that can lead to strange-looking widget layouts.

For bases that are children of tab widgets, the title may be truncated depending on the width of the largest base that is a child of the tab widget. See the description of the MULTILINE keyword to WIDGET_TAB for additional details.

Note ───

You can use language catalogs to internationalize this value with strings in particular languages. For more information, see Chapter 19, "Using Language Catalogs" (*Application Programming*).

───

TLB_FRAME_ATTR

Set this keyword to one of the values shown in the table below to suppress certain aspects of a top-level base's window frame. This keyword applies only to top-level bases. The settings are merely hints to the window system and may be ignored by some window managers. Valid settings are:

1	Base cannot be resized, minimized, or maximized.
2	Suppress display of system menu.
4	Suppress title bar.

8	Base cannot be closed.
16	Base cannot be moved.

This keyword is set bitwise, so multiple effects can be set by adding values together. For example, to make a base that has no title bar (value 4) and cannot be moved (value 16), set the TLB_FRAME_ATTR keyword to 20 (that is, 4+16).

TLB_ICONIFY_EVENTS

Set this keyword when creating a top-level base to make that base return an event when the base is iconified or restored by the user. See the "Events Returned by Base Widgets" section below for more information.

TLB_KILL_REQUEST_EVENTS

Set this keyword, usable only with top-level bases, to send the top-level base a WIDGET_KILL_REQUEST event if a user tries to destroy the widget using the window manager (by default, widgets are simply destroyed). See the "Events Returned by Base Widgets" section below for more information.

Use this keyword to perform complex actions before allowing a widget application to exit. Note that widgets that have this keyword set are responsible for killing themselves after receiving a WIDGET_KILL_REQUEST event—they cannot be destroyed using the usual window system controls.

Use a call to TAG_NAMES with the STRUCTURE_NAME keyword set to differentiate a WIDGET_KILL_REQUEST event from other types of widget events. For example:

```
IF TAG_NAMES(event, /STRUCTURE_NAME) EQ $
    'WIDGET_KILL_REQUEST' THEN ...
```

TLB_MOVE_EVENTS

Set this keyword when creating a top-level base to make that base return an event when the base is moved on the screen by the user. See the "Events Returned by Base Widgets" section below for more information.

TLB_SIZE_EVENTS

Set this keyword, when creating a top-level base, to make that base return an event when the base is resized by the user. See the "Events Returned by Base Widgets" section below for more information.

TOOLBAR

Set this keyword to indicate that the base is used to hold bitmap buttons that make up a toolbar.

Note

Setting this keyword does not cause any changes in behavior; its only affect is to slightly alter the appearance of the bitmap buttons on the base for cosmetic reasons.

Note

On Motif platforms, if bitmap buttons are on a toolbar base that is also EXCLUSIVE or NONEXCLUSIVE, they will not have a separate "toggle" indicator, they will be grouped closely together, and will have a two-pixel shadow border.

Note

This keyword has no effect on Windows platforms.

TRACKING_EVENTS

Set this keyword to cause widget tracking events to be issued for the widget whenever the mouse pointer *enters* or *leaves* the region covered by that widget. Widget tracking events are returned as structures with the following definition:

```
{ WIDGET_TRACKING, ID:0L, TOP:0L, HANDLER:0L, ENTER:0 }
```

ID, TOP, and HANDLER are the standard fields found in every widget event. ENTER is 1 if the tracking event is an entry event, and 0 if it is an exit event.

See "Tracking Events" (Chapter 3, *Widget Application Programming*) for more information.

UNAME

Set this keyword to a string that can be used to identify the widget in your code. You can associate a name with each widget in a specific hierarchy, and then use that name to query the widget hierarchy and get the correct widget ID.

To query the widget hierarchy, use the WIDGET_INFO function with the FIND_BY_UNAME keyword. The UNAME should be unique to the widget hierarchy because the FIND_BY_UNAME keyword returns the ID of the first widget with the specified name.

UNITS

Set this keyword to specify the units used when *supplying* measurements or position values. Set UNITS equal to 0 (zero) to specify that all measurements are in pixels (this is the default), to 1 (one) to specify that all measurements are in inches, or to 2 (two) to specify that all measurements are in centimeters. This keyword does not change the units used in a widget event structure or in most of the fields of the geometry structure returned by WIDGET_INFO.

UVALUE

The "user value" to be assigned to the widget.

Each widget can contain a user-specified value of any data type and organization. This value is not used by the widget in any way, but exists entirely for the convenience of the IDL programmer. This keyword allows you to set this value when the widget is first created.

If UVALUE is not present, the widget's initial user value is undefined.

The user value for a widget can be accessed and modified at any time by using the GET_UVALUE and SET_UVALUE keywords to the WIDGET_CONTROL procedure.

XOFFSET

The horizontal offset of the widget in units specified by the UNITS keyword (pixels are the default) relative to its parent.

Specifying an offset relative to a row or column major base widget does not work because those widgets enforce their own layout policies. This keyword is primarily of use relative to a plain base widget. Note that it is best to avoid using this style of widget layout.

XPAD

The horizontal space, in units specified by the UNITS keyword (pixels are the default), between child widgets and the edges of a row or column major base. The default value of XPAD is platform dependent. This keyword is ignored if either the EXCLUSIVE or NONEXCLUSIVE keyword is present.

XSIZE

The width of the widget in units specified by the UNITS keyword (pixels are the default). Most widgets attempt to size themselves to fit the situation. However, if the

desired effect is not produced, use this keyword to override it. This keyword is only a "hint" to the toolkit and may be ignored in some situations.

X_SCROLL_SIZE

The XSIZE keyword always specifies the width of a widget. When the SCROLL keyword is specified, this size is not necessarily the same as the width of the visible area. The X_SCROLL_SIZE keyword allows you to set the width of the scrolling viewport independently of the actual width of the widget. X_SCROLL_SIZE must be less than XSIZE for scrollbars to appear.

Use of the X_SCROLL_SIZE keyword implies SCROLL. This means that scroll bars will be added in both the horizontal and vertical directions when X_SCROLL_SIZE is specified. Because the default size of the scrolling viewport may differ between platforms, it is best to specify Y_SCROLL_SIZE when specifying X_SCROLL_SIZE.

Note ————————————————————————————————————

X_SCROLL_SIZE and Y_SCROLL_SIZE are ignored if you specify the screen size using the SCR_XSIZE and SCR_YSIZE keywords to the widget creation routine.

——

YOFFSET

The vertical offset of the widget in units specified by the UNITS keyword (pixels are the default) relative to its parent. This offset is specified relative to the *upper left* corner of the parent widget.

Specifying an offset relative to a row or column major base widget does not work because those widgets enforce their own layout policies. This keyword is primarily of use relative to a plain base widget. Note that it is best to avoid using this style of widget layout.

YPAD

The vertical space, in units specified by the UNITS keyword (pixels are the default), between child widgets and the edges of a row or column major base. The default value of YPAD is platform-dependent. This keyword is ignored if either the EXCLUSIVE or NONEXCLUSIVE keyword is present.

YSIZE

The height of the widget in units specified by the UNITS keyword (pixels are the default). Most widgets attempt to size themselves to fit the situation. However, if the

desired effect is not produced, use this keyword to override it. This keyword is only a "hint" to the toolkit and may be ignored in some situations.

Y_SCROLL_SIZE

The YSIZE keyword always specifies the height of a widget. When the SCROLL keyword is specified, this size is not necessarily the same as the height of the visible area. The Y_SCROLL_SIZE keyword allows you to set the height of the scrolling viewport independently of the actual height of the widget. Y_SCROLL_SIZE must be less than YSIZE for scrollbars to appear.

Use of the Y_SCROLL_SIZE keyword implies SCROLL. This means that scroll bars will be added in both the horizontal and vertical directions when Y_SCROLL_SIZE is specified. Because the default size of the scrolling viewport may differ between platforms, it is best to specify X_SCROLL_SIZE when specifying Y_SCROLL_SIZE.

Note ───

X_SCROLL_SIZE and Y_SCROLL_SIZE are ignored if you specify the screen size using the SCR_XSIZE and SCR_YSIZE keywords to the widget creation routine.

───

Keywords to WIDGET_CONTROL

A number of keywords to the WIDGET_CONTROL procedure affect the behavior of base widgets. In addition to those keywords that affect all widgets, the following are particularly useful: CONTEXT_EVENTS, KBRD_FOCUS_EVENTS, TLB_ICONIFY_EVENTS, TLB_MOVE_EVENTS, TLB_SIZE_EVENTS.

Keywords to WIDGET_INFO

A number of keywords to the WIDGET_INFO function return information that applies specifically to base widgets. In addition to those keywords that apply to all widgets, the following are particularly useful: CONTEXT_EVENTS, KBRD_FOCUS_EVENTS, MODAL, STRING_SIZE, TLB_ICONIFY_EVENTS, TLB_KILL_REQUEST_EVENTS, TLB_MOVE_EVENTS, TLB_SIZE_EVENTS.

Events Returned by Base Widgets

Base widgets do not generate any events by default. They can be configured to generate events when the base widget receives the keyboard focus or the user clicks

the right-hand mouse button. In addition, top-level bases can be configured to generate events when the base is resized, moved, iconified, or killed.

Resize Events

Top-level widget bases return the following event structure only when they are resized by the user and the base was created with the TLB_SIZE_EVENTS keyword set:

```
{ WIDGET_BASE, ID:0L, TOP:0L, HANDLER:0L, X:0L, Y:0L }
```

ID is the widget ID of the base generating the event. TOP is the widget ID of the top level widget containing ID. HANDLER contains the widget ID of the widget associated with the handler routine. The X and Y fields return the new width of the base, not including any frame provided by the window manager.

Move Events

Top-level widget bases return the following event structure when the base is moved and the base was created with the TLB_MOVE_EVENTS keyword set:

```
{ WIDGET_TLB_MOVE, ID:0L, TOP:0L, HANDLER:0L, X:0L, Y:0L }
```

ID is the widget ID of the base generating the event. TOP is the widget ID of the top level widget containing ID. HANDLER contains the widget ID of the widget associated with the handler routine. X and Y are the new location of the top left corner of the base.

Note

On Windows, move events are generated while dragging. On UNIX, move events are generated only on the mouse-up.

Note

If both TLB_SIZE_EVENTS and TLB_MOVE_EVENTS are enabled, a user resize operation that causes the top left corner of the base to move will generate both a move event and a resize event.

Iconify Events

Top-level widget bases return the following event structure when the base is iconified or restored and the base was created with the TLB_ICONIFY_EVENTS keyword set:

```
{ WIDGET_TLB_ICONIFY, ID:0L, TOP:0L, HANDLER:0L, ICONIFIED:0 }
```

ID is the widget ID of the base generating the event. TOP is the widget ID of the top level widget containing ID. HANDLER contains the widget ID of the widget

associated with the handler routine. ICONIFIED is 1 (one) if the user iconified the base and 0 (zero) if the user restored the base.

Keyboard Focus Events

Widget bases return the following event structure when the keyboard focus changes and the base was created with the KBRD_FOCUS_EVENTS keyword set:

```
{ WIDGET_KBRD_FOCUS, ID:0L, TOP:0L, HANDLER:0L, ENTER:0 }
```

ID is the widget ID of the base generating the event. TOP is the widget ID of the top level widget containing ID. HANDLER contains the widget ID of the widget associated with the handler routine. The ENTER field returns 1 (one) if the base is gaining the keyboard focus, or 0 (zero) if the base is losing the keyboard focus.

Kill Request Events

Top-level widget bases return the following event structure only when a user tries to destroy the widget using the window manager and the base was created with the TLB_KILL_REQUEST_EVENTS keyword set:

```
{ WIDGET_KILL_REQUEST, ID:0L, TOP:0L, HANDLER:0L }
```

ID is the widget ID of the base generating the event. TOP is the widget ID of the top level widget containing ID. HANDLER contains the widget ID of the widget associated with the handler routine.

Context Menu Events

A base widget created with the CONTEXT_EVENTS keyword set returns the following event structure in response to a right mouse button click:

```
{WIDGET_CONTEXT, ID:0L, TOP:0L, HANDLER:0L, X:0L, Y:0L,
    ROW:0L, COL:0L}
```

The first three fields are the standard fields found in every widget event. The X and Y fields give the device coordinates at which the event occurred, measured from the upper left corner of the base widget. The ROW and COL fields return meaningful information for table widgets and values of zero (0) for other widgets.

Version History

Pre-4.0	Introduced
5.6	Added TLB_ICONIFY_EVENTS, TLB_MOVE_EVENTS, and TOOLBAR keywords; added new event structures for iconify and move events
6.1	Added TAB_MODE keyword
	Added ROW and COL fields to WIDGET_CONTEXT event structure
Pre-6.2	Deprecated APP_MBAR keyword
6.4	Added BITMAP and MASK keywords

For information on obsolete keywords, see Appendix I, "Obsolete Features".

See Also

Chapter 2, "Creating Widget Applications" (*Widget Application Programming*).

WIDGET_BUTTON

The WIDGET_BUTTON function creates button widgets. A button widget is a pushbutton that is activated by moving the mouse cursor over the widget button and pressing a mouse button.

Figure 25-1: A Button Widget

Exclusive And Non-Exclusive Bases

Buttons placed into exclusive or non-exclusive bases (created via the EXCLUSIVE or NONEXCLUSIVE keywords to WIDGET_BASE function) are created as two-state "toggle" buttons, which are controlled by such bases.

For more information on creating buttons, see "Using Button Widgets" (Chapter 4, *Widget Application Programming*).

Bitmap Button Labels

Widget buttons can have either a text label (specified as a string value to the VALUE keyword) or a graphic symbol in the form of a bitmap. Bitmap labels are specified in one of the following ways:

1. By setting the VALUE keyword equal to a string containing the name of an image file in BMP format, and setting the BITMAP keyword:

    ```
    button=WIDGET_BUTTON(base, VALUE='mybitmap.bmp', /BITMAP)
    ```

    For 16- and 256-color bitmap files, IDL uses the color of the pixel in the lower left corner as the transparent color. All pixels of this color become transparent, allowing the button color to show through.

    Note ─────────────────────────────────────
    Displaying bitmapped buttons on 8-bit color X Windows displays may require using additional X colormap colors to allocate colors used by the bitmaps. If the required colormap colors are not available, the button bitmap may not display properly.
    ───

To modify the bitmap after creation, use the /BITMAP keyword with WIDGET_CONTROL:

```
WIDGET_CONTROL, button, SET_VALUE='mybitmap2.bmp', /BITMAP
```

2. By setting the VALUE keyword equal to an *n* x *m* bitmap byte array in which each bit represents a pixel with a value of either zero or one. (Arrays of this type can be produced using the CVTTOBM function.) This method creates a black-and-white bitmap label:

```
button=WIDGET_BUTTON(base, VALUE=bw_arr)
```

To modify the bitmap after creation, simply set a new value using WIDGET_CONTROL:

```
WIDGET_CONTROL, button, SET_VALUE=bw_array2
```

3. By setting the VALUE keyword equal to an *n* x *m* x 3 byte array that represents a 24-bit color image, interleaved by plane, with the planes in the order red, green, blue. There is no transparent pixel in 24-bit button labels. This method creates a color bitmap label:

```
button=WIDGET_BUTTON(base, VALUE=color_array)
```

To modify the bitmap after creation, simply set a new value using WIDGET_CONTROL:

```
WIDGET_CONTROL, button, SET_VALUE=color_array2
```

See "Using Button Widgets" (Chapter 4, *Widget Application Programming*) for additional details on creating image files and arrays for use as button bitmaps.

Syntax

Result = WIDGET_BUTTON(*Parent* [, ACCELERATOR=*string*]
   [, /ALIGN_CENTER | , /ALIGN_LEFT | , /ALIGN_RIGHT] [, /BITMAP]
   [, /CHECKED_MENU] [, /DYNAMIC_RESIZE] [, EVENT_FUNC=*string*]
   [, EVENT_PRO=*string*] [, FONT=*string*] [, FRAME=*width*]
   [, FUNC_GET_VALUE=*string*] [, GROUP_LEADER=*widget_id*] [, /HELP]
   [, KILL_NOTIFY=*string*] [, /MENU] [, /NO_COPY] [, /NO_RELEASE]
   [, NOTIFY_REALIZE=*string*] [, PRO_SET_VALUE=*string*]
   [, /PUSHBUTTON_EVENTS] [, SCR_XSIZE=*width*] [, SCR_YSIZE=*height*]
   [, /SENSITIVE] [, /SEPARATOR] [, TAB_MODE=*value*] [, TOOLTIP=*string*]
   [, /TRACKING_EVENTS] [, UNAME=*string*] [, UNITS={0 | 1 | 2}]
   [, UVALUE=*value*] [, VALUE=*value*] [, X_BITMAP_EXTRA=*bits*]
   [, XOFFSET=*value*] [, XSIZE=*value*] [, YOFFSET=*value*] [, YSIZE=*value*])

X Windows Keywords: [, RESOURCE_NAME=*string*]

Return Value

The returned value of this function is the widget ID of the newly-created button.

Arguments

Parent

The widget ID of the parent for the new button widget. The parent of a button widget must be one of the following:

1. A base widget.

2. A widget created using the MBAR keyword on a top-level base.

3. A button widget which has the MENU keyword set.

Keywords

ACCELERATOR

Set this keyword to assign a key combination that will activate a menu item or button event using the keyboard instead of the mouse. The value of the keyword is a case-insensitive string that specifies zero or more modifier keys (**Ctrl**, **Shift**, or **Alt**) and one other key. (The developer must take special steps to enable **Alt** key accelerators for Macintosh users). See "Enabling Alt Key Accelerators on Macintosh" (Chapter 3, *Widget Application Programming*) for details.) If there is more than one item in the string, a "+" must separate them. For example:

```
bRun = WIDGET_BUTTON( base, VALUE = "Run", ACCELERATOR = "F5" )
bPause = WIDGET_BUTTON( base, VALUE = "Pause", $
   ACCELERATOR = "Ctrl+F5" )
bResume = WIDGET_BUTTON( base, VALUE = "Resume", $
   ACCELERATOR = "Ctrl+Shift+F5" )
```

Accelerators can be defined for menu items and various types of WIDGET_BUTTON on Windows. However, on UNIX, only menu item accelerators are supported. Context menu items do not support accelerators on any platform.

The valid combinations are:

Accelerator Keys	Description
Ctrl, **Shift**, or **Alt** plus an alphanumeric key	A modifier key plus any alphabetic character, A-Z (which is case-insensitive), or a number, 0-9, creates a valid accelerator.
Ctrl, **Shift**, or **Alt** plus a number pad key	A modifier key plus any key on the number pad can be used as an accelerator. However, the **NumLock** key must be activated for any accelerator using number pad keys to function properly. **Note -** On Windows only, a keyboard accelerator using the **Shift** key and a number key on the number pad will not work.
Ctrl, **Shift**, or **Alt** plus the **Backspace**, **Tab** or **Space** key	These miscellaneous keys need a modifier key in the accelerator definition.
Navigation keys (**Home**, **End**, **PageUp**, **PageDown**, **Up**, **Down**, **Left**, **Right**)	The navigation keys do not require a modifier in the accelerator definition. **Prior** and **PageUp** are equivalent as are **Next** and **PageDown**. **Up**, **Down**, **Left**, and **Right** map to the arrow keys.
Function keys (**F1** to **F12**)	Function keys do not need a modifier key in the accelerator definition. However, not all platforms support the use of all function keys as accelerators. See "Successfully Implementing Keyboard Accelerators" (Chapter 3, *Widget Application Programming*) for details.
Return, **Escape**, **Insert**, **Del** keys	These miscellaneous keys do not need a modifier key in the accelerator definition. You must specify **Return** in the accelerator definition to indicate the Enter key on Windows. You must specify **Del** in the accelerator definition to indicate the Delete key.

Table 25-1: Valid ACCELERATOR Keyword Combinations

When an accelerator is defined for a menu item, the ACCELERATOR keyword string is automatically displayed next to the menu item value. The ACCELERATOR keyword string is not included with a button value. Therefore, the VALUE keyword

of a WIDGET_BUTTON that is not a menu item should also indicate the accelerator keyboard shortcut so that the user is aware of the option.

See "Assigning Accelerators in Widget Applications" (Chapter 3, *Widget Application Programming*) for usage details and examples.

Note ───

Ordinarily, accelerators are processed before keyboard events reach widgets that have keyboard focus. Setting IGNORE_ACCELERATORS allows draw widgets and widgets with an editable text area (combobox, property sheet, table and text widgets) to receive keyboard events instead of the accelerator key combinations being captured by the accelerator. See "Disabling Button Widget Accelerators" (Chapter 3, *Widget Application Programming*) for usage details and examples.

───

ALIGN_CENTER

Set this keyword to do both of the following:

- Center the button's label within the button.

- Center the button horizontally with respect to its parent base (if the base was created with the COLUMN keyword set) or vertically with respect to its parent base (if the base was created with the ROW keyword set).

ALIGN_LEFT

Set this keyword to do both of the following:

- Left justify the button's label within the button.

- Align the button in the leftmost available horizontal position with respect to its parent base (if the base was created with the COLUMN keyword set) or in the highest available vertical position with respect to its parent base (if the base was created with the ROW keyword set).

ALIGN_RIGHT

Set this keyword to do both of the following:

- Right justify the button's label within the button.

- Align the button in the rightmost available horizontal position with respect to its parent base (if the base was created with the COLUMN keyword set) or in the lowest available vertical position with respect to its parent base (if the base was created with the ROW keyword set).

BITMAP

Set this keyword to specify that the VALUE keyword specifies the name of a `.bmp` file.

The value of a widget button can be a bitmap as described in "Bitmap Button Labels" on page 2679. If you specify the name of a bitmap file with the VALUE keyword, you must also set the BITMAP keyword.

CHECKED_MENU

Set this keyword on a menu entry button to enable the ability to place a check (Windows) or selection box (Motif) next to the menu entry. The parent widget of the button must be either a button widget created with the MENU keyword or a base widget created with the CONTEXT_MENU keyword.

Note —————————————————————————————

Setting this keyword does not initially "select" the menu item; selection marks are displayed and removed via the SET_BUTTON keyword to WIDGET_CONTROL.

———————————————————————————————————————

DYNAMIC_RESIZE

Set this keyword to create a widget that resizes itself to fit its new value whenever its value is changed. Note that this keyword does not take effect when used with the SCR_XSIZE, SCR_YSIZE, XSIZE, or YSIZE keywords. If one of these keywords is also set, the widget will be sized as specified by the sizing keyword and will never resize itself dynamically.

EVENT_FUNC

A string containing the name of a function to be called by the WIDGET_EVENT function when an event arrives from a widget in the widget hierarchy rooted at the newly-created widget.

EVENT_PRO

A string containing the name of a procedure to be called by the WIDGET_EVENT function when an event arrives from a widget in the widget hierarchy rooted at the newly-created widget.

FONT

The name of the font to be used by the widget. The font specified is a "device font" (an X Windows font on Motif systems; a TrueType or PostScript font on Windows systems). See "About Device Fonts" on page 5580 for details on specifying names for device fonts. If this keyword is omitted, the default font is used.

Note

On Microsoft Windows platforms, if FONT is not specified, IDL uses the system default font. Different versions of Windows use different system default fonts; in general, the system default font is the font appropriate for the version of Windows in question.

FRAME

The value of this keyword specifies the width of a frame in units specified by the UNITS keyword (pixels are the default) to be drawn around the borders of the widget. Note that this keyword is only a "hint" to the toolkit, and may be ignored in some instances.

FUNC_GET_VALUE

A string containing the name of a function to be called when the GET_VALUE keyword to the WIDGET_CONTROL procedure is called for this widget. Using this technique allows you to change the value that should be returned for a widget. Compound widgets use this ability to define their values transparently to the user.

GROUP_LEADER

The widget ID of an existing widget that serves as "group leader" for the newly-created widget. When a group leader is killed, for any reason, all widgets in the group are also destroyed.

A given widget can be in more than one group. The WIDGET_CONTROL procedure can be used to add additional group associations to a widget. It is not possible to remove a widget from an existing group.

HELP

Set this keyword to tell the widget toolkit that this button is a "help" button for a menubar and should be given that appearance. For example, Motif specifies that the help menubar item is displayed on the far right of the menubar. This keyword is ignored in all other contexts and may be ignored by window managers that have no such special appearance defined.

KILL_NOTIFY

Set this keyword to a string that contains the name of a procedure to be called automatically when the specified widget dies. Each widget is allowed a single such "callback" procedure. It can be removed by setting the routine to the null string (' ').

The callback routine is called with the widget identifier as its only argument. At that point, the widget identifier can only be used with the WIDGET_CONTROL procedure to get or set the user value. All other requests that require a widget ID are disallowed for the target widget. The callback is not issued until the WIDGET_EVENT function is called.

MENU

The presence of this keyword indicates that the button will be used to activate a pull-down menu. Such buttons can have button children that are then placed into a pull-down menu.

Under Motif, if the value specified for MENU is greater than 1, the button label is enclosed in a box to indicate that this button is a pull-down menu. See the CW_PDMENU function for a high-level pull-down menu creation utility.

NO_COPY

Usually, when setting or getting widget user values, either at widget creation or using the SET_UVALUE and GET_UVALUE keywords to WIDGET_CONTROL, IDL makes a second copy of the data being transferred. Although this technique is fine for small data, it can have a significant memory cost when the data being copied is large.

If the NO_COPY keyword is set, IDL handles these operations differently. Rather than copy the source data, it takes the data away from the source and attaches it directly to the destination. This feature can be used by compound widgets to obtain state information from a UVALUE without all the memory copying that would otherwise occur. However, it has the side effect of causing the source variable to become undefined. On a "set" operation (using the UVALUE keyword to WIDGET_BUTTON or the SET_UVALUE keyword to WIDGET_CONTROL), the variable passed as value becomes undefined. On a "get" operation (GET_UVALUE keyword to WIDGET_CONTROL), the user value of the widget in question becomes undefined.

NO_RELEASE

Set this keyword to make exclusive and non-exclusive buttons generate only *select* events. This keyword has no effect on regular buttons.

NOTIFY_REALIZE

Set this keyword to a string that contains the name of a procedure to be called automatically when the specified widget is realized. This callback occurs just once (because widgets are realized only once). Each widget is allowed a single such "callback" procedure. It can be removed by setting the routine to the null string (' '). The callback routine is called with the widget ID as its only argument.

PRO_SET_VALUE

A string containing the name of a procedure to be called when the SET_VALUE keyword to the WIDGET_CONTROL procedure is called for this widget. See the description of the PRO_SET_VALUE keyword to WIDGET_CONTROL for information on using this keyword.

PUSHBUTTON_EVENTS

Set this keyword to cause separate button events to be issued for the widget when the left mouse button is pressed and released, or when the spacebar is pressed and released.

Note ──

This keyword has no effect on exclusive or non-exclusive buttons.
──

When this keyword is *not* set and the button is selected, pressing and releasing either the left mouse button or the spacebar generates a single button event, with the SELECT field set equal to 1. When this keyword *is* set:

- Pressing the left mouse button generates a button event with the SELECT field set equal to 1.

- Releasing the left mouse button generates a button event with the SELECT field set equal to 0.

- Pressing the spacebar generates a button event with the SELECT field set equal to 1 immediately followed by a second button event with the SELECT field set equal to 0.

- Pressing and holding the spacebar generates a series of button events, with the value of the SELECT field alternating between 1 and 0. The rate at which events are generated is governed by the key-repeat settings of the operating system.

For the structure of button events, see "Events Returned by Button Widgets" on page 2694.

RESOURCE_NAME

A string containing an X Window System resource name to be applied to the widget. See "RESOURCE_NAME" on page 2665 for a complete discussion of this keyword.

SCR_XSIZE

Set this keyword to the desired "screen" width of the widget, in units specified by the UNITS keyword (pixels are the default). In many cases, setting this keyword is the same as setting the XSIZE keyword.

SCR_YSIZE

Set this keyword to the desired "screen" height of the widget, in units specified by the UNITS keyword (pixels are the default). In many cases, setting this keyword is the same as setting the YSIZE keyword.

SENSITIVE

Set this keyword to control the initial sensitivity state of the widget.

If SENSITIVE is zero, the widget becomes insensitive. If nonzero, it becomes sensitive. When a widget is sensitive, it has normal appearance and can receive user input. For example, a sensitive button widget can be activated by moving the mouse cursor over it and pressing a mouse button. When a widget is insensitive, it indicates the fact by changing its appearance, looking disabled, and it ignores any input.

Sensitivity can be used to control when a user is allowed to manipulate the widget. Note that some widgets do not change their appearance when they are made insensitive, but they cease generating events.

After creating the widget hierarchy, you can change the sensitivity state using the SENSITIVE keyword with the WIDGET_CONTROL procedure.

SEPARATOR

Set this keyword to tell the widget toolkit that this button is part of a pulldown menu pane and that a separator line should be added directly above this entry. This keyword is ignored in all other contexts.

TAB_MODE

Set this keyword to one of the values shown in the table below to determine how the widget hierarchy can be navigated using the **Tab** key. The TAB_MODE setting is inherited by lower-level bases and child widgets from the parent WIDGET_BASE unless it is explicitly set on an individual widget. If the TAB_MODE value of the

widget differs from that of the base, the setting on the widget will be respected when the widget has focus. For example, if a base does not support tabbing, but an individual child widget does support tabbing, this functionality will be enabled when the child widget has focus.

Note ──
It is not possible to tab to disabled (SENSITIVE=0) or hidden (MAP=0) widgets.

Note ──
For radio buttons, the TAB_MODE value is automatically inherited from the parent base and cannot be individually specified. Attempting to set TAB_MODE on a menu item or menu base will generate an error.

Valid settings are:

0	Disable navigation onto or off of the widget. This is the default unless the TAB_MODE has been set on a parent base. Child widgets automatically inherit the tab mode of the parent base as described in "Inheriting the TAB_MODE Value" (Chapter 3, *Widget Application Programming*).
1	Enable navigation onto and off of the widget.
2	Navigate only onto the widget.
3	Navigate only off of the widget.

Note ──
In widget applications on the UNIX platform, the Motif library controls what widgets are brought into and released from focus using tabbing. The TAB_MODE keyword value is always zero, and any attempt to change it is ignored when running a widget application on the UNIX platform. Tabbing behavior may vary significantly between UNIX platforms; do not rely on a particular behavior being duplicated on all UNIX systems.

Once a WIDGET_BUTTON widget receives focus through tabbing, additional navigation capabilities depend upon the platform as follows:

Widget	Description
WIDGET_BUTTON (Grouped, exclusive button widgets)	• On Windows — radio buttons can receive and lose focus through tabbing as long as there is a selected button within the group. Use the arrow keys to change the selection within the group. • On UNIX — the Motif library controls tabbing functionality.
WIDGET_BUTTON (Grouped, non-exclusive button widgets)	• On Windows – toggle buttons (or check boxes) can individually receive and lose focus through tabbing. Use the **Space** key to select or deselect a check box. • On UNIX —the Motif library controls tabbing functionality.

Table 25-2: Tabbing Behavior in Windows and UNIX Widget Applications

After creating the widget hierarchy, you can change tabbing support using the WIDGET_CONTROL procedure's TAB_MODE keyword, or query a widget's support for tabbing using the WIDGET_INFO procedure's TAB_MODE keyword.

See "Tabbing in Widget Applications" (Chapter 3, *Widget Application Programming*) for usage details and examples.

TOOLTIP

Set this keyword to a string that will be displayed when the cursor hovers over the widget. For UNIX platforms, this string must be non-zero in length.

Note ———
Tooltips cannot be created for menu sub-items. The topmost button on a menu can, however, have a tooltip.
———

Note ———
If your application uses hardware rendering and a RETAIN setting of either zero or one, tooltips will cause draw widgets to generate expose events if the tooltip obscures the drawable area. This is true even if the tooltip is associated with another widget.
———

Note

You can use language catalogs to internationalize this value with strings in particular languages. For more information, see Chapter 19, "Using Language Catalogs" (*Application Programming*).

TRACKING_EVENTS

Set this keyword to cause widget tracking events to be issued for the widget whenever the mouse pointer enters or leaves the region covered by that widget. For the structure of tracking events, see "TRACKING_EVENTS" on page 2672 in the documentation for WIDGET_BASE.

UNAME

Set this keyword to a string that can be used to identify the widget in your code. You can associate a name with each widget in a specific hierarchy, and then use that name to query the widget hierarchy and get the correct widget ID.

To query the widget hierarchy, use the WIDGET_INFO function with the FIND_BY_UNAME keyword. The UNAME should be unique to the widget hierarchy because the FIND_BY_UNAME keyword returns the ID of the first widget with the specified name.

UNITS

Set this keyword to specify the units used when *supplying* measurements or position values. Set UNITS equal to 0 (zero) to specify that all measurements are in pixels (this is the default), to 1 (one) to specify that all measurements are in inches, or to 2 (two) to specify that all measurements are in centimeters. This keyword does not change the units used in a widget event structure or in most of the fields of the geometry structure returned by WIDGET_INFO.

UVALUE

The "user value" to be assigned to the widget.

Each widget can contain a user-specified value of any data type and organization. This value is not used by the widget in any way, but exists entirely for the convenience of the IDL programmer. This keyword allows you to set this value when the widget is first created.

If UVALUE is not present, the widget's initial user value is undefined.

VALUE

The initial value setting of the widget. The value of a widget button is the label for that button. You can set VALUE to any of the following:

- a string value, which displays as text;

- an *n* x *m* byte array, which displays as a black-and-white bitmap image;

- an *n* x *m* x 3 byte array, which displays as a 24-bit color bitmap image;

- if the BITMAP keyword is also specified, the name of a bitmap image file that displays as a color bitmap image of the same depth as the image in the file.

See "Bitmap Button Labels" on page 2679 for additional details on using bitmap images as button labels. Also see "Using Button Widgets" (Chapter 4, *Widget Application Programming*) for additional details on using bitmap values for button widgets.

Note ————————————————————————————————

Under Microsoft Windows, including the ampersand character (&) in the value of a button widget causes the window manager to place an underline under the character following the ampersand. (This is a feature of Microsoft Windows, and is generally used to indicate which character is used as a keyboard accelerator for the button.) If you are designing an application that will run on different platforms, you should avoid the use of the ampersand in button value strings.

Note ————————————————————————————————

You can use language catalogs to internationalize this value with strings in particular languages. For more information, see Chapter 19, "Using Language Catalogs" (*Application Programming*).

X_BITMAP_EXTRA

When creating a bitmap button that is not of a "byte-aligned" size (i.e., a dimension is not a multiple of 8), this keyword specifies how many bits of the supplied bitmap must be ignored (within the end byte). For example, to create a 10 by 8 bitmap, you need to supply a 2 by 8 array of bytes and ignore the bottom 6 bits. Therefore, you would specify X_BITMAP_EXTRA = 6.

XOFFSET

The horizontal offset of the widget in units specified by the UNITS keyword (pixels are the default) relative to its parent.

Specifying an offset relative to a row or column major base widget does not work because those widgets enforce their own layout policies. This keyword is primarily of use relative to a plain base widget. Note that it is best to avoid using this style of widget programming.

XSIZE

The width of the widget in units specified by the UNITS keyword (pixels are the default). Most widgets attempt to size themselves to fit the situation. However, if the desired effect is not produced, use this keyword to override it. This keyword is only a "hint" to the toolkit and may be ignored in some situations.

YOFFSET

The vertical offset of the widget in units specified by the UNITS keyword (pixels are the default) relative to its parent. This offset is specified relative to the *upper left* corner of the parent widget.

Specifying an offset relative to a row or column major base widget does not work because those widgets enforce their own layout policies. This keyword is primarily of use relative to a plain base widget. Note that it is best to avoid using this style of widget programming.

YSIZE

The height of the widget in units specified by the UNITS keyword (pixels are the default). Most widgets attempt to size themselves to fit the situation. However, if the desired effect is not produced, use this keyword to override it. This keyword is only a "hint" to the toolkit and may be ignored in some situations.

Keywords to WIDGET_CONTROL

A number of keywords to the WIDGET_CONTROL procedure affect the behavior of button widgets. In addition to those keywords that affect all widgets, the following are particularly useful: DYNAMIC_RESIZE, DYNAMIC_RESIZE, GET_VALUE, INPUT_FOCUS, PUSHBUTTON_EVENTS, SET_BUTTON, SET_VALUE, TOOLTIP, X_BITMAP_EXTRA.

Keywords to WIDGET_INFO

Some keywords to the WIDGET_INFO function return information that applies specifically to button widgets. In addition to those keywords that apply to all widgets, the following are particularly useful: BUTTON_SET, DYNAMIC_RESIZE, PUSHBUTTON_EVENTS, STRING_SIZE, TOOLTIP.

Events Returned by Button Widgets

Pressing the mouse button while the mouse cursor is over a button widget causes the widget to generate an event. The event structure returned by the WIDGET_EVENT function is defined by the following statement:

```
{WIDGET_BUTTON, ID:0L, TOP:0L, HANDLER:0L, SELECT:0}
```

ID is the widget id of the button generating the event. TOP is the widget ID of the top level widget containing ID. HANDLER contains the widget ID of the widget associated with the handler routine. SELECT is set to 1 if the button was set, and 0 if released. Unless the PUSHBUTTON_EVENTS keyword is set, normal buttons do not generate events when released, so SELECT will always be 1. Toggle buttons (children of either an exclusive or non-exclusive base) always return separate events for the set and release actions.

Version History

Pre-4.0	Introduced
5.6	Added CHECKED_MENU and TOOLTIP keywords
6.0	Added PUSHBUTTON_EVENTS keyword
6.1	Added ACCELERATOR and TAB_MODE keywords

CW_BGROUP, CW_PDMENU, "Using Button Widgets" (Chapter 4, *Widget Application Programming*)

WIDGET_COMBOBOX

The WIDGET_COMBOBOX function creates combobox widgets, which are similar to droplist widgets. The combobox display a single entry from a list of options. The main difference between the combobox widget and the droplist widget is that the combobox widget can be created in such a way that the text field is editable, allowing the user to enter a value that is not on the list.

A combobox widget displays a text field and an arrow button. If the combobox is not editable, selecting either the text field or the button reveals a list of options from which to choose. When the user selects a new option from the list, the list disappears and the text field displays the currently selected option. This action generates an event containing the index of the selected item, which ranges from zero to the number of elements in the list minus one.

Figure 25-2: A ComboBox Widget

If the combobox is editable, text can be entered in the text box without causing the list to drop down. This action causes an event in which the index field is set to -1, allowing you to distinguish this event from list selections.

The text of the current selection is returned in the STR field of the WIDGET_COMBOBOX event structure. See "Widget Events Returned by Combobox Widgets" on page 2704 for details.

Note ───
WIDGET_COMBOBOX is not currently available on Compaq True64 UNIX platforms due to that platform's lack of support for the necessary Motif libraries.

───

Syntax

Result = WIDGET_COMBOBOX(*Parent* [, /DYNAMIC_RESIZE] [, /EDITABLE]
   [, EVENT_FUNC=*string*] [, EVENT_PRO=*string*] [, FONT=*string*]
   [, FRAME=*value*] [, FUNC_GET_VALUE=*string*]
   [, GROUP_LEADER=*widget_id*] [, IGNORE_ACCELERATORS=*value*]
   [, KILL_NOTIFY=*string*] [, /NO_COPY] [, NOTIFY_REALIZE=*string*]
   [, PRO_SET_VALUE=*string*] [, RESOURCE_NAME=*string*]
   [, SCR_XSIZE=*width*] [, SCR_YSIZE=*height*] [, /SENSITIVE]
   [, TAB_MODE=*value*] [, /TRACKING_EVENTS] [, UNAME=*string*]
   [, UNITS={0 | 1 | 2}] [, UVALUE=*value*] [, VALUE=*value*] [, XOFFSET=*value*]
   [, XSIZE=*value*] [, YOFFSET=*value*] [, YSIZE=*value*])

Return Value

The returned value of this function is the widget ID of the newly created combobox
widget.

Arguments

Parent

The widget ID of the parent widget for the new combobox widget.

Keywords

DYNAMIC_RESIZE

Set this keyword to create a widget that resizes itself to fit its new value whenever its
value is changed.

Note
This keyword does not take effect when used with the SCR_XSIZE, SCR_YSIZE,
XSIZE, or YSIZE keywords. If one of these keywords is also set, the widget will be
sized as specified by the sizing keyword and will never resize itself dynamically.

EDITABLE

Set this keyword to create an editable combobox. If the combobox is editable, users
can enter or modify items in the text field. Changes in the combobox text field will

cause combobox events with the INDEX field of the event structure set to -1. The current text will be ' in the STR field of the event structure.

EVENT_FUNC

A string containing the name of a function to be called by the WIDGET_EVENT function when an event arrives from a widget in the widget hierarchy rooted at the newly-created widget.

EVENT_PRO

A string containing the name of a procedure to be called by the WIDGET_EVENT function when an event arrives from a widget in the widget hierarchy rooted at the newly-created widget.

FONT

The name of the font to be used by the widget. The font specified is a device font (an X Windows font on Motif systems; a TrueType or PostScript font on Windows systems). See "About Device Fonts" on page 5580 in the *IDL Reference Guide* for details on specifying names for device fonts. If this keyword is omitted, the default font is used.

Note

On Microsoft Windows platforms, if FONT is not specified, IDL uses the system default font. Different versions of Windows use different system default fonts; in general, the system default font is the font appropriate for the version of Windows in question.

FRAME

The value of this keyword specifies the width of a frame in units specified by the UNITS keyword (pixels are the default) to be drawn around the borders of the widget.

Note

This keyword is only a hint to the toolkit, and may be ignored in some instances.

FUNC_GET_VALUE

A string containing the name of a function to be called when the GET_VALUE keyword to the WIDGET_CONTROL procedure is called for this widget. Using this technique allows you to change the value that should be returned for a widget. Compound widgets use this ability to define their values transparently to the user.

GROUP_LEADER

The widget ID of an existing widget that serves as group leader for the newly-created widget. When a group leader is killed, for any reason, all widgets in the group are also destroyed.

A given widget can be in more than one group. The WIDGET_CONTROL procedure can be used to add additional group associations to a widget. You cannot remove a widget from an existing group.

IGNORE_ACCELERATORS

Set this keyword to specify what accelerators are to be ignored when this combobox widget has keyboard focus. Valid values are:

- A string or string array containing any value that is legal for WIDGET_BUTTON's ACCELERATOR keyword

- The number 1, indicating all accelerators should be ignored

Ordinarily, accelerators are processed before keyboard events reach the widget that has the keyboard focus. Consider a case where the accelerator "Ctrl+V" has been mapped to a button that allows the user to paste objects copied from one drawing area into another. In an application that also has a combobox, attempting to use **Ctrl**+**V** to paste text into the combobox would fail as this event would be stolen by the accelerator. Setting IGNORE_ACCELERATORS to "Ctrl+V" allows a combobox widget with an editable text area to receive keyboard events instead of the button with a conflicting accelerator. Once the combobox loses focus, all specified accelerators are automatically re-enabled.

See "Disabling Button Widget Accelerators" (Chapter 3, *Widget Application Programming*) for usage details and examples.

KILL_NOTIFY

Set this keyword to a string that contains the name of a procedure to be called automatically when the specified widget dies. Each widget is allowed a single such callback procedure. This callback procedure can be removed by setting the routine name to the null string (' ').

The callback routine is called with the widget identifier as its only argument. At that point, the widget identifier can only be used with the WIDGET_CONTROL procedure to get or set the user value. All other requests that require a widget ID are disallowed for the target widget. The callback is not issued until the WIDGET_EVENT function is called.

NO_COPY

Usually, when setting or getting widget user values, either at widget creation or using the SET_UVALUE and GET_UVALUE keywords to WIDGET_CONTROL, IDL makes a second copy of the data being transferred. Although this technique works well for small data, it can have a significant memory cost when the data being copied is large.

If the NO_COPY keyword is set, IDL handles these operations differently. Rather than copying the source data, it takes the data away from the source and attaches it directly to the destination. This feature can be used by compound widgets to obtain state information from a UVALUE without all the memory copying that would otherwise occur. However, it has the side effect of causing the source variable to become undefined. Upon a set operation (using the UVALUE keyword to WIDGET_COMBOBOX or the SET_UVALUE keyword to WIDGET_CONTROL), the variable passed as value becomes undefined. Upon a get operation (GET_UVALUE keyword to WIDGET_CONTROL), the user value of the widget in question becomes undefined.

NOTIFY_REALIZE

Set this keyword to a string containing the name of a procedure to be called automatically when the specified widget is realized. This callback occurs just once (because widgets are realized only once). Each widget is allowed a single callback procedure. This callback procedure can be removed by setting the routine name to the null string (' '). The callback routine is called with the widget ID as its only argument.

PRO_SET_VALUE

A string containing the name of a procedure to be called when the SET_VALUE keyword to the WIDGET_CONTROL procedure is called for this widget. See the description of the PRO_SET_VALUE keyword to WIDGET_CONTROL for information on using this keyword.

RESOURCE_NAME

A string containing an X Window System resource name to be applied to the widget. See "RESOURCE_NAME" on page 2665 in the *IDL Reference Guide* for a complete discussion of this keyword.

SCR_XSIZE

Set this keyword to the desired "screen" width of the widget, in units specified by the UNITS keyword (pixels are the default). In many cases, setting this keyword is the same as setting the XSIZE keyword.

SCR_YSIZE

Set this keyword to the desired "screen" height of the widget, in units specified by the UNITS keyword (pixels are the default). In many cases, setting this keyword is the same as setting the YSIZE keyword.

SENSITIVE

Set this keyword to control the initial sensitivity state of the widget.

If SENSITIVE is zero, the widget becomes insensitive. If nonzero, it becomes sensitive. When a widget is sensitive, it has normal appearance and can receive user input. For example, a sensitive button widget can be activated by moving the mouse cursor over it and pressing a mouse button. When a widget is insensitive, it indicates the fact by changing its appearance, looking disabled, and it ignores any input.

Sensitivity can be used to control when a user is allowed to manipulate the widget.

Note ———————————————————————————————————

Some widgets do not change their appearance when they are made insensitive, but they cease generating events.

———

After creating the widget hierarchy, you can change the sensitivity state using the SENSITIVE keyword with the WIDGET_CONTROL.

TAB_MODE

Set this keyword to one of the values shown in the table below to determine how the widget hierarchy can be navigated using the **Tab** key. The TAB_MODE setting is inherited by lower-level bases and child widgets from the parent WIDGET_BASE unless it is explicitly set on an individual widget. If the TAB_MODE value of the widget differs from that of the base, the setting on the widget will be respected when the widget has focus. For example, if a base does not support tabbing, but an individual child widget does support tabbing, this functionality will be enabled when the child widget has focus.

Note ———————————————————————————————————

It is not possible to tab to disabled (SENSITIVE=0) or hidden (MAP=0) widgets.

———

Valid settings are:

0	Disable navigation onto or off of the widget. This is the default unless the TAB_MODE has been set on a parent base. Child widgets automatically inherit the tab mode of the parent base as described in "Inheriting the TAB_MODE Value" (Chapter 3, *Widget Application Programming*).
1	Enable navigation onto and off of the widget.
2	Navigate only onto the widget.
3	Navigate only off of the widget.

Note ───

In widget applications on the UNIX platform, the Motif library controls what widgets are brought into and released from focus using tabbing. The TAB_MODE keyword value is always zero, and any attempt to change it is ignored when running a widget application on the UNIX platform. Tabbing behavior may vary significantly between UNIX platforms; do not rely on a particular behavior being duplicated on all UNIX systems.

───

Once the WIDGET_COMBOBOX has focus, use the up and down arrow keys to navigate among the individual items.

After creating the widget hierarchy, you can change tabbing support using the WIDGET_CONTROL procedure's TAB_MODE keyword, or query a widget's support for tabbing using the WIDGET_INFO procedure's TAB_MODE keyword.

See "Tabbing in Widget Applications" (Chapter 3, *Widget Application Programming*) for usage details and examples.

TRACKING_EVENTS

Set this keyword to cause widget tracking events to be issued for the widget whenever the mouse pointer enters or leaves the region covered by that widget. For the structure of tracking events, see "TRACKING_EVENTS" on page 2672 in the documentation for WIDGET_BASE.

UNAME

Set this keyword to a string, which is used to identify the widget in your code. You can associate a name with each widget in a specific hierarchy, and then use that name to query the widget hierarchy and get the correct widget ID.

To query the widget hierarchy, use the WIDGET_INFO with the FIND_BY_UNAME keyword. The UNAME should be unique to the widget hierarchy because the FIND_BY_UNAME keyword returns the ID of the first widget with the specified name.

UNITS

Set this keyword to specify the units used when *supplying* measurements or position values. Set UNITS equal to 0 (zero) to specify that all measurements are in pixels (this is the default), to 1 (one) to specify that all measurements are in inches, or to 2 (two) to specify that all measurements are in centimeters. This keyword does not change the units used in a widget event structure or in most of the fields of the geometry structure returned by WIDGET_INFO.

UVALUE

The user value to be assigned to the widget.

Each widget can contain a user-specified value of any data type and organization. This value is not used by the widget in any way, but exists entirely for the convenience of the IDL programmer. This keyword allows you to set this value when the widget is first created.

If UVALUE is not present, the widget's initial user value is undefined.

VALUE

The initial value setting of the widget. The value of a combobox widget is a scalar string or array of strings that contains the text of the list items (one list item per array element). Combobox widgets are sized based on the length (in characters) of the longest item specified in the array of values for the VALUE keyword.

The combobox widget will display up to 20 list items at a time. If the VALUE array contains more than 20 elements, scroll bars are added to the list display.

Note ──
Null strings are not allowed in the combobox widget item list.
──

Note ──
You can use language catalogs to internationalize this value with strings in particular languages. For more information, see Chapter 19, "Using Language Catalogs" (*Application Programming*).
──

XOFFSET

The horizontal offset of the widget in units specified by the UNITS keyword (pixels are the default) relative to its parent.

Specifying an offset relative to a row or column major base widget does not work because those widgets enforce their own layout policies. This keyword is primarily of use relative to a plain base widget. You should avoid using this style of widget programming.

XSIZE

The desired width of the combobox widget area, in units specified by the UNITS keyword (pixels are the default). Most widgets attempt to size themselves to fit the situation. However, if the desired effect is not produced, use this keyword to override it. This keyword does not control the size of the combobox button or of the dropped list. Instead, it controls the size around the combobox button and, as such, is not particularly useful.

YOFFSET

The vertical offset of the widget in units specified by the UNITS keyword (pixels are the default) relative to its parent. This offset is specified relative to the *upper left* corner of the parent widget.

Specifying an offset relative to a row or column major base widget does not work because those widgets enforce their own layout policies. This keyword is primarily of use relative to a plain base widget. You should avoid using this style of widget programming.

YSIZE

The desired height of the widget, in units specified by the UNITS keyword (pixels are the default). Most widgets attempt to size themselves to fit the situation. However, if the desired effect is not produced, use this keyword to override it. This keyword does not control the size of the combobox button or of the dropped list. Instead, it controls the size around the combobox button and, as such, is not particularly useful.

Keywords to WIDGET_CONTROL

A number of keywords to the WIDGET_CONTROL affect the behavior of combobox widgets. In addition to those keywords that affect all widgets, the following keywords are particularly useful: COMBOBOX_ADDITEM, COMBOBOX_DELETEITEM, COMBOBOX_INDEX, DYNAMIC_RESIZE, GET_VALUE, IGNORE_ACCELERATORS, SET_COMBOBOX_SELECT, SET_VALUE.

Keywords to WIDGET_INFO

A number of keywords to the WIDGET_INFO return information that applies specifically to combobox widgets. In addition to those keywords that apply to all widgets, the following keywords are particularly useful: COMBOBOX_GETTEXT, COMBOBOX_NUMBER, DYNAMIC_RESIZE, STRING_SIZE.

Widget Events Returned by Combobox Widgets

Pressing the mouse button while the mouse pointer is over an element of a combobox widget causes the widget to change the text field on the combobox and to generate an event. The event structure returned by the WIDGET_EVENT function is defined by the following statement:

```
{WIDGET_COMBOBOX, ID:0L, TOP:0L, HANDLER:0L, INDEX:0L, STR:""}
```

The first three fields are the standard fields found in every widget event. INDEX returns the index of the selected item. This can be used to index the array of names originally used to set the widget's value. If the event was caused by text changes in an editable combobox, the INDEX field will be set to -1. If you are using an editable combobox, it is important to check for the value of -1 prior to using the value of the INDEX field as an index into the array if items. The text of the current selection is returned in the STR field, which may eliminate the need to use the index field in many cases.

Note ───

Platform-specific UI toolkits behave differently if a combobox widget has only a single element. On some platforms, selecting that element again does not generate an event. Events are always generated if the list contains multiple items.

───

Version History

5.6	Introduced
6.1	Added IGNORE_ACCELERATORS and TAB_MODE keywords

WIDGET_CONTROL

The WIDGET_CONTROL procedure is used to realize, manage, and destroy widget hierarchies. It is often used to change the default behavior or appearance of previously-realized widgets.

Syntax

WIDGET_CONTROL [, *Widget_ID*]

Keywords that apply to all widgets: [, BAD_ID=*variable*] [, /CLEAR_EVENTS]
　[, DEFAULT_FONT=*string*{do not specify *Widget_ID*}]
　[, /DELAY_DESTROY{do not specify *Widget_ID*}] [, /DESTROY]
　[, EVENT_FUNC=*string*] [, EVENT_PRO=*string*]
　[, FUNC_GET_VALUE=*string*] [, GET_UVALUE=*variable*]
　[, GROUP_LEADER=*widget_id*] [, /HOURGLASS{do not specify *Widget_ID*}]
　[, KILL_NOTIFY=*string*] [, /MAP] [, /NO_COPY]
　[, NOTIFY_REALIZE=*string*] [, PRO_SET_VALUE=*string*] [, /REALIZE]
　[, /RESET{do not specify *Widget_ID*}] [, SCR_XSIZE=*width*]
　[, SCR_YSIZE=*height*] [, SEND_EVENT=*structure*] [, /SENSITIVE]
　[, SET_UNAME=*string*] [, SET_UVALUE=*value*] [, /SHOW] [, TIMER=*value*]
　[, TLB_GET_OFFSET=*variable*] [, TLB_GET_SIZE=*variable*]
　[, /TLB_KILL_REQUEST_EVENTS] [, TLB_SET_TITLE=*string*]
　[, TLB_SET_XOFFSET=*value*] [, TLB_SET_YOFFSET=*value*]
　[, /TRACKING_EVENTS] [, UNITS={0 | 1 | 2}] [, /UPDATE]
　[, XOFFSET=*value*] [, XSIZE=*value*] [, YOFFSET=*value*] [, YSIZE=*value*]

Keywords that apply to widgets created with WIDGET_ACTIVEX:
　[, GET_VALUE=*value*]

Keywords that apply to widgets created with WIDGET_BASE:
　[, BASE_SET_TITLE=*string*] [, /CONTEXT_EVENTS] [, /ICONIFY]
　[, /KBRD_FOCUS_EVENTS] [, TAB_MODE=*value*]
　[, /TLB_ICONIFY_EVENTS] [, /TLB_KILL_REQUEST_EVENTS]
　[, /TLB_MOVE_EVENTS] [, /TLB_SIZE_EVENTS]

Keywords that apply to widgets created with WIDGET_BUTTON: [, /BITMAP]
　[, /DYNAMIC_RESIZE] [, GET_VALUE=*value*] [, /INPUT_FOCUS]
　[, /PUSHBUTTON_EVENTS] [, /SET_BUTTON] [, SET_VALUE=*value*]
　[, TAB_MODE=*value*] [, TOOLTIP=*string*] [, X_BITMAP_EXTRA=*bits*]

Keywords that apply to widgets created with WIDGET_COMBOBOX:
[, COMBOBOX_ADDITEM=*string*] [, COMBOBOX_DELETEITEM=*integer*]
[, COMBOBOX_INDEX=*integer*] [, /DYNAMIC_RESIZE]
[, GET_VALUE=*value*] [, IGNORE_ACCELERATORS={*string array* | {0 | 1}}]
[, SET_COMBOBOX_SELECT=*integer*] [, SET_VALUE=*value*]
[, TAB_MODE=*value*]

Keywords that apply to widgets created with WIDGET_DRAW:
[, /DRAW_BUTTON_EVENTS] [, /DRAW_EXPOSE_EVENTS]
[, DRAW_KEYBOARD_EVENTS={0 | 1 | 2}] [, /DRAW_MOTION_EVENTS]
[, /DRAW_VIEWPORT_EVENTS] [, /DRAW_WHEEL_EVENTS]
[, DRAW_XSIZE=*integer*] [, DRAW_YSIZE=*integer*]
[, GET_DRAW_VIEW=*variable*] [, GET_UVALUE=*variable*]
[, GET_VALUE=*variable*]
[, IGNORE_ACCELERATORS={*string array* | {0 | 1}}] [, /INPUT_FOCUS]
[, SET_DRAG_NOTIFY=*string*] [, SET_DRAW_VIEW=*[x, y]*]
[, /SET_DROP_EVENTS] [, TOOLTIP=*string*]

Keywords that apply to widgets created with WIDGET_DROPLIST:
[, /DYNAMIC_RESIZE] [, GET_VALUE=*variable*]
[, SET_DROPLIST_SELECT=*integer*] [, SET_VALUE=*value*]
[, TAB_MODE=*value*]

Keywords that apply to widgets created with WIDGET_LABEL:
[, /DYNAMIC_RESIZE] [, GET_VALUE=*value*] [, SET_VALUE=*value*]

Keywords that apply to widgets created with WIDGET_LIST:
[, /CONTEXT_EVENTS] [, SET_LIST_SELECT=*value*]
[, SET_LIST_TOP=*integer*] [, SET_VALUE=*value*] [, TAB_MODE=*value*]

Keywords that apply to widgets created with WIDGET_PROPERTYSHEET:
[, /CONTEXT_EVENTS] [, /EDITABLE] [, GET_VALUE=*variable*]
[, IGNORE_ACCELERATORS={*string array* | {0 | 1}}]
[, /MULTIPLE_PROPERTIES] [, PROPERTYSHEET_SETSELECTED=*empty
string, string,* or *array of strings*] [, REFRESH_PROPERTY=*string*, *array of
strings*, or *integer*] [, SET_VALUE=*value*]

Keywords that apply to widgets created with WIDGET_SLIDER:
[, GET_VALUE=*value*] [, SET_SLIDER_MAX=*value*]
[, SET_SLIDER_MIN=*value*] [, SET_VALUE=*value*][, TAB_MODE=*value*]

Keywords that apply to widgets created with WIDGET_TAB:
[, SET_TAB_CURRENT=*index*] [, SET_TAB_MULTILINE=*value*]
[, TAB_MODE=*value*]

Keywords that apply to widgets created with WIDGET_TABLE:
[, ALIGNMENT={0 | 1 | 2}] [, /ALL_TABLE_EVENTS]
[, AM_PM=*[string, string]*] [, BACKGROUND_COLOR=*array*]
[, COLUMN_LABELS=*string array*] [, COLUMN_WIDTHS=*array*]
[, /CONTEXT_EVENTS] [, DAYS_OF_WEEK=*string_array*{7 names}]
[, /DELETE_COLUMNS{not for row_major mode}] [, /DELETE_ROWS{not
for column_major mode}] [, /EDITABLE] [, EDIT_CELL=*[integer, integer]*]
[, FONT=*string array*] [, FOREGROUND_COLOR=*array*] [, FORMAT=*value*]
[, GET_VALUE=*variable*]
[, IGNORE_ACCELERATORS={*string array* | {0 | 1}}]
[, INSERT_COLUMNS=*value*] [, INSERT_ROWS=*value*]
[, /KBRD_FOCUS_EVENTS] [, MONTHS=*string_array*{12 names}]
[, ROW_LABELS=*string array*] [, ROW_HEIGHTS=*array*]
[, SET_TABLE_SELECT=*[left, top, right, bottom]*]
[, SET_TABLE_VIEW=*[integer, integer]*] [, SET_TEXT_SELECT=*[integer,
integer]*] [, SET_VALUE=*value*] [, TAB_MODE=*value*]
[, TABLE_BLANK=*cells*] [, /TABLE_DISJOINT_SELECTION]
[, TABLE_XSIZE=*columns*] [, TABLE_YSIZE=*rows*]
[, /USE_TABLE_SELECT | , USE_TABLE_SELECT=*[left, top, right, bottom]*]
[, /USE_TEXT_SELECT]

Keywords that apply to widgets created with WIDGET_TEXT:
[, /ALL_TEXT_EVENTS] [, /APPEND] [, /CONTEXT_EVENTS]
[, /EDITABLE] [, GET_VALUE=*variable*]
[, IGNORE_ACCELERATORS={*string array* | {0 | 1}}] [, /INPUT_FOCUS]
[, /KBRD_FOCUS_EVENTS] [, /NO_NEWLINE]
[, SET_TEXT_SELECT=*[integer, integer]*]
[, SET_TEXT_TOP_LINE=*line_number*] [, SET_VALUE=*value*]
[, TAB_MODE=*value*] [, /USE_TEXT_SELECT]

Keywords that apply to widgets created with WIDGET_TREE:
[, /CONTEXT_EVENTS] [, GET_VALUE=*variable*]
[, SET_DRAG_NOTIFY=*string*] [, /SET_DRAGGABLE]
[, /SET_DROP_EVENTS] [, /SET_MASK] [, SET_TREE_BITMAP=*array*]
[, /SET_TREE_EXPANDED] [, SET_TREE_INDEX=*value*]
[, SET_TREE_SELECT={0 | 1 | *widget ID* | *array of widget IDs*}]
[, /SET_TREE_VISIBLE] [, SET_VALUE=*value*] [, TAB_MODE=*value*]

Arguments

Widget_ID

The widget ID of the widget to be manipulated. This argument is required by all operations, unless the description of the specific keyword states otherwise. Note that if *Widget_ID* is not provided for a keyword that needs it, that keyword is quietly ignored.

Keywords

Not all keywords to WIDGET_CONTROL apply to all combinations of widgets. In the following list, descriptions of keywords that affect only certain types of widgets include a list of the widgets for which the keyword is useful.

ALIGNMENT

This keyword applies to widgets created with the WIDGET_TABLE function.

Set this keyword equal to a scalar, 2-D array, or 1-D array specifying the alignment of the contents of each cell. An alignment of 0 (the default) aligns the left edge of the text with the left edge of the cell. An alignment of 2 right-justifies the text, while 1 results in text centered within the cell.

If the USE_TABLE_SELECT keyword is not set:

• If ALIGNMENT is set equal to a scalar, all table cells are aligned as specified. If ALIGNMENT is set equal to a 2-D array, the alignment of each table cell is governed by the corresponding element of the array.

If the USE_TABLE_SELECT keyword is set:

• In standard selection mode, if ALIGNMENT is set equal to a scalar, all cells in the selection are aligned as specified. If ALIGNMENT is set equal to a 2-D array, the alignment of each selected cell is governed by the corresponding element of the array.

• In disjoint selection mode, if ALIGNMENT is set equal to a scalar, all cells in the selection are aligned as specified. If ALIGNMENT is set equal to a 1-D array, the alignment of each selected cell is governed by the corresponding element of the array.

ALL_TABLE_EVENTS

This keyword applies to widgets created with the WIDGET_TABLE function.

Set this keyword to cause the table widget to generate events whenever the user changes the contents of a table cell.

Note

If the EDITABLE keyword is set, an insert character event (TYPE=0) is generated when the user presses the RETURN or ENTER key in the table widget, even if the ALL_TABLE_EVENTS keyword is not set. End-of-line events such as these could be used by the programmer as an indication to check the cell value or to set the currently selected cell to the next cell. See the table below for details on the interaction between ALL_TABLE_EVENTS and EDITABLE.

Keywords		Effects	
ALL_TABLE_EVENTS	**EDITABLE**	**Input changes widget contents?**	**Type of events generated**
Not set	Not set	No	None
Not set	Set	Yes	End-of-line insertion
Set	Not set	No	All events
Set	Set	Yes	All events

Table 25-3: Effects of Using the ALL_TABLE_EVENTS and EDITABLE keywords

ALL_TEXT_EVENTS

This keyword applies to widgets created with the WIDGET_TEXT function.

Set this keyword to cause the text widget to generate events whenever the user changes the contents of the text area.

Note ———————————————————————————————————

If the EDITABLE keyword is set, an insert character event (TYPE=0) is generated when the user presses the RETURN or ENTER key in the text widget, even if the ALL_EVENTS keyword is not set. See the table below for details on the interaction between ALL_TEXT_EVENTS and EDITABLE.

———

Keywords		Effects	
ALL_TEXT_EVENTS	**EDITABLE**	**Input changes widget contents?**	**Type of events generated**
Not set	Not set	No	None
Not set	Set	Yes	End-of-line insertion
Set	Not set	No	All events
Set	Set	Yes	All events

Table 25-4: Effects of Using the ALL_TEXT_EVENTS and EDITABLE keywords

AM_PM

This keyword applies to widgets created with the WIDGET_TABLE function.

Supplies a string array of two names to be used for the names of the AM and PM string when processing explicitly formatted dates (CAPA, CApA, and CapA format codes) with the FORMAT keyword.

Note ———————————————————————————————————

You can use language catalogs to internationalize this value with strings in particular languages. For more information, see Chapter 19, "Using Language Catalogs" (*Application Programming*).

———

APPEND

This keyword applies to widgets created with the WIDGET_TEXT function.

When using the SET_VALUE keyword to set the contents of a text widget (as created with the WIDGET_TEXT procedure), setting this keyword indicates that the supplied text should be appended to the existing contents of the text widget rather than replace it.

BACKGROUND_COLOR

This keyword applies to widgets created with the WIDGET_TABLE function.

Set this keyword to one or more RGB triplets to specify cell background colors. For an RGB triplet, each red, green, and blue byte must be in the range [0,255].

Note ───

A computer's graphics system might not express an arbitrary RGB triplet accurately or be capable of displaying a large number of distinct colors. The actually applied may be different from the color you specify.

───

When you use this keyword in conjunction with USE_TABLE_SELECT, you can specify the set of affected cells. Otherwise, IDL operates on all of the table's cells. If a single color is provided, it is applied to all cells and is used as the default whenever new cells are created. If more than one color is provided, IDL applies the colors row by row, left to right, working from the top row to the bottom row. When there are fewer colors than cells, IDL cycles through the colors repeatedly.

For more information, see "Cell Attributes" (Chapter 7, *Widget Application Programming*).

BAD_ID

This keyword applies to all widgets.

If *Widget_ID* is not a valid widget identifier, this WIDGET_CONTROL normally issues an error and causes program execution to stop. However, if BAD_ID is present and specifies a named variable, the invalid ID is stored into the variable, and this routine quietly returns. If no error occurs, a zero is stored.

BASE_SET_TITLE

This keyword applies to widgets created with the WIDGET_BASE function.

Set this keyword to a scalar string to change the title of the specified base widget. If the parent of the base widget is a tab widget, the title of the corresponding tab in the

tab widget is changed to the provided string. If the parent is not a tab control, this keyword behaves like the keyword TLB_SET_TITLE.

Note

You can use language catalogs to internationalize this value with strings in particular languages. For more information, see Chapter 19, "Using Language Catalogs" (*Application Programming*).

BITMAP

This keyword applies to widgets created with the WIDGET_BUTTON function.

Set this keyword to specify that the SET_VALUE keyword specifies the name of a .bmp file.

The value of a widget button can be a bitmap as described in "Bitmap Button Labels" on page 2679. If you specify the name of a bitmap file with the VALUE keyword, you must also set the BITMAP keyword.

CLEAR_EVENTS

This keyword applies to all widgets.

If set, any events generated by the widget hierarchy rooted at *Widget_ID* which have arrived but have not been processed (via the WIDGET_EVENT procedure) are discarded.

COLUMN_LABELS

This keyword applies to widgets created with the WIDGET_TABLE function.

Set this keyword equal to an array of strings to be used as labels for the columns of the table. If no label is specified for a column, it receives the default label "*n*" where *n* is the column number. If this keyword is set to the empty string ("), all column labels are set to be empty.

Note

You can use language catalogs to internationalize this value with strings in particular languages. For more information, see Chapter 19, "Using Language Catalogs" (*Application Programming*).

COLUMN_WIDTHS

This keyword applies to widgets created with the WIDGET_TABLE function.

Set this keyword equal to a one-dimensional array of widths for the columns of the table widget. The widths are given in the units specified with the UNITS keyword. If no width is specified for a column, that column is set to the default size, which varies by platform. If COLUMN_WIDTHS is set to a scalar value, all of the column widths are set to that value.

Note ──
Column widths are limited to 0.
──

If the USE_TABLE_SELECT keyword is set (in either standard or disjoint selection mode), the indices of the elements of an array specified as the value of the COLUMN_WIDTHS keyword are interpreted as indices into the list of selected columns. For example, if the table is in disjoint selection mode, the current selection includes cells from columns 0, 1, 2, 5, 6, and 7, USE_TABLE_SELECT is set equal to one, and the COLUMN_WIDTHS keyword is set equal to a four-element array [20, 35, 30, 35], the widths of columns 0, 1, 2, and 5 would be modified. Similarly, if the table is in standard selection mode and the USE_TABLE_SELECT keyword is set equal to the array [0, 1, 0, 0], and the COLUMN_WIDTHS keyword is set equal to a four-element array [20, 35, 30, 35], only the width of the first column would be altered.

COMBOBOX_ADDITEM

This keyword applies to widgets created with the WIDGET_COMBOBOX function.

Set this keyword to a non-null string that specifies a new item to add to the list of the combobox. By default, the item will be added to the end of the list. The item can be added to a specified position in the list by setting the COMBOBOX_INDEX keyword in the same call to WIDGET_CONTROL.

COMBOBOX_DELETEITEM

This keyword applies to widgets created with the WIDGET_COMBOBOX function.

Set this keyword to an integer that specifies the zero-based index of the combobox element to be deleted from the list. If the specified element is outside the range of existing elements, no element is deleted.

COMBOBOX_INDEX

This keyword applies to widgets created with the WIDGET_COMBOBOX function.

Set this keyword to an integer that specifies the zero-based index of the position at which a new item will be added to the list when using the COMBOBOX_ADDITEM keyword. The value -1 is a special case that indicates the item should be added to the

end of the list. Note that this special case is provided for convenience, and that an item can also be added to the end of the list by omitting the COMBOBOX_INDEX keyword entirely. If the supplied index is not -1, and is outside the range of zero to the length of the existing list, the item is not added to the list.

Note

You can retrieve the length of the existing list using the COMBOBOX_NUMBER keyword to WIDGET_INFO function.

CONTEXT_EVENTS

This keyword applies to widgets created with the WIDGET_BASE, WIDGET_LIST, WIDGET_PROPERTYSHEET, WIDGET_TABLE, WIDGET_TEXT, and WIDGET_TREE functions.

Set this keyword to cause *context menu events* (or simply *context events*) to be issued when the user clicks the right mouse button over the widget. Set the keyword to 0 (zero) to disable such events. Context events are intended for use with context-sensitive menus (also known as pop-up or shortcut menus); pass the context event ID to the WIDGET_DISPLAYCONTEXTMENU procedure within your widget program's event handler to display the context menu.

Note

You can also capture right mouse button events generated within draw widgets. See the BUTTON_EVENTS keyword to WIDGET_DRAW function for details.

For more on detecting and handling context menu events, see "Context-Sensitive Menus" (Chapter 3, *Widget Application Programming*).

DAYS_OF_WEEK

This keyword applies to widgets created with the WIDGET_TABLE function.

Supplies a string array of 7 names to be used for the names of the days of the week when processing explicitly formatted dates (CDWA, CDwA, and CdwA format codes) with the FORMAT keyword.

Note

You can use language catalogs to internationalize this value with strings in particular languages. For more information, see Chapter 19, "Using Language Catalogs" (*Application Programming*).

DEFAULT_FONT

This keyword applies to all widgets that support fonts. Attempting to set a font on a widget that does not support fonts is not an error, but the attempt is ignored.

Note ───

The WIDGET_BASE, WIDGET_DRAW, WIDGET_TAB, and WIDGET_TREE widgets do *not* support fonts.

──

Do not specify a *Widget ID* when using this keyword.

A string containing the name of the default font to be used.

If the font to be used for a given widget is not explicitly specified (via the FONT keyword to the widget creation function), a default supplied by the window system or server is used. Use this keyword to change the default. See "About Device Fonts" on page 5580 for details on specifying names for device fonts. If this keyword is omitted, the default font is used.

Note ───

On Microsoft Windows platforms, IDL uses the system default font. Different versions of Windows use different system default fonts; in general, the system default font is the font appropriate for the version of Windows in question.

──

DELAY_DESTROY

This keyword applies to all widgets. Do not specify a *Widget ID* when using this keyword.

Normally, when the user destroys a widget hierarchy using the window manager, it is immediately removed. This can cause problems for applications that use the background task facility provided by the XMANAGER procedure if the hierarchy is destroyed while a background task is using it.

If DELAY_DESTROY is set, attempts to destroy the hierarchy are delayed until the next attempt to obtain an event for it. Setting DELAY_DESTROY to zero restores the default behavior.

XMANAGER uses this keyword automatically when managing background tasks. It is not expected that applications will need to use it directly.

DELETE_COLUMNS

This keyword applies to widgets created with the WIDGET_TABLE function.

Set this keyword to delete columns that contain selected cells. If a selection is specified via the USE_TABLE_SELECT keyword (in either standard or disjoint mode), the columns that contain cells specified in the selection array are deleted. If the USE_TABLE_SELECT keyword is *either* absent or set equal to 1, the columns that contain selected cells are deleted.

Warning
You cannot delete columns from a table which displays structure data in /ROW_MAJOR mode (the default).

DELETE_ROWS

This keyword applies to widgets created with the WIDGET_TABLE function.

Set this keyword to delete rows that contain selected cells. If a selection is specified via the USE_TABLE_SELECT keyword (in either standard or disjoint mode), the rows that contain cells specified in the selection array are deleted. If the USE_TABLE_SELECT keyword is *either* absent or set equal to 1, the rows that contain selected cells are deleted.

Warning
You cannot delete rows from a table which displays structure data in /COLUMN_MAJOR mode.

DESTROY

This keyword applies to all widgets.

Set this keyword to destroy the widget and any child widgets in its hierarchy. Any further attempts to use the IDs for these widgets will cause an error.

DRAW_BUTTON_EVENTS

This keyword applies to widgets created with the WIDGET_DRAW function.

Set this keyword to enable button press events for draw widgets. Setting a zero value disables such events.

Note
You can use button events generated by draw widgets to simulate the functionality of the CONTEXT_EVENTS keyword to WIDGET_BASE, WIDGET_LIST, and WIDGET_TEXT. See the BUTTON_EVENTS keyword to WIDGET_DRAW for details.

DRAW_EXPOSE_EVENTS

This keyword applies to widgets created with the WIDGET_DRAW function.

Set this keyword to enable viewport expose events for draw widgets. Setting a zero value disables such events.

Note ———

You must explicitly disable backing store (by setting the RETAIN keyword to WIDGET_DRAW equal to zero) in order to generate expose events.

——

DRAW_KEYBOARD_EVENTS

This keyword applies to widgets created with WIDGET_DRAW.

Set this keyword equal to 1 (one) or 2 to make the draw widget generate an event when it has the keyboard focus and a key is pressed or released. (The method by which a widget receives the keyboard focus is dependent on the window manager in use.) The value of the key pressed is reported in either the CH or the KEY field of the event structure, depending on the type of key pressed. See "Widget Events Returned by Draw Widgets" on page 2775 for details.

- If this keyword is set equal to 1, the draw widget will generate an event when a "normal" key is pressed. "Normal" keys include all keys except function keys and the modifier keys: SHIFT, CONTROL, CAPS LOCK, and ALT. If a modifier key is pressed at the same time as a normal key, the value of the modifier key is reported in the MODIFIERS field of the event structure.

- If this keyword is set equal to 2, the draw widget will generate an event when *either* a normal key or a modifier key is pressed. Values for modifier keys are reported in the KEY field of the event structure, and the MODIFIERS field contains zero.

Note ———

Keyboard events are never generated for function keys.

——

DRAW_MOTION_EVENTS

This keyword applies to widgets created with the WIDGET_DRAW function.

Set this keyword to enable motion events for draw widgets. Setting a zero value disables such events.

DRAW_VIEWPORT_EVENTS

This keyword applies to widgets created with the WIDGET_DRAW function.

Set this keyword to enable viewport motion events for draw widgets. Setting a zero value disables such events.

DRAW_WHEEL_EVENTS

This keyword applies to widgets created with the WIDGET_DRAW function.

Set this keyword to enable wheel events for draw widgets. Setting a zero value disables such events.

DRAW_XSIZE

This keyword applies to widgets created with the WIDGET_DRAW function.

Set this keyword to an integer that specifies the new horizontal size for the graphics region (the *virtual size*) of a draw widget in units specified by the UNITS keyword (pixels are the default). For non-scrollable draw widgets, setting this keyword is the same as setting SCR_XSIZE or XSIZE. However, for scrolling draw widgets DRAW_XSIZE is the only way to change the width of the drawable area (XSIZE sets the viewport size).

DRAW_YSIZE

This keyword applies to widgets created with the WIDGET_DRAW function.

Set this keyword to an integer that specifies the new vertical size for the graphics region (the *virtual size*) of a draw widget in units specified by the UNITS keyword (pixels are the default). For non-scrollable draw widgets, setting this keyword is the same as setting SCR_YSIZE or YSIZE. However, for scrolling draw widgets DRAW_YSIZE is the only way to change the height of the drawable area (YSIZE sets the viewport size).

DYNAMIC_RESIZE

This keyword applies to widgets created with the WIDGET_BUTTON, WIDGET_COMBOBOX, WIDGET_DROPLIST, and WIDGET_LABEL functions.

Set this keyword to activate (if set to 1) or deactivate (if set to 0) dynamic resizing of the specified WIDGET_BUTTON, WIDGET_LABEL, or WIDGET_DROPLIST widget (see the documentation for the DYNAMIC_RESIZE keyword to those procedures for more information about dynamic widget resizing).

EDITABLE

This keyword applies to widgets created with the WIDGET_PROPERTYSHEET, WIDGET_TABLE, and WIDGET_TEXT functions.

Set this keyword to directly edit the contents of a property sheet, text, or table widget. For table widgets, you can control individual cell editability by restricting the targeted cells with USE_TABLE_SELECT. Additionally, when you supply an array of editability values, the values are distributed across the set of target cells. A scalar value is applied to all targeted cells.

For more information, see "Cell Attributes" (Chapter 7, *Widget Application Programming*).

The default value depends on the type of widget as follows:

- Text and table widgets are read-only by default (the default value is 0). The text cannot be modified. See the descriptions of the ALL_TABLE_EVENTS and ALL_TEXT_EVENTS keywords for additional details.

- Property sheet widgets are editable by default (EDITABLE=1). In this default mode, property values can be modified. When a property sheet is marked as read-only (EDITABLE=0), you can select properties and use any scrollbars, but cannot change any values. Setting this keyword to 0 is roughly equivalent to desensitizing all properties by setting the SENSITIVE attribute of *every* property on the property sheet equal to 0.

Note

To set the SENSITIVE attribute of individual properties within a property sheet, use IDLitComponent::RegisterProperty or IDLitComponent::SetPropertyAttribute.

EDIT_CELL

This keyword applies to widgets created with the WIDGET_TABLE function.

Set this keyword equal to a two-element integer array containing the y (row) and x (column) coordinates of a table cell to put that cell into edit mode. For example, to put the top cell in the third column (x index=2) into edit mode, use the following commands:

```
row=0
col=2
WIDGET_CONTROL, table, EDIT_CELL=[row, col]
```

where *table* is the Widget ID of the table widget.

EVENT_FUNC

This keyword applies to all widget primitives (non-compound widgets).

A string containing the name of a function to be called by the WIDGET_EVENT function when an event arrives from a widget in the widget hierarchy given by *Widget_ID*.

This keyword overwrites any event routine supplied by previous uses of the EVENT_FUNC or EVENT_PRO keywords. To specify no event routine, set this keyword to a null string (' ').

EVENT_PRO

This keyword applies to all widget primitives (non-compound widgets).

A string containing the name of a procedure to be called by the WIDGET_EVENT function when an event arrives from a widget in the widget hierarchy given by *Widget_ID*.

This keyword overwrites any event routine supplied by previous uses of the EVENT_FUNC or EVENT_PRO keywords. To specify no event routine, set this keyword to a null string (' ').

FONT

This keyword applies to widgets created with the WIDGET_TABLE function.

Set this keyword to the names of the fonts used by the widget. Specified fonts are "device fonts" (an X Windows font on Motif systems, a TrueType or PostScript font on Windows systems). See "About Device Fonts" on page 5580 for details on specifying names for device fonts. If this keyword is omitted, the default font is used.

You can restrict the set of targeted cells with USE_TABLE_SELECT. Another way to control individual cell fonts is to specify an array of font names. IDL distributes the supplied font names over the set of targeted cells, repeatedly if necessary (if there are fewer fonts than cells). If you provide a scalar string, IDL changes all targeted cells to the same font.

For more information, see "Cell Attributes" (Chapter 7, *Widget Application Programming*).

FOREGROUND_COLOR

This keyword applies to widgets created with the WIDGET_TABLE function.

Set this keyword to one or more RGB triplets to specify cell text colors. For an RGB triplet, each red, green, and blue byte must be in the range [0,255].

Note ————————————————————————————————————

A computer's graphics system might not express an arbitrary RGB triplet accurately or be capable of displaying a large number of distinct colors. The actually applied may be different from the color you specify.

———

When you use this keyword in conjunction with USE_TABLE_SELECT, you can specify the set of affected cells. Otherwise, IDL operates on all of the table's cells. If a single color is provided, it is applied to all cells and is used as the default whenever new cells are created. If more than one color is provided, IDL applies the colors row by row, left to right, working from the top row to the bottom row. When there are fewer colors than cells, IDL cycles through the colors repeatedly.

For more information, see "Cell Attributes" (Chapter 7, *Widget Application Programming*).

FORMAT

This keyword applies to widgets created with the WIDGET_TABLE function.

Set this keyword equal to a single string or a one- or two-dimensional array of strings that specify the format of data displayed within table cells. The string(s) are of the same form as used by the FORMAT keyword to the PRINT procedure, and the default format is the same as that used by the PRINT/PRINTF procedures.

If the USE_TABLE_SELECT keyword is set equal to one, the format is changed only for the currently selected cells. If USE_TABLE_SELECT is set equal to an array, the format is changed for the specified cells.

- In standard selection mode, FORMAT can be set either to a single string or to a two-dimensional array of strings of the same size as the selected area.

- In disjoint selection mode, FORMAT can be set either to a single string or to a one-dimensional array of strings with the same number of elements as the selected area.

FUNC_GET_VALUE

This keyword applies to all widgets.

A string containing the name of a function to be called when the GET_VALUE keyword to the WIDGET_CONTROL procedure is called for this widget. The function specified by FUNC_GET_VALUE is called with the widget ID as an argument. The function specified by FUNC_GET_VALUE should return a value for a

widget. Using this technique allows you to change the value that should be returned for a widget. Compound widgets use this ability to define their values transparently to the user.

GET_DRAW_VIEW

This keyword applies to widgets created with the WIDGET_DRAW function.

Specifies a named variable which will be assigned the current position of a draw widget viewport. The position is returned as a 2-element integer array giving the X and Y position relative to the lower left corner of the graphics area.

GET_UVALUE

This keyword applies to all widgets.

Set this keyword to a named variable to contain the current user value of the widget.

Each widget can contain a user set value of any data type and organization. This value is not used by the widget in any way, and exists entirely for the convenience of the IDL programmer. This keyword allows you to obtain the current user value.

The user value of a widget can be set with the SET_UVALUE keyword to this routine, or with the UVALUE keyword to the routine that created it.

To improve the efficiency of the data transfer, consider using the NO_COPY keyword (described below) with GET_UVALUE.

GET_VALUE

This keyword applies to widgets created with the WIDGET_ACTIVEX, WIDGET_BUTTON, WIDGET_COMBOBOX, WIDGET_DRAW, WIDGET_DROPLIST, WIDGET_LABEL, WIDGET_PROPERTYSHEET, WIDGET_SLIDER, WIDGET_TABLE, WIDGET_TEXT, and WIDGET_TREE functions.

Note

If you would like information about the values returned for a specific compound widget—beginning with the prefix "CW_"—please refer to the description of the compound widget, which may also include a section titled, "Keywords to WIDGET_CONTROL and WIDGET_INFO". Compound widgets are described in the *Reference Guide*.

Set this keyword to a named variable to contain the current value of the widget. The type of value returned depends on the widget type:

- ActiveX: An object reference to the IDLcomActiveX object that underlies the ActiveX widget. See Chapter 4, "Using ActiveX Controls in IDL" (*IDL Connectivity Bridges*) for details.

- Button: If the button label is text, it is returned as a string. Attempts to obtain the value of a button with a bitmap label is an error.

- Combobox: The contents of the list of the combobox widget are returned as a string or string array.

- Draw: The value of a draw widget depends on whether the draw widget uses IDL Direct Graphics or IDL Object Graphics. (The type of graphics used is specified by the GRAPHICS_LEVEL keyword to WIDGET_DRAW.) The two possibilities are:

  A. By default, draw widgets use IDL Direct Graphics. In this case, the value of a draw widget is the IDL window ID for the drawing area. This ID is used with procedures such as WSET, WSHOW, etc., to direct graphics to the widget. The window ID is assigned to drawing area widgets at the time they are realized. If the widget has not yet been realized, a value of -1 is returned.

  B. If the draw widget uses IDL Object Graphics (that is, if the GRAPHICS_LEVEL keyword to WIDGET_DRAW is set equal to 2), the value of the draw widget is the object reference of the window object used in the draw widget.

  To obtain the window number for a newly created draw widget, use GET_VALUE *after* the draw widget has been realized. Draw widgets do not have a window number assigned to them until they are realized. For example, to return the window number of a draw widget in the variable win_num, use the command:

  ```
  WIDGET_CONTROL, my_drawwidget, GET_VALUE=win_num
  ```

  where my_drawwidget is the widget ID of the desired draw widget.

  When using Object Graphics for the widget draw, the following command returns an object reference to the draw window:

  ```
  WIDGET_CONTROL, my_drawwidget, GET_VALUE=oWindow
  ```

  where oWindow is a window object.

- Droplist: The contents of the droplist widget's list are returned as a string or string array.

- Label: The label text is returned as a string.

- Property Sheet: Retrieves the component object(s) that the property sheet is associated with. Use the GET_VALUE keyword to WIDGET_CONTROL.

- Slider: The current value of the slider is returned as an integer.

- Table: Normally, the data for the whole table are returned as a two dimensional array or a vector of structures.

  If the USE_TABLE_SELECT keyword is set, the value returned is a subset of the whole data.

  - If the table is in standard selection mode and the table data is of a single type, the value returned is a two dimensional array. If the table contains structure data, the value returned is a vector of (possibly anonymous) structures.

  - If the table is in disjoint selection mode and the table data is a single type, the value returned is a one-dimensional array of values. If the table contains structure data, the value returned is a single structure in which each field corresponds to a selected cell. In either case, use the TABLE_SELECT keyword to WIDGET_INFO to get the row and column indices of the disjoint values.

  If the USE_TEXT_SELECT keyword is set, the value returned is a string corresponding to the currently-selected text in the currently-selected cell.

- Text: The current contents of the text widget are returned as a string array. If the USE_TEXT_SELECT keyword is also specified, only the contents of the current selection are returned.

- Tree: The label text associated with the node is returned as a string. If the specified widget is the root of the tree then the null string ("") is returned.

- Widget types not listed above do not return a value. Attempting to retrieve the value of such a widget causes an error.

The value of a widget can be set with the SET_VALUE keyword to this routine, or with the VALUE keyword to the routine that created it.

GROUP_LEADER

This keyword applies to all widgets.

The widget ID of an existing widget that serves as "group leader" for the newly-created widget. When a group leader is killed, for any reason, all widgets in the group are also destroyed.

A given widget can be in more than one group. The WIDGET_CONTROL procedure can be used to add additional group associations to a widget. It is not possible to remove a widget from an existing group.

HOURGLASS

This keyword applies to all widgets. Do not specify a *Widget ID* when using this keyword.

Set this keyword to turn on an "hourglass-shaped" cursor for all IDL widgets and graphics windows. The hourglass remains in place until the WIDGET_EVENT function attempts to process the next event. Then the previous cursor is reinstated. If an application starts a time-intensive calculation inside an event-handling routine, the hourglass cursor should be used to indicate that the system is not currently responding to events.

ICONIFY

This keyword applies to all widgets.

Set this keyword to a non-zero value to cause the specified widget to become iconified. Set this keyword to zero to open an iconified widget.

IGNORE_ACCELERATORS

This keyword applies to widgets created with the WIDGET_COMBOBOX, WIDGET_DRAW, WIDGET_PROPERTYSHEET, WIDGET_TABLE, and WIDGET_TEXT functions.

Set this keyword to a list of accelerators that should be ignored while the target widget has the keyboard focus. Using this mechanism, keystrokes that IDL would otherwise deliver only to an accelerated button are allowed to fall through to the target widget. If the keyword is set while the widget already has the focus, the effects are immediate. Acceleration is restored when the target widget loses the focus.

Note ———
See WIDGET_BUTTON's description of the ACCELERATOR keyword for the syntax used to specify accelerators.
———

If you do not set this keyword to a list, you can set it to one of the following values:

1	All existing accelerators are ignored
0	No accelerators are ignored

INPUT_FOCUS

This keyword applies to widgets created with the WIDGET_BUTTON, WIDGET_DRAW, and WIDGET_TEXT functions.

If *Widget_ID* is a text widget or a draw widget, set this keyword to cause the widget to receive the keyboard focus. If *Widget_ID* is a button widget, set this keyword to position the mouse pointer over the button (on Motif), or set the focus to the button so that it can be "pushed" with the spacebar (on Windows). While this keyword will set the focus to widgets of other types, the exact location of the focus is not well defined.

Note ───────────────────────────────

You cannot assign the input focus to an unrealized widget.

─────────────────────────────────────

INSERT_COLUMNS

This keyword applies to widgets created with the WIDGET_TABLE function.

Set this keyword to the number of columns to be added to the right of the rightmost column of the table. If the USE_TABLE_SELECT keyword is set equal to one, the columns are inserted to the left of the current selection. If USE_TABLE_SELECT is set equal to an array, the columns are inserted to the left of the specified selection.

Warning ───────────────────────────────

You cannot insert columns into a table which displays structure data in /ROW_MAJOR (default) mode because it would change the structure.

─────────────────────────────────────

INSERT_ROWS

This keyword applies to widgets created with the WIDGET_TABLE function.

Set this keyword to the number of rows to be added below the bottommost row of the table. If the USE_TABLE_SELECT keyword is set equal to one, the rows are inserted above the current selection. If USE_TABLE_SELECT is set equal to an array, the rows are inserted above the specified selection.

Warning ───────────────────────────────

You cannot insert rows into a table which displays structure data in /COLUMN_MAJOR mode because it would change the structure.

─────────────────────────────────────

KBRD_FOCUS_EVENTS

This keyword applies to widgets created with the WIDGET_BASE, WIDGET_TABLE, and WIDGET_TEXT functions.

Set this keyword to cause widget keyboard focus events to be issued for the widget whenever the keyboard focus of that widget changes. See the KBRD_FOCUS_EVENTS keywords to WIDGET_BASE, WIDGET_TABLE, and WIDGET_TEXT for details.

See "Keyboard Focus Events" (Chapter 3, *Widget Application Programming*) for more information.

KILL_NOTIFY

This keyword applies to all widgets.

Use this keyword to change or remove a previously-specified callback procedure for *Widget_ID*. A previously-defined callback can be removed by setting this keyword to the null string (' ').

The callback routine is called with the widget identifier as its only argument. At that point, the widget identifier can only be used with the WIDGET_CONTROL procedure to get or set the user value. All other requests that require a widget ID are disallowed for the target widget. The callback is not issued until the WIDGET_EVENT function is called.

For a top-level base widget in a widget application, the CLEANUP keyword to XMANAGER can also be used to specify a procedure that will be called when the base widget dies. Note that the *last* call to any of:

- WIDGET_BASE, KILL_NOTIFY
- XMANAGER, CLEANUP
- WIDGET_CONTROL, KILL_NOTIFY

determines the procedure that is executed when the specified top-level base widget dies.

MANAGED

This keyword applies to all widgets.

This keyword is used by the XMANAGER procedure to mark those widgets that it is currently managing. User applications should not use this keyword directly.

MAP

This keyword applies to all widgets.

Set this keyword to zero to unmap the widget hierarchy rooted at the widget specified by *Widget_ID*. The hierarchy disappears from the screen, but still exists.

The mapping operation applies only to base widgets. If the specified widget is not a base, IDL searches upward in the widget hierarchy until it finds the closest base widget. The map operation is applied to that base.

Set MAP to a nonzero value to re-map the widget hierarchy and make it visible. Normally, the widget is automatically mapped when it is realized, so use of the MAP keyword is not required.

MONTHS

This keyword applies to widgets created with the WIDGET_TABLE function.

Supplies a string array of 12 names to be used for the names of the months when processing explicitly formatted dates (CMOA, CMoA, and CmoA format codes) with the FORMAT keyword.

Note

You can use language catalogs to internationalize this value with strings in particular languages. For more information, see Chapter 19, "Using Language Catalogs" (*Application Programming*).

MULTIPLE_PROPERTIES

This keyword applies to widgets created with the WIDGET_PROPERTYSHEET function.

Set this property to 1 to allow multiple properties to be selected at the same time. When this keyword is set, you can hold down the **Ctrl** key while left-clicking with the mouse to make nonadjacent selections, or hold down the **Shift** key to select an adjacent range of properties.

When changing the selection support of a property sheet from multiple selection to single selection (MULTIPLE_PROPERTIES equals 0), the current set of selected properties is cleared unless there is only a single selection.

NO_COPY

This keyword applies to all widgets.

Usually, when setting or getting widget user values, either at widget creation or using the SET_UVALUE and GET_UVALUE keywords to WIDGET_CONTROL, IDL makes a copy of the data being transferred. Although this technique is fine for small data, it can have a significant memory cost when the data being copied is large.

If the NO_COPY keyword is set, IDL handles the SET_UVALUE and GET_UVALUE operations differently. Rather than copy the source data, it takes the data away from the source and attaches it directly to the destination. This feature can be used by compound widgets to obtain state information from a UVALUE without the memory copying that would otherwise occur. However, it has the side effect of causing the source variable to become undefined. On a "set" operation (using the SET_UVALUE keyword to WIDGET_CONTROL), the variable passed as value becomes undefined. On a "get" operation (GET_UVALUE keyword to WIDGET_CONTROL), the user value of the widget in question becomes undefined.

Note
The NO_COPY keyword increases efficiency when sending event structures using the SEND_EVENT keyword to WIDGET_CONTROL.

NO_NEWLINE

This keyword applies to widgets created with the WIDGET_TEXT function.

When setting the value of a multi-line text widget, newline characters are automatically appended to the end of each line of text. The NO_NEWLINE keyword suppresses this action.

NOTIFY_REALIZE

This keyword applies to all widgets.

Set this keyword to a string that contains the name of a procedure to be called automatically when the specified widget is realized. This callback occurs just once (because widgets are realized only once). Each widget is allowed a single such "callback" procedure. A previously-set callback routine can be removed by setting this keyword to the null string (' '). The callback routine is called with the widget ID as its only argument.

PRO_SET_VALUE

This keyword applies to all widgets.

A string containing the name of a procedure to be called when the SET_VALUE keyword to the WIDGET_CONTROL procedure is called for this widget.

The procedure specified by PRO_SET_VALUE is called with two arguments: a *Widget ID* and a *Value*. Using this technique allows you to designate a routine that sets the value for the widget specified by *Widget ID*.

This keyword is intended for use in compound widgets, which use it to define the compound widget's value transparently to the user.

Using this keyword with widget primitives is somewhat problematic, because calling WIDGET_CONTROL, SET_VALUE *within* the procedure will also call the procedure specified by PRO_SET_VALUE. In order to use PRO_SET_VALUE with a widget primitive, the specified procedure must do the following:

1. Process the *Value* supplied to the procedure in the necessary way

2. Unset the PRO_SET_VALUE keyword for the affected widget by setting its value to a null string

3. Set the affected widget's value using the SET_VALUE keyword to WIDGET_CONTROL

4. Reset the PRO_SET_VALUE keyword to the original procedure

PROPERTYSHEET_SETSELECTED

This keyword applies to widgets created with the WIDGET_PROPERTYSHEET function.

This keyword allows programmatic property selection. Set it to a string or an array of strings to identify the properties to appear selected. The strings should match valid property identifiers. When this keyword is set to an empty string, or an array that contains only empty strings, it clears all property selections.

PUSHBUTTON_EVENTS

This keyword applies to widgets created with the WIDGET_BUTTON function.

Set this keyword to a non-zero value to enable pushbutton events for the widget specified by *Widget_ID*. Set the keyword to 0 to disable pushbutton events for the specified widget. For a description of pushbutton events, see "PUSHBUTTON_EVENTS" on page 2687 in the documentation for WIDGET_BUTTON.

REALIZE

This keyword applies to all widgets.

If set, the widget hierarchy is realized. Until the realization step, the widget hierarchy exists only within IDL. Realization is the step of actually creating the widgets on the screen (and mapping them if necessary).

When a previously realized widget gets a new child widget, the new child is automatically realized.

Tip ───

Under Microsoft Windows, when a hidden base is realized, then mapped, a Windows resize message is sent by the windowing system. This "extra" resize event is generated before any manipulation of the base widget by the user.

───

REFRESH_PROPERTY

This keyword applies to widgets created with the WIDGET_PROPERTYSHEET function. Set this keyword to:

- A non-zero numeric value to refresh all properties. Refreshing all properties in this manner is more efficient to use /REFRESH_PROPERTY than WIDGET_CONTROL's SET_VALUE keyword to reload the property sheet.

- A string or string array containing one or more *property identifiers* identifying individual properties to be refreshed. See "Property Identifiers" (Chapter 4, *iTool Developer's Guide*) for information on property identifiers.

The REFRESH_PROPERTY keyword also updates a property's sensitivity and visibility according to the value of the property held by the related component. Although the property sheet knows about its component, the property sheet and underlying component have a clear boundary and can only affect each other through IDL statements. The following example illustrates this. The first selected property in the property sheet is hidden after a 4 second wait as long at the REFRESH_PROPERTY keyword is used. When commented out, there is no notification that the first selected property should be hidden.

```
PRO ExPropSheetRefresh

; Create and initialize the component.
oComp = OBJ_NEW('IDLitVisAxis')
; Create a base and property sheet.
base = WIDGET_BASE(/TLB_SIZE_EVENT, $
   TITLE = 'Single Property Sheet Example')
wPropAxis = WIDGET_PROPERTYSHEET(base, VALUE = oComp, $
UNAME = 'PropSheet', xsize = 45)
; Pre-select the color and transparency properties of
; axis component.
WIDGET_CONTROL, wPropAxis,  $
```

```
        PROPERTYSHEET_SETSELECTED=['Color', 'Transparency']

    ; Activate the widgets.
    WIDGET_CONTROL, base, SET_UVALUE = oComp, /REALIZE
    XMANAGER, 'ExSinglePropSheet', base, /NO_BLOCK

    ; Wait 4 seconds and then hide the first selected property
    ; and refresh the property sheet.
    WAIT, 4
    a = WIDGET_INFO(wPropAxis, /propertysheet_selected)
    oComp->SetPropertyAttribute, a[0], /HIDE
    WIDGET_CONTROL, wPropAxis, /REFRESH_PROPERTY

    END
```

RESET

This keyword applies to all widgets. Do not specify a *Widget ID* when using this keyword. Set the RESET keyword to destroy every currently active widget. This keyword should be used with caution.

ROW_LABELS

This keyword applies to widgets created with the WIDGET_TABLE function.

Set this keyword equal to an array of strings to be used as labels for the rows of the table. If no label is specified for a row, it receives the default label "*n*" where *n* is the row number. If this keyword is set to the empty string (''), all row labels are set to be empty.

ROW_HEIGHTS

This keyword applies to widgets created with the WIDGET_TABLE function.

Set this keyword equal to a one-dimensional array of heights for the rows of the table widget. The heights are given in the units specified with the UNITS keyword. If no height is specified for a row, that row is set to the default size, which varies by platform. If ROW_HEIGHTS is set to a scalar value, all of the row heights are set to that value.

Note

On Microsoft Windows platforms, rows cannot have different heights. You should supply a scalar value, but if you supply an array of values, IDL applies the last value to all rows.

Note ───

Row heights are limited to 0 on Motif and 1 on Windows.

───

If the USE_TABLE_SELECT keyword is set (in either standard or disjoint selection mode), the indices of the elements of the specified array are interpreted as indices into the list of selected rows. For example, if the table is in disjoint selection mode, the current selection includes cells from rows 0, 1, 2, 5, 6, and 7, USE_TABLE_SELECT is set equal to one, and the ROW_HEIGHTS keyword is set equal to a four-element array [20, 35, 30, 35], the height of rows 0, 1, 2, and 5 would be modified. Similarly, if the table is in standard selection mode and the USE_TABLE_SELECT keyword is set equal to the array [0, 1, 0, 0], and the ROW_HEIGHTS keyword is set equal to a four-element array [20, 35, 30, 35], only the height of the first row would be altered.

Note ───

You can make column header cells taller by first selecting them with USE_TABLE_SELECT (using -1 for the row values of the selection indexes the header cells of the selection's columns) and then setting their height with ROW_HEIGHTS.

───

SCR_XSIZE

This keyword applies to all widgets.

Set this keyword to an integer value that represents the widget's new horizontal size, in units specified by the UNITS keyword (pixels are the default). Attempting to change the size of a widget that is part of a menubar or pulldown menu causes an error. This keyword is useful for resizing table, text, list, and scrolling widgets. Note that [XY]SIZE sets client area and SCR_[XY]SIZE sets total area (title bar, borders, menu, client area).

SCR_YSIZE

This keyword applies to all widgets.

Set this keyword to an integer value that represents the widget's new vertical size, in units specified by the UNITS keyword (pixels are the default). Attempting to change the size of a widget that is part of a menubar or pulldown menu causes an error. This keyword is useful for resizing table, text, list, and scrolling widgets. Note that [XY]SIZE sets client area and SCR_[XY]SIZE sets total area (title bar, borders, menu, client area).

SEND_EVENT

This keyword applies to all widgets.

Set this keyword to a structure containing a valid widget event to be sent to the specified widget. The value of SEND_EVENT *must* be a structure and the first three fields must be ID, TOP, and HANDLER (all of LONG type). Additional fields can be of any type.

As a convenience, you can set the values of the ID, TOP, and HANDLER fields to the long integer zero. Setting these fields to zero will result in their being populated with the following values:

ID	the widget ID of the widget specified in the call to WIDGET_CONTROL.
TOP	the widget ID of the top-level base containing ID.
HANDLER	the widget ID of the widget associated with the event handling routine for ID.

To improve the efficiency of the data transfer, consider using the NO_COPY keyword with SEND_EVENT.

SENSITIVE

This keyword applies to all widgets.

Set this keyword to control the sensitivity state of a widget after creation. Use the SENSITIVE keyword with the widget creation function to control the initial sensitivity state.

When a widget is sensitive, it has normal appearance and can receive user input. For instance, a sensitive button widget can be activated by moving the mouse cursor over it and pressing a mouse button. When a widget is insensitive, it indicates the fact by changing its appearance, and ignores any input directed at it. If SENSITIVE is zero, the widget hierarchy becomes insensitive. If nonzero, it becomes sensitive.

Sensitivity can be used to control when a user is allowed to manipulate a widget. It should be noted that some widgets do not change their appearance when they are made insensitive, and simply cease generating events.

Note ————————————————————————————————

For tree widgets (created with the WIDGET_TREE function), only the sensitivity of the root node, and thus of the entire tree, can be changed.

———

SET_BUTTON

This keyword applies to widgets created with the WIDGET_BUTTON function.

This keyword changes the current state of toggle buttons. If set equal to zero, every toggle button in the hierarchy specified by *Widget_ID* is set to the unselected state. If set to a nonzero value, the action depends on the type of base holding the buttons:

- For a non-exclusive base:

  - If a single button is specified by *Widget_ID*, that button is set to the selected state, leaving the state of other buttons in the base unchanged.

  - If the base itself is specified by *Widget_ID*, all buttons are set to the selected state.

- For an exclusive base:

  - If a single button is specified by *Widget_ID*, that button is set to the selected state, and all other buttons in the base are set to the unselected state.

  - If the base itself is specified by *Widget_ID*, IDL generates an error, since an exclusive base can contain at most one selected button.

If the specified *Widget_ID* is a button widget that was created using the CHECKED_MENU keyword, the checked state of the menu item is modified. If the keyword value is nonzero, the menu button is placed in a checked state. If the keyword value is zero, the button is placed in a un-checked state.

SET_COMBOBOX_SELECT

This keyword applies to widgets created with the WIDGET_COMBOBOX function.

Set this keyword to an integer that specifies the zero-based index of the combobox list element to be displayed. If the specified element is outside the range of existing elements, the selection remains unchanged.

SET_DRAG_NOTIFY

This keyword applies to widgets created with the WIDGET_DRAW and WIDGET_TREE functions.

Set this keyword equal to a string containing the name of a function that will be automatically called as the end-user drags over the widget. Alternatively, set this keyword equal to the string:

- • `<inherit>` (including the < and > characters) to have the widget inherit an ancestor's callback

- • `<default>` (including the < and > characters) to use the system default callback.

For more details, see the DRAG_NOTIFY keyword to WIDGET_DRAW or WIDGET_TREE.

SET_DRAGGABLE

This keyword applies to widgets created with the WIDGET_TREE function.

Use this keyword to specify whether or not the widget can be dragged. A value of 1 (one) makes the widget a valid drag item and a value of 0 (zero) makes the widget not draggable. If this keyword is not specified or is set to -1 then the widget inherits its draggability from the nearest ancestor that sets the a draggability value.

Note

Although the root node of a tree widget cannot be dragged nor inherit a value, the value can be set so that child nodes can inherit the value. The default value is 0.

SET_DRAW_VIEW

This keyword applies to widgets created with the WIDGET_DRAW function.

A scrollable draw widget provides a large graphics area which is viewed through a smaller viewport. This keyword allows changing the current position of the viewport. The desired position is specified as a 2-element integer array giving the X and Y position in units specified by the UNITS keyword (pixels are the default) relative to the lower left corner of the graphics area. For example, to position the viewport to the lower left corner of the image:

```
WIDGET_CONTROL, widget, SET_DRAW_VIEW=[0, 0]
```

SET_DROP_EVENTS

This keyword applies to widgets created with the WIDGET_DRAW and WIDGET_TREE functions.

Use this keyword to specify whether or not the widget will generate drop events. See "Widget Events Returned by Draw Widgets" on page 2775 or "Widget Events Returned by Tree Widgets" on page 2931 for an explanation of the event structure.

A value of 1 (one) causes the widget to generate drop events and a value of 0 (zero) causes the widget to not generate drop events. If this keyword is not specified or is set

to -1, the widget inherits this setting from the nearest ancestor that sets a value of zero or one.

Tree root nodes and draw widgets can generate drop events, but cannot inherit. Their default value is 0.

SET_DROPLIST_SELECT

This keyword applies to widgets created with the WIDGET_DROPLIST function.

Set this keyword to an integer that specifies the droplist element to be current (i.e., the element that is displayed on the droplist button). Positions start at zero. If the specified element is outside the possible range, no new selection is set.

SET_LIST_SELECT

This keyword applies to widgets created with the WIDGET_LIST function.

Set this keyword to an integer scalar or vector that specifies the list element or elements to be highlighted. The previous selection (if there is a selection) is cleared. Positions start at zero. If the specified element is outside the possible range, no new selection is set. Note that the MULTIPLE keyword to WIDGET_LIST must have been set if more than a single list element is specified.

If the selected position is not currently on the screen, the list widget automatically move the current scrolling viewport to make it visible. The resulting topmost visible element is toolkit specific. If you wish to ensure a certain element is at the top of the list, use the SET_LIST_TOP keyword (described below) to explicitly set the viewport.

SET_LIST_TOP

This keyword applies to widgets created with the WIDGET_LIST function.

Set this keyword to an integer that specifies the element of the list widget to be positioned at the top of the scrolling list. If the specified element is outside the range of list elements, nothing happens.

SET_MASK

This keyword applies to widgets created with the WIDGET_TREE function.

Use this keyword in conjunction with SET_TREE_BITMAP to create a tree node icon that has transparency. Set the value to 1 (one) to use the bitmap's lower left pixel as the transparent pixel. When the keyword is not supplied or is explicitly set to 0 (zero), then transparency is not used in the bitmap. This keyword is ignored when not used with SET_TREE_BITMAP.

SET_SLIDER_MAX

This keyword applies to widgets created with the WIDGET_SLIDER function.

Set this keyword to a new maximum value for the specified slider widget.

Note ———————————————————————————————

This keyword does not apply to floating-point sliders created with the CW_FSLIDER function.

___

SET_SLIDER_MIN

This keyword applies to widgets created with the WIDGET_SLIDER function.

Set this keyword to a new minimum value for the specified slider widget.

Note ———————————————————————————————

This keyword does not apply to floating-point sliders created with the CW_FSLIDER function.

___

SET_TAB_CURRENT

This keyword applies to widgets created with the WIDGET_TAB function.

Set this keyword equal to the zero-based index of the tab to be set as the current (visible) tab. If the index value is invalid, the value is quietly ignored.

SET_TAB_MULTILINE

This keyword applies to widgets created with the WIDGET_TAB function.

This keyword controls how tabs appear on the tab widget when all of the tabs do not fit on the widget in a single row. This keyword behaves differently on Windows and UNIX systems.

Windows

Set this keyword to cause tabs to be organized in a multi-line display when the width of the tabs exceeds the width of the largest child base widget. If possible, IDL will create tabs that display the full tab text.

If MULTILINE=0 and LOCATION=0 or 1, tabs that exceed the width of the largest child base widget are shown with scroll buttons, allowing the user to scroll through the tabs while the base widget stays immobile.

If LOCATION=1 or 2, a multiline display is always used if the tabs exceed the height of the largest child base widget.

Note ───

The width or height of the tab widget is based on the width or height of the largest base widget that is a child of the tab widget. The text of the tabs (the titles of the tab widget's child base widgets) may be truncated even if the MULTILINE keyword is set.

───

UNIX

Set this keyword equal to an integer that specifies the maximum number of tabs to display per row in the tab widget. If this keyword is not specified (or is explicitly set equal to zero) all tabs are placed in a single row.

Note ───

The width or height of the tab widget is based on the width or height of the largest base widget that is a child of the tab widget. The text of the tabs (the titles of the tab widget's child base widgets) is never truncated in order to make the tabs fit the space available. (Tab text may be truncated if the text of a single tab exceeds the space available, however.) This means that if MULTILINE is set to any value other than one, some tabs may not be displayed.

───

SET_TABLE_SELECT

This keyword applies to widgets created with the WIDGET_TABLE function.

- In standard selection mode, specify a four-element array, of the form [*left, top, right, bottom*] specifying the cells to act upon.

- In disjoint selection mode, specify a 2 x *n* element array of column/row pairs specifying the cells to act upon.

Specifications for cell locations are zero-based (that is, the first data column is column number zero). You can use the value -1 to indicate that IDL should select an entire row or column. For example, to select all of Rows 3 and 4, you can specify either [-1,3,-1,4] or [[-1,3],[-1,4]], depending on the table's selection mode (standard or disjoint, respectively). This method differs from explicitly specifying all the cells of the rows in that IDL also selects the header cells, as if you had clicked on them. To deselect all cells, specify either [-1,-1,-1,-1] (in standard selection mode) or [-1,-1] (in disjoint selection mode).

See "USE_TABLE_SELECT" on page 2752 for details on the selection modes.

If the selected position is not currently on the screen, the table widget automatically moves the current scrolling viewport to make a portion of it visible. The resulting top-left visible cell is toolkit specific. If you wish to ensure a certain element is at the top of the list, use the SET_TABLE_VIEW keyword to explicitly set the viewport.

SET_TABLE_VIEW

This keyword applies to widgets created with the WIDGET_TABLE function.

Set this keyword to a two-element array of zero-based cell indices that specifies the cell of the table widget to the positioned at the top-left of the widget. If the specified cell is outside the range of valid cells, nothing happens.

SET_TEXT_SELECT

This keyword applies to widgets created with the WIDGET_TABLE and WIDGET_TEXT functions.

Use this keyword to clear any current selection in the specified table cell or text widget, and either set a new selection, or simply set the text insertion point. To set a selection, specify a two-element integer array containing the starting position and the length of the selection. For example, to set a selection covering characters 3 though 23:

```
WIDGET_CONTROL, widgetID, SET_TEXT_SELECT=[3, 20]
```

To move the text insertion point without setting a selection, omit the second element, or set it to zero.

SET_TEXT_TOP_LINE

This keyword applies to widgets created with the WIDGET_TEXT function.

Set this keyword to the zero-based line number of the line to be positioned on the topmost visible line in the text widget's viewport. No horizontal scrolling is performed. Note that this is a line number, not a character offset.

SET_TREE_BITMAP

This keyword applies to widgets created with the WIDGET_TREE function.

Set this keyword equal to a 16x16x3 array representing an RGB image that will be displayed next to the node in the tree widget.

Set this keyword equal to zero to revert to the appropriate default system bitmap.

SET_TREE_EXPANDED

This keyword applies to widgets created with the WIDGET_TREE function.

Set this keyword equal to a nonzero value to expand the specified tree widget folder. Set this keyword equal to zero to collapse the specified tree widget folder.

SET_TREE_INDEX

This keyword applies to widgets created with the WIDGET_TREE function.

Use this keyword to change the position of a tree widget node relative to its siblings. The supplied value will be the new zero-based index of the node. Values of -1 and those greater than or equal to the number of siblings result in the node being positioned as the last of the children.

SET_TREE_SELECT

This keyword applies to widgets created with the WIDGET_TREE function.

This keyword has two modes of operation, depending on the widget ID passed to WIDGET_CONTROL:

- If the specified widget ID is for the root node of the tree widget (the tree widget whose *Parent* is a base widget):

    - If the tree widget is in multiple-selection mode and SET_TREE_SELECT is set to an array of widget IDs corresponding to tree widgets that are nodes in the tree, those nodes are selected.

    - If the tree widget is *not* in multiple-selection mode and SET_TREE_SELECT is set to a single widget ID corresponding to a tree widget that is a node in the tree, that node is selected.

    - If the keyword is set to zero, all selections in the tree widget are cleared.

- If the specified widget ID is a tree widget that is a node in a tree:

    - If the keyword is set to a nonzero value, the specified node is selected.

    - If the keyword is set to zero, the specified node is deselected.

Note

If the tree widget is in multiple-selection mode, the selection changes made to the tree widget via this keyword are additive — that is, the current selections are retained and any additional nodes specified by SET_TREE_SELECT are also selected.

SET_TREE_VISIBLE

This keyword applies to widgets created with the WIDGET_TREE function and whose parent widget was also created using the WIDGET_TREE function (that is, tree widgets that are nodes of another tree).

Set this keyword to make the specified tree node *visible* to the user. Setting this keyword has two possible effects:

1. If the specified node is inside a collapsed folder, the folder and all folders above it are expanded to reveal the node.

2. If the specified node is in a portion of the tree that is not currently visible because the tree has scrolled within the parent base widget, the tree view scrolls so that the selected node is at the top of the base widget.

Note
Use of this keyword does not affect the tree widget selection state.

SET_UNAME

This keyword applies to all widgets.

Set this keyword to a string that can be used to identify the widget. You can associate a name with each widget in a specific hierarchy, and then use that name to query the widget hierarchy and get the correct widget ID. You can set the name at creation time, using the UNAME keyword with the creation function.

To query the widget hierarchy, use the WIDGET_INFO function with the FIND_BY_UNAME keyword. The UNAME should be unique to the widget hierarchy because the FIND_BY_UNAME keyword returns the ID of the first widget with the specified name.

SET_UVALUE

This keyword applies to all widgets.

Each widget can contain a user-set value. This value is not used by IDL in any way, and exists entirely for the convenience of the IDL programmer. This keyword allows you to set this value.

To improve the efficiency of the data transfer, consider using the NO_COPY keyword with SET_UVALUE.

SET_VALUE

This keyword applies to widgets created with the WIDGET_BUTTON, WIDGET_COMBOBOX, WIDGET_DROPLIST, WIDGET_LABEL, WIDGET_LIST, WIDGET_PROPERTYSHEET, WIDGET_SLIDER, WIDGET_TABLE, WIDGET_TEXT, and WIDGET_TREE functions.

Sets the value of the specified widget. The meaning of the value differs between widget types:

- Button: The label to be used for the button. This value can be either a scalar string, or a 2D byte array containing a bitmap.

- Combobox: The contents of the combobox widget (string or string array).

- Droplist: The contents of the droplist widget (string or string array).

- Label: The text to be displayed by the label widget.

- List: The contents of the list widget (string or string array).

- Property Sheet: Object references to one or more component objects to be displayed in the property sheet. Any existing associations are lost and the property sheet is reloaded with the new list of properties. To completely clear the property sheet, use a null object reference.

- Slider: The current position of the slider (integer).

- Table: Normally, the data for the whole table is changed to the specified data, which must be of the form of a two dimensional array or a vector of structures. In this form, the table is resized to fit the given data (unless the TABLE_XSIZE or TABLE_YSIZE keywords are given).

   If the USE_TABLE_SELECT keyword is set, the value given is treated as a subset of the whole data, and only the given range of cells are updated. Used in this form, the type of data stored in the table cannot be changed. The data passed in is converted, as appropriate, to the type of the selected cells. If less data is passed in than fits in the current selection, the cells outside the range of data (but inside the selection) are left unchanged. If more data is passed in than fits in the current selection, the extra data is ignored.

   - If the table is in standard selection mode, the data should be a two-dimensional array of values for a single-type table, or a vector of structures for a table that contains structure data.

   - If the table is in disjoint selection mode, the data should be a one-dimensional array of values for a single-type table, or a single structure

with each field corresponding to a cell for a table that contains structure data.

If the USE_TEXT_SELECT keyword is present, the value must be a string, which replaces the currently-selected text in the currently-selected cell.

- Text: The text to be displayed. If the APPEND keyword is also specified, the text is appended to the current contents instead of instead of completely replacing it (string or string array). If the USE_TEXT_SELECT keyword is specified, the new string replaces only the currently-selected text in the text widget.

- Tree: The text to be displayed next to the tree widget node. Setting the value of the root node of a tree has no effect and is quietly ignored.

- Widget types not listed above do not allow the setting of a value. Attempting to set the value of such a widget causes an error.

The value of a widget can also be set with the VALUE keyword to the routine that created it.

Note

You can use language catalogs to internationalize this value with strings in particular languages. For more information, see Chapter 19, "Using Language Catalogs" (*Application Programming*).

SHOW

This keyword applies to all widgets.

Controls the visibility of a widget hierarchy. If set to zero, the hierarchy containing *Widget_ID* is pushed behind any other windows on the screen. If nonzero, the hierarchy is pulled in front.

TAB_MODE

This keyword applies to widgets created with the WIDGET_BASE, WIDGET_BUTTON, WIDGET_COMBOBOX, WIDGET_DROPLIST, WIDGET_LIST, WIDGET_SLIDER, WIDGET_TAB, WIDGET_TABLE, WIDGET_TEXT, WIDGET_TREE.

Set this keyword to one of the values shown in the table below to determine how the widget hierarchy can be navigated using the **Tab** key. The TAB_MODE setting is inherited at creation time by lower-level bases and child widgets from the parent WIDGET_BASE unless it is explicitly set on an individual widget. If the TAB_MODE value of the widget differs from that of the base, the setting on the

widget will be respected when the widget has focus. For example, if a base does not support tabbing, but an individual child widget does support tabbing, this functionality will be enabled when the child widget has focus.

When WIDGET_CONTROL is used to change the TAB_MODE value, the change affects only the widget upon which it is explicitly set. The change is not propagated along the widget hierarchy after it has been created. The TAB_MODE keyword also *cannot* be explicitly set for the following widgets:

- Draw widgets

- Label widgets

- Grouped, exclusive button widgets (radio buttons)

- Menu items or menu bases

Attempting to set TAB_MODE on these widgets will generate an error.

Note ————————————————————————————
It is not possible to tab to disabled (SENSITIVE=0) or hidden (MAP=0) widgets.
—————————————————————————————————

Valid settings are:

0	Disable navigation onto or off of the widget. This is the default value unless the TAB_MODE has been set on a parent base. Child widgets automatically inherit the tab mode of the parent base as described in "Inheriting the TAB_MODE Value" (Chapter 3, *Widget Application Programming*).
1	Enable navigation onto and off of the widget.
2	Navigate only onto the widget.
3	Navigate only off of the widget.

Note ————————————————————————————
In widget applications on the UNIX platform, the Motif library controls what widgets are brought into and released from focus using tabbing. The TAB_MODE keyword value is always zero, and any attempt to change it is ignored when running a widget application on the UNIX platform. Tabbing behavior may vary significantly between UNIX platforms; do not rely on a particular behavior being duplicated on all UNIX systems.
—————————————————————————————————

After creating the widget hierarchy, you can query a widget's support for tabbing using the WIDGET_INFO procedure's TAB_MODE keyword. See "Tabbing in Widget Applications" (Chapter 3, *Widget Application Programming*) for usage details and examples.

TABLE_BLANK

This keyword applies to widgets created with the WIDGET_TABLE function.

Set this keyword equal to a nonzero value to cause the specified cells to be blank. Set this keyword equal to zero to cause the specified cells to display values as usual.

Note

Hiding cell contents using this keyword is a *display-only operation*. The cell contents are not removed from the table, they are simply hidden from view. Any operation that evaluates or changes the value of a cell will operate in the same way on a cell whose contents are hidden as it will on a cell whose contents are visible.

If the USE_TABLE_SELECT keyword is set equal to one, the currently selected cells are blanked or restored. If USE_TABLE_SELECT is set equal to an array, the specified cells are blanked or restored. If USE_TABLE_SELECT is not set, the entire table is hidden or displayed.

TABLE_DISJOINT_SELECTION

This keyword applies to widgets created with the WIDGET_TABLE function.

Set this keyword to enable the ability to select multiple rectangular regions of cells.

TABLE_XSIZE

This keyword applies to widgets created with the WIDGET_TABLE function.

Set this keyword equal to the number of data columns in the table widget. Note that if the table widget was created with row titles enabled (that is, if the NO_HEADERS or NO_COLUMN_HEADERS keywords to WIDGET_TABLE were *not* set), the table will contain one column more than the number specified by TABLE_XSIZE.

If the table is made smaller as a result of the application of the TABLE_XSIZE keyword, the data outside the new range persists, but the number of columns and/or rows changes as expected. If the table is made larger, the data type of the cells in the new columns is set according to the following rules:

1. If the table was not created with either the ROW_MAJOR or COLUMN_MAJOR keywords set (if the table is an array rather than a vector of structures), the new cells have the same type as all the original cells.

2. If the SET_VALUE keyword is given, the types of all columns are set according to the new structure.

3. If the table was created with the ROW_MAJOR keyword set, and the SET_VALUE keyword is not specified, the cells in the new columns inherit their type from the cells to their left.

4. ²If the table was created with the COLUMN_MAJOR keyword set, and the SET_VALUE keyword is not specified, any new columns default to type INT.

TABLE_YSIZE

This keyword applies to widgets created with the WIDGET_TABLE function.

Set this keyword equal to the number of data rows in the table widget. Note that if the table widget was created with column titles enabled (that is, if the NO_HEADERS or NO_ROW_HEADERS keywords to WIDGET_TABLE were *not* set), the table will contain one row more than the number specified by TABLE_YSIZE.

If the table is made smaller as a result of the application of the TABLE_YSIZE keyword, the data outside the new range persists, but the number of columns and/or rows changes as expected. If the table is made larger, the data type of the cells in the new rows is set according to the following rules:

1. If the table was not created with either the ROW_MAJOR or COLUMN_MAJOR keywords set (if the table is an array rather than a vector of structures), the new cells have the same type as all the original cells.

2. If the SET_VALUE keyword is given, the types of all rows are set according to the new structure.

3. If the table was created with the COLUMN_MAJOR keyword set, and the SET_VALUE keyword is not specified, the cells in the new rows inherit their type from the cells above.

4. If the table was created with the ROW_MAJOR keyword set, and the SET_VALUE keyword is not specified, any new rows default to type INT.

TIMER

This keyword applies to all widgets.

If this keyword is present, a WIDGET_TIMER event is generated. Set this keyword to a floating-point value that represents the number of seconds before the timer event arrives. Note that this event is identical to any other widget event except that it contains only the 3 standard event tags. These event structures are defined as:

```
{ WIDGET_TIMER, ID:0L, TOP:0L, HANDLER:0L }
```

It is left to the caller to tell the difference between standard widget events and timer events. The standard way to do this is to use a widget that doesn't normally generate events (e.g., a base or label). Alternately, the TAG_NAMES function can be called with the STRUCTURE_NAME keyword to differentiate a WIDGET_TIMER event from other types of events. For example:

```
IF TAG_NAMES(event, /STRUCTURE_NAME) EQ $
    'WIDGET_TIMER' THEN ...
```

Using the TIMER keyword is more efficient than the background task functionality found in the XMANAGER procedure because it doesn't "poll" like the original background task code. The background task functionality will eventually be eliminated from XMANAGER. We encourage all users to modify their code to use the TIMER keyword instead.

See "Timer Events" (Chapter 3, *Widget Application Programming*) for additional details.

TLB_GET_OFFSET

This keyword applies to all widgets.

Set this keyword to a named variable in which the offset of the upper left corner of the top-level base of the specified widget is returned, in units specified by the UNITS keyword (pixels are the default). The offset is measured in device coordinates relative to the upper-left corner of the screen.

Note ———————————————————————————————

On Windows and Macintosh platforms, the returned position is the upper-left corner of the window *including* border and title bar. On non-Macintosh Motif platforms, the returned position represents the upper-left corner of the window's client area (not including border and titlebar).

——

TLB_GET_SIZE

This keyword applies to all widgets.

Set this keyword to a named variable in which the size of the top-level base of the specified widget is returned, in units specified by the UNITS keyword (pixels are the default). The size is returned as a two-element vector that contains the horizontal and vertical size of the base in device coordinates.

TLB_ICONIFY_EVENTS

This keyword applies to widgets created with the WIDGET_BASE function.

Set this keyword to make the top-level base return an event when the base is iconified or restored by the user.

TLB_KILL_REQUEST_EVENTS

This keyword applies to widgets created with the WIDGET_BASE function.

Use this keyword to set or clear kill request events for the specified top-level base. For more information on these events see "TLB_KILL_REQUEST_EVENTS" on page 2671.

TLB_MOVE_EVENTS

This keyword applies to widgets created with the WIDGET_BASE function.

Set this keyword to make the top-level base return an event when the base is moved by the user. Note that if TLB_SIZE_EVENTS are also enabled, a user resize operation that causes the top left corner of the base widget to move will generate both a move event and a resize event.

TLB_SET_TITLE

This keyword applies to all widgets.

Set this keyword to a scalar string to change the title of the specified top-level base after it has been created.

TLB_SET_XOFFSET

This keyword applies to all widgets.

Use this keyword to set the horizontal position of the top level base of the specified widget. The offset is measured from the upper-left corner of the screen to the upper-left corner of the base, in units specified by the UNITS keyword (pixels are the default).

TLB_SET_YOFFSET

This keyword applies to all widgets.

Use this keyword to set the vertical position of the top-level base of the specified widget. The offset is measured from the upper-left corner of the screen to the upper-left corner of the base, in units specified by the UNITS keyword (pixels are the default).

TLB_SIZE_EVENTS

This keyword applies to widgets created with the WIDGET_BASE function.

Set this keyword to make the top-level base return an event when the base is resized by the user. Note that if TLB_MOVE_EVENTS are also enabled, a user resize operation that causes the top left corner of the base widget to move will generate both a move event and a resize event.

TOOLTIP

This keyword applies to widgets created with the WIDGET_BUTTON and WIDGET_DRAW functions.

Set this keyword to a string that will be displayed when the cursor hovers over the specified widget. For UNIX platforms, this string must be non-zero in length, which means that a tooltip can be modified but not be removed on UNIX versions of IDL.

Note ───

Tooltips cannot be created for menu sub-items. The topmost button on a menu can, however, have a tooltip.

───

Note ───

If your application uses hardware rendering and a RETAIN setting of either zero or one, tooltips will cause draw widgets to generate expose events if the tooltip obscures the drawable area. This is true even if the tooltip is associated with another widget.

───

Note ───

You can use language catalogs to internationalize this value with strings in particular languages. For more information, see Chapter 19, "Using Language Catalogs" (*Application Programming*).

───

TRACKING_EVENTS

This keyword applies to all widgets.

Set this keyword to a non-zero value to enable tracking events for the widget specified by *Widget_ID*. Set the keyword to 0 to disable tracking events for the specified widget. For a description of tracking events, see "TRACKING_EVENTS" on page 2672 in the documentation for WIDGET_BASE.

UNITS

This keyword applies to all widgets.

Use this keyword to specify the unit of measurement used when *supplying* measurements or position values. Set UNITS equal to 0 (zero) to specify that all measurements are in pixels (this is the default), to 1 (one) to specify that all measurements are in inches, or to 2 (two) to specify that all measurements are in centimeters. This keyword does not change the units used in a widget event structure or in most of the fields of the geometry structure returned by WIDGET_INFO.

Note

This keyword does not affect all sizing operations. Specifically, the value of UNITS is ignored when setting the XSIZE or YSIZE keywords to WIDGET_LIST, WIDGET_TABLE, or WIDGET_TEXT functions.

UPDATE

This keyword applies to all widgets.

Use this keyword to enable (if set to 1) or disable (if set to 0) screen updates for the widget hierarchy to which the specified widget belongs. This keyword is useful for preventing unwanted intermediate screen updates when changing the values of many widgets at once or when adding several widgets to a previously-realized widget hierarchy. When first realized, widget hierarchies are set to update.

Note

Although this keyword is legal for any widget, it affects every widget in the hierarchy defined for the specified widget's top-level base widget. In other words, setting UPDATE on a particular widget is equivalent to setting UPDATE on the top-level base widget that is at the top of the specified widget's hierarchy.

Warning

Do not attempt to resize a widget on the Windows platform while UPDATE is turned off. Doing so may prevent IDL from updating the screen properly when UPDATE is turned back on.

See "Preventing Layout Flicker" (Chapter 3, *Widget Application Programming*) for more information.

USE_TABLE_SELECT

This keyword applies to widgets created with the WIDGET_TABLE function.

Set this keyword to modify the behavior of the ALIGNMENT, BACKGROUND_COLOR, COLUMN_WIDTHS, DELETE_COLUMNS, DELETE_ROWS, EDITABLE, FONT, FOREGROUND_COLOR, FORMAT, GET_VALUE, INSERT_COLUMNS, INSERT_ROWS, ROW_HEIGHTS, SET_VALUE, and TABLE_BLANK keywords. If USE_TABLE_SELECT is set, these other keywords apply only to the currently selected cells. Normally, these keywords apply to the entire contents of a table widget.

Note ———

If either the header row or the header column of the table is selected, this keyword modifies the behavior of only the ROW_HEIGHTS or COLUMN_WIDTHS keywords.

———

Note ———

The Microsoft Windows platforms support the ROW_HEIGHTS keyword with the limitation that all rows have the same height. If you supply an array of values, IDL uses the last value for all rows.

———

Selection Modes

The table widget supports two *selection modes*:

- In *standard selection mode*, only a single selection can be created at a given time. Creating a new selection causes the existing selection to disappear.

- In *disjoint selection mode*, multiple selections can be created at one time. Creating a new selection does not cause the existing selection(s) to disappear. A table can be created in disjoint selection mode using either the DISJOINT_SELECTION keyword to WIDGET_TABLE or the TABLE_DISJOINT_SELECTION keyword to WIDGET_CONTROL.

The keywords listed above generate different output or expect different input based on the selection mode. See the description of each keyword for details. For more information on table selection modes, see "Selection Modes" (Chapter 7, *Widget Application Programming*)

Specifying Selections Programmatically

In many cases, your code will use a selection created by the user manually, with the mouse. You can also create selections programmatically, by setting USE_TABLE_SELECT equal to an array.

- In standard selection mode, specify a four-element array, of the form [*left, top, right, bottom*] specifying the rectangle of cells to act upon.

- • In disjoint selection mode, specify a 2 x *n* element array of column/row pairs specifying the cells to act upon.

Specifications for cell locations are zero-based (that is, the first data column is column number zero). You can specify row and column headers by using -1 in the index. Row header cells are indexed by using -1 for the column; column header cells are indexed by using -1 for the row. Ranges can span header cells and value cells.

Note

> Setting USE_TABLE_SELECT equal to an array does *not* change the current table selection. Operations affect the specified cells without changing the current selection. To change the current table selection, use SET_TABLE_SELECT.

Example

To change the column widths of the title column and the first five data columns of a table widget named `wTable`, leaving the widths of the other columns unchanged:

```
WIDGET_CONTROL, wTable, USE_TABLE_SELECT=[-1,0,4,0], $
    COLUMN_WIDTHS=50
```

This command is equivalent to first calling WIDGET_CONTROL and setting the SET_TABLE_SELECT keyword equal to an array, and then calling WIDGET_CONTROL with USE_TABLE_SELECT set equal to one. Please note that the command might change your selection.

For additional examples, see "Using Table Widgets" (Chapter 7, *Widget Application Programming*).

USE_TEXT_SELECT

This keyword applies to widgets created with the WIDGET_TABLE and WIDGET_TEXT functions.

Set this keyword to modify the behavior of the GET_VALUE and SET_VALUE keywords. If USE_TEXT_SELECT is set, GET_VALUE and SET_VALUE apply only to the current text selection. Normally, these keywords apply to the entire contents of a text widget.

Warning

> If the target widget is a table, the selected cell must be in *edit mode* for WIDGET_CONTROL to return the selected text. (A table cell can be selected without being in edit mode; see "Using Table Widgets" (Chapter 7, *Widget Application Programming*) for a discussion of the table widget's edit mode.) In

most cases, to retrieve the value of a table cell, use the USE_TABLE_SELECT keyword rather than USE_TEXT_SELECT.

X_BITMAP_EXTRA

This keyword applies to widgets created with the WIDGET_BUTTON function.

When the value of a button widget is a bitmap, the usual width is taken to be 8 times the number of columns in the source byte array. This keyword can be used to indicate the number of bits in the last byte of each row that should be ignored. The value can range between 0 and 7.

XOFFSET

This keyword applies to all widgets.

Set this keyword to an integer value that specifies the widget's new horizontal offset, in units specified by the UNITS keyword (pixels are the default). Attempting to change the offset of a widget that is the child of a ROW or COLUMN base or a widget that is part of a menubar or pulldown menu causes an error.

XSIZE

This keyword applies to all widgets.

Set this keyword to an integer or floating-point value that represents the widget's new horizontal size.

- Text and List widgets: Size is specified in characters. The UNITS keyword is ignored.

- Table widgets: Size is specified in columns. The width of the row labels is automatically added to this value. The UNITS keyword is ignored.

- All other widgets: If the UNITS keyword is present, size is in the units specified. If the UNITS keyword is not present, the size is specified in pixels.

Note that [XY]SIZE sets client area and SCR_[XY]SIZE sets total area (title bar, borders, menu, client area). For scrollable widgets (e.g., scrolling bases and scrolling draw widgets), this keyword adjusts the *viewport* size. Use the DRAW_XSIZE keyword to change the width of the drawing area in scrolling draw widgets. Attempting to resize a widget that is part of a menubar or pulldown menu causes an error.

See "Widget Sizing" (Chapter 3, *Widget Application Programming*) for more information.

YOFFSET

This keyword applies to all widgets.

Set this keyword to an integer value that specifies the widget's new vertical offset, in units specified by the UNITS keyword (pixels are the default). Attempting to change the offset of a widget that is the child of a ROW or COLUMN base or a widget that is part of a menubar or pulldown menu causes an error.

YSIZE

This keyword applies to all widgets.

Set this keyword to an integer or floating-point value that represents the widget's new vertical size

- Text and List widgets: Size is specified in lines. The UNITS keyword is ignored.

- Table widgets: Size is specified in rows. The height of the column labels is automatically added to this value. The UNITS keyword is ignored.

- All other widgets: If the UNITS keyword is present, size is in the units specified. If the UNITS keyword is not present, the size is specified in pixels.

Note that [XY]SIZE sets client area and SCR_[XY]SIZE sets total area (title bar, borders, menu, client area). For scrollable widgets (e.g., scrolling bases and scrolling draw and table widgets), this keyword adjusts the *viewport* size. Use the DRAW_YSIZE keyword to change the height of the drawing area in scrolling draw widgets. Attempting to resize a widget that is part of a menubar or pulldown menu causes an error.

See "Widget Sizing" (Chapter 3, *Widget Application Programming*) for more information.

Version History

Pre-4.0	Introduced
5.6	Added COMBOBOX_ADDITEM, COMBOBOX_DELETEITEM, COMBOBOX_INDEX, DRAW_KEYBOARD_EVENTS, SET_BUTTON, SET_COMBOBOX_SELECT, SET_TAB_CURRENT, SET_TAB_MULTILINE, SET_TREE_BITMAP, SET_TREE_EXPANDED, SET_TREE_SELECT, SET_TREE_VISIBLE, TABLE_BLANK, TABLE_DISJOINT_SELECTION, TLB_ICONIFY_EVENTS, TLB_MOVE_EVENTS, TLB_SIZE_EVENTS, TOOLTIP keywords
6.0	Added PUSHBUTTON_EVENTS and REFRESH PROPERTY keywords
6.1	Added EDITABLE, MULTIPLE_PROPERTIES, PROPERTYSHEET_SETSELECTED, and TAB_MODE keywords
6.2	Added BACKGROUND_COLOR, DRAW_WHEEL_EVENTS, FONT, FOREGROUND_COLOR, and IGNORE_ACCELERATORS keywords Deprecated CANCEL_BUTTON and DEFAULT_BUTTON keywords
6.3	Added SET_DRAG_NOTIFY, SET_DRAGGABLE, SET_DROP_EVENTS, SET_MASK, and SET_TREE_INDEX keywords

For information on obsolete keywords, see Appendix I, "Obsolete Features".

See Also

Chapter 3, "Widget Application Techniques" (*Widget Application Programming*).

WIDGET_DISPLAYCONTEXTMENU

The WIDGET_DISPLAYCONTEXTMENU procedure displays a *context-sensitive menu* (also known as a *pop-up* or *shortcut* menu). Context-sensitive menus appear when the user clicks the right mouse button over a widget for which a context menu is defined. Because the widget programmer must explicitly detect the right-mouse button click and call WIDGET_DISPLAYCONTEXTMENU to display the context menu, a widget can have any number of associated context menus, which can be displayed under different circumstances.

Context menus are created by placing one or more button widgets on a base widget constructed with the CONTEXT_MENU keyword set. The context menu's base widget must have as its parent a base, draw, list, property sheet, table, tree or text widget; in the case of all but draw widgets, the parent widget must be configured to generate context menu events via the CONTEXT_EVENTS keyword. Draw widgets that support context menus must have the BUTTON_EVENTS keyword set.

The widget application's event handler routine must detect the presence of a context menu event (base, list, and text widgets) or the right mouse-button event (draw and property sheet widgets) and call WIDGET_DISPLAYCONTEXTMENU to display the context menu. Events generated when the user clicks on the context menu's buttons are handled in the normal way. If the user clicks outside the context menu, it is dismissed and no event is generated.

Syntax

WIDGET_DISPLAYCONTEXTMENU, *Parent*, *X*, *Y*, *ContextBase_ID*

Arguments

Parent

The widget ID of the parent widget of the context menu widget.

Note ———

The parent widget must be either a base, list, or text widget with the CONTEXT_EVENTS keyword set or a draw widget with the BUTTON_EVENTS keyword set. In most cases the parent widget can be identified via the ID field of the WIDGET_CONTEXT or WIDGET_DRAW event structure.

———

X

The x location, relative to the parent widget, at which the menu should be displayed. (In most cases this will be the x location of the user's right mouse-button click, as reported in the X field of the WIDGET_CONTEXT or WIDGET_DRAW event structure.)

Y

The y location, relative to the parent widget, at which the menu should be displayed. (In most cases this will be the y location of the user's right mouse-button click, as reported in the Y field of the WIDGET_CONTEXT or WIDGET_DRAW event structure.)

ContextBase_ID

The widget ID of the context menu base widget that contains the context menu to be displayed. Use the CONTEXT_MENU keyword to WIDGET_BASE to create a context menu base.

Note ───

The context menu base must be a child of the widget specified by the *Parent* argument.

───

Keywords

None

Examples

For examples using WIDGET_DISPLAYCONTEXTMENU, see "Context-Sensitive Menus" (Chapter 3, *Widget Application Programming*).

5.5	Introduced

WIDGET_DRAW

The WIDGET_DRAW function is used to create draw widgets. Draw widgets are rectangular areas that IDL treats as standard graphics windows. Draw widgets can use either IDL Direct graphics or IDL Object graphics, depending on the value of the GRAPHICS_LEVEL keyword. Any graphical output that can be produced by IDL, either through the WSET function or by using the object reference of a draw widget's IDLgrWindow object, can be directed to a draw widget. Draw widgets can have optional scroll bars to allow viewing a larger graphics area than could otherwise be displayed in the widget's visible area.

Figure 25-3: A Draw Widget

Note

On some systems, when backing store is provided by the window system (RETAIN=1), reading data from a window using TVRD( ) may cause unexpected results. For example, data may be improperly read from the window even when the image displayed on screen is correct. Having IDL provide the backing store (RETAIN=2) ensures that the window contents will be read properly.

For a more detailed discussion of the draw widget, along with examples, see "Using Draw Widgets" (Chapter 5, *Widget Application Programming*).

Syntax

Result = WIDGET_DRAW(*Parent* [, /APP_SCROLL] [, /BUTTON_EVENTS]
    [, CLASSNAME=*string*] [, /COLOR_MODEL] [, COLORS=*integer*]
    [, DRAG_NOTIFY=*string*] [, /DROP_EVENTS] [, EVENT_FUNC=*string*]
    [, EVENT_PRO=*string*] [, /EXPOSE_EVENTS] [, FRAME=*width*]
    [, FUNC_GET_VALUE=*string*] [, GRAPHICS_LEVEL=2]
    [, GROUP_LEADER=*widget_id*]

[, IGNORE_ACCELERATORS=*value*][, KEYBOARD_EVENTS={1 | 2}]
[, KILL_NOTIFY=*string*] [, /MOTION_EVENTS] [, /NO_COPY]
[, NOTIFY_REALIZE=*string*] [, PRO_SET_VALUE=*string*]
[, RENDERER={0 | 1}] [, RESOURCE_NAME=*string*] [, RETAIN={0 | 1 | 2}]
[, SCR_XSIZE=*width*] [, SCR_YSIZE=*height*] [, /SCROLL] [, /SENSITIVE]
[, TOOLTIP=*string*] [, /TRACKING_EVENTS] [, UNAME=*string*]
[, UNITS={0 | 1 | 2}] [, UVALUE=*value*] [, /VIEWPORT_EVENTS]
[, /WHEEL_EVENTS] [, XOFFSET=*value*] [, XSIZE=*value*]
[, X_SCROLL_SIZE=*width*] [, YOFFSET=*value*] [, YSIZE=*value*]
[, Y_SCROLL_SIZE=*height*])

Return Value

The returned value of this function is the widget ID of the newly-created draw widget.

Arguments

Parent

The widget ID of the parent widget of the new draw widget.

Keywords

APP_SCROLL

Set this keyword to create a scrollable draw widget with horizontal and vertical scrollbars that allow the user to view portions of the widget contents that are not currently on the screen.

The drawable area of a draw widget created with the APP_SCROLL keyword is the same size as the viewable area (the *viewport*). This is useful for displaying very large images, because the memory used by a draw widget is directly related to the size of the drawable area. A draw widget created with the APP_SCROLL keyword also has the concept of a *virtual drawable area*, which is the size of the entire image. The fact that only a portion of the entire image is held in memory means that you must capture events generated when the user adjusts the scroll bars and display the correct portion of the image in your event-handling code.

Note ───

> If the image you are displaying is relatively small or memory is not a concern, consider using the SCROLL keyword rather than APP_SCROLL. With SCROLL, the drawable area is the size of the entire image; this allows IDL to display the appropriate portions of the image automatically when the user adjusts the scroll bars. See "SCROLL" on page 2771 and "Scrolling Draw Widgets" (Chapter 5, *Widget Application Programming*) for details.

───

Specify the size of the viewport using the X_SCROLL_SIZE and Y_SCROLL_SIZE keywords, and the size of the virtual drawable area using the XSIZE and YSIZE keywords. If APP_SCROLL is set, the application generates viewport events even if the VIEWPORT_EVENTS keyword is not set.

If the drawable area uses Direct Graphics (that is, if GRAPHICS_LEVEL is *not* set equal to 2), system backing store is used by default and the viewport is automatically restored after it has been obscured. If you prefer to manually restore the viewport in an event-handling routine, set RETAIN=0 and EXPOSE_EVENTS=1; this allows you to redraw the virtual canvas when your application receives expose events.

If the drawable area uses Object Graphics (that is, if the GRAPHICS_LEVEL keyword is set equal to 2), the application will *not* automatically restore the viewport, and will generate expose events as if RETAIN=0 and EXPOSE_EVENTS=1 had been set.

BUTTON_EVENTS

Set this keyword to make the draw widget generate events when the mouse buttons are pressed or released (and the mouse pointer is in the draw widget). Normally, draw widgets do not generate events.

You can use the event structure generated when the BUTTON_EVENTS keyword is set to emulate the functionality of the CONTEXT_EVENTS keyword to WIDGET_BASE, WIDGET_LIST, and WIDGET_TEXT. To determine whether the user clicked the right mouse button, use the test:

```
IF (event.release EQ 4)
```

where event holds the widget event structure.

For more on detecting and handling context menu events, see "Context-Sensitive Menus" (Chapter 3, *Widget Application Programming*).

CLASSNAME

Note ───

This keyword is honored only if the GRAPHICS_LEVEL keyword is set to 2.

───

Set this keyword to a string containing the name of the window object class to be instantiated and associated with this draw widget. Possible values are:

- IDLgrWindow
- IDLitWindow

The default is IDLgrWindow. If the application needs to process IDLitWindow events (timer events for controlling animations, for example), consider using the IDLitWindow class instead. See Chapter 10, "Animating Objects" (*Object Programming*) for additional information.

COLOR_MODEL

Set this keyword equal to 1 (one) to cause the draw widget's associated IDLgrWindow object to use indexed color. If the COLOR_MODEL keyword is not set, or is set to a value other than one, the draw widget will use RGB color.

This keyword is only valid when the draw widget uses IDL Object Graphics. (The graphics type used by a draw widget is determined by setting the GRAPHICS_LEVEL keyword to WIDGET_DRAW.)

COLORS

The maximum number of color table indices to be used. This parameter has effect *only* if it is supplied when the *first* IDL graphics window is created.

If COLORS is not specified when the first window is created, all or most of the available color indices are allocated, depending upon the window system in use.

To use monochrome windows on a color display, set COLORS equal to 2 when creating the first window. One color table is maintained for all IDL windows. A negative value for COLORS specifies that all but the given number of colors from the shared color table should be used.

DRAG_NOTIFY

Set this keyword equal to a string containing the name of a function that will be automatically called as the end-user drags over the widget. Alternatively, set this keyword equal to the string <default> (including the < and > characters) to use the system default callback.

The callback function's return value informs the widget system "if and where" the drag source can be dropped onto the widget. The widget system then uses this information to provide the end-user with visual feedback about the legality and location of a drop. A secondary ability of the return value is to turn on the plus (+) indicator, which can be handy to distinguish between copies and moves. The following table details the meanings of the valid return values, which can be OR-ed together:

Value	Meaning
0	User cannot drop
1	User can drop onto
2	Show the plus indicator

When a DRAG_NOTIFY callback is not explicitly set on the draw widget or is set to the string <default> then the widget system default callback is used. The default callback returns 0 if drop events are not enabled (DROP_EVENTS=0) and 1 otherwise.

Creating a Drag Notification Callback Routine

The drag notification callback routine has the following signature:

```
FUNCTION Callback_Function_Name, Destination, Source, $
    X, Y, Modifiers, Default
```

where

- *Callback_Function_Name* is the name of the callback function. This value is specified as the value of the DRAG_NOTIFY keyword.

- *Destination* is the widget ID of the draw widget over which the item is dragged.

- *Source* is the widget ID of the item being dragged (this must currently be a tree widget node).

- *X* is the position to the right of the lower left corner of the drawable area, in device coordinates (pixels).

- *Y* is the position above the lower left corner of the drawable area, in device coordinates (pixels).

- *Modifiers* indicates the state of the modifier keys. The widget system generates them by OR-ing the following values together for the depressed keys:

Bitmask	Modifier Key
1	Shift
2	Control
4	Caps Lock
8	Alt

Table 25-5: Bitmask and Corresponding Key

Note

For UNIX, the **Alt** key is the currently mapped MOD1 key.

- *Default* is the value that the default callback would have returned. A common usage is to have the callback return its value after modifying it to show the + indicator.

Specifying a drag notification callback does not enable drop events; you must set the DROP_EVENTS keyword to specify that drop events should be generated. For information on dragging and dropping and draw widgets, see "Using Draw Widgets" (*Widget Application Programming*).

Warning

Custom drag notifications can pose potential dangers, please see the section ""Responding to Drag Notifications (Callbacks)" (*Widget Application Programming*)" in "Using Draw Widgets" (*Widget Application Programming*) to learn more about these potential dangers.

DROP_EVENTS

Use this keyword to specify whether or not the widget will generate drop events when the user drags an item onto the draw area with the mouse cursor and releases the mouse button. See "Widget Events Returned by Draw Widgets" on page 2775 for an explanation of the event structure.

A value of 1 (one) causes the widget to generate drop events and a value of 0 (zero) causes the widget to not generate drop events. The default is to not generate drop events. Specifying a DRAG_NOTIFY callback does not affect a widget's ability to generate drop events.

EVENT_FUNC

A string containing the name of a function to be called by the WIDGET_EVENT function when an event arrives from a widget in the widget hierarchy rooted at the newly-created widget.

EVENT_PRO

A string containing the name of a procedure to be called by the WIDGET_EVENT function when an event arrives from a widget in the widget hierarchy rooted at the newly-created widget.

EXPOSE_EVENTS

Set this keyword to make the draw widget generate event when the visibility of the draw widget changes. This may occur when the widget is hidden behind something else on the screen, brought to the foreground, or when the scroll bars are moved. Normally, draw widgets do not generate events.

If this keyword is set, expose events will be generated only when IDL is unable to restore the contents of the window itself. After the initial draw, expose events are not issued when GRAPHICS_LEVEL=2 and the software renderer is being used (RENDERER=1). In such cases, expose events are not issued because IDL can internally refresh the window itself. On platforms for which OpenGL support is not offered, the software renderer is always being used, and therefore, expose events are not issued after the initial draw.

Note ————————————————————————————

When using hardware rendering, you must explicitly disable backing store (by setting RETAIN=0) in order to generate expose events. Additional expose events may be generated if both EXPOSE_EVENTS and RETAIN=1 are turned on.

Warning ————————————————————————————

Large numbers of events may be generated when EXPOSE_EVENTS is specified. You may wish to compress the events (perhaps using a timer) and only act on a subset.

FRAME

The value of this keyword specifies the width of a frame in units specified by the UNITS keyword (pixels are the default) to be drawn around the borders of the widget. Note that this keyword is only a hint to the toolkit, and may be ignored in some instances.

FUNC_GET_VALUE

A string containing the name of a function to be called when the GET_VALUE keyword to the WIDGET_CONTROL procedure is called for this widget. Using this technique allows you to change the value that should be returned for a widget. Compound widgets use this ability to define their values transparently to the user.

GRAPHICS_LEVEL

Set this keyword equal to 2 (two) to use IDL Object Graphics in the draw widget. If the GRAPHICS_LEVEL keyword is not set, or is set to a value other than two, the draw widget will use IDL Direct Graphics.

GROUP_LEADER

The widget ID of an existing widget that serves as "group leader" for the newly-created widget. When a group leader is killed, for any reason, all widgets in the group are also destroyed.

A given widget can be in more than one group. The WIDGET_CONTROL procedure can be used to add additional group associations to a widget. It is not possible to remove a widget from an existing group.

IGNORE_ACCELERATORS

Set this keyword to specify what WIDGET_BUTTON accelerators are to be ignored when this draw widget has keyboard focus. Setting IGNORE_ACCELERATORS allows a defined list of accelerators to be processed by the draw widget instead of by the conflicting accelerated button. Valid values are:

- A string or string array containing any value that is legal for WIDGET_BUTTON's ACCELERATOR keyword
- The number 1, indicating all accelerators should be ignored

Ordinarily, accelerators are processed before keyboard events reach the widget that has the keyboard focus. Setting IGNORE_ACCELERATORS allows a defined list of accelerators to be processed by the draw widget instead of by associated buttons or menu items. Once the draw widget loses focus, all specified accelerators are automatically re-enabled.

See "Disabling Button Widget Accelerators" (Chapter 3, *Widget Application Programming*) for usage details and examples.

KEYBOARD_EVENTS

Set this keyword equal to 1 (one) or 2 to make the draw widget generate an event when it has the keyboard focus and a key is pressed or released. (The method by which a widget receives the keyboard focus is dependent on the window manager in use.) The value of the key pressed is reported in either the CH or the KEY field of the event structure, depending on the type of key pressed. See "Widget Events Returned by Draw Widgets" on page 2775 for details.

- If this keyword is set equal to 1, the draw widget will generate an event when a "normal" key is pressed. "Normal" keys include all keys except function keys and the modifier keys: SHIFT, CONTROL, CAPS LOCK, and ALT. If a modifier key is pressed at the same time as a normal key, the value of the modifier key is reported in the MODIFIERS field of the event structure.

- If this keyword is set equal to 2, the draw widget will generate an event when *either* a normal key or a modifier key is pressed. Values for modifier keys are reported in the KEY field of the event structure, and the MODIFIERS field contains zero.

Note ——

Keyboard events are never generated for function keys.

———

KILL_NOTIFY

Set this keyword to a string that contains the name of a procedure to be called automatically when the specified widget dies. Each widget is allowed a single such "callback" procedure. It can be removed by setting the routine to the null string (' ').

The callback routine is called with the widget identifier as its only argument. At that point, the widget identifier can only be used with the WIDGET_CONTROL procedure to get or set the user value. All other requests that require a widget ID are disallowed for the target widget. The callback is not issued until the WIDGET_EVENT function is called.

MOTION_EVENTS

Set this keyword to make the draw widget generate events when the mouse cursor moves across the widget. Normally, draw widgets do not generate events.

Draw widgets that return motion events can generate a large number of events that can result in poor performance on slower machines.

Note that it is possible to generate motion events with coordinates outside the draw widget. If you position the mouse cursor inside the draw widget, press the mouse

button, and drag the cursor out of the draw widget, the X and Y fields of the widget event will specify coordinates outside the draw widget.

See "Accessing Draw Widget Events" (Chapter 5, *Widget Application Programming*) for more information.

NO_COPY

Usually, when setting or getting widget user values, either at widget creation or using the SET_UVALUE and GET_UVALUE keywords to WIDGET_CONTROL, IDL makes a second copy of the data being transferred. Although this technique is fine for small data, it can have a significant memory cost when the data being copied is large.

If the NO_COPY keyword is set, IDL handles these operations differently. Rather than copy the source data, it takes the data away from the source and attaches it directly to the destination. This feature can be used by compound widgets to obtain state information from a UVALUE without all the memory copying that would otherwise occur. However, it has the side effect of causing the source variable to become undefined. On a "set" operation (using the UVALUE keyword to WIDGET_DRAW or the SET_UVALUE keyword to WIDGET_CONTROL), the variable passed as value becomes undefined. On a "get" operation (GET_UVALUE keyword to WIDGET_CONTROL), the user value of the widget in question becomes undefined.

NOTIFY_REALIZE

Set this keyword to a string that contains the name of a procedure to be called automatically when the specified widget is realized. This callback occurs just once (because widgets are realized only once). Each widget is allowed a single such "callback" procedure. It can be removed by setting the routine to the null string (' '). The callback routine is called with the widget ID as its only argument.

PRO_SET_VALUE

A string containing the name of a procedure to be called when the SET_VALUE keyword to the WIDGET_CONTROL procedure is called for this widget. See the description of the PRO_SET_VALUE keyword to WIDGET_CONTROL for information on using this keyword.

RENDERER

Set this keyword to an integer value indicating which graphics renderer to use when drawing objects within the window. Valid values are:

- 0 = Platform native OpenGL

- 1 = IDL's software implementation

By default, your platform's native OpenGL implementation is used. If your platform does not have a native OpenGL implementation, IDL's software implementation is used regardless of the value of this property. See "Hardware vs. Software Rendering" (Chapter 2, *Object Programming*) for details. Your choice of renderer may also affect the maximum size of a draw widget. See "IDLgrWindow" on page 4960 for details.

RESOURCE_NAME

A string containing an X Window System resource name to be applied to the widget. See "RESOURCE_NAME" on page 2665 for a complete discussion of this keyword.

RETAIN

Set this keyword to 0, 1, or 2 to specify how backing store should be handled for the draw widget. RETAIN=0 specifies no backing store. RETAIN=1 requests that the server or window system provide backing store. RETAIN=2 specifies that IDL provide backing store directly. See "Backing Store" on page 2780 for details on the use of RETAIN with Direct Graphics. For more information on the use of RETAIN with Object Graphics, see "IDLgrWindow Properties" on page 4963.

Note ───
On Macintosh and Microsoft Windows systems, if you are using software rendering (that is, the RENDERER keyword is set equal to one, or your platform does not have a native OpenGL implementation), IDL will refresh the window automatically regardless of the setting of the RETAIN property.
───

SCR_XSIZE

Set this keyword to the desired "screen" width of the widget, in units specified by the UNITS keyword (pixels are the default). In many cases, setting this keyword is the same as setting the XSIZE keyword.

SCR_YSIZE

Set this keyword to the desired "screen" height of the widget, in units specified by the UNITS keyword (pixels are the default). In many cases, setting this keyword is the same as setting the YSIZE keyword.

SCROLL

Set this keyword to create a scrollable draw widget with horizontal and vertical scrollbars that allow the user to view portions of the widget contents that are not currently on the screen.

Specify the dimensions of the viewport using the X_SCROLL_SIZE and Y_SCROLL_SIZE keywords, and the dimensions of the entire drawable area using the XSIZE and YSIZE keywords. A scrollbar will be added if the viewport dimension is smaller than the corresponding dimension of the drawable area.

Note

While the viewport of a draw widget created with the SCROLL keyword may be smaller than the entire image, the drawable area itself is the same size as the image, and uses memory commensurately. If you want to display a portion of a very large image, consider using the APP_SCROLL keyword rather than SCROLL. The drawable area of a draw widget created with APP_SCROLL is the same size as the viewport. This saves memory when the displayed image is large, but requires extra work on the programmer's part to handle viewport events and display the appropriate portion of the image. See "APP_SCROLL" on page 2761 and "Scrolling Draw Widgets" (Chapter 5, *Widget Application Programming*) for details.

SENSITIVE

Set this keyword to control the initial sensitivity state of the widget.

If SENSITIVE is zero, the widget becomes insensitive. If nonzero, it becomes sensitive. When a widget is sensitive, it has normal appearance and can receive user input. For example, a sensitive button widget can be activated by moving the mouse cursor over it and pressing a mouse button. When a widget is insensitive, it indicates the fact by changing its appearance, looking disabled, and it ignores any input.

Sensitivity can be used to control when a user is allowed to manipulate the widget. Note that some widgets do not change their appearance when they are made insensitive, but they cease generating events.

After creating the widget hierarchy, you can change the sensitivity state using the SENSITIVE keyword with the WIDGET_CONTROL procedure.

TOOLTIP

Set this keyword to a string that will be displayed when the cursor hovers over the widget. For UNIX platforms, this string must be non-zero in length.

Note ───
If your application uses hardware rendering and a RETAIN setting of either zero or one, tooltips will cause draw widgets to generate expose events if the tooltip obscures the drawable area. This is true even if the tooltip is associated with another widget.
───

Note ───
You can use language catalogs to internationalize this value with strings in particular languages. For more information, see Chapter 19, "Using Language Catalogs" (*Application Programming*).
───

TRACKING_EVENTS

Set this keyword to cause widget tracking events to be issued for the widget whenever the mouse pointer enters or leaves the region covered by that widget. For the structure of tracking events, see "TRACKING_EVENTS" on page 2672 in the documentation for WIDGET_BASE.

UNAME

Set this keyword to a string that can be used to identify the widget in your code. You can associate a name with each widget in a specific hierarchy, and then use that name to query the widget hierarchy and get the correct widget ID.

To query the widget hierarchy, use the WIDGET_INFO function with the FIND_BY_UNAME keyword. The UNAME should be unique to the widget hierarchy because the FIND_BY_UNAME keyword returns the ID of the first widget with the specified name.

UNITS

Set this keyword to specify the units used when *supplying* measurements or position values. Set UNITS equal to 0 (zero) to specify that all measurements are in pixels (this is the default), to 1 (one) to specify that all measurements are in inches, or to 2 (two) to specify that all measurements are in centimeters. This keyword does not

change the units used in a widget event structure or in most of the fields of the geometry structure returned by WIDGET_INFO.

UVALUE

The "user value" to be assigned to the widget.

Each widget can contain a user-specified value of any data type and organization. This value is not used by the widget in any way, but exists entirely for the convenience of the IDL programmer. This keyword allows you to set this value when the widget is first created.

If UVALUE is not present, the widget's initial user value is undefined.

VIEWPORT_EVENTS

Set this keyword to enable viewport motion events for draw widgets.

WHEEL_EVENTS

Set this keyword to enable mouse scroll wheel events, which are disabled by default. An event is generated when scroll wheel events are enabled, the widget has the focus (Windows) or the mouse pointer is over the draw widget (Motif), and the user rolls the scroll wheel. This event reports the scroll direction and distance, current mouse coordinates, and modifier keys. See "Widget Events Returned by Draw Widgets" on page 2775 for more information.

When wheel events are not enabled, rolling the scroll wheel affects the vertical scroll bar, if present.

XOFFSET

The horizontal offset of the widget in units specified by the UNITS keyword (pixels are the default) relative to its parent.

Specifying an offset relative to a row or column major base widget does not work because those widgets enforce their own layout policies. This keyword is primarily of use relative to a plain base widget. Note that it is best to avoid using this style of widget layout.

XSIZE

The width of the widget in units specified by the UNITS keyword (pixels are the default). Most widgets attempt to size themselves to fit the situation. However, if the desired effect is not produced, use this keyword to override it. This keyword is only a

"hint" to the toolkit and may be ignored in some situations. By default, draw widgets are 100 pixels wide by 100 pixels high.

X_SCROLL_SIZE

The XSIZE keyword always specifies the width of a widget. When the SCROLL keyword is specified, this size is not necessarily the same as the width of the visible area. The X_SCROLL_SIZE keyword allows you to set the width of the scrolling viewport independently of the actual width of the widget.

Use of the X_SCROLL_SIZE keyword implies SCROLL.

YOFFSET

The vertical offset of the widget in units specified by the UNITS keyword (pixels are the default) relative to its parent. This offset is specified relative to the *upper left* corner of the parent widget.

Specifying an offset relative to a row or column major base widget does not work because those widgets enforce their own layout policies. This keyword is primarily of use relative to a plain base widget. Note that it is best to avoid using this style of widget layout.

YSIZE

The height of the widget in units specified by the UNITS keyword (pixels are the default). Most widgets attempt to size themselves to fit the situation. However, if the desired effect is not produced, use this keyword to override it. This keyword is only a hint to the toolkit and may be ignored in some situations. By default, draw widgets are 100 pixels wide by 100 pixels high.

Y_SCROLL_SIZE

The YSIZE keyword always specifies the height of a widget. When the SCROLL keyword is specified, this size is not necessarily the same as the height of the visible area. The Y_SCROLL_SIZE keyword allows you to set the height of the scrolling viewport independently of the actual height of the widget.

Use of the Y_SCROLL_SIZE keyword implies SCROLL.

Keywords to WIDGET_CONTROL

A number of keywords to the WIDGET_CONTROL procedure affect the behavior of draw widgets. In addition to those keywords that affect all widgets, the following are particularly useful: DRAW_BUTTON_EVENTS, DRAW_EXPOSE_EVENTS,

DRAW_KEYBOARD_EVENTS, DRAW_MOTION_EVENTS, DRAW_VIEWPORT_EVENTS, DRAW_WHEEL_EVENTS, DRAW_XSIZE, DRAW_YSIZE, GET_DRAW_VIEW, GET_VALUE, IGNORE_ACCELERATORS, INPUT_FOCUS, SET_DRAW_VIEW, TOOLTIP.

Keywords to WIDGET_INFO

A number of keywords to the WIDGET_INFO function return information that applies specifically to draw widgets. In addition to those keywords that apply to all widgets, the following are particularly useful: DRAW_BUTTON_EVENTS, DRAW_EXPOSE_EVENTS, DRAW_KEYBOARD_EVENTS, DRAW_MOTION_EVENTS, DRAW_VIEWPORT_EVENTS, DRAW_WHEEL_EVENTS, STRING_SIZE, TOOLTIP.

Widget Events Returned by Draw Widgets

By default, draw widgets do not generate events. If the BUTTON_EVENTS keyword is set when the widget is created, pressing or releasing any mouse button while the mouse cursor is over the draw widget causes events to be generated. Specifying the MOTION_EVENTS keyword causes events to be generated *continuously* as the mouse cursor moves across the draw widget. Specifying the EXPOSE_EVENTS keyword causes events to be generated whenever the visibility of any portion of the draw window (or viewport) changes. Specifying the KEYBOARD_EVENTS keyword causes events to be generated when the draw widget has keyboard focus and a keyboard key is pressed. Specifying the WHEEL_EVENTS keyword causes events to be generated when the draw widget has focus and the scroll wheel is rolled.

Note
For an example using motion events with WIDGET_DRAW, see "Accessing Draw Widget Events" (Chapter 5, *Widget Application Programming*).

Draw widgets can also generate events when an item is dragged onto the drawing area and the mouse button is released. See "Drop Events" on page 2779 and the DROP_EVENTS keyword for details.

The event structure returned by the WIDGET_EVENT function is defined by the following statement:

```
{WIDGET_DRAW, ID:0L, TOP:0L, HANDLER:0L, TYPE: 0, X:0L, Y:0L,
   PRESS:0B, RELEASE:0B, CLICKS:0L, MODIFIERS:0L, CH:0B, KEY:0L }
```

Note —————————————————————————————————————

If you defined your own {WIDGET_DRAW} structures prior to the IDL 5.3 release before the structure was defined by an internal call, the MODIFIERS field will break the existing user code.

Note —————————————————————————————————————

If you defined your own {WIDGET_DRAW} structures prior to the IDL 5.6 release before the structure was defined by an internal call, the CH and KEY fields will break the existing user code.

ID, TOP, and HANDLER are the three standard fields found in every widget event. TYPE returns a value that describes the type of draw widget interaction that generated an event. The values for TYPE are shown in the table below.

0	Button press
1	Button release
2	Motion
3	Viewport moved (scrollbars)
4	Visibility changed (exposed)
5	Key press (ASCII character value reported in CH field)
6	Key press (non-ASCII key value reported in KEY field)
7	Wheel scroll

In most cases, the X and Y fields give the device coordinates at which the event occurred, measured from the lower left corner of the drawing area. If the draw widget was created with the APP_SCROLL keyword set, the values in the X and Y fields are measured from the lower left corner of the *viewport*, not the virtual drawable area. Note that in either case, you can pass the values of the X and Y fields directly to WIDGET_DISPLAYCONTEXTMENU without alteration; IDL will perform the appropriate conversions to display the context menu at the correct position.

For button and "viewport moved" events (that is, when the TYPE field contains 0, 1, or 3), the PRESS and RELEASE fields report which of the left, center, or right mouse button was pressed:

Value	Mouse Button
1	Left
2	Middle
4	Right

Table 25-6: Possible values of the PRESS and RELEASE
Fields During Button Events

For motion and wheel events, both PRESS and RELEASE are zero. For keyboard events, PRESS contains 1 (one) if the key is down and 0 (zero) if it is up; RELEASE contains 0 (zero) if the key is down and 1 (one) if it is up.

Note

IDL obtains information about which mouse button was pressed from the operating system, not from the mouse hardware itself. This means that if the operating system or some extension thereof remaps the mouse buttons, IDL may receive information that one button was pressed even if a different physical button was pressed. For example, if a user remaps the mouse buttons to reverse left and right, and then presses the right physical mouse button, the widget event structure will reflect a left mouse button press.

The CLICKS field has one of three possible sets of values:

- If the event is a button press, the field is set to either 1 or 2. If the time interval between two button-press events is less than the time interval for a double-click event for the platform, the CLICKS field returns 2. If the time interval between button-press events is greater than the time interval for a double-click event for the platform, the CLICKS field returns 1. This means that if you are writing a widget application that requires the user to double-click on a draw widget, you will need to handle two events. The CLICKS field will return a 1 on the first click and a 2 on the second click.

- If the event is a wheel scroll, the field indicates the direction and distance that the wheel was rolled. Forward movement gives a positive value; backward movement gives a negative value. Normally the value is 1 or -1, but other values are possible if the user scrolls quickly.

- If the event is not a button-press or wheel event, the CLICKS field contains a 0.

The MODIFIERS field is valid for button press, button release, motion, wheel, and "normal" keyboard events. It is a bitmask which returns the current state of several keyboard modifier keys at the time the event was generated. If a bit is zero, the key is up. If the bit is set, the key is depressed.

Note ───

"Normal" keyboard events are generated when the KEYBOARD_EVENTS keyword is set equal to one. If KEYBOARD_EVENTS is set equal to two, the key-press event for a modifier key contains zero in the MODIFIERS field and the key value is reported in the KEY field; see below.

───

The value in the MODIFIERS field is generated by OR-ing the following values together if a key is depressed.

Bitmask	Modifier Key
1	Shift
2	Control
4	Caps Lock
8	Alt (see the note following this table)

Table 25-7: Bitmask for the MODIFIERS Field

Note ───

Under UNIX, the **Alt** key is the currently mapped MOD1 key.

───

Keyboard events are generated with the value of the TYPE field equal to 5 or 6. If the event was generated by an ASCII keyboard character, the TYPE field will be set to 5 and the ASCII value of the key will be returned in the CH field. (Note that ASCII values can be converted to the string representing the character using the IDL STRING routine.) If the event was generated due to a non-ASCII keyboard character, the type of the event will be set to 6 and a numeric value representing the key will be returned in the KEY field. The following table lists the possible values of the KEY field.

Note that for the key values reported in the KEY field for the **Shift**, **Control**, **Caps Lock**, and **Alt** keys are not the same as those reported in the MODIFIER field bit mask, since the KEY field is not a bitmask.

Key Field Value	Keyboard Key
1	Shift
2	Control
3	Caps Lock
4	Alt
5	Left
6	Right
7	Up
8	Down
9	Page Up
10	Page Down
11	Home
12	End

Table 25-8: Modifier Key Values Reported in the KEY field

Drop Events

This structure is returned when a drop event occurs:

```
{WIDGET_DROP, ID:0L, TOP:0L, HANDLER:0L, DRAG_ID:0L,
              POSITION:0L, X:0L, Y:0L, MODIFIERS:0L}
```

To receive this event the widget must accept drop events (see DROP_EVENTS for details). The ID field reports the destination widget and the DRAG_ID reports the source. The POSITION field for a draw widget always contains the value 1 (one). The X and Y fields give the pixel coordinates of the drop event relative to the lower left corner of the drawing area. The MODIFIERS field reports which keys were pressed at the time the drop event was generated.

The MODIFIERS field is a bitmask of four values:

Bitmask	Modifier Key
1	Shift
2	Control
4	Caps Lock
8	Alt

Table 25-9: Modifier Key Values Reported in the MODIFIERS field

Note on using CURSOR

Note that the CURSOR procedure is only for use with IDL graphics windows. It should not be used with draw widgets. To obtain the cursor position and button state information from a draw widget, examine the X, Y, PRESS, and RELEASE fields in the structures returned by the draw widget in response to cursor events.

Backing Store

Draw widgets with scroll bars rely on backing store to repaint the visible area of the window as it is moved. Their performance is best on systems that provide backing store. However, if your system does not automatically provide backing store, you can make IDL supply it with the statement:

```
DEVICE, RETAIN=2
```

or by using the RETAIN keyword to WIDGET_DRAW.

Note ───
If you are using graphics acceleration, you may wish to turn off backing store entirely and enable expose events (via the EXPOSE_EVENTS keyword) and redraw the draw widget's contents manually. However, because the number of events generated may be quite high, you might want to enable a timer as well and only redraw the draw widget periodically.
───

Version History

Pre-4.0	Introduced
5.6	Added KEYBOARD_EVENTS and TOOLTIP keywords
6.1	Added IGNORE_ACCELERATORS keyword
6.2	Added CLASSNAME and WHEEL_EVENTS keywords
6.3	Added DRAG_NOTIFY and DROP_EVENTS keywords and Drop event

WIDGET_DROPLIST

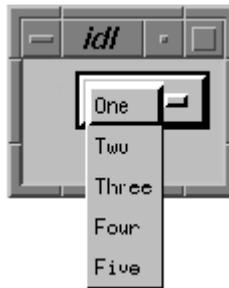
The WIDGET_DROPLIST function creates "droplist" widgets, which display a single entry from a list of options. A droplist widget displays a text field and an arrow button. Selecting either the text field or the button reveals a list of options from which to choose. When the user selects a new option from the list, the list disappears and the text field displays the currently selected option. This action generates an event containing the index of the selected item, which ranges from 0 to the number of elements in the list minus one.


Figure 25-4: A Droplist Widget

Note ──

The WIDGET_COMBOBOX function creates a similar widget that optionally allows users to edit the text displayed by the droplist. The combobox widget is intended to replace the droplist widget; new code should use WIDGET_COMBOBOX rather than WIDGET_DROPLIST.

──

Note ──

The appearance of the droplist widget differs on Motif and Windows platforms. Under Windows, the droplist widget looks the same as the ComboBox widget; under Motif, it appears as shown in the figure above.

──

Syntax

Result = WIDGET_DROPLIST(*Parent* [, /DYNAMIC_RESIZE]
    [, EVENT_FUNC=*string*] [, EVENT_PRO=*string*] [, FONT=*string*]
    [, FRAME=*value*] [, FUNC_GET_VALUE=*string*]
    [, GROUP_LEADER=*widget_id*] [, KILL_NOTIFY=*string*] [, /NO_COPY]

[, NOTIFY_REALIZE=*string*] [, PRO_SET_VALUE=*string*]
[, RESOURCE_NAME=*string*] [, SCR_XSIZE=*width*] [, SCR_YSIZE=*height*]
[, /SENSITIVE] [, TAB_MODE=*value*] [, TITLE=*string*]
[, /TRACKING_EVENTS] [, UNAME=*string*] [, UNITS={0 | 1 | 2}]
[, UVALUE=*value*] [, VALUE=*value*] [, XOFFSET=*value*] [, XSIZE=*value*]
[, YOFFSET=*value*] [, YSIZE=*value*])

Return Value

The returned value of this function is the widget ID of the newly-created droplist widget.

Arguments

Parent

The widget ID of the parent widget for the new droplist widget.

Keywords

DYNAMIC_RESIZE

Note

This keyword is quietly ignored under UNIX. On UNIX systems, droplists do not change their size after being realized.

Set this keyword to create a widget that resizes itself to fit its new value whenever its value is changed. Note that this keyword does not take effect when used with the SCR_XSIZE, SCR_YSIZE, XSIZE, or YSIZE keywords. If one of these keywords is also set, the widget will be sized as specified by the sizing keyword and will never resize itself dynamically.

EVENT_FUNC

A string containing the name of a function to be called by the WIDGET_EVENT function when an event arrives from a widget in the widget hierarchy rooted at the newly-created widget.

EVENT_PRO

A string containing the name of a procedure to be called by the WIDGET_EVENT function when an event arrives from a widget in the widget hierarchy rooted at the newly-created widget.

FONT

The name of the font to be used by the widget. The font specified is a "device font" (an X Windows font on Motif systems; a TrueType or PostScript font on Windows systems). See "About Device Fonts" on page 5580 for details on specifying names for device fonts. If this keyword is omitted, the default font is used.

Note ───

On Microsoft Windows platforms, if FONT is not specified, IDL uses the system default font. Different versions of Windows use different system default fonts; in general, the system default font is the font appropriate for the version of Windows in question.

───

FRAME

The value of this keyword specifies the width of a frame in units specified by the UNITS keyword (pixels are the default) to be drawn around the borders of the widget. Note that this keyword is only a hint to the toolkit, and may be ignored in some instances.

FUNC_GET_VALUE

A string containing the name of a function to be called when the GET_VALUE keyword to the WIDGET_CONTROL procedure is called for this widget. Using this technique allows you to change the value that should be returned for a widget. Compound widgets use this ability to define their values transparently to the user.

GROUP_LEADER

The widget ID of an existing widget that serves as "group leader" for the newly-created widget. When a group leader is killed, for any reason, all widgets in the group are also destroyed.

A given widget can be in more than one group. The WIDGET_CONTROL procedure can be used to add additional group associations to a widget. It is not possible to remove a widget from an existing group.

KILL_NOTIFY

Set this keyword to a string that contains the name of a procedure to be called automatically when the specified widget dies. Each widget is allowed a single such "callback" procedure. It can be removed by setting the routine to the null string (' ').

The callback routine is called with the widget identifier as its only argument. At that point, the widget identifier can only be used with the WIDGET_CONTROL procedure to get or set the user value. All other requests that require a widget ID are disallowed for the target widget. The callback is not issued until the WIDGET_EVENT function is called.

NO_COPY

Usually, when setting or getting widget user values, either at widget creation or using the SET_UVALUE and GET_UVALUE keywords to WIDGET_CONTROL, IDL makes a second copy of the data being transferred. Although this technique is fine for small data, it can have a significant memory cost when the data being copied is large.

If the NO_COPY keyword is set, IDL handles these operations differently. Rather than copy the source data, it takes the data away from the source and attaches it directly to the destination. This feature can be used by compound widgets to obtain state information from a UVALUE without all the memory copying that would otherwise occur. However, it has the side effect of causing the source variable to become undefined. On a "set" operation (using the UVALUE keyword to WIDGET_DROPLIST or the SET_UVALUE keyword to WIDGET_CONTROL), the variable passed as value becomes undefined. On a "get" operation (GET_UVALUE keyword to WIDGET_CONTROL), the user value of the widget in question becomes undefined.

NOTIFY_REALIZE

Set this keyword to a string that contains the name of a procedure to be called automatically when the specified widget is realized. This callback occurs just once (because widgets are realized only once). Each widget is allowed a single such "callback" procedure. It can be removed by setting the routine to the null string (' '). The callback routine is called with the widget ID as its only argument.

PRO_SET_VALUE

A string containing the name of a procedure to be called when the SET_VALUE keyword to the WIDGET_CONTROL procedure is called for this widget. See the description of the PRO_SET_VALUE keyword to WIDGET_CONTROL for information on using this keyword.

RESOURCE_NAME

A string containing an X Window System resource name to be applied to the widget. See "RESOURCE_NAME" on page 2665 for a complete discussion of this keyword.

SCR_XSIZE

Set this keyword to the desired "screen" width of the widget, in units specified by the UNITS keyword (pixels are the default). In many cases, setting this keyword is the same as setting the XSIZE keyword.

SCR_YSIZE

Set this keyword to the desired "screen" height of the widget, in units specified by the UNITS keyword (pixels are the default). In many cases, setting this keyword is the same as setting the YSIZE keyword.

SENSITIVE

Set this keyword to control the initial sensitivity state of the widget.

If SENSITIVE is zero, the widget becomes insensitive. If nonzero, it becomes sensitive. When a widget is sensitive, it has normal appearance and can receive user input. For example, a sensitive button widget can be activated by moving the mouse cursor over it and pressing a mouse button. When a widget is insensitive, it indicates the fact by changing its appearance, looking disabled, and it ignores any input.

Sensitivity can be used to control when a user is allowed to manipulate the widget. Note that some widgets do not change their appearance when they are made insensitive, but they cease generating events.

After creating the widget hierarchy, you can change the sensitivity state using the SENSITIVE keyword with the WIDGET_CONTROL procedure.

TAB_MODE

Set this keyword to one of the values shown in the table below to determine how the widget hierarchy can be navigated using the **Tab** key. The TAB_MODE setting is inherited by lower-level bases and child widgets from the parent WIDGET_BASE unless it is explicitly set on an individual widget. If the TAB_MODE value of the widget differs from that of the base, the setting on the widget will be respected when the widget has focus. For example, if a base does not support tabbing, but an individual child widget does support tabbing, this functionality will be enabled when the child widget has focus.

Note ───

It is not possible to tab to disabled (SENSITIVE=0) or hidden (MAP=0) widgets.

───

Valid settings are:

0	Disable navigation onto or off of the widget. This is the default unless the TAB_MODE has been set on a parent base. Child widgets automatically inherit the tab mode of the parent base as described in "Inheriting the TAB_MODE Value" (Chapter 3, *Widget Application Programming*).
1	Enable navigation onto and off of the widget.
2	Navigate only onto the widget.
3	Navigate only off of the widget.

Note ───

In widget applications on the UNIX platform, the Motif library controls what widgets are brought into and released from focus using tabbing. The TAB_MODE keyword value is always zero, and any attempt to change it is ignored when running a widget application on the UNIX platform. Tabbing behavior may vary significantly between UNIX platforms; do not rely on a particular behavior being duplicated on all UNIX systems.

───

Once a WIDGET_DROPLIST widget receives focus through tabbing, additional navigation capabilities depend upon the platform as follows:

- On Windows – droplist widgets can receive and lose focus through tabbing.

- On UNIX — the Motif library controls tabbing functionality.

After creating the widget hierarchy, you can change tabbing support using the WIDGET_CONTROL procedure's TAB_MODE keyword, or query a widget's support for tabbing using the WIDGET_INFO procedure's TAB_MODE keyword.

See "Tabbing in Widget Applications" (Chapter 3, *Widget Application Programming*) for usage details and examples.

TITLE

Set this keyword to a string to be used as the title for the droplist widget.

Note ──

You can use language catalogs to internationalize this value with strings in particular languages. For more information, see Chapter 19, "Using Language Catalogs" (*Application Programming*).

──

TRACKING_EVENTS

Set this keyword to cause widget tracking events to be issued for the widget whenever the mouse pointer enters or leaves the region covered by that widget. For the structure of tracking events, see "TRACKING_EVENTS" on page 2672 in the documentation for WIDGET_BASE.

UNAME

Set this keyword to a string that can be used to identify the widget in your code. You can associate a name with each widget in a specific hierarchy, and then use that name to query the widget hierarchy and get the correct widget ID.

To query the widget hierarchy, use the WIDGET_INFO function with the FIND_BY_UNAME keyword. The UNAME should be unique to the widget hierarchy because the FIND_BY_UNAME keyword returns the ID of the first widget with the specified name.

UNITS

Set this keyword to specify the units used when *supplying* measurements or position values. Set UNITS equal to 0 (zero) to specify that all measurements are in pixels (this is the default), to 1 (one) to specify that all measurements are in inches, or to 2 (two) to specify that all measurements are in centimeters. This keyword does not change the units used in a widget event structure or in most of the fields of the geometry structure returned by WIDGET_INFO.

UVALUE

The "user value" to be assigned to the widget.

Each widget can contain a user-specified value of any data type and organization. This value is not used by the widget in any way, but exists entirely for the convenience of the IDL programmer. This keyword allows you to set this value when the widget is first created.

If UVALUE is not present, the widget's initial user value is undefined.

VALUE

The initial value setting of the widget. The value of a droplist widget is a scalar string or array of strings that contains the text of the list items—one list item per array element. List widgets are sized based on the length (in characters) of the longest item specified in the array of values for the VALUE keyword.

Note ───

You can use language catalogs to internationalize this value with strings in particular languages. For more information, see Chapter 19, "Using Language Catalogs" (*Application Programming*).

───

XOFFSET

The horizontal offset of the widget in units specified by the UNITS keyword (pixels are the default) relative to its parent.

Specifying an offset relative to a row or column major base widget does not work because those widgets enforce their own layout policies. This keyword is primarily of use relative to a plain base widget. Note that it is best to avoid using this style of widget programming.

XSIZE

The desired width of the droplist widget area, in units specified by the UNITS keyword (pixels are the default). Most widgets attempt to size themselves to fit the situation. However, if the desired effect is not produced, use this keyword to override it. This keyword does not control the size of the droplist button or of the dropped list. Instead, it controls the size "around" the droplist button and, as such, is not particularly useful.

YOFFSET

The vertical offset of the widget in units specified by the UNITS keyword (pixels are the default) relative to its parent. This offset is specified relative to the *upper left* corner of the parent widget.

Specifying an offset relative to a row or column major base widget does not work because those widgets enforce their own layout policies. This keyword is primarily of use relative to a plain base widget. Note that it is best to avoid using this style of widget programming.

YSIZE

The desired height of the widget, in units specified by the UNITS keyword (pixels are the default). Most widgets attempt to size themselves to fit the situation. However, if the desired effect is not produced, use this keyword to override it. This keyword does not control the size of the droplist button or of the dropped list. Instead, it controls the size "around" the droplist button and, as such, is not particularly useful.

Keywords to WIDGET_CONTROL

A number of keywords to the WIDGET_CONTROL procedure affect the behavior of droplist widgets. In addition to those keywords that affect all widgets, the following are particularly useful: DYNAMIC_RESIZE, GET_VALUE, SET_DROPLIST_SELECT, SET_VALUE.

Keywords to WIDGET_INFO

A number of keywords to the WIDGET_INFO function return information that applies specifically to droplist widgets. In addition to those keywords that apply to all widgets, the following are particularly useful: DROPLIST_NUMBER, DROPLIST_SELECT, DYNAMIC_RESIZE, STRING_SIZE.

Widget Events Returned by Droplist Widgets

Pressing the mouse button while the mouse cursor is over an element of a droplist widget causes the widget to change the label on the droplist button and to generate an event. The event structure returned by the WIDGET_EVENT function is defined by the following statement:

```
{ WIDGET_DROPLIST, ID:0L, TOP:0L, HANDLER:0L, INDEX:0L }
```

The first three fields are the standard fields found in every widget event. INDEX returns the index of the selected item. This can be used to index the array of names originally used to set the widget's value.

Note
Platform-specific UI toolkits behave differently if a droplist widget has only a single element. On some platforms, selecting that element again does not generate an event. Events are always generated if the list contains multiple items.

Version History

4.0	Introduced
6.1	Added TAB_MODE keyword

CW_PDMENU, WIDGET_BUTTON, WIDGET_COMBOBOX, WIDGET_LIST

WIDGET_EVENT

The WIDGET_EVENT function returns events for the widget hierarchy rooted at *Widget_ID*. Widgets communicate information by generating events. Events are generated when a button is pressed, a slider position is changed, and so forth.

Note ──

Widget applications should use the XMANAGER procedure in preference to calling WIDGET_EVENT directly. See "Widget Event Processing" (Chapter 2, *Widget Application Programming*).

──

Event Processing

Events for a given widget are processed in the order that they are generated. The event processing performed by WIDGET_EVENT consists of the following steps, applied iteratively:

1. Wait for an event from one of the specified widgets to arrive.

2. Starting with the widget that generated the event, move up the widget hierarchy looking for a widget that has an associated event-handling procedure or function. Event-handling routines are associated with a widget via the EVENT_PRO and EVENT_FUNC keywords to the widget creation functions or the WIDGET_CONTROL procedure.

3. If an event-handling *procedure* is found, it is called with the event as its argument. The HANDLER field of the event is set to the widget ID of the widget associated with the handling procedure. When the procedure returns, WIDGET_EVENT returns to the first step above and starts searching for events. Hence, event-handling procedures are said to "swallow" events.

4. If an event-handling *function* is found, it is called with the event as its argument. The HANDLER field of the event is set to the widget ID of the widget associated with the handling function.

   When the function returns, its value is examined. If the value is not a structure, it is discarded and WIDGET_EVENT returns to the first step. This behavior allows event-handling functions to selectively act like event-handling procedures and "swallow" events.

   If the returned value is a structure, it is checked to ensure that it has the standard first three fields: ID, TOP, and HANDLER. If any of these fields is missing, IDL issues an error. Otherwise, the returned value replaces the event found in the first step and WIDGET_EVENT continues moving up the widget

hierarchy looking for another event handler routine, as described in step 2, above.

In situations where an event structure is returned, event functions are said to "rewrite" events. This ability to rewrite events is the basis of *compound widgets*, which combine several widgets to give the appearance of a single, more complicated widget. Compound widgets are an important widget programming concept. For more information, see "Creating a Compound Widget" (Chapter 2, *Widget Application Programming*).

5. If an event reaches the top of a widget hierarchy without being swallowed by an event handler, it is returned as the value of WIDGET_EVENT.

6. If WIDGET_EVENT was called without an argument, and there are no widgets left on the screen that are being managed (as specified via the MANAGED keyword to the WIDGET_CONTROL procedure) and could generate events, WIDGET_EVENT ends the search and returns an *empty event* (a standard widget event structure with the top three fields set to zero).

Note

Do not interrupt the event loop by placing a STOP or EXIT command in the event-handler or other callback routine. The presence of either command will cause the widget routine to exit with an error.

Syntax

Result = WIDGET_EVENT([*Widget_ID*]) [, BAD_ID=*variable*] [, /NOWAIT]
  [, /SAVE_HOURGLASS]

UNIX Keywords: [, /YIELD_TO_TTY]

Return Value

A widget event is returned in a structure. The exact contents of this structure vary depending upon the type of widget involved. The first three elements of this structure, however, are always the same.

```
{ WIDGET, ID:0L, TOP:0L, HANDLER:0L, ... }
```

Any other elements vary from widget type to type. The three fixed elements are:

Value	Meaning
ID	The widget ID of the widget that generated the event.
TOP	The widget ID of the top level base for the widget hierarchy containing ID.
HANDLER	When an event is passed as the argument to an event handling procedure or function, as discussed in the previous section, this field contains the identifier of the widget associated with the handler routine. When an event is returned from WIDGET_EVENT, this value is always zero to indicate that no handler routine was found.

Table 25-10: Common Event Structure Fields

Arguments

Widget_ID

Widget_ID specifies the widget hierarchy for which events are desired. The first available event for the specified widget or any of its children is returned. If this argument is not specified, WIDGET_EVENT processes events for all existing widgets.

Widget_ID can also be an array of widget identifiers, in which case all of the specified widget hierarchies are searched.

Note

Attempting to obtain events for a widget hierarchy which is not producing events will hang IDL, unless the NOWAIT keyword is used.

Keywords

BAD_ID

If one of the values supplied via *Widget_ID* is not a valid widget identifier, this function normally issues an error and causes program execution to stop. However, if BAD_ID is present and specifies a named variable, the invalid ID is stored into the variable, and this routine quietly returns. If no error occurs, a zero is stored.

This keyword can be used to handle the situation in which IDL is waiting within WIDGET_EVENT when the user kills the widget hierarchy.

This keyword has meaning only if *Widget_ID* is explicitly specified.

NOWAIT

When no events are currently available for the specified widget hierarchy, WIDGET_EVENT normally waits until one is available and then returns it. However, if NOWAIT is set and no events are present, it immediately returns. In this case, the ID field of the returned structure will be zero.

SAVE_HOURGLASS

Set this keyword to prevent the hourglass cursor from being cleared by WIDGET_EVENT. This keyword can be of use if a program has to poll a widget periodically during a long computation.

YIELD_TO_TTY

This keyword is only available on UNIX platforms.

Unless the NOWAIT keyword is specified, WIDGET_EVENT does not return until the asked for event is available. If the user should enter a line of input from the keyboard, it cannot be processed until WIDGET_EVENT returns. If the YIELD_TO_TTY keyword is specified and the user enters a line of input, WIDGET_EVENT returns immediately. In this case, the ID field of the returned structure will be zero.

Note

This keyword is supported under UNIX only, and there are no plans to extend it to other operating systems. Do not use it if you intend to use non-UNIX systems.

Keywords that apply to widgets created with WIDGET_LIST:
[, /CONTEXT_EVENTS] [, /LIST_MULTIPLE] [, /LIST_NUMBER]
[, /LIST_NUM_VISIBLE] [, /LIST_SELECT] [, /LIST_TOP]

Keywords that apply to widgets created with WIDGET_PROPERTYSHEET:
[, /CONTEXT_EVENTS] [, COMPONENT=*objref*]
[, /MULTIPLE_PROPERTIES] [, PROPERTY_VALID=*string*]
[, PROPERTY_VALUE=*string*] [, /PROPERTYSHEET_NSELECTED]
[, /PROPERTYSHEET_SELECTED]

Keywords that apply to widgets created with WIDGET_SLIDER:
[, /SLIDER_MIN_MAX]

Keywords that apply to widgets created with WIDGET_TAB:
[, /TAB_CURRENT] [, /TAB_MULTILINE] [, /TAB_NUMBER]

Keywords that apply to widgets created with WIDGET_TABLE:
[, /COLUMN_WIDTHS] [, /CONTEXT_EVENTS] [, /ROW_HEIGHTS]
[, /TABLE_ALL_EVENTS] [, /TABLE_BACKGROUND_COLOR]
[, /TABLE_DISJOINT_SELECTION] [, /TABLE_EDITABLE]
[, /TABLE_EDIT_CELL] [, /TABLE_FONT]
[. /TABLE_FOREGROUND_COLOR] [, /TABLE_SELECT] [, /TABLE_VIEW]
[, /TEXT_SELECT] [, /USE_TABLE_SELECT]

Keywords that apply to widgets created with WIDGET_TEXT:
[, /CONTEXT_EVENTS] [, /TEXT_ALL_EVENTS] [, /TEXT_EDITABLE]
[, /TEXT_NUMBER] [, TEXT_OFFSET_TO_XY=*integer*] [, /TEXT_SELECT]
[, /TEXT_TOP_LINE] [, TEXT_XY_TO_OFFSET=*[column, line]*]

Keywords that apply to widgets created with WIDGET_TREE:
[, /CONTEXT_EVENTS] [, /DRAG_NOTIFY] [, /DRAGGABLE]
[, /DROP_EVENTS] [, /MASK] [, /TREE_BITMAP]
[, /TREE_DRAG_SELECT] [, /TREE_EXPANDED] [, /TREE_FOLDER]
[, /TREE_INDEX] [, /TREE_ROOT] [, /TREE_SELECT]

Return Value

Returns the specified information for the given widget ID. If the SYSTEM_COLORS
keyword is specified, a structure is returned. See "The
WIDGET_SYSTEM_COLORS Structure" on page 2823 for details.

Arguments

Widget_ID

Usually this argument should be the widget ID of the widget for which information is desired. If the ACTIVE or VERSION keywords are specified, this argument is not required.

Widget_ID can also be an array of widget identifiers, in which case the result is an array with the same structure in which information on all the specified widgets is returned.

Keywords

Not all keywords to WIDGET_INFO apply to all combinations of widgets. In the following list, descriptions of keywords that affect only certain types of widgets include a list of the widgets for which the keyword is useful.

ACTIVE

This keyword applies to all widgets.

Set this keyword to return 1 if there is at least one realized, managed, top-level widget on the screen. Otherwise, 0 is returned.

ALL_CHILDREN

This keyword applies to all widget types.

Set this keyword to have the widget system return an array that contains the widget IDs of the given widget's immediate children. A scalar is returned if the widget contains only one child. If the widget does not have any children then the return value is the scalar value 0 (zero). When there are multiple children, the returned array is ordered according to the position of the children. This keyword can only be applied to one widget at a time. The N_CHILDREN keyword complements ALL_CHILDREN.

Note ───

If the widget possesses a context menu then the returned array will include the context base. Widget types can be discovered using the TYPE and NAME keywords to WIDGET_INFO.

───

BUTTON_SET

This keyword applies to widgets created with the WIDGET_BUTTON function.

Set this keyword to return the "set" state of a widget button. If the button is currently set, 1 (one) is returned. If the button is currently not set, 0 (zero) is returned. This keyword is intended for use with exclusive, non-exclusive and checked menu buttons.

CHILD

This keyword applies to all widgets.

Set this keyword to return the widget ID of the first child of the widget specified by *Widget_ID*. If the widget has no children, 0 is returned.

COLUMN_WIDTHS

This keyword applies to widgets created with the WIDGET_TABLE function.

Set this keyword to return an array of long integers giving the width of each column in the table. If USE_TABLE_SELECT is set equal to one, only the column widths for columns that contain currently-selected cells are returned. If USE_TABLE_SELECT is set equal to an array, only the column widths for columns that contain specified cells are returned.

COMBOBOX_GETTEXT

This keyword applies to widgets created with the WIDGET_COMBOBOX function.

Set this keyword to return the current text from the text box of the specified combobox widget. Note that when using an editable combobox, the text displayed in the text box may not be an item from the list of values in the combobox list. To obtain the index of the selected item, inspect the INDEX field of the event structure returned by the combobox widget.

COMBOBOX_NUMBER

This keyword applies to widgets created with the WIDGET_COMBOBOX function.

Set this keyword to return the number of elements currently contained in the list of the specified combobox widget.

COMPONENT

This keyword applies to widgets created with the WIDGET_PROPERTYSHEET function.

Set this keyword to an object reference to indicate which object to query. This is most useful when the property sheet references multiple objects. If this keyword is not specified, the first (possibly only) object is queried.

CONTEXT_EVENTS

This keyword applies to widgets created with the WIDGET_BASE, WIDGET_LIST, WIDGET_PROPERTYSHEET, WIDGET_TABLE, WIDGET_TEXT or WIDGET_TREE functions.

Set this keyword to determine whether the widget specified by *Widget_ID* is configured to generate context events (that is, the widget was created with the CONTEXT_EVENTS keyword set). The return value is 1 (one) if context events will be generated, or 0 (zero) otherwise.

DRAG_NOTIFY

This keyword applies to widgets created with the WIDGET_DRAW and WIDGET_TREE functions.

Set this keyword to retrieve the name of the drag notification callback. If the widget is using the default callback, the return value will be the string <default> (including the < and > characters). If the widget is using the callback of its parent node, the return value will be the string <inherit> (including the < and > characters). When inheriting, the name of the callback that is ultimately invoked can be discovered by walking up the tree widget hierarchy until <inherit> is not returned. For more details, see the DRAG_NOTIFY keyword of WIDGET_DRAW and WIDGET_TREE.

DRAGGABLE

This keyword applies to widgets created with the WIDGET_TREE function.

Set this keyword to determine whether the tree widget is draggable. Possible return values are:

1	The widget is draggable because the DRAGGABLE keyword was set when the widget was created.
0	The widget is not draggable because the DRAGGABLE keyword was explicitly set to 0 when the widget was created.
-1	The widget inherits the draggability setting of its parent. To determine the actual draggability of the widget, you must walk up the widget hierarchy until an ancestor of the selected widget returns 1 or 0.

Although it is never draggable, the root node of a tree widget can set DRAGGABLE to 1 or 0 so that its children can inherit the value. WIDGET_INFO will return the current setting.

DRAW_BUTTON_EVENTS

This keyword applies to widgets created with the WIDGET_DRAW function.

Set this keyword to return 1 if *Widget_ID* is a draw widget with the BUTTON_EVENTS attribute set. Otherwise, 0 is returned.

DRAW_EXPOSE_EVENTS

This keyword applies to widgets created with the WIDGET_DRAW function.

Set this keyword to return 1 if *Widget_ID* is a draw widget with the EXPOSE_EVENTS attribute set. Otherwise, 0 is returned.

DRAW_KEYBOARD_EVENTS

This keyword applies to widgets created with the WIDGET_DRAW function.

Set this keyword to return an integer specifying the type of keyboard events currently generated by the draw widget specified by *Widget_ID*. Possible values are:

- 0: No keyboard events are generated

- 1: Keyboard events are generated for "normal" keys (all keys except function keys and modifier keys: SHIFT, CONTROL, CAPS LOCK, and ALT).

- 2: Keyboard events are generated for "normal" keys and modifier keys.

Note ───

Keyboard events are never generated for function keys.

───

DRAW_MOTION_EVENTS

This keyword applies to widgets created with the WIDGET_DRAW function.

Set this keyword to return 1 if *Widget_ID* is a draw widget with the MOTION_EVENTS attribute set. Otherwise, 0 is returned.

DRAW_VIEWPORT_EVENTS

This keyword applies to widgets created with the WIDGET_DRAW function.

Set this keyword to return 1 if *Widget_ID* is a draw widget with the VIEWPORT_EVENTS attribute set. Otherwise, 0 is returned.

DRAW_WHEEL_EVENTS

This keyword applies to widgets created with the WIDGET_DRAW function.

If this keyword is set and the provided widget ID is for a draw widget, WIDGET_INFO returns True (1) if mouse wheel events are enabled for the given draw widget and False (0) if wheel events are disabled. WIDGET_INFO also returns False if this keyword is used on non-draw widgets.

DROP_EVENTS

This keyword applies to widgets created with the WIDGET_DRAW and WIDGET_TREE functions.

Set this keyword to determine whether or not a widget generates drop events.

Possible return values are:

1	The widget will generate drop events because the DROP_EVENTS keyword was set when the widget was created.
0	The widget will not generate drop events because the DROP_EVENTS keyword was explicitly set to 0 when the widget was created.
-1	The widget inherits the DROP_EVENTS setting of its parent. To determine whether a widget that reports -1 will generate drop events, you must walk up the widget hierarchy until an ancestor of the selected widget returns 1 or 0.

Widgets can generate drop events regardless of whether or not a drag notification callback has been specified (explicitly or inherited implicitly).

DROPLIST_NUMBER

This keyword applies to widgets created with the WIDGET_DROPLIST function.

Set this keyword to return the number of elements currently contained in the specified droplist widget.

DROPLIST_SELECT

This keyword applies to widgets created with the WIDGET_DROPLIST function.

Set this keyword to return the zero-based number of the currently-selected element (i.e., the currently-displayed element) in the specified droplist widget.

DYNAMIC_RESIZE

This keyword applies to widgets created with the WIDGET_BUTTON, WIDGET_COMBOBOX, WIDGET_DROPLIST, and WIDGET_LABEL functions.

Set this keyword to return a True value (1) if the widget specified by *Widget_ID* is a button, droplist, or label widget that has had its DYNAMIC_RESIZE attribute set. Otherwise, False (0) is returned.

EVENT_FUNC

This keyword applies to all widgets.

Set this keyword to return a string containing the name of the event handler function associated with *Widget_ID*. A null string is returned if no event handler function exists.

EVENT_PRO

This keyword applies to all widgets.

Set this keyword to return a string containing the name of the event handler procedure associated with *Widget_ID*. A null string is returned if no event handler procedure exists.

FIND_BY_UNAME

This keyword applies to all widgets.

Set this keyword to a UNAME value that will be searched for in the widget hierarchy, and if a widget with the given UNAME is in the hierarchy, its ID is returned. The search starts in the hierarchy with the given widget ID and travels down, and this keyword returns the widget ID of the first widget that has the specified UNAME value.

If a widget is not found, 0 is returned.

FONTNAME

This keyword applies to all widgets that support fonts. If the specified widget does not support fonts, WIDGET_INFO returns an empty string.

Note ————————————————————————————

The WIDGET_BASE, WIDGET_DRAW, WIDGET_TAB, and WIDGET_TREE widgets do *not* support fonts.

——

Set this keyword to return a string containing the name of the font being used by the specified widget. The returned name can then be used when creating other widgets or with the SET_FONT keyword to the DEVICE procedure.

Note ————————————————————————————————————

> If the widget being queried has not yet been realized, this keyword will return the default font even if another font has been specified. To ensure that you are retrieving the correct font, query for the font name *after* realizing the widget.

——

You can use this keyword to retrieve the name of the *default* font used by one type of widget and use the same font in other contexts. For example, the following code retrieves the default font used for buttons and writes into the drawable area of a draw widget using the same font:

```
wBase = WIDGET_BASE(/ROW)
wButton = WIDGET_BUTTON(wBase, VALUE="Button")
wDraw = WIDGET_DRAW(wBase, XSIZE=200, YSIZE=100)
WIDGET_CONTROL, wBase, /REALIZE
strFont = WIDGET_INFO(wButton, /FONTNAME)
DEVICE, SET_FONT=strFont
WIDGET_CONTROL, wDraw, GET_VALUE=iWindow
WSET, iWindow
XYOUTS, 100, 50, 'Same Font as Button', FONT=0, /DEVICE, $
    ALIGNMENT=.5
```

This method allows you to synchronize the fonts in several widgets without knowing in advance which font is in use.

The format of the returned font name is platform dependent. See "About Device Fonts" on page 5580 for additional details.

GEOMETRY

This keyword applies to all widgets.

Note ————————————————————————————————————

> Some widgets have no geometry values of their own. For example, only the root node of a tree widget hierarchy has associated geometry values. Similarly, buttons created on a pop-up menu have no geometry. Widgets with no intrinsic geometry values will return a WIDGET_GEOMETRY structure containing all zeroes.

——

Set this keyword to return a WIDGET_GEOMETRY structure that describes the offset and size information for the widget specified by *Widget_ID*. This structure has the following definition:

```
{ WIDGET_GEOMETRY,
```

```
         XOFFSET:0.0,
         YOFFSET:0.0,
         XSIZE:0.0,
         YSIZE:0.0,
         SCR_XSIZE:0.0,
         SCR_YSIZE:0.0,
         DRAW_XSIZE:0.0,
         DRAW_YSIZE:0.0,
         MARGIN:0.0,
         XPAD:0.0,
         YPAD:0.0,
         SPACE:0.0 }
```

With the exception of MARGIN, all of the structure's fields correspond to the keywords of the same name to the various widget routines. MARGIN is the width of any frame added to the widget, in units specified by the UNITS keyword (pixels are the default). Therefore, the actual width of any widget is:

```
SCR_XSIZE + (2* MARGIN)
```

The actual height of any widget is:

```
SCR_YSIZE + (2 * MARGIN)
```

Note ——

Different window managers may use different *window dressing* (borders, margins, scrollbars, *etc*.). As a result, running a given segment of widget code on different platforms may yield different geometry.

——

Note ——

In most cases, setting SCR_XSIZE (or SCR_YSIZE) for a base widget should override the value set via the XSIZE (or YSIZE) keyword. For *unrealized* base widgets on Microsoft Windows platforms, however, the returned WIDGET_GEOMETRY structure will report the specified value of XSIZE (or YSIZE) rather than the value supplied via the SCR_XSIZE (or SCR_YSIZE) keyword.

——

Note ——

For table widgets, the YSIZE and XSIZE values return the total number of rows and columns, which may differ from the visible number of rows and columns.

——

KBRD_FOCUS_EVENTS

This keyword applies to all widgets.

Set this keyword to return the keyboard focus events status of the widget specified by *Widget ID*. WIDGET_INFO returns 1 (one) if keyboard focus events are currently enabled for the widget, or 0 (zero) if they are not. Only base, table, and text widgets can generate keyboard focus events.

LIST_MULTIPLE

This keyword applies to widgets created with the WIDGET_LIST function.

Set this keyword equal to a named variable that will contain a non-zero value if the list widget supports multiple item selections. See the MULTIPLE keyword to WIDGET_LIST for more on multiple item selections.

LIST_NUMBER

This keyword applies to widgets created with the WIDGET_LIST function.

Set this keyword to return the number of elements currently contained in the specified list widget.

LIST_NUM_VISIBLE

This keyword applies to widgets created with the WIDGET_LIST function.

Set this keyword to return the number of elements that can be visible in the scrolling viewport of the specified list widget. Note that this value can be larger than the total number of elements actually in the list.

LIST_SELECT

This keyword applies to widgets created with the WIDGET_LIST function.

Set this keyword to return the index or indices of the currently selected (highlighted) element or elements in the specified list widget. Note that this offset is zero-based. If no element is currently selected, -1 is returned.

LIST_TOP

This keyword applies to widgets created with the WIDGET_LIST function.

Set this keyword to return the zero-based offset of the topmost element currently visible in the specified list widget.

MANAGED

This keyword applies to all widgets.

Set this keyword to return 1 if the specified widget is managed, or 0 otherwise. If no widget ID is specified in the call to WIDGET_INFO, the return value will be an array containing the widget IDs of all currently-managed widgets.

MAP

This keyword applies to all widgets.

Set this keyword to return True (1) if the widget specified by *Widget_ID* is mapped (visible), or False (0) otherwise. Note that when a base widget is unmapped, all of its children are unmapped. If WIDGET_INFO reports that a particular widget is unmapped, it may be because a parent in the widget hierarchy has been unmapped.

MASK

This keyword applies to widgets created with the WIDGET_TREE function.

Set this keyword to determine whether a widget's bitmap makes use of transparency. The return value will be 1 (one) if the bitmap uses transparency, or 0 (zero) otherwise. The tree root node and nodes that use the default icon always return 1. For more information, see the MASK keyword to WIDGET_TREE.

MODAL

This keyword applies to widgets created with the WIDGET_BASE function and the MODAL keyword.

If this keyword is set, WIDGET_INFO will return True (1) if the base widget specified by *Widget_ID* is a modal base widget, or False (0) otherwise.

MULTIPLE_PROPERTIES

This keyword applies to widgets created with the WIDGET_PROPERTYSHEET function.

Set this keyword to return the property sheet's current selection mode. A value of 1 indicates support for multiple property selection. A value of 0 indicates that only single property selection is permitted.

N_CHILDREN

This keyword applies to all widget types.

Set this keyword to return the number of children that belong to a widget. This keyword complements the ALL_CHILDREN keyword.

Note ———
If the widget possesses a context menu then the count will include the context base.
——

NAME

This keyword applies to all widgets.

Set this keyword to return the widget type name of the widget specified by
Widget_ID. The returned value will be one of the following strings: "BASE",
"BUTTON", "COMBOBOX", "DRAW", "DROPLIST", "LABEL", "LIST",
"PROPERTYSHEET", "SLIDER", "TAB", "TABLE", "TEXT", or "TREE". Set the
TYPE keyword to return the widget's type code.

PARENT

This keyword applies to all widgets.

Set this keyword to return the widget ID of the parent of the widget specified by
Widget_ID. If the widget is a top-level base (i.e., it has no parent), 0 is returned.

PROPERTY_VALID

This keyword applies to widgets created with the WIDGET_PROPERTYSHEET
function.

Set this keyword to a scalar string or one-element string array that contains a property
identifier. If the specified property is included in the property sheet, WIDGET_INFO
will return 1; if the property is not included in the property sheet, WIDGET_INFO
will return 0. Comparisons are case-insensitive.

Note ———
Property identifiers returned in the IDENTIFIER field of an event structure
generated by a property sheet widget can be assumed to be valid.
——

PROPERTY_VALUE

This keyword applies to widgets created with the WIDGET_PROPERTYSHEET
function.

Set this keyword to a string that contains a property identifier. If the specified
property is included in the property sheet, WIDGET_INFO will return the value of
the property. If the specified property is not included in the property sheet,
WIDGET_INFO will generate an error; use the PROPERTY_VALID keyword to

WIDGET_INFO to check for validity before retrieving the property value. Comparisons are case-insensitive.

If the property sheet contains multiple components, use the COMPONENT keyword to indicate which component the property value should be retrieved from.

Note on use of this keyword

When a user changes a value in the property sheet widget, the actual value of the underlying property does not change automatically. Use this keyword to retrieve the value specified by the user, then apply the new value to the underlying component. The following code snippet illustrates this process:

```
PRO prop_event, e

; Get the value of the changed property, using the component and
; property identifier information contained in the widget event.
value = WIDGET_INFO( e.id, COMPONENT = e.component, $
   PROPERTY_VALUE = e.identifier )

; Set the component's property's value
e.component->SetPropertyByIdentifier, e.identifier, value

END
```

PROPERTYSHEET_NSELECTED

This keyword applies to widgets created with the WIDGET_PROPERTYSHEET function.

Set this keyword to return the number of currently selected properties. The COMPONENT keyword is not required.

PROPERTYSHEET_SELECTED

This keyword applies to widgets created with the WIDGET_PROPERTYSHEET function.

Set this keyword to return the identifiers of the currently selected properties. The return value depends on the number of rows selected as follows:

Selection	Return Value
No Properties Selected	Returns an empty string (' ').
Single Property Selected	Returns a string containing the property identifier.
Multiple Properties Selected	Returns an array of strings containing each selected property's identifier.

Table 25-11: Possible Return Values

The COMPONENT keyword is not required.

PUSHBUTTON_EVENTS

This keyword applies to widgets created with the WIDGET_BUTTON function.

Set this keyword to return the pushbutton events status for the widget specified by *Widget_ID*. WIDGET_INFO returns 1 if pushbutton events are currently enabled for the widget, or 0 otherwise.

REALIZED

This keyword applies to all widgets.

Set this keyword to return 1 if the widget specified by *Widget_ID* has been realized. If the widget has not been realized, 0 is returned.

ROW_HEIGHTS

This keyword applies to widgets created with the WIDGET_TABLE function.

Set this keyword to return an array of floating-point values giving the height of each row in the table. If USE_TABLE_SELECT is set equal to one, only the row heights for rows that contain currently selected cells are returned. If USE_TABLE_SELECT is set equal to an array, only the row heights for rows that contain specified cells are returned.

Note —————————————————————————————————————

On Microsoft Windows platforms, all value rows have the same height, but the column header can have a distinct height. The column header is indexed by a value of -1 for the row.

———

SENSITIVE

This keyword applies to all widgets.

Set this keyword to return true (1) if the widget specified by *Widget_ID* is sensitive (enabled), or false (0) otherwise. Note that when a base is made insensitive, all its children are made insensitive. If WIDGET_INFO reports that a particular widget is insensitive, it may be because a parent in the widget hierarchy has been made insensitive.

SIBLING

This keyword applies to all widgets.

Set this keyword to return the widget ID of the first sibling of the widget specified by *Widget_ID*. If the widget is the last sibling in the chain, 0 is returned.

SLIDER_MIN_MAX

This keyword applies to widgets created with the WIDGET_SLIDER function.

Set this keyword to return the current minimum and maximum values of the specified slider as a two-element integer array. Element 0 is the minimum value and element 1 is the maximum value.

STRING_SIZE

This keyword applies to all widget types.

Set this keyword to retrieve the dimensions of a string. The return value is a two-element vector containing the string's width and height in pixels. A widget identifier must always be specified in the call. The keyword's value can be either the measured string or a two-element vector containing first the string and then a font. If a font is specified, that font is used in the calculations. Otherwise, the widget's font is used. In the case of a table widget with multiple fonts, the default font is used. See "About Device Fonts" on page 5580 for details on specifying names for device fonts.

Note ————————————————————————————————————

When you are using the dimensions returned by this keyword, take into account the padding that a widget uses around a string. STRING_SIZE returns the exact dimensions, which if used can cut off the string's edges.

Note ————————————————————————————————————

This keyword's height results might not be 100% reliable from calculation of the specified font's overall size. The calculation uses the span between the maximum ascender and descender in the font's catalogue, regardless of whether those letters appear in the specified string being measured.

SYSTEM_COLORS

This keyword applies to all widgets.

Set this keyword and supply the widget ID of any widget to cause WIDGET_INFO to return an IDL structure that contains RGB values used for 25 IDL display elements.

For more detailed information on the WIDGET_SYSTEM_COLORS structure fields and their meaning see the "The WIDGET_SYSTEM_COLORS Structure" on page 2823.

TAB_CURRENT

This keyword applies to widgets created with the WIDGET_TAB function.

Set this keyword to return the zero-based index of the current tab in the tab widget.

TAB_MODE

This keyword applies to all widgets.

Set this keyword to return what support the specified widget has for navigating among widgets using the **Tab** key. Possible return values are:

0	Navigation is not supported onto or off of the widget
1	Navigation is supported onto and off of the widget
2	Navigation is supported only onto the widget
3	Navigation is supported only off of the widget

Note ───

In widget applications on the UNIX platform, the Motif library controls what widgets are brought into and released from focus using tabbing. The TAB_MODE keyword value is always zero, and any attempt to change it is ignored when running a widget application on the UNIX platform. Tabbing behavior may vary significantly between UNIX platforms; do not rely on a particular behavior being duplicated on all UNIX systems.

───

TAB_MULTILINE

This keyword applies to widgets created with the WIDGET_TAB function.

Set this keyword to return the current setting of the multi-line mode for the tab widget.

TAB_NUMBER

This keyword applies to widgets created with the WIDGET_TAB function.

Set this keyword to return the number of tabs contained in the tab widget.

TABLE_ALL_EVENTS

This keyword applies to widgets created with the WIDGET_TABLE function.

Set this keyword to return 1 (one) if *Widget_ID* is a table widget with the ALL_EVENTS attribute set. Otherwise, 0 (zero) is returned.

TABLE_BACKGROUND_COLOR

This keyword applies to widgets created with the WIDGET_TABLE function.

Set this keyword to return the background colors of table cells. Colors are returned as RGB triplets, where each byte for red, green, and blue is in the range [0,255]. Normally all of the table's cells are queried, but you can indicate a subset with the USE_TABLE_SELECT keyword. If all of the colors are identical, the return value is a three-element vector of bytes (an RGB triplet). If any one color is different, the return value has all of the colors in an array whose dimensions mirror the query set specification.

Note ———————————————————————————————————————

On systems that do not support a large number of colors, the color value returned by WIDGET_INFO may not match the value specified via WIDGET_TABLE or WIDGET_CONTROL exactly. The value returned by WIDGET_INFO is the color that was actually applied.

———

For more information on the return value, see "Cell Attributes" (Chapter 7, *Widget Application Programming*).

TABLE_DISJOINT_SELECTION

This keyword applies to widgets created with the WIDGET_TABLE function.

Set this keyword to return 1 (one) if the widget specified by *Widget_ID* has disjoint selection enabled. Otherwise, 0 (zero) is returned.

TABLE_EDITABLE

This keyword applies to widgets created with the WIDGET_TABLE function.

Set this keyword to return the editability of table cells. Values are returned as single bytes containing 0 (not editable) or 1 (editable). Normally all of the table's cells are queried, but you can indicate a subset with the USE_TABLE_SELECT keyword. If all of the values are identical, the return value is a scalar byte. If any one value is different, the return value has all of the values in an array whose dimensions mirror the query set specification.

For more information on the return value, see "Cell Attributes" (Chapter 7, *Widget Application Programming*).

Note ———————————————————————————————————————

When using a table with mixed editability, it is important that you take care when using the return value from TABLE_EDITABLE in a conditional because the value might not be scalar.

———

TABLE_EDIT_CELL

This keyword applies to widgets created with the WIDGET_TABLE function.

Set this keyword to return a two-element integer array containing the row and column coordinates of the currently editable cell. If none of the cells in the table widget is currently editable, the array [-1, -1] is returned.

TABLE_FONT

This keyword applies to widgets created with the WIDGET_TABLE function.

Set this keyword to return the font names of table cells. Values are returned as strings. Normally all of the table's cells are queried, but you can indicate a subset with the USE_TABLE_SELECT keyword. If all of the font names are identical, the return value is a scalar string. If any one font is different, the return value has all of the values in an array whose dimensions mirror the query set specification.

For more information on the return value, see "Cell Attributes" (Chapter 7, *Widget Application Programming*).

Note ──

On Microsoft Windows platforms, the returned font description is functionally equivalent to the originally specified font, but might have modifiers in a different order.

──

TABLE_FOREGROUND_COLOR

This keyword applies to widgets created with the WIDGET_TABLE function.

Set this keyword to return the text colors of table cells. Colors are returned as RGB triplets, where each byte for red, green, and blue is in the range [0,255]. Normally all of the table's cells are queried, but you can indicate a subset with the USE_TABLE_SELECT keyword. If all of the colors are identical, the return value is a three-element vector of bytes (an RGB triplet). If any one color is different, the return value has all of the colors in an array whose dimensions mirror the query set specification.

Note ──

On systems that do not support a large number of colors, the color value returned by WIDGET_INFO may not match the value specified via WIDGET_TABLE or WIDGET_CONTROL exactly. The value returned by WIDGET_INFO is the color that was actually applied.

──

For more information on the return value, see "Cell Attributes" (Chapter 7, *Widget Application Programming*).

TABLE_SELECT

This keyword applies to widgets created with the WIDGET_TABLE function.

Set this keyword to return the currently-selected (highlighted) cells in the specified table widget.

- In standard selection mode, this keyword returns an array of the form [*left*, *top*, *right*, *bottom*] containing the zero-based indices of the columns and rows that define the selection.

- In disjoint selection mode (enabled by setting the DISJOINT_SELECTION keyword to WIDGET_TABLE), this keyword returns a 2 x *n* array of column/row pairs containing the zero-based indices the selected cells.

TABLE_VIEW

This keyword applies to widgets created with the WIDGET_TABLE function.

Set this keyword to return a two-element array of the form [*left*, *top*] containing the zero-based offsets of the top-left cell currently visible in the specified table widget.

TEXT_ALL_EVENTS

This keyword applies to widgets created with the WIDGET_TEXT function.

Set this keyword to return 1 if *Widget_ID* is a text widget with the ALL_EVENTS attribute set. Otherwise, 0 is returned.

TEXT_EDITABLE

This keyword applies to widgets created with the WIDGET_TEXT function.

Set this keyword to return 1 if *Widget_ID* is a text widget that allows user editing of its contents. Otherwise, 0 is returned.

TEXT_NUMBER

This keyword applies to widgets created with the WIDGET_TEXT function.

Set this keyword to return the number of characters currently contained in the specified text widget, including end-of-line characters.

Note

On Windows platforms, Carriage Return/Line Feed pairs count as a single character.

TEXT_OFFSET_TO_XY

This keyword applies to widgets created with the WIDGET_TEXT function.

Use this keyword to translate a text widget character offset into column and line form. The value of this keyword should be set to the character offset (an integer) to be translated. WIDGET_INFO returns a two-element integer array giving the column (element 0) and line (element 1) corresponding to the offset. If the offset specified is out of range, the array [-1,-1] is returned.

TEXT_SELECT

This keyword applies to widgets created with the WIDGET_TABLE and WIDGET_TEXT functions.

Set this keyword to return the starting character offset and length (in characters) of the selected (highlighted) text in the specified text widget or table cell. WIDGET_INFO returns a two-element integer array containing the starting position of the highlighted text as an offset from character zero of the text in the text widget or table cell (element 0), and length of the current selection (element 1).

TEXT_TOP_LINE

This keyword applies to widgets created with the WIDGET_TEXT function.

Set this keyword to return the zero-based line number of the line currently at the top of a text widget's display viewport. Note that this value is different from the zero-based character offset of the characters in the line. The character offset can be calculated from the line offset via the TEXT_XY_TO_OFFSET keyword.

TEXT_XY_TO_OFFSET

This keyword applies to widgets created with the WIDGET_TEXT function.

Use this keyword to translate a text widget position given in line and column form into a character offset. The value of this keyword should be set to a two-element integer array specifying the column (element 0) and line (element 1) position. WIDGET_INFO returns the character offset (as a longword integer) corresponding to the position. If the position specified is out of range, -1 is returned.

TLB_ICONIFY_EVENTS

This keyword applies to widgets created with the WIDGET_BASE function.

Set this keyword to return 1 if the top-level base widget specified by *Widget_ID* is set to return iconify events. Otherwise, 0 is returned.

TLB_KILL_REQUEST_EVENTS

This keyword applies to widgets created with the WIDGET_BASE function.

Set this keyword to return 1 if the top-level base widget specified by *Widget_ID* is set to return kill request events. Otherwise, 0 is returned.

TLB_MOVE_EVENTS

This keyword applies to widgets created with the WIDGET_BASE function.

Set this keyword to return 1 if the top-level base widget specified by *Widget_ID* is set to return move events. Otherwise, 0 is returned.

TLB_SIZE_EVENTS

This keyword applies to widgets created with the WIDGET_BASE function.

Set this keyword to return 1 if the top-level base widget specified by *Widget_ID* is set to return resize events. Otherwise, 0 is returned.

TOOLTIP

This keyword applies to widgets created with the WIDGET_BUTTON and WIDGET_DRAW functions.

Set this keyword to have the WIDGET_INFO function return the text of the tooltip of the widget. If the widget does not have a tooltip, a null string will be returned.

TRACKING_EVENTS

This keyword applies to all widgets.

Set this keyword to return the tracking events status for the widget specified by *Widget_ID*. WIDGET_INFO returns 1 if tracking events are currently enabled for the widget. Otherwise, 0 is returned.

TREE_BITMAP

This keyword applies to widgets created with the WIDGET_TREE function.

Set this keyword to return a 16x16x3 array containing the RGB image specified as the tree widget node's bitmap. If the node uses the default bitmap or is a tree root, then scalar zero is returned. This keyword can only be applied to one widget at a time.

TREE_DRAG_SELECT

This keyword applies to widgets created with the WIDGET_TREE function.

Set this keyword to return a modified selection list that does not include nodes that have a selected ancestor. This is useful when an application automatically copies or moves a selected folder's children, as does the WIDGET_TREE_MOVE routine.

There are two modes of operation, depending on the widget ID passed to WIDGET_INFO:

- If the specified widget ID is the root node of a tree, the returned value is either a scalar or vector of node widget IDs, depending on whether or not multiple nodes are selected. Only those nodes that are selected and do not have a selected ancestor are reported. If no nodes are selected, -1 is returned.

- If the specified widget ID represents a node in the tree, then the returned value is 1 (one) if the node is both selected and has no selected ancestors, or 0 (zero) otherwise.

By providing the "pruned" list of nodes to the copy or move routine, an application that automatically copies or moves all of a selected node's children will avoid copying or moving both the parent and then, later, any selected children. If you use the WIDGET_TREE_MOVE routine, you should use this keyword when retrieving the list of selected nodes.

Use TREE_SELECT to retrieve the full list of selected nodes.

TREE_EXPANDED

This keyword applies to widgets created with the WIDGET_TREE function.

Set this keyword to return 1 (one) if the specified tree widget node is a folder that is expanded, or 0 (zero) if the specified node is a folder that is collapsed.

Note
Only tree widget nodes created with the FOLDER keyword can be expanded or collapsed. This keyword will always return 0 (zero) if the specified tree widget node is not a folder.

TREE_FOLDER

This keyword applies to widgets created with the WIDGET_TREE function.

Set this keyword to determine if a tree widget node is a folder or leaf node. The root and folders result in a return value of 1 (one) and leaf nodes return 0 (zero).

TREE_INDEX

This keyword applies to widgets created with the WIDGET_TREE function.

Set this keyword to return the position of the specified tree widget. The return value is the zero-based index of the widget relative to its siblings.

TREE_ROOT

This keyword applies to widgets created with the WIDGET_TREE function.

Set this keyword to return the widget ID of the *root node* of the tree widget hierarchy of which *Widget ID* is a part. The root node is the tree widget whose parent is a base widget.

TREE_SELECT

This keyword applies to widgets created with the WIDGET_TREE function.

Set this keyword to return information about the nodes selected in the specified tree widget. This keyword has two modes of operation, depending on the widget ID passed to WIDGET_INFO:

- If the specified widget ID is for the root node of the tree widget (the tree widget whose *Parent* is a base widget), this keyword returns either the widget ID of the selected node or (if multiple nodes are selected) an array of widget IDs of the selected nodes. If no nodes are selected, -1 is returned.

- If the specified widget ID is a tree widget that is a node in a tree, this keyword returns 1 (one) if the node is selected or 0 (zero) if it is not selected.

This keyword returns the exact list of selected nodes. If you are passing the list of nodes to a routine that moves or copies selected nodes, consider using the TREE_DRAG_SELECT keyword instead.

TYPE

This keyword applies to all widgets.

Set this keyword to return the type code of the specified *Widget_ID*. Possible values are given the following table. Note that you can set the NAME keyword to return string names instead.

Value	Type
0	Base
1	Button
2	Slider
3	Text
4	Draw

Table 25-12: Widget Type Codes

Value	Type
5	Label
6	List
8	Droplist
9	Table
10	Tab
11	Tree
12	Combobox
13	Property sheet

Table 25-12: Widget Type Codes (Continued)

UNAME

This keyword applies to all widgets.

Set this keyword to have the WIDGET_INFO function return the user name of the widget.

UNITS

This keyword applies to all widgets.

Set this keyword to specify the units used when *returning* measurements or position values for most widget types. Set UNITS equal to 0 (zero) to specify that all measurements are in pixels (this is the default), to 1 (one) to specify that all measurements are in inches, or to 2 (two) to specify that all measurements are in centimeters. This keyword does not change the units used in a widget event structure or in most of the fields of the geometry structure returned by WIDGET_INFO.

Note ───

This keyword does not affect all sizing operations. Specifically, the value of UNITS is ignored when retrieving the XSIZE or YSIZE of a WIDGET_LIST, WIDGET_TABLE, or WIDGET_TEXT functions.

───

UPDATE

This keyword applies to all widgets.

Set this keyword to return 1 if the widget hierarchy that contains *Widget_ID* is set to display updates. Otherwise, 0 is returned. See "UPDATE" on page 2752.

USE_TABLE_SELECT

This keyword applies to widgets created with the WIDGET_TABLE function.

Set this keyword to modify the behavior of the COLUMN_WIDTHS, ROW_HEIGHTS, TABLE_BACKGROUND_COLOR, TABLE_EDITABLE, TABLE_FONT, and TABLE_FOREGROUND_COLOR keywords. If USE_TABLE_SELECT is set, these keywords apply only to the currently selected cells. If USE_TABLE_SELECT is not set, these keywords apply to the entire contents of a table widget.

The USE_TABLE_SELECT keyword can be specified as an array of coordinates (disjoint selection mode) or as a four-element array of the form [*left*, *top*, *right*, *bottom*] (standard selection mode), giving the group of cells to act on. You can specify header cells by using -1 in the appropriate index: row header cells use -1 for the column, and column header cells use -1 for the row. Ranges can span header and value cells.

VALID_ID

This keyword applies to all widgets.

Set this keyword to return 1 if *Widget_ID* represents a currently valid widget. Otherwise, 0 is returned.

VERSION

This keyword applies to all widgets.

Set this keyword to return a structure that gives information about the widget implementation. This structure has the following definition:

```
{ WIDGET_VERSION, STYLE:'', TOOLKIT:'', RELEASE:'' }
```

STYLE is the style of widget toolkit used. TOOLKIT is the implementation of the toolkit. RELEASE is the version level of the toolkit. This field can be used to distinguish between different releases of a given toolkit, such as Motif 1.0 and Motif 1.1.

VISIBLE

This keyword applies to all widgets.

Set this keyword to return True (1) if the widget specified by *Widget_ID* is visible, or False (0) otherwise. A widget is visible if:

- it has been realized,
- it and all of its ancestors are mapped.

Note

The value returned by WIDGET_INFO when this keyword is set is not affected if the widget is minimized or obscured by another window. Widgets that are visible in the sense of this keyword may not be immediately apparent to a person viewing a particular display device.

The WIDGET_SYSTEM_COLORS Structure

When the SYSTEM_COLORS keyword is specified in a call to WIDGET_INFO, IDL returns a WIDGET_SYSTEM_COLORS structure. This allows application developers to determine what colors are used in IDL application widgets, so they can design widgets for their application with the same look and feel as the supplied IDL widgets.

The WIDGET_SYSTEM_COLORS structure consists of 25 fields, each containing a three-element vector corresponding to the Red, Green, and Blue color values used for various widget elements. The vector elements are integers ranging between 0 and 255 if a color value is available (vector elements contain –1 if the color value is unavailable). The field names and meaning on the Windows and UNIX operating systems are shown in the following table.

Field Names	Windows Platform	UNIX Platform
DARK_SHADOW_3D	Dark shadow color for 3D display elements.	N/A
FACE_3D	Face color for 3D display elements and dialog boxes.	Base background color for all widgets.

Table 25-13: WIDGET_SYSTEM_COLORS Structure Fields

Field Names	Windows Platform	UNIX Platform
LIGHT_EDGE_3D	Highlight color for 3D edges that face the light source.	Color of top and left edges of 3D widgets.
LIGHT_3D	Light color for 3D display elements.	Color of highlight rectangle around widgets with the keyboard focus.
SHADOW_3D	Color for 3D edges that face away from the light source.	Color of bottom and right edges of 3D widgets.
ACTIVE_BORDER	Active window's border color.	Push button background color when button is armed.
ACTIVE_CAPTION	Active window's caption color.	N/A
APP_WORKSPACE	Background color of MDI applications.	N/A
DESKTOP	Desktop color.	N/A
BUTTON_TEXT	Text color on push buttons.	Widget text color.
CAPTION_TEXT	Color of text in caption, size box, and scroll bar arrow box.	Widget text color.
GRAY_TEXT	Color of disabled text.	N/A
HIGHLIGHT	Color of item(s) selected in a widget.	Toggle button fill color.
HIGHLIGHT_TEXT	Color of text of item(s) selected in a widget.	N/A
INACTIVE_BORDER	Inactive window's border color.	N/A

Table 25-13: WIDGET_SYSTEM_COLORS Structure Fields (Continued)

Field Names	Windows Platform	UNIX Platform
INACTIVE_CAPTION	Inactive window's caption color.	N/A
INACTIVE_CAPTION_TEXT	Inactive window's caption text color.	N/A
TOOLTIP_BK	Background color for tooltip controls.	N/A
TOOLTIP_TEXT	Text color for tooltip controls.	N/A
MENU	Menu background color.	N/A
MENU_TEXT	Menu text color.	N/A
SCROLLBAR	Color of scroll bar "gray" area.	Color of scroll bar "gray" area.
WINDOW_BK	Window background color.	Base background color for all widgets.
WINDOW_FRAME	Window frame color.	Widget border color.
WINDOW_TEXT	Text color in windows.	Widget text color.

Table 25-13: WIDGET_SYSTEM_COLORS Structure Fields (Continued)

Version History

Pre-4.0	Introduced
5.6	Added BUTTON_SET, COMBOBOX_GETTEXT, COMBOBOX_NUMBER, FONTNAME, MAP, SENSITIVE, TAB_CURRENT, TAB_MULTILINE, TAB_NUMBER, TABLE_DISJOINT_SELECTION, TLB_ICONIFY_EVENTS, TLB_MOVE_EVENTS, TLB_SIZE_EVENTS, TOOLTIP, TREE_EXPANDED, TREE_ROOT, TREE_SELECT, and VISIBLE keywords
6.0	Added COMPONENT, PROPERTY_VALID, PROPERTY_VALUE, and PUSHBUTTON_EVENTS keywords

6.1	Added MULTIPLE_PROPERTIES, PROPERTYSHEET_NSELECTED, PROPERTYSHEET_SELECTED, TAB_MODE keywords
6.2	Added DRAW_WHEEL_EVENTS, STRING_SIZE, TABLE_BACKGROUND_COLOR, TABLE_FONT, and TABLE_FOREGROUND_COLOR keywords
6.3	Added DRAG_NOTIFY, DRAGGABLE, DROP_EVENTS, TREE_BITMAP, TREE_FOLDER, TREE_INDEX, ALL_CHILDREN, N_CHILDREN, MASK, and TREE_DRAG_SELECT keywords

Chapter 2, "Creating Widget Applications" (*Widget Application Programming*).

WIDGET_LABEL

The WIDGET_LABEL function is used to create label widgets. Label widgets display static text. They are similar to single-line text widgets but are optimized for small labeling purposes. If you need to display more than a single line of text, or if the text must be editable by the user, use a text widget.

Figure 25-5: A Label Widget

Syntax

Result = WIDGET_LABEL(*Parent* [, /ALIGN_CENTER | , /ALIGN_LEFT | , /ALIGN_RIGHT] [, /DYNAMIC_RESIZE] [, FONT=*string*] [, FRAME=*width*] [, FUNC_GET_VALUE=*string*] [, GROUP_LEADER=*widget_id*] [, KILL_NOTIFY=*string*] [, /NO_COPY] [, NOTIFY_REALIZE=*string*] [, PRO_SET_VALUE=*string*] [, RESOURCE_NAME=*string*] [, SCR_XSIZE=*width*] [, SCR_YSIZE=*height*] [, /SENSITIVE] [, /SUNKEN_FRAME] [, /TRACKING_EVENTS] [, UNAME=*string*] [, UNITS={0 | 1 | 2}] [, UVALUE=*value*] [, VALUE=*value*] [, XOFFSET=*value*] [, XSIZE=*value*] [, YOFFSET=*value*] [, YSIZE=*value*])

Return Value

The returned value of this function is the widget ID of the newly-created label widget.

Arguments

Parent

The widget ID of the parent widget for the new label widget.

Keywords

ALIGN_CENTER

Set this keyword to center justify the label text.

ALIGN_LEFT

Set this keyword to left justify the label text.

ALIGN_RIGHT

Set this keyword to right justify the label text.

DYNAMIC_RESIZE

Set this keyword to create a widget that resizes itself to fit its new value whenever its value is changed. Note that this keyword cannot be used with the SCR_XSIZE, SCR_YSIZE, XSIZE, or YSIZE keywords. If one of these keywords is also set, the widget will be sized as specified by the sizing keyword and will never resize itself dynamically.

FONT

The name of the font to be used by the widget. The font specified is a "device font" (an X Windows font on Motif systems; a TrueType or PostScript font on Windows systems). See "About Device Fonts" on page 5580 for details on specifying names for device fonts. If this keyword is omitted, the default font is used.

Note

On Microsoft Windows platforms, if FONT is not specified, IDL uses the system default font. Different versions of Windows use different system default fonts; in general, the system default font is the font appropriate for the version of Windows in question.

FRAME

The value of this keyword specifies the width of a frame in units specified by the UNITS keyword (pixels are the default) to be drawn around the borders of the widget. Note that this keyword is only a "hint" to the toolkit, and may be ignored in some instances.

FUNC_GET_VALUE

A string containing the name of a function to be called when the GET_VALUE keyword to the WIDGET_CONTROL procedure is called for this widget. Using this technique allows you to change the value that should be returned for a widget. Compound widgets use this ability to define their values transparently to the user.

GROUP_LEADER

The widget ID of an existing widget that serves as "group leader" for the newly-created widget. When a group leader is killed, for any reason, all widgets in the group are also destroyed.

A given widget can be in more than one group. The WIDGET_CONTROL procedure can be used to add additional group associations to a widget. It is not possible to remove a widget from an existing group.

KILL_NOTIFY

Set this keyword to a string that contains the name of a procedure to be called automatically when the specified widget dies. Each widget is allowed a single such "callback" procedure. It can be removed by setting the routine to the null string (' ').

The callback routine is called with the widget identifier as its only argument. At that point, the widget identifier can only be used with the WIDGET_CONTROL procedure to get or set the user value. All other requests that require a widget ID are disallowed for the target widget. The callback is not issued until the WIDGET_EVENT function is called.

NO_COPY

Usually, when setting or getting widget user values, either at widget creation or using the SET_UVALUE and GET_UVALUE keywords to WIDGET_CONTROL, IDL makes a second copy of the data being transferred. Although this technique is fine for small data, it can have a significant memory cost when the data being copied is large.

If the NO_COPY keyword is set, IDL handles these operations differently. Rather than copy the source data, it takes the data away from the source and attaches it directly to the destination. This feature can be used by compound widgets to obtain state information from a UVALUE without all the memory copying that would otherwise occur. However, it has the side effect of causing the source variable to become undefined. On a "set" operation (using the UVALUE keyword to WIDGET_LABEL or the SET_UVALUE keyword to WIDGET_CONTROL), the variable passed as value becomes undefined. On a "get" operation (GET_UVALUE

keyword to WIDGET_CONTROL), the user value of the widget in question becomes undefined.

NOTIFY_REALIZE

Set this keyword to a string that contains the name of a procedure to be called automatically when the specified widget is realized. This callback occurs just once (because widgets are realized only once). Each widget is allowed a single such "callback" procedure. It can be removed by setting the routine to the null string (`' '`). The callback routine is called with the widget ID as its only argument.

PRO_SET_VALUE

A string containing the name of a procedure to be called when the SET_VALUE keyword to the WIDGET_CONTROL procedure is called for this widget. See the description of the PRO_SET_VALUE keyword to WIDGET_CONTROL for information on using this keyword.

RESOURCE_NAME

A string containing an X Window System resource name to be applied to the widget. See "RESOURCE_NAME" on page 2665 for a complete discussion of this keyword.

SCR_XSIZE

Set this keyword to the desired "screen" width of the widget, in units specified by the UNITS keyword (pixels are the default). In many cases, setting this keyword is the same as setting the XSIZE keyword.

SCR_YSIZE

Set this keyword to the desired "screen" height of the widget, in units specified by the UNITS keyword (pixels are the default). In many cases, setting this keyword is the same as setting the YSIZE keyword.

SENSITIVE

Set this keyword to control the initial sensitivity state of the widget.

If SENSITIVE is zero, the widget becomes insensitive. If nonzero, it becomes sensitive. When a widget is sensitive, it has normal appearance and can receive user input. For example, a sensitive button widget can be activated by moving the mouse cursor over it and pressing a mouse button. When a widget is insensitive, it indicates the fact by changing its appearance, looking disabled, and it ignores any input.

Sensitivity can be used to control when a user is allowed to manipulate the widget. Note that some widgets do not change their appearance when they are made insensitive, but they cease generating events.

After creating the widget hierarchy, you can change the sensitivity state using the SENSITIVE keyword with the WIDGET_CONTROL procedure.

SUNKEN_FRAME

Set this keyword to create a three dimensional, bevelled border around the label widget. The resulting frame gives the label a "sunken" appearance, similar to what is often seen in application status bars.

TRACKING_EVENTS

Set this keyword to cause widget tracking events to be issued for the widget whenever the mouse pointer enters or leaves the region covered by that widget. For the structure of tracking events, see "TRACKING_EVENTS" on page 2672 in the documentation for WIDGET_BASE.

UNAME

Set this keyword to a string that can be used to identify the widget in your code. You can associate a name with each widget in a specific hierarchy, and then use that name to query the widget hierarchy and get the correct widget ID.

To query the widget hierarchy, use the WIDGET_INFO function with the FIND_BY_UNAME keyword. The UNAME should be unique to the widget hierarchy because the FIND_BY_UNAME keyword returns the ID of the first widget with the specified name.

UNITS

Set this keyword to specify the units used when *supplying* measurements or position values. Set UNITS equal to 0 (zero) to specify that all measurements are in pixels (this is the default), to 1 (one) to specify that all measurements are in inches, or to 2 (two) to specify that all measurements are in centimeters. This keyword does not change the units used in a widget event structure or in most of the fields of the geometry structure returned by WIDGET_INFO.

UVALUE

The "user value" to be assigned to the widget.

Each widget can contain a user-specified value of any data type and organization. This value is not used by the widget in any way, but exists entirely for the

convenience of the IDL programmer. This keyword allows you to set this value when the widget is first created.

If UVALUE is not present, the widget's initial user value is undefined.

VALUE

The initial value setting of the widget. The value of a widget label is a string containing the text for the label.

Note —————————————————————————————

You can use language catalogs to internationalize this value with strings in particular languages. For more information, see Chapter 19, "Using Language Catalogs" (*Application Programming*).

XOFFSET

The horizontal offset of the widget in units specified by the UNITS keyword (pixels are the default) relative to its parent.

Specifying an offset relative to a row or column major base widget does not work because those widgets enforce their own layout policies. This keyword is primarily of use relative to a plain base widget. Note that it is best to avoid using this style of widget programming.

XSIZE

The width of the widget in units specified by the UNITS keyword (pixels are the default). Most widgets attempt to size themselves to fit the situation. However, if the desired effect is not produced, use this keyword to override it. This keyword is only a "hint" to the toolkit and may be ignored in some situations.

YOFFSET

The vertical offset of the widget in units specified by the UNITS keyword (pixels are the default) relative to its parent. This offset is specified relative to the *upper left* corner of the parent widget.

Specifying an offset relative to a row or column major base widget does not work because those widgets enforce their own layout policies. This keyword is primarily of use relative to a plain base widget. Note that it is best to avoid using this style of widget programming.

YSIZE

The height of the widget in units specified by the UNITS keyword (pixels are the default). Most widgets attempt to size themselves to fit the situation. However, if the desired effect is not produced, use this keyword to override it. This keyword is only a "hint" to the toolkit and may be ignored in some situations.

Keywords to WIDGET_CONTROL

A number of keywords to the WIDGET_CONTROL procedure affect the behavior of label widgets. In addition to those keywords that affect all widgets, the following are particularly useful: DYNAMIC_RESIZE, GET_VALUE, SET_VALUE.

Keywords to WIDGET_INFO

Some keywords to the WIDGET_INFO function return information that applies specifically to label widgets. In addition to those keywords that apply to all widgets, the following are particularly useful: DYNAMIC_RESIZE, STRING_SIZE.

Widget Events Returned by Label Widgets

Label widgets do not return an event structure.

Version History

Pre-4.0	Introduced
5.6	Added SUNKEN_FRAME keyword

See Also

CW_FIELD, WIDGET_TEXT

WIDGET_LIST

The WIDGET_LIST function is used to create list widgets. A list widget offers the user a list of text elements from which to choose. List widgets have a vertical scrollbar when there are more list items than are specified by the HEIGHT keyword. The user can select an item by pointing at it with the mouse cursor and pressing a button. This action generates an event containing the index of the selected item, which ranges from 0 to the number of elements in the list minus one.

Figure 25-6: A List Widget

Syntax

Result = WIDGET_LIST(*Parent* [, /CONTEXT_EVENTS]
   [, EVENT_FUNC=*string*] [, EVENT_PRO=*string*] [, FONT=*string*]
   [, FRAME=*width*] [, FUNC_GET_VALUE=*string*]
   [, GROUP_LEADER=*widget_id*] [, KILL_NOTIFY=*string*] [, /MULTIPLE]
   [, /NO_COPY] [, NOTIFY_REALIZE=*string*] [, PRO_SET_VALUE=*string*]
   [, RESOURCE_NAME=*string*] [, SCR_XSIZE=*width*] [, SCR_YSIZE=*height*]
   [, /SENSITIVE] [, TAB_MODE=*value*] [, /TRACKING_EVENTS]
   [, UNAME=*string*] [, UNITS={0 | 1 | 2}] [, UVALUE=*value*] [, VALUE=*value*]
   [, XOFFSET=*value*] [, XSIZE=*value*] [, YOFFSET=*value*] [, YSIZE=*value*])

Return Value

The returned value of this function is the widget ID of the newly-created list widget.

Arguments

Parent

The widget ID of the parent widget for the new list widget.

Keywords

CONTEXT_EVENTS

Set this keyword to cause context menu events (or simply context events) to be issued when the user clicks the right mouse button over the widget. Set the keyword to 0 (zero) to disable such events. Context events are intended for use with context-sensitive menus (also known as pop-up or shortcut menus); pass the context event ID to the WIDGET_DISPLAYCONTEXTMENU procedure within your widget program's event handler to display the context menu.

For more on detecting and handling context menu events, see "Context-Sensitive Menus" (Chapter 3, *Widget Application Programming*).

EVENT_FUNC

A string containing the name of a function to be called by the WIDGET_EVENT function when an event arrives from a widget in the widget hierarchy rooted at the newly-created widget.

EVENT_PRO

A string containing the name of a procedure to be called by the WIDGET_EVENT function when an event arrives from a widget in the widget hierarchy rooted at the newly-created widget.

FONT

The name of the font to be used by the widget. The font specified is a "device font" (an X Windows font on Motif systems; a TrueType or PostScript font on Windows systems). See "About Device Fonts" on page 5580 for details on specifying names for device fonts. If this keyword is omitted, the default font is used.

Note

On Microsoft Windows platforms, if FONT is not specified, IDL uses the system default font. Different versions of Windows use different system default fonts; in general, the system default font is the font appropriate for the version of Windows in question.

FRAME

The value of this keyword specifies the width of a frame in units specified by the UNITS keyword (pixels are the default) to be drawn around the borders of the widget. Note that this keyword is only a "hint" to the toolkit, and may be ignored in some instances.

FUNC_GET_VALUE

A string containing the name of a function to be called when the GET_VALUE keyword to the WIDGET_CONTROL procedure is called for this widget. Using this technique allows you to change the value that should be returned for a widget. Compound widgets use this ability to define their values transparently to the user.

GROUP_LEADER

The widget ID of an existing widget that serves as "group leader" for the newly-created widget. When a group leader is killed, for any reason, all widgets in the group are also destroyed.

A given widget can be in more than one group. The WIDGET_CONTROL procedure can be used to add additional group associations to a widget. It is not possible to remove a widget from an existing group.

KILL_NOTIFY

Set this keyword to a string that contains the name of a procedure to be called automatically when the specified widget dies. Each widget is allowed a single such "callback" procedure. It can be removed by setting the routine to the null string (' ').

The callback routine is called with the widget identifier as its only argument. At that point, the widget identifier can only be used with the WIDGET_CONTROL procedure to get or set the user value. All other requests that require a widget ID are disallowed for the target widget. The callback is not issued until the WIDGET_EVENT function is called.

MULTIPLE

Set this keyword to allow the user to select more than one item from the list in a single operation. Multiple selections are handled using the platform's native mechanism:

Motif

Holding down the Shift key and clicking an item selects the range from the previously selected item to the new item. Holding down the mouse button when selecting items

also selects a range. Holding down the Control key and clicking an item toggles that item between the selected and unselected state.

Windows

Holding down the Shift key and clicking an item selects the range from the previously selected item to the new item. Holding down the Control key and clicking an item toggles that item between the selected and unselected state.

NO_COPY

Usually, when setting or getting widget user values, either at widget creation or using the SET_UVALUE and GET_UVALUE keywords to WIDGET_CONTROL, IDL makes a second copy of the data being transferred. Although this technique is fine for small data, it can have a significant memory cost when the data being copied is large.

If the NO_COPY keyword is set, IDL handles these operations differently. Rather than copy the source data, it takes the data away from the source and attaches it directly to the destination. This feature can be used by compound widgets to obtain state information from a UVALUE without all the memory copying that would otherwise occur. However, it has the side effect of causing the source variable to become undefined. On a "set" operation (using the UVALUE keyword to WIDGET_LIST or the SET_UVALUE keyword to WIDGET_CONTROL), the variable passed as value becomes undefined. On a "get" operation (GET_UVALUE keyword to WIDGET_CONTROL), the user value of the widget in question becomes undefined.

NOTIFY_REALIZE

Set this keyword to a string that contains the name of a procedure to be called automatically when the specified widget is realized. This callback occurs just once (because widgets are realized only once). Each widget is allowed a single such "callback" procedure. It can be removed by setting the routine to the null string (` `). The callback routine is called with the widget ID as its only argument.

PRO_SET_VALUE

A string containing the name of a procedure to be called when the SET_VALUE keyword to the WIDGET_CONTROL procedure is called for this widget. See the description of the PRO_SET_VALUE keyword to WIDGET_CONTROL for information on using this keyword.

RESOURCE_NAME

A string containing an X Window System resource name to be applied to the widget. See "RESOURCE_NAME" on page 2665 for a complete discussion of this keyword.

SCR_XSIZE

Set this keyword to the desired "screen" width of the widget, in units specified by the UNITS keyword (pixels are the default). In many cases, setting this keyword is the same as setting the XSIZE keyword.

SCR_YSIZE

Set this keyword to the desired "screen" height of the widget, in units specified by the UNITS keyword (pixels are the default). In many cases, setting this keyword is the same as setting the YSIZE keyword.

SENSITIVE

Set this keyword to control the initial sensitivity state of the widget.

If SENSITIVE is zero, the widget becomes insensitive. If nonzero, it becomes sensitive. When a widget is sensitive, it has normal appearance and can receive user input. For example, a sensitive button widget can be activated by moving the mouse cursor over it and pressing a mouse button. When a widget is insensitive, it indicates the fact by changing its appearance, looking disabled, and it ignores any input.

Sensitivity can be used to control when a user is allowed to manipulate the widget. Note that some widgets do not change their appearance when they are made insensitive, but they cease generating events.

After creating the widget hierarchy, you can change the sensitivity state using the SENSITIVE keyword with the WIDGET_CONTROL procedure.

TAB_MODE

Set this keyword to one of the values shown in the table below to determine how the widget hierarchy can be navigated using the **Tab** key. The TAB_MODE setting is inherited by lower-level bases and child widgets from the parent WIDGET_BASE unless it is explicitly set on an individual widget. If the TAB_MODE value of the widget differs from that of the base, the setting on the widget will be respected when the widget has focus. For example, if a base does not support tabbing, but an individual child widget does support tabbing, this functionality will be enabled when the child widget has focus.

Note ———

It is not possible to tab to disabled (SENSITIVE=0) or hidden (MAP=0) widgets.

_____

Valid settings are:

0	Disable navigation onto or off of the widget. This is the default unless the TAB_MODE has been set on a parent base. Child widgets automatically inherit the tab mode of the parent base as described in "Inheriting the TAB_MODE Value" (Chapter 3, *Widget Application Programming*).
1	Enable navigation onto and off of the widget.
2	Navigate only onto the widget.
3	Navigate only off of the widget.

Note ———

In widget applications on the UNIX platform, the Motif library controls what widgets are brought into and released from focus using tabbing. The TAB_MODE keyword value is always zero, and any attempt to change it is ignored when running a widget application on the UNIX platform. Tabbing behavior may vary significantly between UNIX platforms; do not rely on a particular behavior being duplicated on all UNIX systems.

_____

Once the WIDGET_LIST has focus, use the up and down arrow keys to navigate among the individual items.

After creating the widget hierarchy, you can change tabbing support using the WIDGET_CONTROL procedure's TAB_MODE keyword, or query a widget's support for tabbing using the WIDGET_INFO procedure's TAB_MODE keyword.

See "Tabbing in Widget Applications" (Chapter 3, *Widget Application Programming*) for usage details and examples.

TRACKING_EVENTS

Set this keyword to cause widget tracking events to be issued for the widget whenever the mouse pointer enters or leaves the region covered by that widget. For the structure of tracking events, see "TRACKING_EVENTS" on page 2672 in the documentation for WIDGET_BASE.

UNAME

Set this keyword to a string that can be used to identify the widget in your code. You can associate a name with each widget in a specific hierarchy, and then use that name to query the widget hierarchy and get the correct widget ID.

To query the widget hierarchy, use the WIDGET_INFO function with the FIND_BY_UNAME keyword. The UNAME should be unique to the widget hierarchy because the FIND_BY_UNAME keyword returns the ID of the first widget with the specified name.

UNITS

Set this keyword to specify the units used when *supplying* measurements or position values. Set UNITS equal to 0 (zero) to specify that all measurements are in pixels (this is the default), to 1 (one) to specify that all measurements are in inches, or to 2 (two) to specify that all measurements are in centimeters. This keyword does not change the units used in a widget event structure or in most of the fields of the geometry structure returned by WIDGET_INFO.

Note

This keyword does not affect all sizing operations. Specifically, the value of UNITS is ignored when setting the XSIZE or YSIZE keywords to WIDGET_LIST.

UVALUE

The "user value" to be assigned to the widget.

Each widget can contain a user-specified value of any data type and organization. This value is not used by the widget in any way, but exists entirely for the convenience of the IDL programmer. This keyword allows you to set this value when the widget is first created.

If UVALUE is not present, the widget's initial user value is undefined.

VALUE

The initial value setting of the widget. The value of a list widget is a scalar string or array of strings that contains the text of the list items—one list item per array element. List widgets are sized based on the length (in characters) of the longest item specified in the array of values for the VALUE keyword.

Note
> You can use language catalogs to internationalize this value with strings in particular languages. For more information, see Chapter 19, "Using Language Catalogs" (*Application Programming*).

Note that the value of a list widget can only be set. It cannot be retrieved using WIDGET_CONTROL.

XOFFSET

The horizontal offset of the widget in units specified by the UNITS keyword (pixels are the default) relative to its parent.

Specifying an offset relative to a row or column major base widget does not work because those widgets enforce their own layout policies. This keyword is primarily of use relative to a plain base widget. Note that it is best to avoid using this style of widget programming.

XSIZE

The desired width of the widget, in characters. Most widgets attempt to size themselves to fit the situation. However, if the desired effect is not produced, use this keyword to override it. Note that the final size of the widget may be adjusted to include space for scrollbars (which are not always visible), so your widget may be slightly larger than specified.

YOFFSET

The vertical offset of the widget in units specified by the UNITS keyword (pixels are the default) relative to its parent. This offset is specified relative to the *upper left* corner of the parent widget.

Specifying an offset relative to a row or column major base widget does not work because those widgets enforce their own layout policies. This keyword is primarily of use relative to a plain base widget. Note that it is best to avoid using this style of widget programming.

YSIZE

The desired height of the widget, in number of list items visible. Most widgets attempt to size themselves to fit the situation. However, if the desired effect is not produced, use this keyword to override it. Note that the final size of the widget may be adjusted to include space for scrollbars (which are not always visible), so your widget may be slightly larger than specified.

Keywords to WIDGET_CONTROL

A number of keywords to the WIDGET_CONTROL procedure affect the behavior of list widgets. In addition to those keywords that affect all widgets, the following are particularly useful: CONTEXT_EVENTS, SET_LIST_SELECT, SET_LIST_TOP, SET_VALUE.

Keywords to WIDGET_INFO

A number of keywords to the WIDGET_INFO function return information that applies specifically to list widgets. In addition to those keywords that apply to all widgets, the following are particularly useful: CONTEXT_EVENTS, LIST_MULTIPLE, LIST_NUMBER, LIST_NUM_VISIBLE, LIST_SELECT, LIST_TOP, STRING_SIZE.

Widget Events Returned by List Widgets

List widgets generate an event when the user selects a value or values from the list. They can also be configured to generate events when the user clicks the right-hand mouse button over the widget.

Pressing the mouse button while the mouse cursor is over an element of a list widget causes the widget to highlight the appearance of that element and to generate an event. The appearance of any previously selected element is restored to normal at the same time. The event structure returned by the WIDGET_EVENT function is defined by the following statement:

```
{WIDGET_LIST, ID:0L, TOP:0L, HANDLER:0L, INDEX:0L, CLICKS:0L}
```

The first three fields are the standard fields found in every widget event. INDEX returns the index of the selected item. This index can be used to subscript the array of names originally used to set the widget's value. The CLICKS field returns either 1 or 2, depending upon how the list item was selected. If the list item is double-clicked, CLICKS is set to 2.

Note

If you are writing a widget application that requires the user to double-click on a list widget, you will need to handle two events. The CLICKS field will return a 1 on the first click and a 2 on the second click.

Context Menu Events

A list widget created with the CONTEXT_EVENTS keyword set returns the
following event structure in response to a right mouse button click:

```
{WIDGET_CONTEXT, ID:0L, TOP:0L, HANDLER:0L, X:0L, Y:0L,
    ROW:0L, COL:0L}
```

The first three fields are the standard fields found in every widget event. The X and Y
fields give the device coordinates at which the event occurred, measured from the
upper left corner of the list widget. The ROW and COL fields return meaningful
information for table widgets and values of zero (0) for other widgets.

Version History

Pre-4.0	Introduced
6.1	Added TAB_MODE keyword
6.1	Added ROW and COL fields to WIDGET_CONTEXT event structure

WIDGET_PROPERTYSHEET

The WIDGET_PROPERTYSHEET function creates a property sheet widget, which exposes the *properties* of an IDL object subclassed from the IDLitComponent class in a graphical interface. The property sheet widget must be a child of a base or tab widget, and it cannot be the parent of any other widget.

The IDLitComponent class was designed for use by the IDL iTools system. As a result, all IDLit* objects subclass from IDLitComponent, so properties of object classes written for the IDL iTools system can be displayed in a property sheet. In addition, most IDLgr* objects (some do not such as IDLgrFont, IDLgrPrinter, IDLgrPattern, and so on) subclass from IDLitComponent, which means that properties of standard IDL graphics objects can be displayed in a property sheet even if the rest of the iTools framework is not in use.

In order to be shown in a property sheet, object properties must be *registered* and *visible*. In addition, in order for property values shown in a property sheet to be editable by the user, the property must be *sensitive*. For information on registering properties, see "Registering Properties" (Chapter 4, *iTool Developer's Guide*). For information on making properties visible and sensitive, see "Property Attributes" (Chapter 4, *iTool Developer's Guide*).

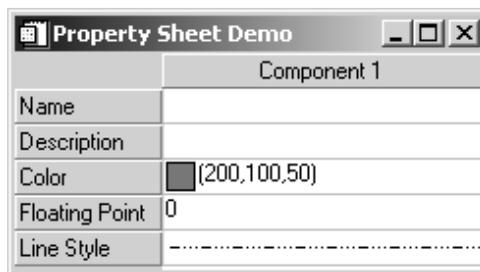
The name of the changed property is placed into an IDL event, and the object is updated when this event is processed. An existing property sheet can also be assigned a new component, causing it to reload with the new list of properties and their values.


Figure 25-7: A Property Sheet Widget

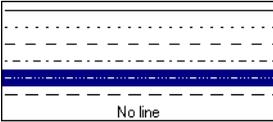
Property Sheet Widget Data Types and Controls

The following controls are available for the corresponding data types in property sheet widgets:

Data Type	Control
Boolean	Droplist with two choices: True or False
Number	One of the following: • Edit control that accepts +, -, 0123456789, plus decimal points, e, E, d and D for floating point numbers. • Slider • Spinner
String	Text box, expandable when string length exceeds visible area.
Color	Color picker.
Line Style	Droplist displaying seven line style choices:
Line Thickness	Droplist displaying ten line thickness choices:
Symbol	Droplist displaying eight symbol choices:


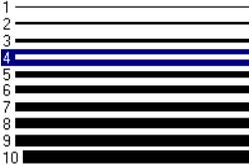


Table 25-14: WIDGET_PROPERTYSHEET Controls for Data Types

Data Type	Control
String list	Droplist displaying a list of strings.
User-Defined	**Edit** button linked to user-defined control (see "User-defined Properties" (Chapter 6, *Widget Application Programming*)).

Table 25-14: WIDGET_PROPERTYSHEET Controls for Data Types

Syntax

Result = WIDGET_PROPERTYSHEET(*Parent* [, /ALIGN_BOTTOM
|, /ALIGN_CENTER |, /ALIGN_LEFT |, /ALIGN_RIGHT |, /ALIGN_TOP]
[, /CONTEXT_EVENTS] [, /EDITABLE] [, EVENT_FUNC=*string*]
[, EVENT_PRO=*string*] [, FONT=*string*] [, FRAME=*width*]
[, FUNC_GET_VALUE=*string*] [, IGNORE_ACCELERATORS=*value*]
[, KILL_NOTIFY=*string*] [, /MULTIPLE_PROPERTIES] [, /NO_COPY]
[, NOTIFY_REALIZE=*string*] [, PRO_SET_VALUE=*string*]
[, SCR_XSIZE=*width*] [, SCR_YSIZE=*height*] [, /SENSITIVE]
[, /SUNKEN_FRAME] [, /TRACKING_EVENTS] [, UNAME=*string*]
[,UNITS={0 | 1 | 2}] [, UVALUE=*value*] [, VALUE=*value*] [, XOFFSET=*value*]
[, XSIZE=*value*] [, YOFFSET=*value*] [, YSIZE=*value*])

Return Value

The returned value of this function is the widget ID of the newly-created property sheet widget.

Arguments

Parent

The widget ID of the parent for the new property sheet widget. *Parent* must be a base or tab widget.

Keywords

ALIGN_BOTTOM

Set this keyword to align the new widget with the bottom of its parent base. To take effect, the parent must be a ROW base.

ALIGN_CENTER

Set this keyword to align the new widget with the center of its parent base. To take effect, the parent must be a ROW or COLUMN base. In ROW bases, the new widget will be vertically centered. In COLUMN bases, the new widget will be horizontally centered.

ALIGN_LEFT

Set this keyword to align the new widget with the left side of its parent base. To take effect, the parent must be a COLUMN base.

ALIGN_RIGHT

Set this keyword to align the new widget with the right side of its parent base. To take effect, the parent must be a COLUMN base.

ALIGN_TOP

Set this keyword to align the new widget with the top of its parent base. To take effect, the parent must be a ROW base.

CONTEXT_EVENTS

Set this keyword to cause *context menu events* (or simply *context events*) to be issued when the user clicks the right mouse button over the widget. Set the keyword to 0 (zero) to disable such events. Context events are intended for use with context-sensitive menus (also known as pop-up or shortcut menus); pass the context event ID to the WIDGET_DISPLAYCONTEXTMENU procedure within your widget program's event handler to display the context menu.

For more on detecting and handling context menu events, see "Context-Sensitive Menus" (Chapter 3, *Widget Application Programming*).

Note ───

With regard to /CONTEXT_EVENTS, the Motif and Windows version of the property sheet differ very slightly. In the Motif version, individually desensitized cells cannot generate context events, though their row label can.

───

EDITABLE

Set this keyword to 0 (zero) to mark a property sheet as read-only. Property sheet widgets are editable by default (EDITABLE=1). In this default mode, property values can be modified. When a property sheet is marked as read-only (EDITABLE=0), you

can select properties and use any scrollbars, but cannot change any values. Setting this keyword to 0 is roughly equivalent to desensitizing all properties by setting the SENSITIVE attribute of *every* property on the property sheet equal to 0.

Three things that determine the appearance of a property sheet data cells are, in order of greatest to least precedence:

1. Sensitivity of the entire widget — If SENSITIVE=0 for WIDGET_PROPERTYSHEET then no selection or scrolling is possible.

2. Editability of the entire widget — If EDITABLE=0 for the property sheet (meaning it is marked as read-only), cells can be selected but cannot be changed. If EDITABLE=1 (the default value meaning properties can be selected and modified), then the editability of individual properties is controlled by their individual sensitivity values.

3. Sensitivity of an individual property — If SENSITIVE=0 for an individual property (set using the RegisterProperty or SetPropertyAttribute methods of IDLitComponent), then the individual property cannot be selected or changed.

Note

To set the SENSITIVE attribute of individual properties within a property sheet, use IDLitComponent::RegisterProperty or IDLitComponent::SetPropertyAttribute.

EVENT_FUNC

A string containing the name of a function to be called by the WIDGET_EVENT function when an event arrives from a widget in the widget hierarchy rooted at the newly-created widget.

EVENT_PRO

A string containing the name of a procedure to be called by the WIDGET_EVENT function when an event arrives from a widget in the widget hierarchy rooted at the newly-created widget.

FONT

The name of the font to be used by the widget. The font specified is a device font (an X Windows font on Motif systems; a TrueType or PostScript font on Windows systems). See "About Device Fonts" in Appendix I of the *IDL Reference Guide* manual for details on specifying names for device fonts. If this keyword is omitted, the default font is used.

Note ──

On Microsoft Windows platforms, if FONT is not specified, IDL uses the system default font. Different versions of Windows use different system default fonts; in general, the system default font is the font appropriate for the version of Windows in question.

───

FRAME

The value of this keyword specifies the width of a frame in units specified by the UNITS keyword (pixels are the default) to be drawn around the borders of the widget. Note that this keyword is only a "hint" to the toolkit, and may be ignored in some instances. If SUNKEN_FRAME is also set, FRAME is ignored.

FUNC_GET_VALUE

A string containing the name of a function to be called when the GET_VALUE keyword to the WIDGET_CONTROL procedure is called for this widget. Using this technique allows you to change the value that should be returned for a widget. Compound widgets use this ability to define their values transparently to the user.

IGNORE_ACCELERATORS

Set this keyword to specify what WIDGET_BUTTON accelerators are to be ignored when this propertysheet widget has keyboard focus. Valid values are:

- A string or string array containing any value that is legal for WIDGET_BUTTON's ACCELERATOR keyword

- The number 1, indicating all accelerators should be ignored

Ordinarily, accelerators are processed before keyboard events reach the widget that has the keyboard focus. Consider a case where the accelerator "Ctrl+V" has been mapped to a button that allows the user to paste objects copied from one drawing area into another. In an application that also has a propertysheet, attempting to use **Ctrl**+**V** to paste text into the propertysheet would fail as this event would be stolen by the accelerator. Setting IGNORE_ACCELERATORS to "Ctrl+V" allows a propertysheet widget with an editable text area to receive keyboard events instead of the button with a conflicting accelerator. Once the propertysheet text field loses focus, all specified accelerators are automatically re-enabled.

See "Disabling Button Widget Accelerators" (Chapter 3, *Widget Application Programming*) for usage details and examples.

KILL_NOTIFY

Set this keyword to a string that contains the name of a procedure to be called automatically when the specified widget dies. Each widget is allowed a single such "callback" procedure. It can be removed by setting the routine to the null string (' ').

The callback routine is called with the widget identifier as its only argument. At that point, the widget identifier can only be used with the WIDGET_CONTROL procedure to get or set the user value. All other requests that require a widget ID are disallowed for the target widget. The callback is not issued until the WIDGET_EVENT function is called.

MULTIPLE_PROPERTIES

Set this property to 1 to allow multiple properties to be selected at the same time. When this keyword is set, you can hold down the **Ctrl** key while left-clicking with the mouse to make nonadjacent selections, or hold down the **Shift** key to select an adjacent range of properties in a property sheet. Set this property to 0 (zero) to disallow multiple property selection. This is the default. See "Selecting Properties" (Chapter 6, *Widget Application Programming*) for more information.

NO_COPY

Usually, when setting or getting widget user values, either at widget creation or using the SET_UVALUE and GET_UVALUE keywords to WIDGET_CONTROL, IDL makes a second copy of the data being transferred. Although this technique is fine for small data, it can have a significant memory cost when the data being copied is large.

If the NO_COPY keyword is set, IDL handles these operations differently. Rather than copy the source data, it takes the data away from the source and attaches it directly to the destination. This feature can be used by compound widgets to obtain state information from a UVALUE without all the memory copying that would otherwise occur. However, it has the side effect of causing the source variable to become undefined. During a set operation (using the UVALUE keyword to WIDGET_BASE or the SET_UVALUE keyword to WIDGET_CONTROL), the variable passed as value becomes undefined. During a get operation (GET_UVALUE keyword to WIDGET_CONTROL), the user value of the widget in question becomes undefined.

NOTIFY_REALIZE

Set this keyword to a string that contains the name of a procedure to be called automatically when the specified widget is realized. This callback occurs just once (because widgets are realized only once). Each widget is allowed a single such

callback procedure. It can be removed by setting the routine to the null string (' ').
The callback routine is called with the widget ID as its only argument.

PRO_SET_VALUE

A string containing the name of a procedure to be called when the SET_VALUE
keyword to the WIDGET_CONTROL procedure is called for this widget. See the
description of the PRO_SET_VALUE keyword to WIDGET_CONTROL for
information on using this keyword.

SCR_XSIZE

Set this keyword to the desired screen width of the widget, in units specified by the
UNITS keyword (pixels are the default). If neither XSIZE nor SCR_XSIZE is
specified, then the property sheet widget will be naturally sized based on the width of
cell contents. See "Property Sheet Sizing" (Chapter 6, *Widget Application
Programming*) for details.

SCR_YSIZE

Set this keyword to the desired screen height of the widget, in units specified by the
UNITS keyword (pixels are the default). If neither YSIZE nor SCR_YSIZE is
specified, the property sheet will use a default height. This default is based on the
number of rows: 10, or the number of visible properties, whichever is less.

SENSITIVE

Set this keyword to control the initial sensitivity state of the widget.

If SENSITIVE is zero, the widget becomes insensitive. If nonzero, it becomes
sensitive. When a widget is sensitive, it has normal appearance and can receive user
input. For example, a sensitive button widget can be activated by moving the mouse
cursor over it and pressing a mouse button. When a widget is insensitive, it indicates
the fact by changing its appearance, looking disabled, and it ignores any input.

Sensitivity can be used to control when a user is allowed to manipulate the widget.

Note ───────────────────────────────────────

Some widgets do not change their appearance when they are made insensitive, but
they cease generating events.

───

After creating the widget hierarchy, you can change the sensitivity state using the
SENSITIVE keyword with the WIDGET_CONTROL procedure.

SUNKEN_FRAME

Set this keyword to create the appearance of a three-dimensional, beveled border around the property sheet widget. This makes the widget appear slightly inset. If the FRAME keyword is also set, SUNKEN_FRAME overrides the setting, and the frame's width will be the minimum necessary to give the appearance of indentation.

TRACKING_EVENTS

Set this keyword to cause widget tracking events to be issued for the widget whenever the mouse pointer enters or leaves the region covered by that widget. For the structure of tracking events, see "TRACKING_EVENTS" in the *IDL Reference Guide* manual in the documentation for WIDGET_BASE.

UNAME

Set this keyword to a string that can be used to identify the widget in your code. You can associate a name with each widget in a specific hierarchy, and then use that name to query the widget hierarchy and get the correct widget ID.

To query the widget hierarchy, use the WIDGET_INFO function with the FIND_BY_UNAME keyword. The UNAME should be unique to the widget hierarchy because the FIND_BY_UNAME keyword returns the ID of the first widget with the specified name.

UNITS

Set this keyword to specify the units used when *supplying* measurements or position values. Set UNITS equal to 0 (zero) to specify that all measurements are in pixels (this is the default), to 1 (one) to specify that all measurements are in inches, or to 2 (two) to specify that all measurements are in centimeters. This keyword does not change the units used in a widget event structure or in most of the fields of the geometry structure returned by WIDGET_INFO.

UVALUE

The user value to be assigned to the widget. Each widget can contain a user-specified value of any data type and organization. This value is not used by the widget in any way, but exists entirely for the convenience of the IDL programmer. This keyword allows you to set this value when the widget is first created.

If UVALUE is not present, the widget's initial user value is undefined.

The user value for a widget can be accessed and modified at any time by using the GET_UVALUE and SET_UVALUE keywords to the WIDGET_CONTROL procedure.

VALUE

Set this keyword to the object reference or array of object references to objects that subclass from the IDLitComponent class. Registered properties of the specified objects will be displayed in the property sheet.

If a single object reference is supplied, the property sheet will have a single column containing the object's properties. If an array of object references is supplied, the property sheet will have multiple columns.

Note
Due to limitations of the user interface controls that underlie the property sheet widget, a property sheet can display properties for at most 100 component objects.

Note
All object references must be to objects of the same type.

If no object references are supplied, the property sheet will initially be empty. Object references can be loaded into an existing property sheet using the SET_VALUE keyword to WIDGET_CONTROL. Whenever the value is set, via SET_VALUE, the property sheet widget is loaded with the registered, visible properties of the new component. Setting the value to a null object will clear the property sheet widget. A null object can be created by calling the OBJ_NEW function without any arguments:

```
nullObject = OBJ_NEW()
```

XOFFSET

The horizontal offset of the widget in units specified by the UNITS keyword (pixels are the default) relative to its parent.

Specifying an offset relative to a row or column major base widget does not work because those widgets enforce their own layout policies. This keyword is primarily of use relative to a bulletin board base widget. Note that it is best to avoid using this style of widget layout.

XSIZE

The widget width, measured in average character widths of the widget's font. This value includes the row label, but does not include any vertical scrollbar or frame thickness. If neither XSIZE nor SCR_XSIZE is specified, then the property sheet

widget will be naturally sized based on the width of cell contents. See "Property Sheet Sizing" (Chapter 6, *Widget Application Programming*) for details.

YOFFSET

The vertical offset of the widget in units specified by the UNITS keyword (pixels are the default) relative to its parent. This offset is specified relative to the *upper left* corner of the parent widget.

Specifying an offset relative to a row or column major base widget does not work because those widgets enforce their own layout policies. This keyword is primarily of use relative to a bulletin board base widget. Note that it is best to avoid using this style of widget layout.

YSIZE

The desired height of the widget, in number of visible properties. The ultimate height of the property sheet in pixels will include the heights of the column header, the possible horizontal scrollbar, and any frame. If neither YSIZE nor SCR_YSIZE is specified, the property sheet will use a default height. This default is based on the number of rows: 10, or the number of visible properties, whichever is less.

Keywords to WIDGET_CONTROL

A number of keywords to the WIDGET_CONTROL affect the behavior of property sheet widgets. In addition to those keywords that affect all widgets, the following keywords are particularly useful: CONTEXT_EVENTS, EDITABLE, IGNORE_ACCELERATORS, MULTIPLE_PROPERTIES, PROPERTYSHEET_SETSELECTED, REFRESH_PROPERTY.

Keywords to WIDGET_INFO

Some keywords to WIDGET_INFO return information that applies specifically to property sheet widgets. In addition to those keywords that apply to all widgets, the following keywords are particularly useful: COMPONENT, CONTEXT_EVENTS MULTIPLE_PROPERTIES, PROPERTY_VALID, PROPERTY_VALUE, PROPERTYSHEET_NSELECTED, PROPERTYSHEET_SELECTED, STRING_SIZE.

Widget Events Returned by Property Sheet Widgets

Several variations of the property sheet widget event structure depend upon the specific event being reported. All of these structures contain the standard three fields (ID, TOP, and HANDLER). The select and change events also include an integer TYPE field that indicates which type of structure has been returned or which type of event was generated. Programs should always check the TYPE field before referencing fields that are not present in all property sheet event structures, unless the CONTEXT_EVENTS keyword is set. When handling context menu events, the event structure name must be used instead of the TYPE field. The different property sheet widget event structures are described below.

Change Event (TYPE=0)

This event is generated whenever the user enters a new value for a property. It is also used to signal that a user-defined property needs to be changed. The following statement defines the event structure returned by the WIDGET_EVENT function:

```
{WIDGET_PROPSHEET_CHANGE, ID:0L, TOP:0L, HANDLER:0L, TYPE:0L,
    COMPONENT:OBJREF, IDENTIFIER:"", PROPTYPE:0L, SET_DEFINED: OL}
```

The COMPONENT field contains an object reference to the object associated with the property sheet. When multiple objects are associated with the property sheet, this field indicates which object is to change.

The IDENTIFIER field specifies the value of the property's identifier attribute. This identifier is unique among all of the component's properties.

The PROPTYPE field indicates the type of the property (integer, string, etc.). The integer values for these types are:

0	USERDEF
1	BOOLEAN
2	INTEGER
3	FLOAT
4	STRING
5	COLOR
6	LINESTYLE
7	SYMBOL

8	THICKNESS
9	ENUMLIST

The SET_DEFINED field indicates whether or not an undefined property is having its value set. In most circumstances, along with its new value, the property should have its UNDEFINED attribute set to zero. If a property is never marked as undefined, this field can be ignored. See "Changing Properties" (Chapter 6, *Widget Application Programming*) for more information.

Select Event (TYPE=1)

The select event is generated whenever the current row or column in the property sheet changes. Navigation between cells is performed by clicking on a cell. When the property sheet is realized, no properties are selected by default. However a single property or multiple properties can be selected programmatically using the PROPERTYSHEET_SETSELECTED keyword to the WIDGET_CONTROL procedure.

The following statement defines the event structure returned by the WIDGET_EVENT function:

```
{WIDGET_PROPSHEET_SELECT, ID:0L, TOP:0L, HANDLER:0L, TYPE:0L,
    COMPONENT:OBJREF, IDENTIFIER:"", NSELECTED:0L }
```

The COMPONENT tag is a reference to the object associated with the selected property value. When multiple objects (also known as components) are associated with the property sheet, this member indicates which one object had one of its property values selected. If a property (instead of a property value) is selected, the COMPONENT tag always contains an object reference to the first object, even if there are multiple objects in the property sheet.

The IDENTIFIER field specifies the value of the property's identifier attribute. This identifier is unique among all properties of the component. When multiple selections are made, this field holds the identifier of the first item selected. This is not the first item selected with the mouse, but the first item encountered in the property sheet definition among those which are selected. To return the identifiers of all the selected properties, use WIDGET_INFO with the /PROPERTYSHEET_SELECTED keyword.

The NSELECTED field specifies the total number of currently selected properties. This is equivalent to calling WIDGET_INFO with /PROPERTYSHEET_NSELECTED. See "Accessing Property Sheet Selection Events" (Chapter 6, *Widget Application Programming*) for more information.

Context Menu Events

A property sheet widget created with the CONTEXT_EVENTS keyword set returns the following event structure in response to a right mouse button click:

```
{WIDGET_CONTEXT, ID:0L, TOP:0L, HANDLER:0L, X:0L, Y:0L,
   ROW:0L, COL:0L}
```

The first three fields are the standard fields found in every widget event. The X and Y fields give the device coordinates at which the event occurred, measured from the upper left corner of the property sheet widget. The ROW and COL fields return meaningful information for table widgets and values of zero (0) for other widgets.

Note

When working with property sheet context menu events, it is important to notice that the event structure does not have a TYPE field, so special code is needed for the property sheet event handler. Instead of keying off the TYPE field, use the structure's name. See "Property Sheet Context Menu Example" on page 2859 for sample code.

Example

Single Property Sheet Example

Enter the following program in the IDL Editor:

```
; ExSinglePropSheet
;
; Creates a base with a property sheet. Only the
; default properties are visible. The property sheet's
; event handler sets values and reveals selection
; changes.

; Handler for selection or value modification events.
PRO PropertyEvent, event

IF (event.type EQ 0) THEN BEGIN ; Value changed.

   ; Get the value of the property identified by
   ; event.identifier.
   value = WIDGET_INFO(event.ID, COMPONENT = event.component, $
      PROPERTY_VALUE = event.identifier)

   ; Set the component's property value.
   event.component->SetPropertyByIdentifier, event.identifier, $
      value
```

```
      PRINT, 'Changed: ', event.identifier, ': ', value

   ENDIF ELSE BEGIN ; Selection changed.

      ; Return information about single or multiple property
      ; selections.
      vNumSelected = WIDGET_INFO(event.ID, /PROPERTYSHEET_NSELECTED)
      vSelected = WIDGET_INFO(event.ID, /PROPERTYSHEET_SELECTED)
      PRINT, 'Number properties selected: ' + STRING(vNumSelected)
      PRINT, 'Selected properties: '
      PRINT, vSelected

   ENDELSE

END

; Handler for property sheet resize event.
PRO ExSinglePropSheet_event, event

prop = WIDGET_INFO(event.top, $
   FIND_BY_UNAME = 'PropSheet')
WIDGET_CONTROL, prop, SCR_XSIZE = event.x, $
   SCR_YSIZE = event.y

END

; Handler for top-level base kill event.
PRO CleanupEvent, baseID

WIDGET_CONTROL, baseID, GET_UVALUE = oComp
OBJ_DESTROY, oComp

END

PRO ExSinglePropSheet

; Create and initialize the component.
oComp = OBJ_NEW('IDLitVisAxis')

; Create a base and property sheet.
base = WIDGET_BASE(/TLB_SIZE_EVENT, $
   TITLE = 'Single Property Sheet Example', $
   KILL_NOTIFY = 'CleanupEvent')
prop = WIDGET_PROPERTYSHEET(base, VALUE = oComp, $
   EVENT_PRO = 'PropertyEvent', UNAME = 'PropSheet', $
   YSIZE=20, /MULTIPLE_PROPERTIES)

; Activate the widgets.
WIDGET_CONTROL, base, SET_UVALUE = oComp, /REALIZE
```

```
XMANAGER, 'ExSinglePropSheet', base, /NO_BLOCK

END
```

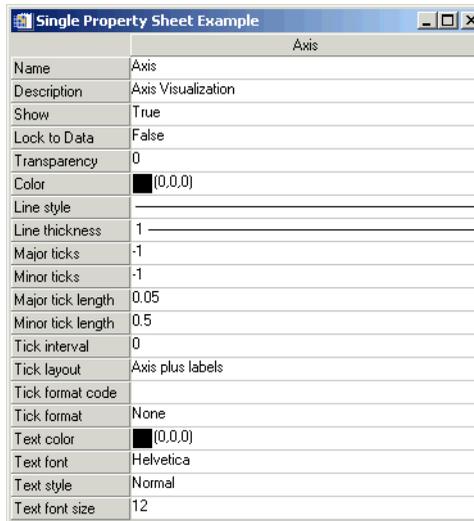
Save this program as `exsinglepropsheet.pro`, then compile and run the program. A property sheet entitled Single Property Sheet Example is displayed:


Figure 25-8: Single Property Sheet Example

For examples of the types of settings possible from the property sheet:

- Click the **Show** setting box, click the drop-down button, and select `False` from the list.

- Click the **Major tick length** setting box, click its drop-down button, and move the slider to select a new value.

- Click the **Text color** setting box, click the drop-down button, and select a new color from the color selector.

Property Sheet Context Menu Example

The following simple example shows how to key event handling off of the event structure name instead of the event type. Attempting to use the CONTEXT_EVENTS keyword without this type of code will cause an error, because, unlike the WIDGET_PROPSHEET_CHANGE and WIDGET_PROPSHEET_SELECT event structures, the WIDGET_CONTEXT structure does not have a TYPE field.

```
; propsheet_context.pro
; For accessing property sheet widget context menus.

PRO prop_event, event

   ; Initiate event based on event structure name, not event type.
   SWITCH TAG_NAMES( EVENT, /STRUCTURE_NAME ) OF

   'WIDGET_PROPSHEET_CHANGE': $
      ; Placeholder for desired code.
      BEGIN
         BREAK
      END

   'WIDGET_PROPSHEET_SELECT': $
      ; Placeholder for desired code.
      BEGIN
         BREAK
      END

   'WIDGET_CONTEXT': $
      BEGIN
         contextBase = WIDGET_INFO( event.id, $
            FIND_BY_UNAME = 'contextMenu' )

         ; Display the context menu at the x, y location
         ; of the right mouse click.
         WIDGET_DISPLAYCONTEXTMENU, $
            event.id, event.x, event.y, contextBase
         BREAK
      END
   ENDSWITCH
END

PRO prop_cleanup, propSheet

   ; Clean up object references.
   WIDGET_CONTROL, propSheet, GET_UVALUE = oAxis
   OBJ_DESTROY, oAxis

END

PRO yes_event, event

   print, 'Yes'

END

PRO no_event, event
```

```
      print, 'No'

END

PRO propsheet_context

   tlb = WIDGET_BASE( /ROW, XOFFSET = 100, YOFFSET = 100 )

   ; Create a property sheet with axis properties.
   oAxis = OBJ_NEW( 'IDLitVisAxis' )

   propSheet = WIDGET_PROPERTYSHEET( tlb, $
      VALUE=oAxis, UVALUE=oAxis, KILL_NOTIFY='prop_cleanup', $
      /CONTEXT_EVENTS, EVENT_PRO = 'prop_event' )

   ; Create a base for the context menu.
   contextBase = WIDGET_BASE( propSheet, /CONTEXT_MENU, $
      UNAME = 'contextMenu' )

   ; Add two buttons to the context menu's base.
   cb1 = WIDGET_BUTTON( contextBase, VALUE = 'Yes', $
      EVENT_PRO = 'yes_event' )
   cb2 = WIDGET_BUTTON( contextBase, VALUE = 'No', $
      EVENT_PRO = 'no_event' )

   ; Activate the widgets.
   WIDGET_CONTROL, tlb, /REALIZE
   XMANAGER, 'propsheet_context', tlb, /NO_BLOCK

END
```

Save and run the example. Left-clicking selects a property. Right-clicking brings up the context menu. Selecting one of the context menu items prints a related string to the Output Log window.

Version History

6.0	Introduced
6.1	Added EDITABLE, FRAME, IGNORE_ACCELERATORS, MULTIPLE_PROPERTIES, and SUNKEN_FRAME keywords
	Added NSELECTED field to WIDGET_PROPSHEET_SELECT event structure
	Added ROW and COL fields to WIDGET_CONTEXT event structure

"Using Property Sheet Widgets" (Chapter 6, *Widget Application Programming*)

WIDGET_SLIDER

The WIDGET_SLIDER function is used to create slider widgets. Slider widgets are used to indicate an integer value from a range of possible values. They consist of a rectangular region which represents the possible range of values. Inside this region is a sliding pointer that displays the current value. This pointer can be manipulated by the user via the mouse, or from within IDL via the WIDGET_CONTROL procedure.

Figure 25-9: A Slider Widget

To indicate floating-point values, see CW_FSLIDER.

Syntax

Result = WIDGET_SLIDER(*Parent* [, /DRAG] [, EVENT_FUNC=*string*]
   [, EVENT_PRO=*string*] [, FONT=*string*] [, FRAME=*width*]
   [, FUNC_GET_VALUE=*string*] [, GROUP_LEADER=*widget_id*]
   [, KILL_NOTIFY=*string*] [, MAXIMUM=*value*] [, MINIMUM=*value*]
   [, /NO_COPY] [, NOTIFY_REALIZE=*string*] [, PRO_SET_VALUE=*string*]
   [, RESOURCE_NAME=*string*] [, SCR_XSIZE=*width*] [, SCR_YSIZE=*height*]
   [, SCROLL=*units*] [, /SENSITIVE] [, /SUPPRESS_VALUE]
   [, TAB_MODE=*value*] [, TITLE=*string*] [, /TRACKING_EVENTS]
   [, UNAME=*string*] [, UNITS={0 | 1 | 2}] [, UVALUE=*value*] [, VALUE=*value*]
   [, /VERTICAL] [, XOFFSET=*value*] [, XSIZE=*value*] [, YOFFSET=*value*]
   [, YSIZE=*value*])

Return Value

The returned value of this function is the widget ID of the newly-created slider widget.

Arguments

Parent

The widget ID of the parent for the new slider widget.

Keywords

DRAG

Set this keyword to cause events to be generated continuously while the slider is being dragged by the user. Normally, slider widgets generate position events only when the slider comes to rest at its final position and the mouse button is released.

When a slider widget is set to return drag events, a large number of events can be generated. On slower machines, poor performance can result. Therefore, this option should only be used when detailed or truly interactive control is required.

EVENT_FUNC

A string containing the name of a function to be called by the WIDGET_EVENT function when an event arrives from a widget in the widget hierarchy rooted at the newly-created widget.

EVENT_PRO

A string containing the name of a procedure to be called by the WIDGET_EVENT function when an event arrives from a widget in the widget hierarchy rooted at the newly-created widget.

FONT

The name of the font to be used by the widget. The font specified is a "device font" (an X Windows font on Motif systems; a TrueType or PostScript font on Windows systems). See "About Device Fonts" on page 5580 for details on specifying names for device fonts. If this keyword is omitted, the default font is used.

Note
On Microsoft Windows platforms, if FONT is not specified, IDL uses the system default font. Different versions of Windows use different system default fonts.

FRAME

The value of this keyword specifies the width of a frame in units specified by the UNITS keyword (pixels are the default) to be drawn around the borders of the widget. Note that this keyword is only a "hint" to the toolkit, and may be ignored in some instances.

FUNC_GET_VALUE

A string containing the name of a function to be called when the GET_VALUE keyword to the WIDGET_CONTROL procedure is called for this widget. Using this technique allows you to change the value that should be returned for a widget. Compound widgets use this ability to define their values transparently to the user.

GROUP_LEADER

The widget ID of an existing widget that serves as "group leader" for the newly-created widget. When a group leader is killed, for any reason, all widgets in the group are also destroyed.

A given widget can be in more than one group. The WIDGET_CONTROL procedure can be used to add additional group associations to a widget. It is not possible to remove a widget from an existing group.

KILL_NOTIFY

Set this keyword to a string that contains the name of a procedure to be called automatically when the specified widget dies. Each widget is allowed a single such "callback" procedure. It can be removed by setting the routine to the null string (' ').

The callback routine is called with the widget identifier as its only argument. At that point, the widget identifier can only be used with the WIDGET_CONTROL procedure to get or set the user value. All other requests that require a widget ID are disallowed for the target widget. The callback is not issued until the WIDGET_EVENT function is called.

MAXIMUM

The maximum value of the range encompassed by the slider. If this keyword is not supplied, a default of 100 is used.

MINIMUM

The minimum value of the range encompassed by the slider. If this keyword is not supplied, a default of 0 is used.

NO_COPY

Usually, when setting or getting widget user values, either at widget creation or using the SET_UVALUE and GET_UVALUE keywords to WIDGET_CONTROL, IDL makes a second copy of the data being transferred. Although this technique is fine for small data, it can have a significant memory cost when the data being copied is large.

If the NO_COPY keyword is set, IDL handles these operations differently. Rather than copy the source data, it takes the data away from the source and attaches it directly to the destination. This feature can be used by compound widgets to obtain state information from a UVALUE without all the memory copying that would otherwise occur. However, it has the side effect of causing the source variable to become undefined. On a "set" operation (using the UVALUE keyword to WIDGET_SLIDER or the SET_UVALUE keyword to WIDGET_CONTROL), the variable passed as value becomes undefined. On a "get" operation (GET_UVALUE keyword to WIDGET_CONTROL), the user value of the widget in question becomes undefined.

NOTIFY_REALIZE

Set this keyword to a string that contains the name of a procedure to be called automatically when the specified widget is realized. This callback occurs just once (because widgets are realized only once). Each widget is allowed a single such "callback" procedure. It can be removed by setting the routine to the null string (' '). The callback routine is called with the widget ID as its only argument.

PRO_SET_VALUE

A string containing the name of a procedure to be called when the SET_VALUE keyword to the WIDGET_CONTROL procedure is called for this widget. See the description of the PRO_SET_VALUE keyword to WIDGET_CONTROL for information on using this keyword.

RESOURCE_NAME

A string containing an X Window System resource name to be applied to the widget. See "RESOURCE_NAME" on page 2665 for a complete discussion of this keyword.

SCR_XSIZE

Set this keyword to the desired "screen" width of the widget, in units specified by the UNITS keyword (pixels are the default). In many cases, setting this keyword is the same as setting the XSIZE keyword.

SCR_YSIZE

Set this keyword to the desired "screen" height of the widget, in units specified by the UNITS keyword (pixels are the default). In many cases, setting this keyword is the same as setting the YSIZE keyword.

SCROLL

Set the SCROLL keyword to an integer value specifying the number of integer units the scroll bar should move when the user clicks the left mouse button inside the slider area (Motif) or on the slider arrows (Windows), but not on the slider itself. The default on both platforms is 0.1 x (MAXIMUM - MINIMUM), which is 10% of the slider range.

SENSITIVE

Set this keyword to control the initial sensitivity state of the widget.

If SENSITIVE is zero, the widget becomes insensitive. If nonzero, it becomes sensitive. When a widget is sensitive, it has normal appearance and can receive user input. For example, a sensitive button widget can be activated by moving the mouse cursor over it and pressing a mouse button. When a widget is insensitive, it indicates the fact by changing its appearance, looking disabled, and it ignores any input.

Sensitivity can be used to control when a user is allowed to manipulate the widget. Note that some widgets do not change their appearance when they are made insensitive, but they cease generating events.

After creating the widget hierarchy, you can change the sensitivity state using the SENSITIVE keyword with the WIDGET_CONTROL procedure.

SUPPRESS_VALUE

Set this keyword to inhibit the display of the current slider value.

Sliders work only with integer units. This keyword can be used to suppress the actual value of a slider so that a program can present the user with a slider that seems to work in other units (such as floating-point) or with a non-linear scale.

TRACKING_EVENTS

Set this keyword to cause widget tracking events to be issued for the widget whenever the mouse pointer enters or leaves the region covered by that widget. For the structure of tracking events, see "TRACKING_EVENTS" on page 2672 in the documentation for WIDGET_BASE.

TAB_MODE

Set this keyword to one of the values shown in the table below to determine how the widget hierarchy can be navigated using the **Tab** key. The TAB_MODE setting is inherited by lower-level bases and child widgets from the parent WIDGET_BASE unless it is explicitly set on an individual widget. If the TAB_MODE value of the widget differs from that of the base, the setting on the widget will be respected when the widget has focus. For example, if a base does not support tabbing, but an individual child widget does support tabbing, this functionality will be enabled when the child widget has focus.

Note ——
It is not possible to tab to disabled (SENSITIVE=0) or hidden (MAP=0) widgets.
——

Valid settings are:

0	Disable navigation onto or off of the widget. This is the default unless the TAB_MODE has been set on a parent base. Child widgets automatically inherit the tab mode of the parent base as described in "Inheriting the TAB_MODE Value" (Chapter 3, *Widget Application Programming*).
1	Enable navigation onto and off of the widget.
2	Navigate only onto the widget.
3	Navigate only off of the widget.

Note ——
In widget applications on the UNIX platform, the Motif library controls what widgets are brought into and released from focus using tabbing. The TAB_MODE keyword value is always zero, and any attempt to change it is ignored when running a widget application on the UNIX platform. Tabbing behavior may vary significantly between UNIX platforms; do not rely on a particular behavior being duplicated on all UNIX systems.
——

Once the WIDGET_SLIDER has focus, use the **Home** and **End** keys, and right and left arrow keys to change the marker value on Windows. The **Page Up** and **Page Down** keys can also be used on Windows to increase or decrease the slider maker value by multiple units at a time. On UNIX, the Motif library controls tabbing functionality.

After creating the widget hierarchy, you can change tabbing support using the WIDGET_CONTROL procedure's TAB_MODE keyword, or query a widget's support for tabbing using the WIDGET_INFO procedure's TAB_MODE keyword.

See "Tabbing in Widget Applications" (Chapter 3, *Widget Application Programming*) for usage details and examples.

TITLE

A string containing the title to be used for the slider widget.

Note
You can use language catalogs to internationalize this value with strings in particular languages. For more information, see Chapter 19, "Using Language Catalogs" (*Application Programming*).

UNAME

Set this keyword to a string that can be used to identify the widget in your code. You can associate a name with each widget in a specific hierarchy, and then use that name to query the widget hierarchy and get the correct widget ID.

To query the widget hierarchy, use the WIDGET_INFO function with the FIND_BY_UNAME keyword. The UNAME should be unique to the widget hierarchy because the FIND_BY_UNAME keyword returns the ID of the first widget with the specified name.

UNITS

Set this keyword to specify the units used when *supplying* measurements or position values. Set UNITS equal to 0 (zero) to specify that all measurements are in pixels (this is the default), to 1 (one) to specify that all measurements are in inches, or to 2 (two) to specify that all measurements are in centimeters. This keyword does not change the units used in a widget event structure or in most of the fields of the geometry structure returned by WIDGET_INFO.

UVALUE

The "user value" to be assigned to the widget.

Each widget can contain a user-specified value of any data type and organization. This value is not used by the widget in any way, but exists entirely for the convenience of the IDL programmer. This keyword allows you to set this value when the widget is first created.

If UVALUE is not present, the widget's initial user value is undefined.

VALUE

The initial value setting of the widget. The value of a widget slider is the integer value of the current slider position.

VERTICAL

Set this keyword to create a vertical slider. If this keyword is omitted, the slider is horizontal.

XOFFSET

The horizontal offset of the widget in units specified by the UNITS keyword (pixels are the default) relative to its parent. This offset is specified relative to the *upper left* corner of the parent widget.

Specifying an offset relative to a row or column major base widget does not work because those widgets enforce their own layout policies. This keyword is primarily of use relative to a plain base widget. Note that it is best to avoid using this style of widget programming.

XSIZE

The width of the widget in units specified by the UNITS keyword (pixels are the default). Most widgets attempt to size themselves to fit the situation. However, if the desired effect is not produced, use this keyword to override it. This keyword is only a "hint" to the toolkit and may be ignored in some situations.

Note

Setting XSIZE for a vertical slider (created with the VERTICAL keyword) does not change the visible width of the slider itself, but does change the amount of horizontal space occupied by the widget within its parent base.

YOFFSET

The vertical offset of the widget in units specified by the UNITS keyword (pixels are the default) relative to its parent. This offset is specified relative to the *upper left* corner of the parent widget.

Specifying an offset relative to a row or column major base widget does not work because those widgets enforce their own layout policies. This keyword is primarily of use relative to a plain base widget. Note that it is best to avoid using this style of widget programming.

YSIZE

The height of the widget in units specified by the UNITS keyword (pixels are the default). Most widgets attempt to size themselves to fit the situation. However, if the desired effect is not produced, use this keyword to override it. This keyword is only a "hint" to the toolkit and may be ignored in some situations.

Note

Setting YSIZE for a horizontal slider does not change the visible height of the slider itself, but does change the amount of vertical space occupied by the widget within its parent base.

Keywords to WIDGET_CONTROL

A number of keywords to the WIDGET_CONTROL procedure affect the behavior of slider widgets. In addition to those keywords that affect all widgets, the following are particularly useful: GET_VALUE, SET_SLIDER_MAX, SET_SLIDER_MIN, SET_VALUE.

Keywords to WIDGET_INFO

Some keywords to the WIDGET_INFO function return information that applies specifically to slider widgets. In addition to those keywords that apply to all widgets, the following are particularly useful: SLIDER_MIN_MAX, STRING_SIZE.

Widget Events Returned by Slider Widgets

Slider widgets generate events when the mouse is used to change their value. The event structure returned by the WIDGET_EVENT function is defined by the following statement:

```
{WIDGET_SLIDER, ID:0L, TOP:0L, HANDLER:0L, VALUE:0L, DRAG:0}
```

ID is the widget ID of the button generating the event. TOP is the widget ID of the top level widget containing ID. HANDLER contains the widget ID of the widget associated with the handler routine. VALUE returns the new value of the slider. DRAG returns integer 1 if the slider event was generated as part of a drag operation, or zero if the event was generated when the user had finished positioning the slider. Note that the slider widget only generates events during the drag operation if the DRAG keyword is set. When the DRAG keyword is set, the DRAG field can be used to avoid computationally expensive operations until the user releases the slider.

Known Implementation Problems

Under Motif 1.0, vertical sliders with a title organized in row bases get horizontally truncated and the slider doesn't show (the title does). Use the XSIZE keyword to work around this.

Version History

Pre-4.0	Introduced
6.1	Added TAB_MODE keyword

CW_FSLIDER

WIDGET_TAB

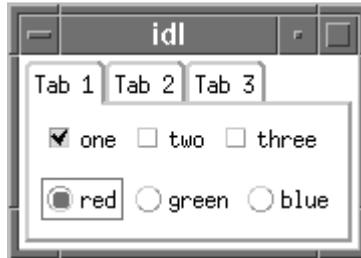
The WIDGET_TAB function is used to create a tab widget. Tab widgets present a display area on which different pages (base widgets and their children) can be displayed by selecting the appropriate tab — that is, selecting a tab displays the contents of a specified base widget within the tab widget. The titles of the tabs are supplied as the values of the TITLE keyword for each of the tab widget's child base widgets.


Figure 25-10: A Tab Widget

For a more detailed discussion of the tab widget, along with examples, see "Using Tab Widgets" (Chapter 8, *Widget Application Programming*).

Syntax

Result = WIDGET_TAB(*Parent* [, /ALIGN_BOTTOM | , /ALIGN_CENTER | , /ALIGN_LEFT | , /ALIGN_RIGHT | , /ALIGN_TOP] [, EVENT_FUNC=*string*] [, EVENT_PRO=*string*] [, FUNC_GET_VALUE=*string*] [, GROUP_LEADER=*widget_id*] [, KILL_NOTIFY=*string*] [, LOCATION={0 | 1 | 2 | 3}] [, MULTILINE=0 | 1 (Windows) or *num* tabs per row (Motif)] [, /NO_COPY] [, NOTIFY_REALIZE=*string*] [, PRO_SET_VALUE=*string*] [, SCR_XSIZE=*width*] [, SCR_YSIZE=*height*] [, /SENSITIVE] [, TAB_MODE=*value*] [, /TRACKING_EVENTS] [, UNAME=*string*] [, UNITS={0 | 1 | 2}] [, UVALUE=*value*] [, XOFFSET=*value*] [, XSIZE=*value*] [, YOFFSET=*value*] [, YSIZE=*value*])

Return Value

The returned value of this function is the widget ID of the newly-created tab widget.

Arguments

Parent

The widget ID of the parent for the new tab widget.

Note

Only base widgets can be the parent of a tab widget.

Keywords

ALIGN_BOTTOM

Set this keyword to align the new widget with the bottom of its parent base. To take effect, the parent must be a ROW base.

ALIGN_CENTER

Set this keyword to align the new widget with the center of its parent base. To take effect, the parent must be a ROW or COLUMN base. In ROW bases, the new widget will be vertically centered. In COLUMN bases, the new widget will be horizontally centered.

ALIGN_LEFT

Set this keyword to align the new widget with the left side of its parent base. To take effect, the parent must be a COLUMN base.

ALIGN_RIGHT

Set this keyword to align the new widget with the right side of its parent base. To take effect, the parent must be a COLUMN base.

ALIGN_TOP

Set this keyword to align the new widget with the top of its parent base. To take effect, the parent must be a ROW base.

EVENT_FUNC

A string containing the name of a function to be called by the WIDGET_EVENT function when an event arrives from a widget in the widget hierarchy rooted at the newly-created widget.

EVENT_PRO

A string containing the name of a procedure to be called by the WIDGET_EVENT function when an event arrives from a widget in the widget hierarchy rooted at the newly-created widget.

FUNC_GET_VALUE

A string containing the name of a function to be called when the GET_VALUE keyword to the WIDGET_CONTROL procedure is called for this widget. Using this technique allows you to change the value that should be returned for a widget. Compound widgets use this ability to define their values transparently to the user.

GROUP_LEADER

The widget ID of an existing widget that serves as group leader for the newly-created widget. When a group leader is killed, for any reason, all widgets in the group are also destroyed.

A given widget can be in more than one group. The WIDGET_CONTROL procedure can be used to add additional group associations to a widget. You cannot remove a widget from an existing group.

KILL_NOTIFY

Set this keyword to a string that contains the name of a procedure to be called automatically when the specified widget dies. Each widget is allowed a single such "callback" procedure. It can be removed by setting the routine to the null string (' ').

The callback routine is called with the widget identifier as its only argument. At that point, the widget identifier can only be used with the WIDGET_CONTROL procedure to get or set the user value. All other requests that require a widget ID are disallowed for the target widget. The callback is not issued until the WIDGET_EVENT function is called.

LOCATION

Set this keyword equal to an integer that specifies which edge of the tab widget will contain the tabs. The possible values are:

0	The tabs are placed along the top of the widget, which is the default behavior.
1	The tabs are placed along the bottom of the widget.

2	The tabs are placed along the left edge of the widget. The text label for each tab is displayed vertically. On Windows platforms, setting the keyword to this value implies the MULTILINE keyword.
3	The tabs are placed along the right edge of the widget. The text label for each tab is displayed vertically. On Windows platforms, setting the keyword to this value implies the MULTILINE keyword.

MULTILINE

This keyword controls how tabs appear on the tab widget when all of the tabs do not fit on the widget in a single row. This keyword behaves differently on Windows and Motif systems.

Windows

Set this keyword to cause tabs to be organized in a multiline display when the width of the tabs exceeds the width of the largest child base widget. If possible, IDL will create tabs that display the full tab text.

If MULTILINE = 0 and LOCATION = 0 or 1, tabs that exceed the width of the largest child base widget are shown with scroll buttons, allowing the user to scroll through the tabs while the base widget stays immobile.

If LOCATION = 1 or 2, a multiline display is always used if the tabs exceed the height of the largest child base widget.

Note ───

The width or height of the tab widget is based on the width or height of the largest base widget that is a child of the tab widget. The text of the tabs (the titles of the tab widget's child base widgets) may be truncated even if the MULTILINE keyword is set.

───

Motif

Set this keyword equal to an integer that specifies the maximum number of tabs to display per row in the tab widget. If this keyword is not specified (or is explicitly set equal to zero) all tabs are placed in a single row.

Note ───────────────────────────────────

The width or height of the tab widget is based on the width or height of the largest base widget that is a child of the tab widget. The text of the tabs (the titles of the tab widget's child base widgets) is never truncated in order to make the tabs fit the space available. However, tab text may be truncated if the text of a single tab exceeds the space available. If MULTILINE is set to any value other than one, some tabs may not be displayed.

──

NO_COPY

Usually, when setting or getting widget user values, either at widget creation or using the SET_UVALUE and GET_UVALUE keywords to WIDGET_CONTROL, IDL makes a second copy of the data being transferred. Although this technique is fine for small data, it can have a significant memory cost when the data being copied is large.

If the NO_COPY keyword is set, IDL handles these operations differently. Rather than copying the source data, it takes the data away from the source and attaches it directly to the destination. This feature can be used by compound widgets to obtain state information from a UVALUE without all the memory copying that would otherwise occur. However, it has the side effect of causing the source variable to become undefined. Upon a set operation (using the UVALUE keyword to WIDGET_TAB or the SET_UVALUE keyword to WIDGET_CONTROL), the variable passed as value becomes undefined. Upon a get operation (GET_UVALUE keyword to WIDGET_CONTROL), the user value of the widget in question becomes undefined.

NOTIFY_REALIZE

Set this keyword to a string containing the name of a procedure to be called automatically when the specified widget is realized. This callback occurs just once (because widgets are realized only once). Each widget is allowed a single callback procedure. This callback procedure can be removed by setting the routine name to the null string (`' '`). The callback routine is called with the widget ID as its only argument.

PRO_SET_VALUE

A string containing the name of a procedure to be called when the SET_VALUE keyword to the WIDGET_CONTROL procedure is called for this widget. See the description of the PRO_SET_VALUE keyword to WIDGET_CONTROL for information on using this keyword.

SCR_XSIZE

Set this keyword to the desired screen width of the widget, in units specified by the UNITS keyword (pixels are the default). In many cases, setting this keyword is the same as setting the XSIZE keyword.

SCR_YSIZE

Set this keyword to the desired screen height of the widget, in units specified by the UNITS keyword (pixels are the default). In many cases, setting this keyword is the same as setting the YSIZE keyword.

SENSITIVE

Set this keyword to control the initial sensitivity state of the widget.

If SENSITIVE is zero, the widget becomes insensitive. If nonzero, it becomes sensitive. When a widget is sensitive, it has normal appearance and can receive user input. For example, a sensitive button widget can be activated by moving the mouse cursor over it and pressing a mouse button. When a widget is insensitive, it indicates the fact by changing its appearance, looking disabled, and it ignores any input.

Sensitivity can be used to control when a user is allowed to manipulate the widget.

Note

Some widgets do not change their appearance when they are made insensitive, but they cease generating events.

After creating the widget hierarchy, you can change the sensitivity state using the SENSITIVE keyword with the WIDGET_CONTROL.

TAB_MODE

Set this keyword to one of the values shown in the table below to determine how the widget hierarchy can be navigated using the **Tab** key. The TAB_MODE setting is inherited by lower-level bases and child widgets from the parent WIDGET_BASE unless it is explicitly set on an individual widget. If the TAB_MODE value of the widget differs from that of the base, the setting on the widget will be respected when the widget has focus. For example, if a base does not support tabbing, but an individual child widget does support tabbing, this functionality will be enabled when the child widget has focus.

Note

It is not possible to tab to disabled (SENSITIVE=0) or hidden (MAP=0) widgets.

Valid settings are:

0	Disable navigation onto or off of the widget. This is the default unless the TAB_MODE has been set on a parent base. Child widgets automatically inherit the tab mode of the parent base as described in "Inheriting the TAB_MODE Value" (Chapter 3, *Widget Application Programming*).
1	Enable navigation onto and off of the widget.
2	Navigate only onto the widget.
3	Navigate only off of the widget.

Note ───

In widget applications on the UNIX platform, the Motif library controls what widgets are brought into and released from focus using tabbing. The TAB_MODE keyword value is always zero, and any attempt to change it is ignored when running a widget application on the UNIX platform. Tabbing behavior may vary significantly between UNIX platforms; do not rely on a particular behavior being duplicated on all UNIX systems.

───

When a WIDGET_TAB widget receives focus through tabbing, the tab title is outlined. Navigate to other tabs using the **End** key, **Home** key, or the right and left arrow keys to switch focus between the tabs. Pressing the **Tab** key brings into focus the first child widget on the tab capable of receiving focus. On UNIX, the Motif library controls tabbing functionality

After creating the widget hierarchy, you can change tabbing support using the WIDGET_CONTROL procedure's TAB_MODE keyword, or query a widget's support for tabbing using the WIDGET_INFO procedure's TAB_MODE keyword.

See "Tabbing in Widget Applications" (Chapter 3, *Widget Application Programming*) for usage details and examples.

TRACKING_EVENTS

Set this keyword to cause widget tracking events to be issued for the widget whenever the mouse pointer enters or leaves the region covered by that widget. For the structure of tracking events, see "TRACKING_EVENTS" on page 2672 in the documentation for WIDGET_BASE.

UNAME

Set this keyword to a string, which is used to identify the widget in your code. You can associate a name with each widget in a specific hierarchy, and then use that name to query the widget hierarchy and get the correct widget ID.

To query the widget hierarchy, use the WIDGET_INFO with the FIND_BY_UNAME keyword. The UNAME should be unique to the widget hierarchy because the FIND_BY_UNAME keyword returns the ID of the first widget with the specified name.

UNITS

Set this keyword to specify the units used when *supplying* measurements or position values. Set UNITS equal to 0 (zero) to specify that all measurements are in pixels (this is the default), to 1 (one) to specify that all measurements are in inches, or to 2 (two) to specify that all measurements are in centimeters. This keyword does not change the units used in a widget event structure or in most of the fields of the geometry structure returned by WIDGET_INFO.

UVALUE

The user value to be assigned to the widget.

Each widget can contain a user-specified value of any data type and organization. This value is not used by the widget in any way, but exists entirely for the convenience of the IDL programmer. This keyword allows you to set this value when the widget is first created.

If UVALUE is not present, the widget's initial user value is undefined.

XOFFSET

The horizontal offset of the widget in units specified by the UNITS keyword (pixels are the default) relative to its parent. This offset is specified relative to the *upper left* corner of the parent widget.

Specifying an offset relative to a row or column major base widget does not work because those widgets enforce their own layout policies. This keyword is primarily of use relative to a plain base widget. You should avoid using this style of widget programming.

XSIZE

The width of the widget in units specified by the UNITS keyword (pixels are the default). Most widgets attempt to size themselves to fit the situation. However, if the

desired effect is not produced, use this keyword to override it. This keyword is only a hint to the toolkit and may be ignored in some situations.

YOFFSET

The vertical offset of the widget in units specified by the UNITS keyword (pixels are the default) relative to its parent. This offset is specified relative to the *upper left* corner of the parent widget.

Specifying an offset relative to a row or column major base widget does not work because those widgets enforce their own layout policies. This keyword is primarily of use relative to a plain base widget. You should avoid using this style of widget programming.

YSIZE

The height of the widget in units specified by the UNITS keyword (pixels are the default). Most widgets attempt to size themselves to fit the situation. However, if the desired effect is not produced, use this keyword to override it. This keyword is only a hint to the toolkit and may be ignored in some situations.

Keywords to WIDGET_CONTROL

A number of keywords to the WIDGET_CONTROL affect the behavior of tab widgets. In addition to those keywords that affect all widgets, the following keywords are particularly useful: BASE_SET_TITLE, SET_TAB_CURRENT, SET_TAB_MULTILINE.

Keywords to WIDGET_INFO

Some keywords to the WIDGET_INFO return information that applies specifically to tab widgets. In addition to those keywords that apply to all widgets, the following keywords are particularly useful: STRING_SIZE, TAB_CURRENT, TAB_MULTILINE, TAB_NUMBER.

Widget Events Returned by Tab Widgets

Tab widgets generate events when a new tab is selected. The event structure returned by the WIDGET_EVENT function is defined by the following statement:

```
{WIDGET_TAB, ID:0L, TOP:0L, HANDLER:0L, TAB:0L}
```

ID is the widget ID of the button generating the event. TOP is the widget ID of the top level widget containing ID. HANDLER contains the widget ID of the widget

associated with the handler routine. TAB returns the zero-based index of the tab selected.

Version History

5.6	Introduced
6.1	Added TAB_MODE keyword

See Also

"Using Tab Widgets" (Chapter 8, *Widget Application Programming*)

WIDGET_TABLE

The WIDGET_TABLE function creates table widgets. Table widgets are used to display two-dimensional data in tabular format. Individual table cells (or ranges of cells) can be selected for editing by the user. They can have one or more rows and columns, and automatically create scroll bars when viewing more data than can otherwise be displayed on the screen.

Figure 25-11: A Table Widget

For a more detailed discussion of the table widget, along with examples, see "Using Table Widgets" (Chapter 7, *Widget Application Programming*).

Note on Table Sizing

Table widgets are sized according to the value of the following pairs of keywords to WIDGET_TABLE, in order of precedence: SCR_XSIZE/SCR_YSIZE, XSIZE/YSIZE, X_SCROLL_SIZE/Y_SCROLL_SIZE, VALUE. If either dimension remains unspecified by one of the above keywords, the default value of six (columns or rows) is used when the table is created. If the width or height specified is less than the size of the table, scroll bars are added automatically.

Syntax

Result = WIDGET_TABLE(*Parent* [, ALIGNMENT={0 | 1 | 2}] [, /ALL_EVENTS]
   [, AM_PM=*[string*, *string]*] [, BACKGROUND_COLOR=*array*]
   [, COLUMN_LABELS=*string_array*]
   [, /COLUMN_MAJOR | , /ROW_MAJOR] [, COLUMN_WIDTHS=*array*]
   [, /CONTEXT_EVENTS] [, DAYS_OF_WEEK=*string_array*{7 names}]
   [, /DISJOINT_SELECTION] [, /EDITABLE] [, EVENT_FUNC=*string*]

[, EVENT_PRO=*string*] [, FONT=*string*] [, FOREGROUND_COLOR=*array*]
[, FORMAT=*value*] [, FRAME=*width*] [, FUNC_GET_VALUE=*string*]
[, GROUP_LEADER=*widget_id*] [, IGNORE_ACCELERATORS=*value*]
[, /KBRD_FOCUS_EVENTS] [, KILL_NOTIFY=*string*]
[, MONTHS=*string_array*{12 names}] [, /NO_COLUMN_HEADERS]
[, /NO_COPY] [, /NO_HEADERS] [, /NO_ROW_HEADERS]
[, NOTIFY_REALIZE=*string*] [, PRO_SET_VALUE=*string*]
[, /RESIZEABLE_COLUMNS] [, /RESIZEABLE_ROWS{not supported in
Windows}] [, RESOURCE_NAME=*string*] [, ROW_HEIGHTS=*array*]
[, ROW_LABELS=*string_array*] [, SCR_XSIZE=*width*] [, SCR_YSIZE=*height*]
[, /SCROLL] [, /SENSITIVE] [, TAB_MODE=*value*] [, /TRACKING_EVENTS]
[, UNAME=*string*] [, UNITS={0 | 1 | 2}] [, UVALUE=*value*] [, VALUE=*value*]
[, XOFFSET=*value*] [, XSIZE=*value*] [, X_SCROLL_SIZE=*width*]
[, YOFFSET=*value*] [, YSIZE=*value*] [, Y_SCROLL_SIZE=*height*])

Return Value

The returned value of this function is the widget ID of the newly-created table widget.

Arguments

Parent

The widget ID of the parent widget for the new table widget.

Keywords

ALIGNMENT

Set this keyword equal to a scalar or 2-D array specifying the alignment of the text
within each cell. An alignment of 0 (the default) aligns the left edge of the text with
the left edge of the cell. An alignment of 2 right-justifies the text, while 1 results in
text centered within the cell. If ALIGNMENT is set equal to a scalar, all table cells
are aligned as specified. If ALIGNMENT is set equal to a 2-D array, the alignment of
each table cell is governed by the corresponding element of the array.

Note

ALIGNMENT cannot be applied to the column or row headers of a table widget.

ALL_EVENTS

Set this keyword to cause the table widget to generate events whenever the user changes the contents of a table cell.

Note

If the EDITABLE keyword is set, an insert character event (TYPE=0) is generated when you press the **Return** or **Enter** key in the table widget, even if the ALL_EVENTS keyword is not set. You could use such end-of-line events as an indication to check the cell value or to set the currently selected cell to the next cell. See the table below for details on the interaction between ALL_EVENTS and EDITABLE.

Keywords		Effects	
ALL_EVENTS	**EDITABLE**	**Input changes widget contents?**	**Type of events generated.**
Not set	Not set	No	None
Not set	Set	Yes	End-of-line insertion
Set	Not set	No	All events
Set	Set	Yes	All events

Table 25-15: Effects of Using the ALL_EVENTS and EDITABLE Keywords

AM_PM

Supplies a string array of two names to be used for the names of the AM and PM string when processing explicitly formatted dates (CAPA, CApA, and CapA format codes) with the FORMAT keyword.

Note

You can use language catalogs to internationalize this value with strings in particular languages. For more information, see Chapter 19, "Using Language Catalogs" (*Application Programming*).

BACKGROUND_COLOR

Set this keyword to one or more RGB triplets to specify cell background colors. For an RGB triplet, each red, green, and blue byte must be in the range [0,255].

If a single color is provided, it is applied to all cells and is used as the default whenever new cells are created. If more than one color is provided, IDL applies the colors row by row, left to right, working from the top row to the bottom row. When there are fewer colors than cells, IDL cycles through the colors repeatedly.

Note ────────────────────────────

A computer's graphics system might not express an arbitrary RGB triplet accurately or be capable of displaying a large number of distinct colors. The actually applied may be different from the color you specify.

────────────────────────────────────

For more information, see "Cell Attributes" (Chapter 7, *Widget Application Programming*).

COLUMN_LABELS

Set this keyword equal to an array of strings used as labels for the columns of the table widget. The default labels are of the form "*n*", where *n* is the column number. If this keyword is set to the empty string (' '), all column labels are set to be empty.

Note ────────────────────────────

You can use language catalogs to internationalize this value with strings in particular languages. For more information, see Chapter 19, "Using Language Catalogs" (*Application Programming*).

────────────────────────────────────

COLUMN_MAJOR

This keyword is only valid if the table data is organized as a vector of structures rather than a two-dimensional array. See the VALUE keyword for details.

Set this keyword to specify that the data should be read into the table as if each element of the vector is a structure containing one column's data. Note that the structures must all be of the same type, and must have one field for each row in the table. If this keyword is not set, the table widget behaves as if the ROW_MAJOR keyword were set.

COLUMN_WIDTHS

Set this keyword equal to an array of widths for the columns of the table widget. The widths are given in any of the units as specified with the UNITS keyword. If no width

is specified for a column, that column is set to the default size, which varies by platform. If COLUMN_WIDTHS is set to a scalar value, all columns are set to that width.

Note ───

Column widths are limited to 0.
───

CONTEXT_EVENTS

Set this keyword to cause context menu events (or simply context events) to be issued when you click the right mouse button over the widget. Set the keyword to 0 (zero) to disable such events. This is the default. Context events are intended for use with context-sensitive menus (also known as pop-up or shortcut menus). Pass the context event ID to the WIDGET_DISPLAYCONTEXTMENU procedure within your widget program's event handler to display the context menu.

For more on detecting and handling context menu events, see "Context-Sensitive Menus" (Chapter 3, *Widget Application Programming*).

DAYS_OF_WEEK

Supplies a string array of seven names to be used for the names of the days of the week when processing explicitly formatted dates (CDWA, CDwA, and CdwA format codes) with the FORMAT keyword.

Note ───

You can use language catalogs to internationalize this value with strings in particular languages. For more information, see Chapter 19, "Using Language Catalogs" (*Application Programming*).
───

DISJOINT_SELECTION

Set this keyword to enable the ability to select multiple rectangular regions of cells. The regions can be overlapping, touching, or entirely distinct.

Setting this keyword changes the data structures returned by the TABLE_SELECT keyword to WIDGET_INFO and the GET_VALUE keyword to WIDGET_CONTROL. Similarly, the data structures you supply via the SET_TABLE_SELECT and SET_VALUE keywords to WIDGET_CONTROL are different in disjoint mode.

See "Selection Modes" (Chapter 7, *Widget Application Programming*) for additional details.

EDITABLE

Set this keyword to allow or deny direct user editing of table cells. The default value is zero, which prevents user editing. Non-zero values permit user editing. Scalar values are applied to all cells and used as the default for new cells. When you supply an array, the values are applied row by row, left to right, working from the top row to the bottom row. When there are fewer values than cells, IDL cycles through the values repeatedly. Each value should be a single byte.

See "ALL_EVENTS" on page 2885 for a description of how EDITABLE interacts with the ALL_EVENTS keyword.

Note

The method by which table widgets are placed into edit mode is dependent upon the windowing system. See "Edit Mode" (*Widget Application Programming*).

EVENT_FUNC

Set this keyword to a string containing the name of a function to be called by the WIDGET_EVENT function when an event arrives from a widget in the widget hierarchy rooted at the newly-created widget.

EVENT_PRO

Set this keyword to a string containing the name of a procedure to be called by the WIDGET_EVENT function when an event arrives from a widget in the widget hierarchy rooted at the newly-created widget.

FONT

Set this keyword to the names of the fonts used by the widget. Specified fonts are "device fonts" (an X Windows font on Motif systems, a TrueType or PostScript font on Windows systems). See "About Device Fonts" on page 5580 for details on specifying names for device fonts. If this keyword is omitted, the default font is used.

When you supply a scalar value, IDL uses the font for all cells and as the default table font. It uses the default font in headers and new cells. If you supply more than one font, IDL applies these fonts row by row, left to right, working from the top row to the bottom row, repeatedly if necessary (if there are fewer fonts than cells).

Note

On Microsoft Windows platforms, if FONT is not specified, IDL uses the system default font. Different versions of Windows use different system default fonts; in

general, the system default font is the font appropriate for the version of Windows in question.

FOREGROUND_COLOR

Set this keyword to one or more RGB triplets to specify cell text colors. For an RGB triplet, each red, green, and blue byte must be in the range [0,255].

If a single color is provided, it is applied to all cells and is used as the default whenever new cells are created. If more than one color is provided, IDL applies the colors row by row, left to right, working from the top row to the bottom row. When there are fewer colors than cells, IDL cycles through the colors repeatedly.

Note

A computer's graphics system might not express an arbitrary RGB triplet accurately or be capable of displaying a large number of distinct colors. The actually applied may be different from the color you specify.

For more information, see "Cell Attributes" (Chapter 7, *Widget Application Programming*).

FORMAT

Set this keyword equal to a single string or array of strings that specify the format of data displayed within table cells. The string(s) are of the same form as used by the FORMAT keyword to the PRINT procedure, and the default format is the same as that used by the PRINT procedure.

Warning

If the format specified is incompatible with the data displayed in a table cell, an error message is generated. Since the error is generated *for each cell displayed*, the number of messages printed is potentially large, and can slow execution significantly. Note also that each time a new cell is displayed (when scroll bars are repositioned, for example), a new error is generated *for each cell displayed*.

FRAME

The value of this keyword specifies the width of a frame in units specified by the UNITS keyword (pixels are the default) to be drawn around the borders of the widget. Note that this keyword is only a "hint" to the toolkit, and may be ignored in some instances.

FUNC_GET_VALUE

A string containing the name of a function to be called when the GET_VALUE keyword to the WIDGET_CONTROL procedure is called for this widget. Using this technique allows you to change the value that should be returned for a widget. Compound widgets use this ability to define their values transparently to the user.

GROUP_LEADER

The widget ID of an existing widget that serves as "group leader" for the newly-created widget. When a group leader is killed, for any reason, all widgets in the group are also destroyed.

A given widget can be in more than one group. The WIDGET_CONTROL procedure can be used to add additional group associations to a widget. It is not possible to remove a widget from an existing group.

IGNORE_ACCELERATORS

Set this keyword to specify what WIDGET_BUTTON accelerators are to be ignored when this table widget has keyboard focus. Valid values are:

- A string or string array containing any value that is legal for WIDGET_BUTTON's ACCELERATOR keyword

- The number 1, indicating all accelerators should be ignored

Ordinarily, accelerators are processed before keyboard events reach the widget that has the keyboard focus. Consider a case where the accelerator "Ctrl+V" has been mapped to a button that allows the user to paste objects copied from one drawing area into another. In an application that also has a table, attempting to use **Ctrl**+**V** to paste text into the table cell would fail as this event would be stolen by the accelerator. Setting IGNORE_ACCELERATORS to "Ctrl+V" allows a table widget with an editable text area to receive keyboard events instead of the button with a conflicting accelerator. Once a table loses focus, all specified accelerators are automatically re-enabled.

Note ───
Accelerators are suspended only when a table cell is in edit mode.
───

See "Disabling Button Widget Accelerators" (Chapter 3, *Widget Application Programming*) for usage details and examples.

KBRD_FOCUS_EVENTS

Set this keyword to make the base return keyboard focus events whenever the keyboard focus of the base changes. See "Widget Events Returned by Table Widgets" on page 2899 for more information.

KILL_NOTIFY

Set this keyword to a string that contains the name of a procedure to be called automatically when the specified widget dies. Each widget is allowed a single such "callback" procedure. It can be removed by setting the routine to the null string (' ').

The callback routine is called with the widget identifier as its only argument. At that point, the widget identifier can only be used with the WIDGET_CONTROL procedure to get or set the user value. All other requests that require a widget ID are disallowed for the target widget. The callback is not issued until the WIDGET_EVENT function is called.

MONTHS

Supplies a string array of 12 names to be used for the names of the months when processing explicitly formatted dates (CMOA, CMoA, and CmoA format codes) with the FORMAT keyword.

Note

You can use language catalogs to internationalize this value with strings in particular languages. For more information, see Chapter 19, "Using Language Catalogs" (*Application Programming*).

NO_COLUMN_HEADERS

Set this keyword to disable the display of the table widget's column header area. The setting for the NO_HEADERS keyword supersedes any setting for this keyword.

NO_COPY

Usually, when setting or getting widget user values, either at widget creation or using the SET_UVALUE and GET_UVALUE keywords to WIDGET_CONTROL, IDL makes a second copy of the data being transferred. Although this technique is fine for small data, it can have a significant memory cost when the data being copied is large.

If the NO_COPY keyword is set, IDL handles these operations differently. Rather than copy the source data, it takes the data away from the source and attaches it directly to the destination. This feature can be used by compound widgets to obtain

state information from a UVALUE without all the memory copying that would otherwise occur. However, it has the side effect of causing the source variable to become undefined. On a "set" operation (using the UVALUE keyword to WIDGET_TABLE or the SET_UVALUE keyword to WIDGET_CONTROL), the variable passed as value becomes undefined. On a "get" operation (GET_UVALUE keyword to WIDGET_CONTROL), the user value of the widget in question becomes undefined.

NO_HEADERS

Set this keyword to disable the display of the table widget's header area (where row and column labels are normally displayed).

NO_ROW_HEADERS

Set this keyword to disable the display of the table widget's row header area. The setting for the NO_HEADERS keyword supersedes any setting for this keyword.

NOTIFY_REALIZE

Set this keyword to a string that contains the name of a procedure to be called automatically when the specified widget is realized. This callback occurs just once (because widgets are realized only once). Each widget is allowed a single such "callback" procedure. It can be removed by setting the routine to the null string (' '). The callback routine is called with the widget ID as its only argument.

PRO_SET_VALUE

A string containing the name of a procedure to be called when the SET_VALUE keyword to the WIDGET_CONTROL procedure is called for this widget. See the description of the PRO_SET_VALUE keyword to WIDGET_CONTROL for information on using this keyword.

RESIZEABLE_COLUMNS

Set this keyword to allow the user to change the size of columns using the mouse. Note that if the NO_HEADERS keyword was set, the columns cannot be resized interactively.

RESIZEABLE_ROWS

Set this keyword to allow the user to change the size of rows using the mouse. Note that if the NO_HEADERS keyword was set, the rows cannot be resized interactively.

Under Microsoft Windows, the row size cannot be changed.

RESOURCE_NAME

A string containing an X Window System resource name to be applied to the widget. See "RESOURCE_NAME" on page 2665 for a complete discussion of this keyword.

ROW_HEIGHTS

Set this keyword equal to an array of heights for the rows of the table widget. The heights are given in any of the units as specified with the UNITS keyword. If no height is specified for a row, that row is set to the default size, which varies by platform. If ROW_HEIGHTS is set to a scalar value, all of the row heights are set to that value.

Note ───

On Microsoft Windows platforms, rows cannot have different heights. If you supply an array of values, IDL applies the last value to all rows.

───

Note ───

Row heights are limited to 0 on Motif and 1 on Windows.

───

ROW_LABELS

Set this keyword equal to an array of strings to be used as labels for the rows of the table. If no label is specified for a row, it receives the default label "*n*", where *n* is the row number. If this keyword is set to the empty string (`' '`), all row labels are set to be empty.

ROW_MAJOR

This keyword is only valid if the table data is organized as a vector of structures rather than a two-dimensional array. See the VALUE keyword for details.

Set this keyword to specify that the data should be read into the table as if each element of the vector is a structure containing one row's data. Note that the structures must all be of the same type, and must have one field for each column in the table. This is the default behavior if neither the COLUMN_MAJOR or ROW_MAJOR keyword is set.

SCR_XSIZE

Set this keyword to the desired "screen" width of the widget, in units specified by the UNITS keyword (pixels are the default). Note that the screen width of the widget *includes* the width of scroll bars, if any are present. Setting SCR_XSIZE overrides

values set for the XSIZE or X_SCROLL_SIZE keywords. See "Note on Table Sizing" on page 2883.

SCR_YSIZE

Set this keyword to the desired "screen" height of the widget, in units specified by the UNITS keyword (pixels are the default). Note that the screen height of the widget *includes* the height of scroll bars, if any are present. Setting SCR_YSIZE overrides values set for the YSIZE or Y_SCROLL_SIZE keywords. See "Note on Table Sizing" on page 2883.

SCROLL

Set this keyword to give the widget scroll bars that allow viewing portions of the widget contents that are not currently on the screen. See "Note on Table Sizing" on page 2883

SENSITIVE

Set this keyword to control the initial sensitivity state of the widget.

If SENSITIVE is zero, the widget becomes insensitive. If nonzero, it becomes sensitive. When a widget is sensitive, it has normal appearance and can receive user input. For example, a sensitive button widget can be activated by moving the mouse cursor over it and pressing a mouse button. When a widget is insensitive, it indicates the fact by changing its appearance, looking disabled, and it ignores any input.

Sensitivity can be used to control when a user is allowed to manipulate the widget. Note that some widgets do not change their appearance when they are made insensitive, but they cease generating events.

After creating the widget hierarchy, you can change the sensitivity state using the SENSITIVE keyword with the WIDGET_CONTROL procedure.

TAB_MODE

Set this keyword to one of the values shown in the table below to determine how the widget hierarchy can be navigated using the **Tab** key. The TAB_MODE setting is inherited by lower-level bases and child widgets from the parent WIDGET_BASE unless it is explicitly set on an individual widget. If the TAB_MODE value of the widget differs from that of the base, the setting on the widget will be respected when the widget has focus. For example, if a base does not support tabbing, but an individual child widget does support tabbing, this functionality will be enabled when the child widget has focus.

Note ―――

It is not possible to tab to disabled (SENSITIVE=0) or hidden (MAP=0) widgets.

―――

Valid settings are:

0	Disable navigation onto or off of the widget. This is the default unless the TAB_MODE has been set on a parent base. Child widgets automatically inherit the tab mode of the parent base as described in "Inheriting the TAB_MODE Value" (Chapter 3, *Widget Application Programming*).
1	Enable navigation onto and off of the widget.
2	Navigate only onto the widget.
3	Navigate only off of the widget.

Note ―――

In widget applications on the UNIX platform, the Motif library controls what widgets are brought into and released from focus using tabbing. The TAB_MODE keyword value is always zero, and any attempt to change it is ignored when running a widget application on the UNIX platform. Tabbing behavior may vary significantly between UNIX platforms; do not rely on a particular behavior being duplicated on all UNIX systems.

―――

When a WIDGET_TABLE widget receives focus through tabbing, the result is platform dependent:

- On Windows – table widgets can receive and lose focus through tabbing, but the focus is not clearly depicted.
- On UNIX – the Motif library controls tabbing functionality.

After creating the widget hierarchy, you can change tabbing support using the WIDGET_CONTROL procedure's TAB_MODE keyword, or query a widget's support for tabbing using the WIDGET_INFO procedure's TAB_MODE keyword.

See "Tabbing in Widget Applications" (Chapter 3, *Widget Application Programming*) for usage details and examples.

TRACKING_EVENTS

Set this keyword to cause widget tracking events to be issued for the widget whenever the mouse pointer enters or leaves the region covered by that widget. For the structure

of tracking events, see "TRACKING_EVENTS" on page 2672 in the documentation for WIDGET_BASE.

UNAME

Set this keyword to a string that can be used to identify the widget in your code. You can associate a name with each widget in a specific hierarchy, and then use that name to query the widget hierarchy and get the correct widget ID.

To query the widget hierarchy, use the WIDGET_INFO function with the FIND_BY_UNAME keyword. The UNAME should be unique to the widget hierarchy because the FIND_BY_UNAME keyword returns the ID of the first widget with the specified name.

UNITS

Set this keyword to specify the units used when *supplying* measurements or position values. Set UNITS equal to 0 (zero) to specify that all measurements are in pixels (this is the default), to 1 (one) to specify that all measurements are in inches, or to 2 (two) to specify that all measurements are in centimeters. This keyword does not change the units used in a widget event structure or in most of the fields of the geometry structure returned by WIDGET_INFO.

Note
This keyword does not affect all sizing operations. Specifically, the value of UNITS is ignored when setting the XSIZE or YSIZE keywords.

UVALUE

The "user value" to be assigned to the widget.

Each widget can contain a user-specified value of any data type and organization. This value is not used by the widget in any way, but exists entirely for the convenience of the IDL programmer. This keyword allows you to set this value when the widget is first created.

If UVALUE is not present, the widget's initial user value is undefined.

VALUE

The initial value setting of the widget. The value of a table widget is either a two-dimensional array of any data type or a vector of structures, representing the contents of the table.

If the value is specified as a two-dimensional array, all data must be of the same data type.

If the value is specified as a vector of structures, it can be displayed either in column-major or row-major format by setting either the COLUMN_MAJOR keyword or the ROW_MAJOR keyword. All of the structures must be of the same type, and must contain one field for each row (if COLUMN_MAJOR is set) or column (if ROW_MAJOR is set) in the table. (Setting ROW_MAJOR means that each structure is given its own row, and hence the number of columns should match the number of fields.) If neither keyword is set, the data is displayed in row major format. The individual structure fields can be of any data type.

Note ───

If the VALUE keyword is not specified, the data in the created table will be of type STRING.

───

If none of [XY]SIZE, SCR_[XY]SIZE, or [XY]_SCROLL_SIZE is present, the size of the table is determined by the size of the array or vector of structures specified by VALUE. See "Note on Table Sizing" on page 2883.

XOFFSET

The horizontal offset of the widget in units specified by the UNITS keyword (pixels are the default) relative to its parent. This offset is specified relative to the *upper left* corner of the parent widget.

Specifying an offset relative to a row or column major base widget does not work because those widgets enforce their own layout policies. This keyword is primarily of use relative to a plain base widget. Note that it is best to avoid using this style of widget programming.

XSIZE

The width of the widget in columns. If row labels are present, one column is automatically added to this value. See "Note on Table Sizing" on page 2883.

X_SCROLL_SIZE

The XSIZE keyword always specifies the width of a widget, in columns. When the SCROLL keyword is specified, this size is not necessarily the same as the width of the visible area. The X_SCROLL_SIZE keyword allows you to set the width of the scrolling viewport independently of the actual width of the widget. See "Note on Table Sizing" on page 2883.

Use of the X_SCROLL_SIZE keyword implies SCROLL. This means that scroll bars will be added in both the horizontal and vertical directions when X_SCROLL_SIZE is specified. Because the default size of the scrolling viewport may differ between platforms, it is best to specify Y_SCROLL_SIZE when specifying X_SCROLL_SIZE.

YOFFSET

The vertical offset of the widget in units specified by the UNITS keyword (pixels are the default) relative to its parent. This offset is specified relative to the *upper left* corner of the parent widget.

Specifying an offset relative to a row or column major base widget does not work because those widgets enforce their own layout policies. This keyword is primarily of use relative to a plain base widget. Note that it is best to avoid using this style of widget programming.

YSIZE

The height of the widget in rows. If column labels are present, one row is automatically added to this value. See "Note on Table Sizing" on page 2883.

Y_SCROLL_SIZE

The YSIZE keyword always specifies the height of a widget in rows. When the SCROLL keyword is specified, this size is not necessarily the same as the height of the visible area. The Y_SCROLL_SIZE keyword allows you to set the height of the scrolling viewport independently of the actual height of the widget. See "Note on Table Sizing" on page 2883.

Use of the Y_SCROLL_SIZE keyword implies SCROLL. This means that scroll bars will be added in both the horizontal and vertical directions when Y_SCROLL_SIZE is specified. Because the default size of the scrolling viewport may differ between platforms, it is best to specify X_SCROLL_SIZE when specifying Y_SCROLL_SIZE.

Keywords to WIDGET_CONTROL

A number of keywords to the WIDGET_CONTROL procedure affect the behavior of table widgets. In addition to those keywords that affect all widgets, the following are particularly useful: ALIGNMENT, ALL_TABLE_EVENTS, BACKGROUND_COLOR, COLUMN_LABELS, COLUMN_WIDTHS, CONTEXT_EVENTS, DELETE_COLUMNS, DELETE_ROWS, EDITABLE, FOREGROUND_COLOR, EDIT_CELL, FONT, FORMAT, GET_VALUE,

IGNORE_ACCELERATORS, INSERT_COLUMNS, INSERT_ROWS, KBRD_FOCUS_EVENTS, ROW_LABELS, ROW_HEIGHTS, SET_TABLE_SELECT, SET_TABLE_VIEW, SET_TEXT_SELECT, SET_VALUE, TABLE_BLANK, TABLE_DISJOINT_SELECTION, TABLE_XSIZE, TABLE_YSIZE, USE_TABLE_SELECT, USE_TEXT_SELECT.

Keywords to WIDGET_INFO

A number of keywords to the WIDGET_INFO function return information that applies specifically to table widgets. In addition to those keywords that apply to all widgets, the following are particularly useful: COLUMN_WIDTHS, CONTEXT_EVENTS, KBRD_FOCUS_EVENTS, ROW_HEIGHTS, STRING_SIZE, TABLE_ALL_EVENTS, TABLE_BACKGROUND_COLOR, TABLE_DISJOINT_SELECTION, TABLE_EDITABLE, TABLE_EDIT_CELL, TABLE_FONT, TABLE_FOREGROUND_COLOR, TABLE_SELECT, TABLE_VIEW, TEXT_SELECT, USE_TABLE_SELECT.

Widget Events Returned by Table Widgets

There are several variations of the table widget event structure depending on the specific event being reported. All of these structures contain the standard three fields (ID, TOP, and HANDLER). Several contain an integer TYPE field that indicates which type of structure has been returned. Others, such as keyboard focus and context menu event structures, do not. If an event structure is known to have a TYPE field, check this first before branching to further event handling code. If it is possible that the event structure is a keyboard focus or context menu type, check the STRUCTURE_NAME of the event structure first. The different table widget event structures are described below.

Insert Single Character (TYPE = 0)

This is the type of structure returned when a single character is typed into a cell of a table widget by a user.

```
{WIDGET_TABLE_CH, ID:0L, TOP:0L, HANDLER:0L, TYPE:0, OFFSET:0L,
   CH:0B, X:0L, Y:0L }
```

OFFSET is the (zero-based) insertion position that will result after the character is inserted. CH is the ASCII value of the character. X and Y give the zero-based address of the cell within the table.

Insert Multiple Characters (TYPE = 1)

This is the type of structure returned when multiple characters are pasted into a cell by the window system.

```
{WIDGET_TABLE_STR, ID:0L, TOP:0L, HANDLER:0L, TYPE:1, OFFSET:0L,
    STR:'', X:0L, Y:0L}
```

OFFSET is the (zero-based) insertion position that will result after the text is inserted. STR is the string to be inserted. X and Y give the zero-based address of the cell within the table.

Delete Text (TYPE = 2)

This is the type of structure returned when any amount of text is deleted from a cell of a table widget.

```
{WIDGET_TABLE_DEL, ID:0L, TOP:0L, HANDLER:0L, TYPE:2, OFFSET:0L,
    LENGTH:0L, X:0L, Y:0L}
```

OFFSET is the (zero-based) character position of the first character deleted. It is also the insertion position that will result when the next character is inserted. LENGTH gives the number of characters involved. X and Y give the zero-based address of the cell within the table.

Text Selection (TYPE = 3)

This is the type of structure returned when an area of text is selected (highlighted) by the user.

```
{WIDGET_TABLE_TEXT_SEL, ID:0L, TOP:0L, HANDLER:0L, TYPE:3,
    OFFSET:0L, LENGTH:0L, X:0L, Y:0L}
```

The event announces a change in the insertion point. OFFSET is the (zero-based) character position of the first character to be selected. LENGTH gives the number of characters involved. A LENGTH of zero indicates that the widget has no selection, and that the insertion position is given by OFFSET. X and Y give the zero-based address of the cell within the table.

Note

Text insertion, text deletion, or any change in the current insertion point causes any current selection to be lost. In such cases, the loss of selection is implied by the text event reporting the insert/delete/movement and a separate zero length selection event is not sent.

Cell Selection (TYPE = 4)

This is the type of structure returned when range of cells is selected (highlighted) or deselected by the user.

```
{WIDGET_TABLE_CELL_SEL, ID:0L, TOP:0L, HANDLER:0L, TYPE:4,
    SEL_LEFT:0L, SEL_TOP:0L, SEL_RIGHT:0L, SEL_BOTTOM:0L}
```

The event announces a change in the currently selected cells. The range of cells selected is given by the zero-based indices into the table specified by the SEL_LEFT, SEL_TOP, SEL_RIGHT, and SEL_BOTTOM fields.

Note ───

If the table is in disjoint selection mode, selecting an additional region will result in a new WIDGET_TABLE_CELL_SEL event that reflects only the newly-selected cells. Use WIDGET_INFO, /TABLE_SELECT to obtain the entire selected region in disjoint selection mode.

───

When cells are deselected (either by changing the selection or by clicking in the upper left corner of the table) an event is generated in which the SEL_LEFT, SEL_TOP, SEL_RIGHT, and SEL_BOTTOM fields contain the value -1. This means that two WIDGET_TABLE_CELL_SEL events are generated when an existing selection is changed to a new selection. If your code pays attention to WIDGET_TABLE_CELL_SEL events, be sure to differentiate between select and deselect events.

Note ───

If the table is in disjoint selection mode and a new cell range is selected *starting on a previously-selected cell*, the previously selected cells are deselected but a WIDGET_TABLE_CELL_DESEL event is generated for the deselection rather than a WIDGET_TABLE_CELL_SEL event. See "Cell Deselection (Disjoint Mode) (TYPE = 9)" on page 2902 for details.

───

Row Height Changed (TYPE = 6)

This is the type of structure returned when a row height is changed by the user.

```
{WIDGET_TABLE_ROW_HEIGHT, ID:0L, TOP:0L, HANDLER:0L, TYPE:6,
    ROW:0L, HEIGHT:0L}
```

The event announces that the height of the given row has been changed by the user. The ROW field contains the zero-based row number, and the HEIGHT field contains the new height.

Column Width Changed (TYPE = 7)

This is the type of structure returned when a column width is changed by the user.

```
{WIDGET_TABLE_COL_WIDTH, ID:0L, TOP:0L, HANDLER:0L, TYPE:7,
   COL:0L, WIDTH:0L}
```

The event announces that the width of the given column has been changed by the user. The COL field contains the zero-based column number, and the WIDTH field contains the new width.

Invalid Data (TYPE = 8)

This is the type of structure returned when the text entered by the user does not pass validation, and the user has finished editing the field (by hitting TAB or ENTER).

```
{WIDGET_TABLE_INVALID_ENTRY, ID:0L, TOP:0L, HANDLER:0L, TYPE:8,
   STR:'', X:0L, Y:0L}
```

When this event is generated, the cell's data is left unchanged. The invalid contents entered by the user is given as a text string in the STR field. The cell location is given by the X and Y fields.

Cell Deselection (Disjoint Mode) (TYPE = 9)

This is the type of structure returned when selected cells are de-selected by the user *and the table is in disjoint selection mode*. It is identical to the (TYPE = 4) WIDGET_TABLE_CELL_SEL event structure except for the name and type value.

This event occurs when the user holds down the control key when starting a selection and the cell used to start the selection was already selected. In contrast, if the user starts a selection with the control key down but starts on a cell that was not selected, the normal WIDGET_TABLE_CELL_SEL is generated.

```
{WIDGET_TABLE_CELL_DESEL, ID:0L, TOP:0L, HANDLER:0L, TYPE:9,
   SEL_LEFT:0L, SEL_TOP:0L, SEL_RIGHT:0L, SEL_BOTTOM:0L}
```

The range of cells selected is given by the zero-based indices into the table specified by the SEL_LEFT, SEL_TOP, SEL_RIGHT, and SEL_BOTTOM fields.

Keyboard Focus Events

Table widgets return the following event structure when the keyboard focus changes and the base was created with the KBRD_FOCUS_EVENTS keyword set:

```
{ WIDGET_KBRD_FOCUS, ID:0L, TOP:0L, HANDLER:0L, ENTER:0 }
```

ID is the widget ID of the table widget generating the event. TOP is the widget ID of the top level widget containing ID. HANDLER contains the widget ID of the widget

associated with the handler routine. The ENTER field returns 1 (one) if the table widget is gaining the keyboard focus, or 0 (zero) if the table widget is losing the keyboard focus.

Context Menu Events

A table widget created with the CONTEXT_EVENTS keyword set returns the following event structure in response to a right mouse button click:

```
{WIDGET_CONTEXT, ID:0L, TOP:0L, HANDLER:0L, X:0L, Y:0L,
    ROW:0L, COL:0L}
```

The first three fields are the standard fields found in every widget event. The X and Y fields give the device coordinates at which the event occurred, measured from the upper left corner of the table widget. The ROW and COL fields return meaningful information for table widgets and values of zero (0) for other widgets.

For table widgets, ROW and COL indicate the zero-based index of the cell that was clicked on when the context menu was initiated. The upper-left data cell has a row and column index of 0,0. Row and column headers have indices of -1. If the context-menu event takes place outside of all table cells and headers, then both ROW and COL will have values of -1.

Note
When working with table widget context menu events or keyboard focus events, it is important to notice that the event structures do not have a TYPE field, so special code is needed for the table event handler. Instead of keying off the TYPE field, use the event structure's name. See "Property Sheet Context Menu Example" on page 2859 for sample code dealing with the same issue.

Version History

5.0	Introduced
5.6	Added DISJOINT_SELECTION keyword and cell deselection (TYPE = 9) event

6.1	Added ROW and COL fields to WIDGET_CONTEXT event structure
	Added CONTEXT_EVENTS, IGNORE_ACCELERATORS, NO_COLUMN_HEADERS, NO_ROW_HEADERS, and TAB_MODE keywords
6.2	Added BACKGROUND_COLOR, EDITABLE, FONT, and FOREGROUND_COLOR keywords

See Also

WIDGET_CONTROL

WIDGET_TEXT

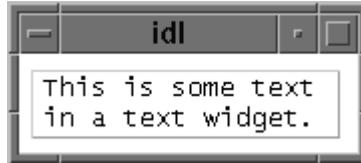
The WIDGET_TEXT function creates text widgets. Text widgets display text and optionally get textual input from the user. They can have one or more lines, and can optionally contain scroll bars to allow viewing more text than can otherwise be displayed on the screen.


Figure 25-12: A Text Widget

Syntax

Result = WIDGET_TEXT(*Parent* [, /ALL_EVENTS] [, /CONTEXT_EVENTS]
   [, /EDITABLE] [, EVENT_FUNC=*string*] [, EVENT_PRO=*string*]
   [, FONT=*string*] [, FRAME=*width*] [, FUNC_GET_VALUE=*string*]
   [, GROUP_LEADER=*widget_id*] [, IGNORE_ACCELERATORS=*value*]
   [, /KBRD_FOCUS_EVENTS] [, KILL_NOTIFY=*string*] [, /NO_COPY]
   [, /NO_NEWLINE] [, NOTIFY_REALIZE=*string*] [, PRO_SET_VALUE=*string*]
   [, RESOURCE_NAME=*string*] [, SCR_XSIZE=*width*] [, SCR_YSIZE=*height*]
   [, /SCROLL] [, /SENSITIVE] [, TAB_MODE=*value*] [, /TRACKING_EVENTS]
   [, UNAME=*string*] [, UNITS={0 | 1 | 2}] [, UVALUE=*value*] [, VALUE=*value*]
   [, /WRAP] [, XOFFSET=*value*] [, XSIZE=*value*] [, YOFFSET=*value*]
   [, YSIZE=*value*])

Return Value

The returned value of this function is the widget ID of the newly-created text widget.

Arguments

Parent

The widget ID of the parent widget for the new text widget.

Keywords

ALL_EVENTS

Set this keyword to cause the text widget to generate events whenever the user changes the contents of the text area.

Note ───

If the EDITABLE keyword is set, an insert character event (TYPE=0) is generated when the user presses the RETURN or ENTER key in the text widget, even if the ALL_EVENTS keyword is not set. See the table below for details on the interaction between ALL_EVENTS and EDITABLE.

───

Keywords		Effects	
ALL_EVENTS	**EDITABLE**	**Input changes widget contents?**	**Type of events generated.**
Not set	Not set	No	None
Not set	Set	Yes	End-of-line insertion
Set	Not set	No	All events
Set	Set	Yes	All events

Table 25-16: Effects of using the ALL_EVENTS and EDITABLE keywords

CONTEXT_EVENTS

Set this keyword to cause context menu events (or simply context events) to be issued when the user clicks the right mouse button over the widget. Set the keyword to 0 (zero) to disable such events. Context events are intended for use with context-sensitive menus (also known as pop-up or shortcut menus); pass the context event ID to the WIDGET_DISPLAYCONTEXTMENU procedure within your widget program's event handler to display the context menu.

For more on detecting and handling context menu events, see "Context-Sensitive Menus" (Chapter 3, *Widget Application Programming*).

EDITABLE

Set this keyword to allow direct user editing of the text widget contents. Normally, the text in text widgets is read-only. See ALL_EVENTS for a description of how EDITABLE interacts with the ALL_EVENTS keyword.

See "ALL_TEXT_EVENTS" on page 2710 for a description of how EDITABLE interacts with the ALL_TEXT_EVENTS keyword.

EVENT_FUNC

A string containing the name of a function to be called by the WIDGET_EVENT function when an event arrives from a widget in the widget hierarchy rooted at the newly-created widget.

EVENT_PRO

A string containing the name of a procedure to be called by the WIDGET_EVENT function when an event arrives from a widget in the widget hierarchy rooted at the newly-created widget.

FONT

The name of the font to be used by the widget. The font specified is a "device font" (an X Windows font on Motif systems; a TrueType or PostScript font on Windows systems). See "About Device Fonts" on page 5580 for details on specifying names for device fonts. If this keyword is omitted, the default font is used.

Note ———————————————————————————

On Microsoft Windows platforms, if FONT is not specified, IDL uses the system default font. Different versions of Windows use different system default fonts.

———————————————————————————————

FRAME

The value of this keyword specifies the width of a frame in units specified by the UNITS keyword (pixels are the default) to be drawn around the borders of the widget.

Note ———————————————————————————

This keyword is only a "hint" to the toolkit, and may be ignored in some instances. Under Microsoft Windows, text widgets *always* have frames.

———————————————————————————————

FUNC_GET_VALUE

A string containing the name of a function to be called when the GET_VALUE keyword to the WIDGET_CONTROL procedure is called for this widget. Using this technique allows you to change the value that should be returned for a widget. Compound widgets use this ability to define their values transparently to the user.

GROUP_LEADER

The widget ID of an existing widget that serves as "group leader" for the newly-created widget. When a group leader is killed, for any reason, all widgets in the group are also destroyed.

A given widget can be in more than one group. The WIDGET_CONTROL procedure can be used to add additional group associations to a widget. It is not possible to remove a widget from an existing group.

IGNORE_ACCELERATORS

Set this keyword to specify what WIDGET_BUTTON accelerators are to be ignored when this text widget has keyboard focus. Valid values are:

- A string or string array containing any value that is legal for WIDGET_BUTTON's ACCELERATOR keyword
- The number 1, indicating all accelerators should be ignored

Ordinarily, accelerators are processed before keyboard events reach the widget that has the keyboard focus. Consider a case where the accelerator "Ctrl+V" has been mapped to a button that allows the user to paste objects copied from one drawing area into another. In an application that also has a text widget, attempting to use **Ctrl**+**V** to paste text into the text widget would fail as this event would be stolen by the accelerator. Setting IGNORE_ACCELERATORS to "Ctrl+V" allows a text widget with an editable text area to receive keyboard events instead of the button with a conflicting accelerator. Once the text widget loses focus, all specified accelerators are automatically re-enabled.

See "Disabling Button Widget Accelerators" (Chapter 3, *Widget Application Programming*) for usage details and examples.

KBRD_FOCUS_EVENTS

Set this keyword to make the text widget return keyboard focus events whenever the keyboard focus of the widget changes. See "Widget Events Returned by Text Widgets" on page 2915 for more information.

KILL_NOTIFY

Set this keyword to a string that contains the name of a procedure to be called automatically when the specified widget dies. Each widget is allowed a single such "callback" procedure. It can be removed by setting the routine to the null string (' ').

The callback routine is called with the widget identifier as its only argument. At that point, the widget identifier can only be used with the WIDGET_CONTROL procedure to get or set the user value. All other requests that require a widget ID are disallowed for the target widget. The callback is not issued until the WIDGET_EVENT function is called.

NO_COPY

Usually, when setting or getting widget user values, either at widget creation or using the SET_UVALUE and GET_UVALUE keywords to WIDGET_CONTROL, IDL makes a second copy of the data being transferred. Although this technique is fine for small data, it can have a significant memory cost when the data being copied is large.

If the NO_COPY keyword is set, IDL handles these operations differently. Rather than copy the source data, it takes the data away from the source and attaches it directly to the destination. This feature can be used by compound widgets to obtain state information from a UVALUE without all the memory copying that would otherwise occur. However, it has the side effect of causing the source variable to become undefined. On a "set" operation (using the UVALUE keyword to WIDGET_TEXT or the SET_UVALUE keyword to WIDGET_CONTROL), the variable passed as value becomes undefined. On a "get" operation (GET_UVALUE keyword to WIDGET_CONTROL), the user value of the widget in question becomes undefined.

NO_NEWLINE

Normally, when setting the value of a multi-line text widget, newline characters are automatically appended to the end of each line of text. Set this keyword to suppress this action.

NOTIFY_REALIZE

Set this keyword to a string that contains the name of a procedure to be called automatically when the specified widget is realized. This callback occurs just once (because widgets are realized only once). Each widget is allowed a single such "callback" procedure. It can be removed by setting the routine to the null string (' '). The callback routine is called with the widget ID as its only argument.

PRO_SET_VALUE

A string containing the name of a procedure to be called when the SET_VALUE keyword to the WIDGET_CONTROL procedure is called for this widget. See the description of the PRO_SET_VALUE keyword to WIDGET_CONTROL for information on using this keyword.

RESOURCE_NAME

A string containing an X Window System resource name to be applied to the widget. See "RESOURCE_NAME" on page 2665 for a complete discussion of this keyword.

SCR_XSIZE

Set this keyword to the desired "screen" width of the widget, in units specified by the UNITS keyword (pixels are the default). In many cases, setting this keyword is the same as setting the XSIZE keyword.

SCR_YSIZE

Set this keyword to the desired "screen" height of the widget, in units specified by the UNITS keyword (pixels are the default). In many cases, setting this keyword is the same as setting the YSIZE keyword.

SCROLL

Set this keyword to give the widget scroll bars that allow viewing portions of the widget contents that are not currently on the screen.

SENSITIVE

Set this keyword to control the initial sensitivity state of the widget.

If SENSITIVE is zero, the widget becomes insensitive. If nonzero, it becomes sensitive. When a widget is sensitive, it has normal appearance and can receive user input. For example, a sensitive button widget can be activated by moving the mouse cursor over it and pressing a mouse button. When a widget is insensitive, it indicates the fact by changing its appearance, looking disabled, and it ignores any input.

Sensitivity can be used to control when a user is allowed to manipulate the widget. Note that some widgets do not change their appearance when they are made insensitive, but they cease generating events.

After creating the widget hierarchy, you can change the sensitivity state using the SENSITIVE keyword with the WIDGET_CONTROL procedure.

TAB_MODE

Set this keyword to one of the values shown in the table below to determine how the widget hierarchy can be navigated using the **Tab** key. The TAB_MODE setting is inherited by lower-level bases and child widgets from the parent WIDGET_BASE unless it is explicitly set on an individual widget. If the TAB_MODE value of the widget differs from that of the base, the setting on the widget will be respected when the widget has focus. For example, if a base does not support tabbing, but an individual child widget does support tabbing, this functionality will be enabled when the child widget has focus.

Note

It is not possible to tab to disabled (SENSITIVE=0) or hidden (MAP=0) widgets.

Valid settings are:

0	Disable navigation onto or off of the widget. This is the default unless the TAB_MODE has been set on a parent base. Child widgets automatically inherit the tab mode of the parent base as described in "Inheriting the TAB_MODE Value" (Chapter 3, *Widget Application Programming*).
1	Enable navigation onto and off of the widget.
2	Navigate only onto the widget.
3	Navigate only off of the widget.

If TAB_MODE is set equal to either 1 or 3 (that is, if the user can navigate off of the widget using the Tab key), then tab characters are not inserted into multi-line text widgets and no keypress event is generated when the Tab key is pressed. (Tab characters are never inserted into single-line text widgets.)

Note

In widget applications on the UNIX platform, the Motif library controls what widgets are brought into and released from focus using tabbing. The TAB_MODE keyword value is always zero, and any attempt to change it is ignored when running a widget application on the UNIX platform. Tabbing behavior may vary significantly between UNIX platforms; do not rely on a particular behavior being duplicated on all UNIX systems.

After creating the widget hierarchy, you can change tabbing support using the WIDGET_CONTROL procedure's TAB_MODE keyword, or query a widget's support for tabbing using the WIDGET_INFO procedure's TAB_MODE keyword.

See "Tabbing in Widget Applications" (Chapter 3, *Widget Application Programming*) for usage details and examples.

TRACKING_EVENTS

Set this keyword to cause widget tracking events to be issued for the widget whenever the mouse pointer enters or leaves the region covered by that widget. For the structure of tracking events, see "TRACKING_EVENTS" on page 2672 in the documentation for WIDGET_BASE.

UNAME

Set this keyword to a string that can be used to identify the widget in your code. You can associate a name with each widget in a specific hierarchy, and then use that name to query the widget hierarchy and get the correct widget ID.

To query the widget hierarchy, use the WIDGET_INFO function with the FIND_BY_UNAME keyword. The UNAME should be unique to the widget hierarchy because the FIND_BY_UNAME keyword returns the ID of the first widget with the specified name.

UNITS

Set this keyword to specify the units used when *supplying* measurements or position values. Set UNITS equal to 0 (zero) to specify that all measurements are in pixels (this is the default), to 1 (one) to specify that all measurements are in inches, or to 2 (two) to specify that all measurements are in centimeters. This keyword does not change the units used in a widget event structure or in most of the fields of the geometry structure returned by WIDGET_INFO.

Note ───
This keyword does not affect all sizing operations. Specifically, the value of UNITS is ignored when setting the XSIZE or YSIZE keywords to WIDGET_TEXT.
──

UVALUE

The "user value" to be assigned to the widget.

Each widget can contain a user-specified value of any data type and organization. This value is not used by the widget in any way, but exists entirely for the

convenience of the IDL programmer. This keyword allows you to set this value when the widget is first created.

If UVALUE is not present, the widget's initial user value is undefined.

VALUE

The initial value setting of the widget. The value of a text widget is the current text displayed by the widget.

VALUE can be either a string or an array of strings. Note that variables returned by the GET_VALUE keyword to WIDGET_CONTROL are always string arrays, even if a scalar string is specified in the call to WIDGET_TEXT. When setting this value using WIDGET_CONTROL, by default the old text is replaced by the new text. Specifying the APPEND keyword to WIDGET_CONTROL causes the new text to be appended to the old text.

Note ───
You can use language catalogs to internationalize this value with strings in particular languages. For more information, see Chapter 19, "Using Language Catalogs" (*Application Programming*).
───

WRAP

Set this keyword to indicate that scrolling or multi-line text widgets should automatically break lines between words to keep the text from extending past the right edge of the text display area. Note that carriage returns are *not* automatically entered when lines wrap; the value of the text widget will remain a single-element array unless you explicitly enter a carriage return.

Note ───
On Windows, the maximum line length for a multi-line text widget is 1024 characters, regardless of this keyword value.
───

XOFFSET

The horizontal offset of the widget in units specified by the UNITS keyword (pixels are the default) relative to its parent. This offset is specified relative to the *upper left* corner of the parent widget.

Specifying an offset relative to a row or column major base widget does not work because those widgets enforce their own layout policies. This keyword is primarily of use relative to a plain base widget. Note that it is best to avoid using this style of widget programming.

XSIZE

The width of the widget in characters. Note that the physical width of the text widget depends on both the value of XSIZE and on the size of the font used. The default value of XSIZE varies according to your windowing system. On Windows, the default size is roughly 20 characters. On Motif, the default size depends on the width of the text widget.

YOFFSET

The vertical offset of the widget in units specified by the UNITS keyword (pixels are the default) relative to its parent. This offset is specified relative to the *upper left* corner of the parent widget.

Specifying an offset relative to a row or column major base widget does not work because those widgets enforce their own layout policies. This keyword is primarily of use relative to a plain base widget. Note that it is best to avoid using this style of widget programming.

YSIZE

The height of the widget in text lines. Note that the physical height of the text widget depends on both the value of YSIZE and on the size of the font used. The default value of YSIZE is one line.

Keywords to WIDGET_CONTROL

A number of keywords to the WIDGET_CONTROL procedure affect the behavior of text widgets. In addition to those keywords that affect all widgets, the following are particularly useful: ALL_TEXT_EVENTS, APPEND, CONTEXT_EVENTS, EDITABLE, GET_VALUE, KBRD_FOCUS_EVENTS, IGNORE_ACCELERATORS, INPUT_FOCUS, NO_NEWLINE, SET_TEXT_SELECT, SET_TEXT_TOP_LINE, SET_VALUE, USE_TEXT_SELECT.

Keywords to WIDGET_INFO

A number of keywords to the WIDGET_INFO function return information that applies specifically to text widgets. In addition to those keywords that apply to all widgets, the following are particularly useful: CONTEXT_EVENTS, KBRD_FOCUS_EVENTS, STRING_SIZE, TEXT_ALL_EVENTS, TEXT_EDITABLE, TEXT_NUMBER, TEXT_OFFSET_TO_XY, TEXT_SELECT, TEXT_TOP_LINE, TEXT_XY_TO_OFFSET.

Widget Events Returned by Text Widgets

There are several variations of the text widget event structure depending on the specific event being reported. All of these structures contain the standard three fields (ID, TOP, and HANDLER) as well as an integer TYPE field that indicates which type of structure has been returned. Programs should always check the type field before referencing fields that are not present in all text event structures. The different text widget event structures are described below.

Insert Single Character (TYPE = 0)

This is the type of structure returned when a single character is typed or pasted into a text widget by a user.

```
{ WIDGET_TEXT_CH, ID:0L, TOP:0L, HANDLER:0L, TYPE:0, OFFSET:0L,
  CH:0B }
```

OFFSET is the (zero-based) insertion position that will result after the character is inserted. CH is the ASCII value of the character.

Insert Multiple Characters (TYPE = 1)

This is the type of structure returned when multiple characters are pasted into a text widget by the window system.

```
{ WIDGET_TEXT_STR, ID:0L, TOP:0L, HANDLER:0L, TYPE:1, OFFSET:0L,
  STR:'' }
```

OFFSET is the (zero-based) insertion position that will result after the text is inserted. STR is the string to be inserted.

Delete Text (TYPE = 2)

This is the type of structure returned when any amount of text is deleted from a text widget.

```
{ WIDGET_TEXT_DEL, ID:0L, TOP:0L, HANDLER:0L, TYPE:2, OFFSET:0L,
  LENGTH:0L }
```

OFFSET is the (zero-based) character position of the first character to be deleted. It is also the insertion position that will result when the characters have been deleted. LENGTH gives the number of characters involved. A LENGTH of zero indicates that no characters were deleted.

Selection (TYPE = 3)

This is the type of structure returned when an area of text is selected (highlighted) by the user.

```
{ WIDGET_TEXT_SEL, ID:0L, TOP:0L, HANDLER:0L, TYPE:3, OFFSET:0L,
  LENGTH:0L }
```

The event announces a change in the insertion point. OFFSET is the (zero-based) character position of the first character to be selected. LENGTH gives the number of characters involved. A LENGTH of zero indicates that no characters are selected, and the new insertion position is given by OFFSET.

Note that text insertion, text deletion, or any change in the current insertion point causes any current selection to be lost. In such cases, the loss of selection is implied by the text event reporting the insert/delete/movement and a separate zero length selection event is *not* sent.

Keyboard Focus Events

Text widgets return the following event structure when the keyboard focus changes and the widget was created with the KBRD_FOCUS_EVENTS keyword set:

```
{ WIDGET_KBRD_FOCUS, ID:0L, TOP:0L, HANDLER:0L, ENTER:0 }
```

The first three fields are the standard fields found in every widget event. The ENTER field returns 1 (one) if the text widget is gaining the keyboard focus, or 0 (zero) if the text widget is losing the keyboard focus.

Context Menu Events

A text widget created with the CONTEXT_EVENTS keyword set returns the following event structure in response to a right mouse button click:

```
{WIDGET_CONTEXT, ID:0L, TOP:0L, HANDLER:0L, X:0L, Y:0L,
  ROW:0L, COL:0L}
```

The first three fields are the standard fields found in every widget event. The X and Y fields give the device coordinates at which the event occurred, measured from the upper left corner of the text widget. The ROW and COL fields return meaningful information for table widgets and values of zero (0) for other widgets.

Version History

Pre-4.0	Introduced
6.1	Added IGNORE_ACCELERATORS and TAB_MODE keywords
	Added ROW and COL fields to WIDGET_CONTEXT event structure

See Also

CW_FIELD, XDISPLAYFILE

WIDGET_TREE

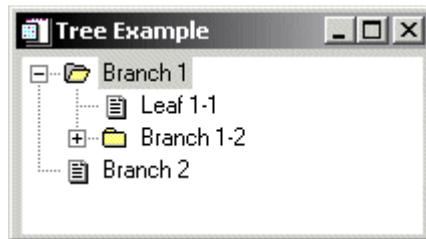
The WIDGET_TREE function is used to create and populate a tree widget. The tree widget presents a hierarchical view that can be used to organize a wide variety of data structures and information. The WIDGET_TREE function performs two separate tasks: creating the tree widget and populating the tree widget with *nodes* (branches and leaves).Branches on the tree can be expanded or collapsed by the user, displaying different portions of the structure.


Figure 25-13: A Tree Widget

For a more detailed discussion of the tree widget, along with examples, see "Using Tree Widgets" (Chapter 9, *Widget Application Programming*).

Syntax

Result = WIDGET_TREE(*Parent* [, /ALIGN_BOTTOM | , /ALIGN_CENTER | , /ALIGN_LEFT | , /ALIGN_RIGHT | , /ALIGN_TOP] [, BITMAP=*array*] [, /CONTEXT_EVENTS] [, DRAG_NOTIFY=*string*] [, /DRAGGABLE] [, /DROP_EVENTS] [, EVENT_FUNC=*string*] [, EVENT_PRO=*string*] [, /EXPANDED] [, /FOLDER] [, FUNC_GET_VALUE=*string*] [, GROUP_LEADER=*widget_id*] [, INDEX=*value*] [, KILL_NOTIFY=*string*] [, /MASK] [, /MULTIPLE] [, /NO_COPY] [, NOTIFY_REALIZE=*string*] [, PRO_SET_VALUE=*string*] [, SCR_XSIZE=*width*] [, SCR_YSIZE=*height*] [, /SENSITIVE] [, TAB_MODE=*value*] [, /TRACKING_EVENTS] [, UNAME=*string*] [, UNITS={0 | 1 | 2}] [, UVALUE=*value*] [, VALUE=*string*] [, XOFFSET=*value*] [, XSIZE=*value*] [, YOFFSET=*value*] [, YSIZE=*value*])

Return Value

The returned value of this function is the widget ID of the newly-created tree widget.

Arguments

Parent

The widget ID of the parent for the new tree widget. *Parent* can be either a base widget or a tree widget.

- If *Parent* is a base widget, WIDGET_TREE will create a tree widget that contains no other tree widgets. This type of tree widget is referred to as a *root node*.

- If *Parent* is a tree widget, WIDGET_TREE will create a new tree widget (called a *node*) in the specified tree widget.

    Note

    With the exception of the first tree widget created (the *root node*, whose *Parent* is a base widget), a tree widget (or *node*) must be created with the FOLDER keyword in order to serve as the *Parent* for other tree widgets.

Keywords

ALIGN_BOTTOM

Set this keyword to align the new widget with the bottom of its parent base. To take effect, the parent must be a ROW base.

ALIGN_CENTER

Set this keyword to align the new widget with the center of its parent base. To take effect, the parent must be a ROW or COLUMN base. In ROW bases, the new widget will be vertically centered. In COLUMN bases, the new widget will be horizontally centered.

ALIGN_LEFT

Set this keyword to align the new widget with the left side of its parent base. To take effect, the parent must be a COLUMN base.

ALIGN_RIGHT

Set this keyword to align the new widget with the right side of its parent base. To take effect, the parent must be a COLUMN base.

ALIGN_TOP

Set this keyword to align the new widget with the top of its parent base. To take effect, the parent must be a ROW base.

BITMAP

Set this keyword equal to a 16x16x3 array representing an RGB image that will be displayed next to the node in the tree widget. Set this keyword equal to 0 (zero) to use a default system bitmap.

CONTEXT_EVENTS

Set this keyword to cause context menu events (or simply context events) to be issued when the user clicks the right mouse button over the widget. Set the keyword to 0 (zero) to disable such events. Context events are intended for use with context-sensitive menus (also known as pop-up or shortcut menus); pass the context event ID to the WIDGET_DISPLAYCONTEXTMENU within your widget program's event handler to display the context menu.

For more on detecting and handling context menu events, see "Context-Sensitive Menus" (Chapter 3, *Widget Application Programming*).

This keyword is only valid if the *Parent* of the tree widget is a base widget.

DRAG_NOTIFY

Set this keyword equal to a string containing the name of a function that will be automatically called as the end-user drags over the widget. Alternatively, set this keyword equal to the string:

- <inherit> (including the < and > characters) to have the widget inherit an ancestor's callback
- <default> (including the < and > characters) to use the system default callback.

The callback function's return value informs the widget system "if and where" the drag source can be dropped onto the widget. The widget system then uses this information to provide the end-user with visual feedback about the legality and location of a drop. A secondary ability of the return value is to turn on the plus (+) indicator, which can be handy to distinguish between copies and moves. The

following table details the meanings of the valid return values, which can be OR-ed together:

Value	Meaning
0	User cannot drop
1	User can drop above
2	User can drop onto
4	User can drop below
8	Show the plus indicator

When a DRAG_NOTIFY callback is not explicitly specified, it is inherited from the parent tree widget. If none of the widget's ancestor tree nodes have a DRAG_NOTIFY callback or the callback is set to the string <default> then the widget system uses a default that is suitable for copying and moving nodes. The default return values are detailed in the following table and further text:

Tree Widget Type	Expanded	Return Value	Meaning
Root		2	Onto
Folder	No	7	Above, Onto, Below
	Yes	3	Above, Onto
Leaf		5	Above, Below

The default callback also compares the dragged nodes with the destination. If the destination matches or is a descendant of any of the dragged nodes then the default callback returns 0 (zero). Finally, if the destination will not generate drop events (DROP_EVENTS = 0) then the default callback will return 0.

Creating a Drag Notification Callback Routine

The drag notification callback routine has the following signature:

```
FUNCTION Callback_Function_Name, Destination, Source, $
   Modifiers, Default
```

where

- *Callback_Function_Name* is the name of the callback function. This value is specified as the value of the DRAG_NOTIFY keyword.

- *Destination* is the widget ID of the widget over which the item is dragged.

- *Source* is the widget ID of the item being dragged (this must currently be a tree widget node).

- *Modifiers* indicates the state of the modifier keys. The widget system generates them by OR-ing the following values together for the depressed keys:

Bitmask	Modifier Key
1	Shift
2	Control
4	Caps Lock
8	Alt

Table 25-17: Bitmask and Corresponding Key

Note

For UNIX, the **Alt** key is the currently mapped MOD1 key.

- *Default* is the value that the default callback would have returned. Although it is merely a suggested value, it can be used to screen out common situations that the default callback catches. A common usage is to have the callback return its value after modifying it to show the + indicator.

Specifying a drag notification callback does not enable drop events; you must set the DROP_EVENTS keyword to specify that drop events should be generated. For additional information on dragging and dropping and tree widgets, see "Using Tree Widgets" (Chapter 9, *Widget Application Programming*).

Warning
Custom drag notifications can pose potential dangers, please see the section "Responding to Drag Notifications" in "Using Tree Widgets" (Chapter 9, *Widget Application Programming*) to learn more about these potential dangers.

DRAGGABLE

Use this keyword to specify whether or not the widget can be dragged. A value of 1 (one) makes the widget a valid drag item and a value of 0 (zero) makes the widget not draggable. If this keyword is not specified or is set to -1 then the widget inherits its draggability from the nearest ancestor to set a value.

Note
Although the root node of a tree widget cannot be dragged nor inherit a value, the value can be set so that child nodes can inherit the value. The default value is 0.

DROP_EVENTS

Use this keyword to specify whether or not the widget will generate drop events. See "Widget Events Returned by Tree Widgets" on page 2931 for an explanation of the event structure.

A value of 1 (one) causes the widget to generate drop events and a value of 0 (zero) causes the widget to not generate drop events. If this keyword is not specified or is set to -1, the widget inherits this setting from the nearest ancestor that sets a value of zero or one.

Tree root nodes can generate drop events, but cannot inherit. Their default value is 0. Specifying a DRAG_NOTIFY callback does not affect a widget's ability to generate drop events.

EVENT_FUNC

A string containing the name of a function to be called by the WIDGET_EVENT function when an event arrives from a widget in the widget hierarchy rooted at the newly-created widget.

EVENT_PRO

A string containing the name of a procedure to be called by the WIDGET_EVENT function when an event arrives from a widget in the widget hierarchy rooted at the newly-created widget.

EXPANDED

If the tree node being created is a *folder* (specified by the FOLDER keyword), set this keyword to cause the folder to be initially displayed expanded, showing all of its immediate child entries. By default, folders are initially displayed collapsed.

This keyword is only valid if the *Parent* of the tree widget is another tree widget.

FOLDER

Set this keyword to cause the tree node being created to act as a *folder* (that is, as a branch of the tree rather than a leaf).

Note

With the exception of the root node (the tree widget whose *Parent* widget is a base widget), only tree nodes that have the FOLDER keyword set can act as the parent for other tree widgets.

This keyword is only valid if the *Parent* of the tree widget is another tree widget.

FUNC_GET_VALUE

A string containing the name of a function to be called when the GET_VALUE keyword to the WIDGET_CONTROL procedure is called for this widget. Using this technique allows you to change the value that should be returned for a widget. Compound widgets use this ability to define their values transparently to the user.

GROUP_LEADER

The widget ID of an existing widget that serves as group leader for the newly-created widget. When a group leader is killed, for any reason, all widgets in the group are also destroyed.

A given widget can be in more than one group. The WIDGET_CONTROL procedure can be used to add additional group associations to a widget. You cannot remove a widget from an existing group.

INDEX

Use this keyword to specify the position of the new tree widget node relative to its siblings. The supplied value is the zero-based index of the new node. A value of -1 and values greater than or equal to the current number of children result in the new node being positioned as the last child. This is the default behavior when INDEX is not specified.

KILL_NOTIFY

Set this keyword to a string that contains the name of a procedure to be called automatically when the specified widget dies. Each widget is allowed a single such "callback" procedure. It can be removed by setting the routine to the null string (' ').

The callback routine is called with the widget identifier as its only argument. At that point, the widget identifier can only be used with the WIDGET_CONTROL procedure to get or set the user value. All other requests that require a widget ID are disallowed for the target widget. The callback is not issued until the WIDGET_EVENT function is called.

MASK

Set this keyword in conjunction with BITMAP to create a tree node icon that has transparency. When set to 1 (one), all bitmap pixels that match the lower left pixel are treated as transparent, allowing the widget's background color to show through. The default value is 0 (zero). The MASK keyword is ignored if not used with the BITMAP keyword.

MULTIPLE

Set this keyword to enable multiple selection operations in the tree widget. If enabled, multiple elements in the tree widget can be selected at one time by holding down the **Control** or **Shift** key while clicking the left mouse button.

This keyword is only valid if the *Parent* of the tree widget is a base widget.

NO_COPY

Usually, when setting or getting widget user values, either at widget creation or using the SET_UVALUE and GET_UVALUE keywords to WIDGET_CONTROL, IDL makes a second copy of the data being transferred. Although this technique works well for small data, it can have a significant memory cost when the data being copied is large.

If the NO_COPY keyword is set, IDL handles these operations differently. Rather than copying the source data, it takes the data away from the source and attaches it directly to the destination. This feature can be used by compound widgets to obtain state information from a UVALUE without all the memory copying that would otherwise occur. However, it has the side effect of causing the source variable to become undefined. Upon a set operation (using the UVALUE keyword to WIDGET_TREE or the SET_UVALUE keyword to WIDGET_CONTROL), the variable passed as value becomes undefined. Upon a get operation (GET_UVALUE

keyword to WIDGET_CONTROL), the user value of the widget in question becomes undefined.

NOTIFY_REALIZE

Set this keyword to a string containing the name of a procedure to be called automatically when the specified widget is realized. This callback occurs just once (because widgets are realized only once). Each widget is allowed a single such callback procedure. This callback procedure can be removed by setting the routine name to the null string (`''`). The callback routine is called with the widget ID as its only argument.

PRO_SET_VALUE

A string containing the name of a procedure to be called when the SET_VALUE keyword to the WIDGET_CONTROL procedure is called for this widget. See the description of the PRO_SET_VALUE keyword to WIDGET_CONTROL for information on using this keyword.

SCR_XSIZE

Set this keyword to the desired screen width of the widget, in units specified by the UNITS keyword (pixels are the default). In many cases, setting this keyword is the same as setting the XSIZE keyword.

SCR_YSIZE

Set this keyword to the desired screen height of the widget, in units specified by the UNITS keyword (pixels are the default). In many cases, setting this keyword is the same as setting the YSIZE keyword.

SENSITIVE

Set this keyword to control the initial sensitivity state of the widget.

If SENSITIVE is zero, the widget becomes insensitive. If nonzero, it becomes sensitive. When a widget is sensitive, it has normal appearance and can receive user input. For example, a sensitive button widget can be activated by moving the mouse cursor over it and pressing a mouse button. When a widget is insensitive, it indicates the fact by changing its appearance, looking disabled, and it ignores any input.

Sensitivity can be used to control when a user is allowed to manipulate the widget.

Note —————————————————————————————————————

Some widgets do not change their appearance when they are made insensitive, but they cease generating events.

———

After creating the widget hierarchy, you can change the sensitivity state using the SENSITIVE keyword with the WIDGET_CONTROL.

This keyword is only valid if the *Parent* of the tree widget is a base widget.

TAB_MODE

Set this keyword to one of the values shown in the table below to determine how the widget hierarchy can be navigated using the **Tab** key. The TAB_MODE setting is inherited by lower-level bases and child widgets from the parent WIDGET_BASE unless it is explicitly set on an individual widget. If the TAB_MODE value of the widget differs from that of the base, the setting on the widget will be respected when the widget has focus. For example, if a base does not support tabbing, but an individual child widget does support tabbing, this functionality will be enabled when the child widget has focus.

Note —————————————————————————————————————

It is not possible to tab to disabled (SENSITIVE=0) or hidden (MAP=0) widgets.

———

Valid settings are:

0	Disable navigation onto or off of the widget. This is the default unless the TAB_MODE has been set on a parent base. Child widgets automatically inherit the tab mode of the parent base as described in "Inheriting the TAB_MODE Value" (Chapter 3, *Widget Application Programming*).
1	Enable navigation onto and off of the widget.
2	Navigate only onto the widget.
3	Navigate only off of the widget.

Note ───

In widget applications on the UNIX platform, the Motif library controls what widgets are brought into and released from focus using tabbing. The TAB_MODE keyword value is always zero, and any attempt to change it is ignored when running a widget application on the UNIX platform. Tabbing behavior may vary significantly between UNIX platforms; do not rely on a particular behavior being duplicated on all UNIX systems.

───

Once a WIDGET_TREE widget receives focus through tabbing, additional navigation capabilities are platform dependent:

- • On Windows – tree widgets can receive and lose focus through tabbing.

- • On UNIX - the Motif library controls tabbing functionality.

Use the arrow keys to select higher or lower level nodes once a tree widget has focus. The TAB_MODE specified for the root tree widget defines the tabbing support for all of its nodes.

After creating the widget hierarchy, you can change tabbing support using the WIDGET_CONTROL procedure's TAB_MODE keyword, or query a widget's support for tabbing using the WIDGET_INFO procedure's TAB_MODE keyword.

See "Tabbing in Widget Applications" (Chapter 3, *Widget Application Programming*) for usage details and examples.

TRACKING_EVENTS

Set this keyword to cause widget tracking events to be issued for the widget whenever the mouse pointer enters or leaves the region covered by that widget. For the structure of tracking events, see "TRACKING_EVENTS" on page 2672 in the documentation for WIDGET_BASE.

This keyword is only valid if the *Parent* of the tree widget is a base widget.

UNAME

Set this keyword to a string that can be used to identify the widget in your code. You can associate a name with each widget in a specific hierarchy, and then use that name to query the widget hierarchy and get the correct widget ID.

To query the widget hierarchy, use the WIDGET_INFO with the FIND_BY_UNAME keyword. The UNAME should be unique to the widget hierarchy because the FIND_BY_UNAME keyword returns the ID of the first widget with the specified name.

UNITS

Set this keyword to specify the units used when *supplying* measurements or position values. Set UNITS equal to 0 (zero) to specify that all measurements are in pixels (this is the default), to 1 (one) to specify that all measurements are in inches, or to 2 (two) to specify that all measurements are in centimeters. This keyword does not change the units used in a widget event structure or in most of the fields of the geometry structure returned by WIDGET_INFO.

UVALUE

The user value to be assigned to the widget.

Each widget can contain a user-specified value of any data type and organization. This value is not used by the widget in any way, but exists entirely for the convenience of the IDL programmer. This keyword allows you to set this value when the widget is first created.

If UVALUE is not present, the widget's initial user value is undefined.

VALUE

Set this keyword equal to a string containing the text that will be displayed next to the branch or leaf of the tree. If the widget value is not explicitly set, either in the call to WIDGET_TREE or using the SET_VALUE keyword to WIDGET_CONTROL, the default value of "Tree" is provided.

Note

You can use language catalogs to internationalize this value with strings in particular languages. For more information, see Chapter 19, "Using Language Catalogs" (*Application Programming*).

This keyword is only valid if the *Parent* of the tree widget is another tree widget.

XOFFSET

The horizontal offset of the widget in units specified by the UNITS keyword (pixels are the default) relative to its parent. This offset is specified relative to the *upper left* corner of the parent widget.

Specifying an offset relative to a row or column major base widget does not work because those widgets enforce their own layout policies. This keyword is primarily of use relative to a plain base widget. You should avoid using this style of widget programming.

XSIZE

The width of the widget in units specified by the UNITS keyword (pixels are the default). Most widgets attempt to size themselves to fit the situation. However, if the desired effect is not produced, use this keyword to override it. This keyword is only a hint to the toolkit and may be ignored in some situations.

YOFFSET

The vertical offset of the widget in units specified by the UNITS keyword (pixels are the default) relative to its parent. This offset is specified relative to the *upper left* corner of the parent widget.

Specifying an offset relative to a row or column major base widget does not work because those widgets enforce their own layout policies. This keyword is primarily of use relative to a plain base widget. You should avoid using this style of widget programming.

YSIZE

The height of the widget in units specified by the UNITS keyword (pixels are the default). Most widgets attempt to size themselves to fit the situation. However, if the desired effect is not produced, use this keyword to override it. This keyword is only a hint to the toolkit and may be ignored in some situations.

Keywords to WIDGET_CONTROL

A number of keywords to the WIDGET_CONTROL affect the behavior of tree widgets. In addition to those keywords that affect all widgets, the following keywords are particularly useful: CONTEXT_EVENTS, SET_DRAG_NOTIFY, SET_DRAGGABLE, SET_DROP_EVENTS, SET_MASK, SET_TREE_BITMAP, SET_TREE_EXPANDED, SET_TREE_INDEX, SET_TREE_SELECT, SET_TREE_VISIBLE.

Keywords to WIDGET_INFO

Some keywords to the WIDGET_INFO return information that applies specifically to tree widgets. In addition to those keywords that apply to all widgets, the following keywords are particularly useful: CONTEXT_EVENTS, DRAG_NOTIFY, DRAGGABLE, DROP_EVENTS, MASK, TREE_BITMAP, TREE_DRAG_SELECT, TREE_EXPANDED, TREE_FOLDER, TREE_INDEX, TREE_ROOT, TREE_SELECT.

Widget Events Returned by Tree Widgets

Tree widgets generate events when tree elements are selected or deselected, expanded or collapsed. They can also be configured to generate events when the user clicks the right-hand mouse button over the widget. Several variations of the tree widget event structure depend upon the specific event being reported. All of these structures contain the standard three fields (ID, TOP, and HANDLER) as well as an integer TYPE field that indicates which type of structure has been returned. Programs should always check the type field before referencing fields that are not present in all tree event structures. The different tree widget event structures are described below.

Drop Events

This structure is returned when a drop event occurs:

```
{WIDGET_DROP, ID:0L, TOP:0L, HANDLER:0L, DRAG_ID:0L,
            POSITION:0L, X:0L, Y:0L, MODIFIERS:0L}
```

To receive this event the widget must accept drop events (see DROP_EVENTS for details). The ID field reports the destination widget and the DRAG_ID reports the source. The POSITION field indicates where the user dropped. The possible values are similar to those of the DRAG_NOTIFY callback, but only one of the three possible positions is returned:

Position	Meaning
1	The user is inserting above the destination widget
2	The user is dropping onto the destination widget
4	The user is inserting below the destination widget

The X and Y fields give the pixel coordinates of the drop event relative to the upper left corner of the destination's root tree. Finally, the modifiers field reports which keys were pressed at the time the drop event was generated. The MODIFIERS field is a bitmask of four values:

Bitmask	Modifier Key
1	Shift

Bitmask	Modifier Key
2	Control
4	Caps Lock
8	Alt

Select Events (TYPE = 0)

This structure is returned when the currently selected node in the tree widget changes:

```
{WIDGET_TREE_SEL, ID:0L, TOP:0L, HANDLER:0L, TYPE:0, CLICKS:0L}
```

The CLICKS field indicates the number of mouse-button clicks that occurred when the event took place. This field contains 1 (one) when the item is selected, or 2 when the user double-clicks on the item.

Expand Events (TYPE = 1)

This structure is returned when a folder in the tree widget expands or collapses:

```
{WIDGET_TREE_EXPAND, ID:0L, TOP:0L, HANDLER:0L, TYPE:1, EXPAND:0L}
```

The EXPAND field contains 1 (one) if the folder expanded or 0 (zero) if the folder collapsed.

Context Menu Events

A tree widget created with the CONTEXT_EVENTS keyword set returns the following event structure in response to a right mouse button click:

```
{WIDGET_CONTEXT, ID:0L, TOP:0L, HANDLER:0L, X:0L, Y:0L,
   ROW:0L, COL:0L}
```

The first three fields are the standard fields found in every widget event. The X and Y fields give the device coordinates at which the event occurred, measured from the upper left corner of the tree widget. The ROW and COL fields return meaningful information for table widgets and values of zero (0) for other widgets.

Version History

5.6	Introduced
6.1	Added TAB_MODE keyword
	Added ROW and COL fields to WIDGET_CONTEXT event structure
6.3	Added DRAG_NOTIFY, DRAGGABLE, DROP_EVENTS, INDEX, and MASK keywords
	Added Drop event
	Deprecated TOP keyword

"Using Tree Widgets" (Chapter 9, *Widget Application Programming*)

WIDGET_TREE_MOVE

The WIDGET_TREE_MOVE procedure copies and moves tree widget nodes from one tree to another or within the same tree.

WIDGET_TREE_MOVE has two parameters that specify the widget IDs of the nodes to copy and the folder (or root) in which to move (or copy) them. Each of the nodes in the first parameter will be moved (or copied). The default behavior is to duplicate the entire hierarchy rooted at each folder.

These properties are automatically inherited by all newly created nodes:

- FOLDER, EXPANDED
- BITMAP, MASK
- DRAGGABLE, DRAG_NOTIFY, DROP_EVENTS
- VALUE, UVALUE, UNAME
- EVENT_FUNC, EVENT_PRO

Move operations handle any data associated with UVALUEs by taking data away from the source and attaching it to the destination node, without making a temporary copy. This allows for an efficient transfer of large data during a move. The callback function can be used to adjust the values based on the parent's values.

The following keywords represent properties that are not transferred:

- FUNC_GET_VALUE
- PRO_SET_VALUE
- NOTIFY_REALIZE
- KILL_NOTIFY

If these keywords must be set, the new node could be destroyed and recreated in the procedure's callback (with the same parent and index). An alternative is to write a fully custom version of WIDGET_TREE_MOVE.

For a more detailed discussion of the tree widget, along with examples, see "Using Tree Widgets" (Chapter 9, *Widget Application Programming*).

This routine is written in the IDL language. Its source code can be found in the file `widget_treet_move.pro` in the `lib` subdirectory of the IDL distribution.

Syntax

WIDGET_TREE_MOVE, wMoveNodes, wDestFolder
  [, CALLBACK_FUNC=*name*] [, /COPY] [, INDEX=*value*] [, /SELECT]
  [, /UPDATE] [, USERDATA=*value*]

Arguments

wMoveNodes

The widget IDs of the nodes that are to be moved or copied. The value can be a scalar
or a vector. By default, moving or copying a folder node duplicates the entire
hierarchy rooted at that folder. If a node in the list is a descendant of another node in
the list, then it will be copied twice: once as a member of the list and once as a
member of the ancestor's descendants. For drag and drop implementations, this
situation can be avoided by using the TREE_DRAG_SELECT keyword to
WIDGET_INFO, which removes "duplicate" nodes from a tree's current selection.

wDestFolder

The widget ID of the destination folder or tree root. The value must be a scalar. If the
INDEX keyword is not specified then the moved/copied nodes will be placed at the
end of the destination folder's current list of children.

Keywords

CALLBACK_FUNC

Set this keyword to the name of a function to customize node moving and/or copying.
The callback is invoked immediately after each and every node is duplicated. The
callback must be defined as:

```
FUNCTION Name, wOriginalNode, wNewNode, USERDATA=value
```

The value from the USERDATA keyword is passed to the callback function. During
move operations, the original node's UVALUE is efficiently transferred to the new
node. Copy operations duplicate all UVALUEs.

The callback's return value should typically be 1 (one). This causes the new node's
children to be duplicated. Entire hierarchies can be duplicated in this manner. This is
the default behavior when a callback is not specified. However, if a "flat copy" is
desired, then 0 (zero) should be returned. Return values of 0 stop further duplication

of the new node so that its children are not recursively copied. Mixing return values of 0 and 1 is possible and can produce more sophisticated moves/copies.

COPY

Set this keyword to make a copy of the widgets in wMoveNodes. If not set then the original wMoveNodes are destroyed.

INDEX

Set this keyword to an integer to specify the relative position at which to insert wMoveNodes into the wDestFolder. The position is zero-based and a value of -1 (the default value) inserts at the tail.

SELECT

Set this keyword to select the newly moved/copied nodes.

UPDATE

Set this keyword to allow the source and destination trees to be visually updated during the operation. The default is to turn off updates to prevent flickering.

USERDATA

Set this keyword to a value that is passed to the CALLBACK_FUNC function.

Examples

For examples using WIDGET_TREE_MOVE, see "Using Tree Widgets" (Chapter 9, *Widget Application Programming*).

Version History

6.3	Introduced

See Also

WIDGET_TREE, WIDGET_CONTROL, WIDGET_INFO

WINDOW

The WINDOW procedure creates a window for the display of graphics or text. It is only necessary to use WINDOW if more than one simultaneous window or a special size window is desired because a window is created automatically the first time any display procedure attempts to access the window system. The newly-created window becomes the current window, and the system variable !D.WINDOW is set to that window's window index. (See the description of the WSET procedure for a discussion of the current IDL window.)

The behavior of WINDOW varies slightly depending on the window system in effect. See the discussion of IDL graphics devices in Appendix A, "IDL Direct Graphics Devices" for additional details.

Note —————————————————————————————————————

For more information on window placement and multi-monitor configurations, see "Multi-Monitor Configurations" (*Using IDL*).

Syntax

WINDOW [, *Window_Index*] [, COLORS=*value*] [, /FREE] [, /PIXMAP]
   [, RETAIN={0 | 1 | 2}] [, TITLE=*string*] [, XPOS=*value*] [, YPOS=*value*]
   [, XSIZE=*pixels*] [, YSIZE=*pixels*]

Arguments

Window_Index

The window index for the newly-created window. A window index is an integer value between 0 and 31 that is used to refer to the window. If this parameter is omitted, window index 0 is used. If the value of *Window_Index* specifies an existing window, the existing window is deleted and a new one is created. If you need to create more than 32 windows, use the FREE keyword described below.

Keywords

COLORS

Note
This keyword is ignored under Microsoft Windows.

The maximum number of color table indices to be used when drawing. This keyword has an effect only if supplied when the first window is created. If COLORS is not present when the first window is created, all or most of the available color indices are allocated depending upon the window system in use.

To use monochrome windows on a color display in X Windows, use COLORS = 2 when creating the first window. One color table is maintained for all windows. A negative value for COLORS specifies that all but the given number of colors from the shared color table should be allocated.

Although this keyword is ignored under Microsoft Windows, we could use the following code to use a monochrome window on all platforms:

```
WINDOW, COLORS=2 ; ignored on Windows
white=!D.N_COLORS-1
PLOT, FINDGEN(20), COLOR=white
```

FREE

Set this keyword to create a window using the smallest unused window index above 32. If this keyword is present, the *Window_Index* argument can be omitted. The default position of the new window is opposite that of the current window. Using the FREE keyword allows the creation of a large number of windows. The system variable !D.WINDOW is set to the index of the newly-created window.

PIXMAP

Set the PIXMAP keyword to specify that the window being created is actually an invisible portion of the display memory called a pixmap.

Note
On Microsoft Windows systems, the number of pixmap windows that can be created is limited by system GDI resources. The number of pixmap windows IDL can create is constrained by the total amount of GDI memory, the amount of GDI memory used by other applications, and the size of the IDL pixmap windows.

RETAIN

Set this keyword to 0, 1, or 2 to specify how backing store should be handled for the window:

- 0 = no backing store
- 1 = requests that the server or window system provide backing store
- 2 = specifies that IDL provide backing store directly

See "Backing Store" on page 5409 for details.

TITLE

A scalar string that contains the window's label. If not specified, the window is given a label of the form "IDL *n*", where *n* is the index number of the window. For example, to create a window with the label "IDL Graphics", enter:

```
WINDOW, TITLE='IDL Graphics'
```

XPOS

The X position of the window, specified in device coordinates. On Motif platforms, XPOS specifies the X position of the *lower* left corner and is measured from the lower left corner of the screen. On Windows platforms, XPOS specifies the X position of the *upper* left corner and is measured from the upper left corner of the screen. That is, specifying

```
WINDOW, XPOS = 0, YPOS = 0
```

will create a window in the lower left corner on Motif machines and in the upper left corner on Windows machines.

If no position is specified, the position of the window is determined from the value of Window Index using the following rules:

- Window 0 is placed in the upper right hand corner.
- Even numbered windows are placed on the top half of the screen and odd numbered windows are placed on the bottom half.
- Windows 0,1,4,5,8, and 9 are placed on the right side of the screen and windows 2,3,6, and 7 are placed on the left.

Note ───

The order of precedence (highest to lowest) for positioning windows is: XPOS/YPOS keywords to WINDOW, the value of the IDL_GR_WIN_LAYOUT preference (Microsoft Windows only), and the optional index argument to WINDOW. Also realize that setting LOCATION is only a request to the Window manager and may not always be honored due to system peculiarities.

───

YPOS

The Y position of the window, specified in device coordinates. See the description of XPOS for details.

XSIZE

The width of the window in pixels.

YSIZE

The height of the window in pixels.

Examples

Create graphics window number 0 with a size of 400 by 400 pixels and a title that reads "Square Window" by entering:

```
WINDOW, 0, XSIZE=400, YSIZE=400, TITLE='Square Window'
```

WRITE_BMP

The WRITE_BMP procedure writes an image and its color table vectors to a Microsoft Windows Version 3 device independent bitmap file (.BMP).

WRITE_BMP does not handle 1-bit-deep images or compressed images, and is not fast for 4-bit images. The algorithm works best on images where the number of bytes in each scan-line is evenly divisible by 4.

This routine is written in the IDL language. Its source code can be found in the file write_bmp.pro in the lib subdirectory of the IDL distribution.

Syntax

WRITE_BMP, *Filename*, *Image*[, *R*, *G*, *B*] [, /FOUR_BIT] [, IHDR=*structure*]
    [, HEADER_DEFINE=*h*{define *h* before call}] [, /RGB]

Arguments

Filename

A scalar string containing the full pathname of the bitmap file to write.

Image

The array to write into the new bitmap file. The array should be scaled into a range of bytes for 8- and 24-bit deep images. Scale to 0-15 for 4-bit deep images. If the image has 3 dimensions and the first dimension is 3, a 24-bit deep bitmap file is created.

Note ───

For 24-bit images, color interleaving is blue, green, red: *Image*[0, *i*, *j*] = blue, *Image*[1, *i*, *j*] = green, *Image*[2, *i*, *j*] = red.

───

R, G, B

Color tables. If omitted, the colors loaded in the COLORS common block are used.

Keywords

FOUR_BIT

Set this keyword to write as a 4-bit device independent bitmap. If omitted or zero, an 8-bit deep bitmap is written.

IHDR

Set this keyword to a BITMAPINFOHEADER structure containing the file header fields that are not obtained from the image itself. The fields in this structure that can be set are: `bi{XY}PelsPerMeter`, `biClrUsed`, and `biClrImportant`.

HEADER_DEFINE

If this keyword is set, WRITE_BMP returns an empty BITMAPINFOHEADER structure, containing zeros. No other actions are performed. This structure may be then modified with the pertinent fields and passed in via the IHDR keyword parameter. See the Microsoft Windows Programmers Reference Guide for a description of each field in the structure.

Note: this parameter must be defined *before* the call. For example:

```
H = 0
WRITE_BMP, HEADER_DEFINE = H
```

RGB

Set this keyword to reverse the color interleaving for 24-bit images to red, green, blue: *Image*[0, *i*, *j*] = red, *Image*[1, *i*, *j*] = green, *Image*[2, *i*, *j*] = blue. By default, 24-bit images are written with color interleaving of blue, green, red.

Examples

The following command captures the contents of the current IDL graphics window and saves it to a Microsoft Windows Bitmap file with the name `test.bmp`. Note that this works only on a PseudoColor (8-bit) display:

```
WRITE_BMP, 'test.bmp', TVRD()
```

The following commands scale an image to 0-15, and then write a 4-bit BMP file, using a grayscale color table:

```
; Create a ramp from 0 to 255:
r = BYTSCL(INDGEN(16))

WRITE_BMP, 'test.bmp', BYTSCL(Image, MAX=15), r, r, r, /FOUR
```

Version History

Pre-4.0	Introduced

READ_BMP, QUERY_* Routines

WRITE_GIF

The WRITE_GIF procedure writes an image and its color table vectors to a Graphics Interchange Format (GIF) file.

WRITE_GIF produces 8-bit non-interlaced GIF files.

Note

The GIF format uses compression technologies that may be subject to license restrictions. If you receive a warning when attempting to use this routine, contact ITT Visual Information Solutions for information about licensing options.

This routine is written in the IDL language. Its source code can be found in the file write_gif.pro in the lib subdirectory of the IDL distribution.

Syntax

WRITE_GIF, *Filename*, *Image*[, *R*, *G*, *B*] [, BACKGROUND_COLOR=*value*]
    [, /CLOSE] [, DELAY_TIME=*integer*] [, DISPOSAL_METHOD=*integer*]
    [, /MULTIPLE] [, REPEAT_COUNT=*integer*] [, TRANSPARENT=*value*]
    [, USER_INPUT=*value*]

Arguments

Filename

A scalar string containing the full pathname of the GIF file to write.

Image

The array to write into the new GIF file.

R, G, B

The Red, Green, and Blue color vectors to be written with to the GIF file. If *R*, *G*, *B* values are not provided, the last color table established using LOADCT is saved, and the table is padded to 256 entries. If no color table has been established, WRITE_GIF calls LOADCT to load the grayscale entry (table 0). For GIF files with multiple images, when writing the second and subsequent images, if R, G, B are present then they will be written into the local color map for the current image.

Keywords

BACKGROUND_COLOR

Set this keyword to a byte value giving the index within the global color table to be designated as the background. The default value is 0.

CLOSE

Set this keyword to close any open files. The CLOSE keyword is only useful if a file containing multiple images (as specified by the MULTIPLE keyword) is being written. If the CLOSE keyword is specified, nothing is written to the file, and all other parameters are ignored.

DELAY_TIME

For multi-image GIF files, set this keyword to an integer giving the delay in hundredths (1/100) of a second after the decoder displays the current image. This keyword can be set to a different value for each image within the file.

DISPOSAL_METHOD

For multi-image GIF files, set this keyword to an integer giving the method that the decoder should use for disposing the current image after display. Possible values are:

0	No disposal specified. The decoder is not required to take any action.
1	Do not dispose. The graphic is to be left in place.
2	Restore to background color. The area used by the graphic must be restored to the background color.
3	Restore to previous. The decoder is required to restore the area overwritten by the graphic with what was there prior to rendering the graphic.

This keyword can be set to a different value for each image within the file.

MULTIPLE

Set this keyword to write multiple images to a file. Each call to WRITE_GIF writes the next image, with the file remaining open between calls. The *Filename* argument is ignored after the first call, *but must be supplied*. All images written to a GIF file must be the same size.

REPEAT_COUNT

For multi-image GIF files, set this keyword to an integer giving the number of times that the decoder should repeat the animation. Set this keyword to zero to repeat an infinite number of times. This keyword is written using the Netscape application extension and may not be recognized by some decoders.

TRANSPARENT

Set this keyword to a byte value giving the index within the color table to be designated as the transparent color. If this keyword is not present or is set to -1 then no transparent index is written. This keyword can be set to a different value for each image within the file.

USER_INPUT

Set this keyword to a flag indicating whether the decoder should require user input before continuing processing. The nature of the user input is determined by the application (carriage return, mouse button click, etc.). When DELAY_TIME is used and USER_INPUT is set, the decoder should continue processing when user input is received or when the delay time expires, whichever occurs first. This keyword may be set to a different value for each image within the file.

Example

The following command captures the contents of the current IDL graphics window and saves it to a GIF file named test.gif. Note that this works only on a PseudoColor (8-bit) display:

```
WRITE_GIF, 'test.gif', TVRD()
```

Version History

Pre-4.0	Introduced
6.4	Added BACKGROUND_COLOR, DELAY_TIME, DISPOSAL_METHOD, REPEAT_COUNT, TRANSPARENT, and USER_INPUT keywords

READ_GIF, WRITE_JPEG, QUERY_* Routines

WRITE_IMAGE

The WRITE_IMAGE procedure writes an image and its color table vectors, if any, to a file of a specified type. WRITE_IMAGE can write most types of image files supported by IDL.

Syntax

WRITE_IMAGE, *Filename*, *Format*, *Data* [, *Red*, *Green*, *Blue*] [, /APPEND]

Arguments

Filename

A scalar string containing the name of the file to write.

Format

A scalar string containing the name of the file format to write. The following are the supported formats:

- BMP
- GIF
- JPEG
- PNG
- PPM
- SRF
- TIFF

Data

An IDL variable containing the image data to write to the file.

Red

An optional vector containing the red channel of the color table if a colortable exists.

Green

An optional vector containing the green channel of the color table if a colortable exists.

Blue

An optional vector containing the blue channel of the color table if a colortable exists.

Keywords

APPEND

Set this keyword to force the image to be appended to the file instead of overwriting the file. APPEND may be used with image formats that supports multiple images per file and is ignored for formats that support only a single image per file.

Version History

5.3	Introduced

WRITE_JPEG

The WRITE_JPEG procedure writes compressed images to files. JPEG (Joint Photographic Experts Group) is a standardized compression method for full-color and gray-scale images. This procedure is based in part on the work of the Independent JPEG Group.

As the Independent JPEG Group states, JPEG is intended for real-world scenes (such as digitized photographs). Line art, such as drawings or IDL plots, and other unrealistic images are not its strong suit. Note also that JPEG is a lossy compression scheme. That is, the output image is *not* identical to the input image. Hence you cannot use JPEG if you must have identical output bits. On typical images of real-world scenes, however, very good compression levels can be obtained with no visible change, and amazingly high compression levels are possible if you can tolerate a low-quality image. You can trade off output image quality against compressed file size by adjusting a compression parameter. Files are encoded in JFIF, the JPEG File Interchange Format; however, such files are usually simply called JPEG files.

If you need to store images in a format that uses lossless compression, consider using the WRITE_PNG procedure. This procedure writes a Portable Network Graphics (PNG) file using lossless compression with either 8 or 16 data bits per channel. To store 8-bit or 24-bit images without compression, consider using WRITE_BMP (for Microsoft Bitmap format files) or WRITE_TIFF (to write Tagged Image Format Files).

For a short technical introduction to the JPEG compression algorithm, see: Wallace, Gregory K. "The JPEG Still Picture Compression Standard", *Communications of the ACM*, April 1991 (vol. 34, no. 4), pp. 30-44.

Note ———————————————————————————————

All JPEG files consist of byte data. Input data is converted to bytes before being written to a JPEG file.

———————————————————————————————————————

Syntax

WRITE_JPEG [, *Filename*], *Image* [, /ORDER] [, /PROGRESSIVE]
   [, QUALITY=*value*{0 to 100}] [, TRUE={1 | 2 | 3}] [, UNIT=*lun*]

Arguments

Filename

A string containing the name of file to be written in JFIF (JPEG) format. If this parameter is not present, the UNIT keyword must be specified.

Image

A byte array of either two or three dimensions, containing the image to be written. Grayscale images must have two dimensions. TrueColor images must have three dimensions with the index of the dimension that contains the color specified with the TRUE keyword.

Keywords

ORDER

JPEG/JFIF images are normally written in top-to-bottom order. If the image array is in the standard IDL order (i.e., from bottom-to-top) set ORDER to 0, its default value. If the image array is in top-to-bottom order, ORDER must be set to 1.

PROGRESSIVE

Set this keyword to write the image as a series of scans of increasing quality. When used with a slow communications link, a decoder can generate a low-quality image very quickly, and then improve its quality as more scans are received.

Warning —————————————————————————————

Not all JPEG applications can handle progressive JPEG files, and it is up the JPEG reader to progressively display the JPEG image. For example, IDL's READ_JPEG routine ignores the progressive readout request and reads the entire image in at the first reading.

QUALITY

This keyword specifies the quality index, in the range of 0 (terrible) to 100 (excellent) for the JPEG file. The default value is 75, which corresponds to very good quality. Lower values of QUALITY produce higher compression ratios and smaller files.

TRUE

This keyword specifies the index, starting at 1, of the dimension over which the color is interleaved. For example, for an image that is pixel interleaved and has dimensions of (3, *m*, *n*), set TRUE to 1. Specify 2 for row-interleaved images (*m*, 3, *n*); and 3 for band-interleaved images (*m*, *n*, 3). If TRUE is not set, the image is assumed to have no interleaving (it is not a TrueColor image).

UNIT

This keyword designates the logical unit number of an already open file to receive the output, allowing multiple JFIF images per file or the embedding of JFIF images in other data files. If this keyword is used, *Filename* should not be specified.

Note

When opening a file intended for use with the UNIT keyword, if the filename does not end in .jpg, or .jpeg, you must specify the STDIO keyword to OPEN in order for the file to be compatible with WRITE_JPEG.

Examples

Write the image contained in the array A, using JPEG compression with a quality index of 25. The image is stored in bottom-to-top order:

```
image = DIST(100)
WRITE_JPEG, 'test1.jpg', image, QUALITY=25
```

Write a TrueColor image to a JPEG file. The image is contained in the band-interleaved array A with dimensions (*m*, *n*, 3). Assume it is stored in top-to-bottom order:

```
WRITE_JPEG, 'test2.jpg', image, TRUE=3, /ORDER
```

Also see the example in "Converting Indexed Images to RGB Images" on page 2557.

READ_JPEG, WRITE_GIF, QUERY_* Routines

WRITE_JPEG2000

The WRITE_JPEG2000 procedure writes image data into a JPEG2000 file. This procedure is a wrapper around the IDLffJPEG2000 object interface that presents JPEG2000 image writing in a familiar way to users of the WRITE_* image routines. However this procedure is not as efficient as the object interface and the object interface should be used whenever possible. See "IDLffJPEG2000" (Chapter 30, *IDL Reference Guide*) for information about the object interface.

Syntax

WRITE_JPEG2000, *Filename*, *Image* [, *Red*, *Green*, *Blue*] [, N_LAYERS=*value*] [, N_LEVELS=*value*] [, /ORDER] [, /REVERSIBLE]

Arguments

Filename

A scalar string containing the full path and filename of the JPEG2000 file to write. If the file suffix is .jp2 or .jpx (case insensitive), the file is written using the JP2 file format. Otherwise the file is written as a raw JPEG2000 code stream.

Image

A byte or integer array of either two or three dimensions, containing the image to be written. Single channel images must have dimensions of [*Width*, *Height*]. Multi-channel images must have dimensions of [*nComponents*, *Width*, *Height*], where *nComponents* is the number of components present in the image.

Red, Green, Blue

For single-channel images, *Red*, *Green*, and *Blue* should contain the red, green, and blue color vectors to be stored within the JPEG2000 palette. For multi-channel images, these arguments are ignored.

Keywords

N_LAYERS

Set this keyword to a positive integer specifying the number of quality layers. Each layer contains the information required to represent the image at a higher quality, given the information from all the previous layers. A larger number of layers takes

longer to encode and produces a larger file, but provides more flexibility when decoding. The default is 1. If N_LAYERS is greater than1, the layers will be assigned roughly logarithmically-spaced bit rates, with the last layer containing all of the compressed bits.

N_LEVELS

Set this keyword to an integer specifying the number of wavelet decomposition levels, or stages, in the range of 0...15. A value of zero indicates that no wavelet transform will be used. Higher values will typically give better compression. If this keyword is omitted, then the default value of 5 is used. If the file is in JP2 format, and a *Red*, *Green*, *Blue* palette is present, then the default is N_LEVELS=0.

ORDER

JPEG2000 images are assumed to be stored in top-to-bottom order, while IDL usually assumes images are in bottom-to-top order. By default (ORDER = 0), WRITE_JPEG2000 will automatically flip the input arrays to match JPEG2000's top-to-bottom order. Setting ORDER to a nonzero value will save the image directly to the JPEG2000 file without doing the vertical flip.

REVERSIBLE

Set this keyword to specify that reversible (lossless) compression should be used. The default is to use irreversible (lossy) compression. If the file is in JP2 format, and a Red, Green, Blue palette is present, then the default is REVERSIBLE=1.

Example

For an example, see READ_JPEG2000.

Version History

6.1	Introduced

See Also

QUERY_JPEG2000, READ_JPEG2000

WRITE_NRIF

The WRITE_NRIF procedure writes an image and its color table vectors to an NCAR Raster Interchange Format (NRIF) rasterfile.

WRITE_NRIF only writes 8- or 24-bit deep rasterfiles of types "Indexed Color" (8-bit) and "Direct Color integrated" (24-bit). The color map is included only for 8-bit files.

See the document "NCAR Raster Interchange Format and TAGS Raster Reference Manual," available from the Scientific Computing Division, National Center for Atmospheric Research, Boulder, CO, 80307-3000, for information on the structure of NRIF files.

This routine is written in the IDL language. Its source code can be found in the file `write_nrif.pro` in the `lib` subdirectory of the IDL distribution.

Syntax

WRITE_NRIF, *File*, *Image* [, *R*, *G*, *B*]

Arguments

File

A scalar string containing the full path name of the NRIF file to write.

Image

The byte array to be written to the NRIF file. If *Image* has the dimensions (*n,m*), an 8-bit NRIF file with color tables is created. If *Image* has the dimensions (3,*n,m*), a 24-bit NRIF file is created, where each byte triple represents the red, green, and blue intensities at (*n,m*) on a scale from 0 to 255. The NRIF image will be rendered from bottom to top, in accordance with IDL standards.

R, G, B

The Red, Green, and Blue color vectors to be used as a color table with 8-bit images. If color vectors are supplied, they are included in the output (8-bit images only). If *R*, *G*, *B* values are not provided, the last color table established using LOADCT is included. If no color table has been established, WRITE_NRIF calls LOADCT to load the grayscale entry (table 0).

Note ——————————————————————————————————

WRITE_NRIF does not recognize color vectors loaded directly using TVLCT, so if a custom color table is desired and it is not convenient to use XPALETTE, include the R, G, and B vectors that were used to create the color table.

——

Version History

Pre-4.0	Introduced

WRITE_PICT

The WRITE_PICT procedure writes an image and its color table vectors to a PICT (version 2) format image file. The PICT format is used by Apple Macintosh computers.

Note: WRITE_PICT only works with 8-bit displays

This routine is written in the IDL language. Its source code can be found in the file `write_pict.pro` in the `lib` subdirectory of the IDL distribution.

Syntax

WRITE_PICT, *Filename* [, *Image*, *R*, *G*, *B*]

Arguments

Filename

A scalar string containing the full pathname of the PICT file to write.

Image

The byte array to be written to the PICT file. If *Image* is omitted, the entire current graphics window is read into an array and written to the PICT file.

R, G, B

The Red, Green, and Blue color vectors to be written to the PICT file. If *R*, *G*, *B* values are not provided, the last color table established using LOADCT is included. If no color table has been established, WRITE_PICT calls LOADCT to load the grayscale entry (table 0).

Examples

Create a pseudo screen dump from the current window. Note that this works only on a PseudoColor (8-bit) display:

```
WRITE_PICT, 'test.pict', TVRD()
```

Version History

Pre-4.0	Introduced

See Also

READ_PICT, QUERY_* Routines

WRITE_PNG

The WRITE_PNG procedure writes a 2-D or 3-D IDL variable into a Portable Network Graphics (PNG) file. The data in the file is stored using lossless compression with either 8 or 16 data bits per channel, based on the input IDL variable type. 3-D IDL variables must have the number of channels as their leading dimension (pixel interleaved). For BYTE format 2-D IDL variables, an optional palette may be stored in the image file along with a list of pixel values which are to be considered transparent by a reading program.

Note ——————————————————————————

IDL supports version 1.2.7 of the PNG Library.

——————————————————————————————————

Syntax

WRITE_PNG, *Filename*, *Image*[, *R*, *G*, *B*] [, /ORDER] [, /VERBOSE]
   [, TRANSPARENT=*array*]

Arguments

Filename

A scalar string containing the full pathname of the PNG file to write.

Image

The array to write into the new PNG file. If *Image* is one of the integer data types, it is converted to type unsigned integer (UINT) and written out at 16 data bits per channel. All other data types are converted to bytes and written out at 8-bits per channel.

Note ——————————————————————————

If *Image* is two-dimensional (single-channel) and *R*, *G*, and *B* are provided, all input data types (including integer) are converted to bytes and written out as 8-bit data.

——————————————————————————————————

R, G, B

For single-channel images, *R*, *G*, and *B* should contain the red, green, and blue color vectors, respectively. For multi-channel images, these arguments are ignored.

Keywords

ORDER

Set this keyword to indicate that the rows of the image should be written from bottom to top. The rows are written from top to bottom by default. ORDER provides compatibility with PNG files written using versions of IDL prior to IDL 5.4, which wrote PNG files from bottom to top.

VERBOSE

Produces additional diagnostic output during the write.

TRANSPARENT

Set this keyword to an array of pixel index values which are to be treated as "transparent" for the purposes of image display. This keyword is valid only if *Image* is a single-channel (color indexed) image and the R, G, B palette is provided.

Examples

Create an RGBA (16-bits/channel) and a Color Indexed (8-bits/channel) image with a palette.

```
rgbdata = UINDGEN(4,320,240)
cidata = BYTSCL(DIST(256))
red = INDGEN(256)
green = INDGEN(256)
blue = INDGEN(256)
WRITE_PNG,'rgb_image.png',rgbdata
WRITE_PNG,'ci_image.png',cidata,red,green,blue

; Query and Read the data:
names = ['rgb_image.png','ci_image.png','unknown.png']
FOR i=0,N_ELEMENTS(names)-1 DO BEGIN
   ok = QUERY_PNG(names[i],s)
   IF (ok) THEN BEGIN
      HELP,s,/STRUCTURE
      IF (s.HAS_PALETTE) THEN BEGIN
         img = READ_PNG(names[i],rpal,gpal,bpal)
         HELP,img,rpal,gpal,bpal
      ENDIF ELSE BEGIN
         img = READ_PNG(names[i])
         HELP,img
      ENDELSE
   ENDIF ELSE BEGIN
```

```
        PRINT,names[i],' is not a PNG file'
      ENDELSE
   ENDFOR
```

Version History

5.2	Introduced

READ_PNG, QUERY_* Routines

WRITE_PPM

The WRITE_PPM procedure writes an image to a PPM (TrueColor) or PGM (gray scale) file. This routine is written in the IDL language. Its source code can be found in the file write_ppm.pro in the lib subdirectory of the IDL distribution.

Note ───

WRITE_PPM only writes 8-bit deep PGM/PPM files of the standard type. Images should be ordered so that the first row is the top row.

PPM/PGM format is supported by the PBMPLUS toolkit for converting various image formats to and from portable formats, and by the Netpbm package.

──

Syntax

WRITE_PPM, *Filename*, *Image* [, /ASCII]

Arguments

Filename

A scalar string specifying the full pathname of the PPM or PGM file to write.

Image

The 2D (gray scale) or 3D (TrueColor) array to be written to a file.

Keywords

ASCII

Set this keyword to force WRITE_PPM to use formatted ASCII input/output to write the image data. The default is to use the far more efficient binary input/output (RAWBITS) format.

Examples

```
image = DIST(100)
WRITE_PPM, 'file.ppm', image
```

Version History

4.0	Introduced

READ_PPM, QUERY_* Routines

WRITE_SPR

The WRITE_SPR procedure writes a row-indexed sparse array structure to a specified file. Row-indexed sparse arrays are created using the SPRSIN function.

Syntax

WRITE_SPR, *AS*, *Filename*

Arguments

AS

A row-indexed sparse array created by SPRSIN.

Filename

The name of the file that will contain AS.

Keywords

None.

Examples

```
; Create an array:
A = [[3.,0., 1., 0., 0.],$
     [0.,4., 0., 0., 0.],$
     [0.,7., 5., 9., 0.],$
     [0.,0., 0., 0., 2.],$
     [0.,0., 0., 6., 5.]]

; Convert it to sparse storage format:
A = SPRSIN(A)

; Store it in the file sprs.as:
WRITE_SPR, A, 'sprs.as'
```

Version History

Pre-4.0	Introduced

See Also

FULSTR, LINBCG, SPRSAB, SPRSAX, SPRSIN, READ_SPR

WRITE_SRF

The WRITE_SRF procedure writes an image and its color table vectors to a Sun Raster File (SRF).

WRITE_SRF only writes 32-, 24-, and 8-bit-deep rasterfiles of type RT_STANDARD. Use the UNIX command `rasfilter8to1` to convert these files to 1-bit deep files. See the file `/usr/include/rasterfile.h` for the structure of Sun rasterfiles.

This routine is written in the IDL language. Its source code can be found in the file `write_srf.pro` in the `lib` subdirectory of the IDL distribution.

Syntax

WRITE_SRF, *Filename* [, *Image*, *R*, *G*, *B*] [, /ORDER] [, /WRITE_32]

Arguments

Filename

A scalar string containing the full pathname of the SRF to write.

Image

The array to be written to the SRF. If *Image* has dimensions (3,*n*,*m*), a 24-bit SRF is written. If *Image* is omitted, the entire current graphics window is read into an array and written to the SRF file. *Image* should be of byte type, and in top to bottom scan line order.

R, G, B

The Red, Green, and Blue color vectors to be written to the file. If *R*, *G*, *B* values are not provided, the last color table established using LOADCT is included. If no color table has been established, WRITE_SRF calls LOADCT to load the grayscale entry (table 0).

Keywords

ORDER

Set this keyword to write the image from the top down instead of from the bottom up. This setting is only necessary when writing a file from the current IDL graphics window; it is ignored when writing a file from a data array passed as a parameter.

WRITE_32

Set this keyword to write a 32-bit file. If the input image is a TrueColor image, dimensioned (3, *n, m*), it is normally written as a 24-bit raster file.

Examples

Create a pseudo screen dump from the current window:

```
WRITE_SRF, 'test.srf', TVRD()
```

Version History

WRITE_SYLK

The WRITE_SYLK function writes the contents of an IDL variable to a SYLK (Symbolic Link) format spreadsheet data file.

Note ———

This routine writes only numeric and string SYLK data. It cannot handle spreadsheet and cell formatting information (cell width, text justification, font type, date, time, monetary notations, etc.). A given SYLK data file cannot be appended with data blocks through subsequent calls.

——

This routine is written in the IDL language. Its source code can be found in the file write_sylk.pro in the lib subdirectory of the IDL distribution.

Syntax

Result = WRITE_SYLK(*File*, *Data* [, STARTCOL=*column*] [, STARTROW=*row*])

Return Value

The function returns TRUE if the write operation was successful.

Arguments

File

A scalar string specifying the full path name of the SYLK file to write.

Data

A scalar, vector, or 2D array to be written to *File*.

Keywords

STARTCOL

Set this keyword to the first column of spreadsheet cells to write. If not specified, the write operation begins with the first column found in the file (column 0).

STARTROW

Set this keyword to the first row of spreadsheet cells to write. If not specified, the write operation begins with the first row of cells found in the file (row 0).

Examples

Suppose you wish to write the contents of a 2 by 2 floating-point array, data, to a SYLK data file called "bar.slk" such that the matrix would appear with it's upper left data at the cell in the 10th row and the 20th column. Use the following command:

```
status = WRITE_SYLK('bar.slk', data, STARTROW = 9, STARTCOL = 19)
```

The IDL variable status will contain the value 1 if the operation was successful.

Version History

4.0	Introduced

READ_SYLK

WRITE_TIFF

The WRITE_TIFF procedure can write TIFF files with one or more channels, where each channel can contain 1, 4, 8, 16, or 32-bit integer pixels, or floating-point values.

Syntax

WRITE_TIFF, *Filename [, Image]* [, /APPEND]
    [, BITS_PER_SAMPLE={1 | 4 | 8}] [, RED, GREEN, BLUE=*value*] [, /CMYK]
    [, COMPRESSION={0 | 1 | 2 | 3}] [, DESCRIPTION=*string*]
    [, DOCUMENT_NAME=*string*] [, DOT_RANGE=*intarray*]
    [, GEOTIFF=*structure*] [, /LONG | , /SHORT | , /FLOAT]
    [, ICC_PROFILE=*bytearray*] [, ORIENTATION=*value*] [, PHOTOSHOP=*array*]
    [, PLANARCONFIG={1 | 2}] [, UNITS={1 | 2 | 3}] [, /VERBOSE]
    [, XPOSITION=*units*] [, XRESOL=*pixels/inch*] [, YPOSITION=*units*]
    [, YRESOL=*pixels/inch*]

Arguments

Filename

A scalar string containing the full pathname of the TIFF to write.

Image

The array to be written to the TIFF. If *Image* has dimensions (k,n,m), a k-channel TIFF is written. *Image* should be in top to bottom scan line order. By default, this array is converted to byte format before being written (see the LONG, SHORT and FLOAT keywords below). Note that many TIFF readers can read only one- or three-channel images.

Note ——
The Image argument is ignored if PLANARCONFIG is set to 2 and the RED, GREEN, and BLUE keywords have been set to 2D arrays.
——

Note ——
Grayscale TIFF images are written out with the PhotometricInterpretation tag set to BlackIsZero, implying that values of 0 should correspond to black. If you want values of 0 to correspond to white, you should invert your pixel values before calling WRITE_TIFF.
——

Keywords

APPEND

Set this keyword to specify that the image should be added to the existing file, creating a multi-image TIFF file.

BITS_PER_SAMPLE

Set this keyword to either 1, 4, or 8 to create a grayscale image file with the specified number of bits per pixel. For 1-bit (bi-level) images, an output pixel is assigned the value 1 (one) if the corresponding input pixel is nonzero. For 4-bit grayscale images, the input pixel values *must* be in the range 0 through 15, or the image will be garbled. The default is BITS_PER_SAMPLE=8. This keyword is ignored if an RGB image or color palette is present, or if one of the FLOAT, LONG, or SHORT keywords is set.

CMYK

Set this keyword to indicate that *Image* contains a 4-channel image, where the channels represent colors in the CMYK color-separated format. This corresponds to setting PhotometricInterpretation = 5 in the resulting TIFF file, which allows TIFF readers to interpret the image as CMYK. The *Image* argument can either be (4, *Columns*, *Rows*) or (*Columns*, *Rows*, 4) depending upon the PLANARCONFIG keyword.

Note
If Image has 4 channels but the CMYK keyword is not set, then the image is written as a standard multi-channel image, with PhotometricInterpretation = 2.

COMPRESSION

Set this keyword to select the type of compression to be used:

0	None (default)
1	LZW
2	PackBits
3	JPEG (ITIFF files)

Note ———

For COMPRESSION=3 (JPEG), all images are assumed to be in top-to-bottom order, and the ORIENTATION keyword should not be specified. If your input image is not in top-to-bottom order, you should use REVERSE(*image*, 2) to flip the order before calling WRITE_TIFF.

———

DESCRIPTION

Set this keyword to a scalar string containing the value of the ImageDescription tag to be stored in the TIFF file. If this keyword is not provided then the ImageDescription tag is set to "IDL TIFF file".

DOCUMENT_NAME

Set this keyword to a scalar string containing the value of the DocumentName tag to be stored in the TIFF file. If this keyword is not provided then the DocumentName tag is set to the filename.

DOT_RANGE

Set this keyword to a two-element integer array containing the TIFF DotRange tag value. If this keyword is not provided then the DotRange tag is not stored. The DotRange tag is typically only present in CMYK TIFF files. DOT_RANGE[0] gives the image value that corresponds to a 0% dot, while DOT_RANGE[1] gives the image value that corresponds to a 100% dot.

FLOAT

Set this keyword to write the pixel components as floating-point entities (the default is 8-bit).

GEOTIFF

Set this keyword to an anonymous structure containing one field for each of the GeoTIFF tags and keys to be written into the file. The GeoTIFF structure is formed using fields named from the following table.

Anonymous Structure Field Name	IDLDatatype
TAGS:	
"MODELPIXELSCALETAG"	DOUBLE[3]
"MODELTRANSFORMATIONTAG"	DOUBLE[4,4]

"VERTICALUNITSGEOKEY"	INT

Table 25-18: GEOTIFF Structures (Continued)

Note

If a GeoTIFF key appears multiple times in a file, only the value for the first instance of the key is returned.

ICC_PROFILE

Set this keyword to a byte array containing the ICC_PROFILE tag, as returned by the READ_TIFF routine.

Note

The ICC_PROFILE tag is an opaque byte array. It is assumed that the tag will be read from an existing file, and written out to a new file without modification.

LONG

Set this keyword to write the pixel components as unsigned 32-bit entities (the default is 8-bit).

ORIENTATION

Set this keyword to an integer value to specify the orientation of the TIFF image. The default is ORIENTATION=1.

Note

For COMPRESSION=3 (JPEG), all images are assumed to be in top-to-bottom order, and this keyword should not be specified.

Possible values are:

0	Column 0 represents the left-hand side, and row 0 represents the bottom (same as 4)
1	Column 0 represents the left-hand side, and row 0 represents the top.
2	Column 0 represents the right-hand side, and row 0 represents the top.
3	Column 0 represents the right-hand side, and row 0 represents the bottom.
4	Column 0 represents the left-hand side, and row 0 represents the bottom (same as 0)
5	Column 0 represents the top, and row 0 represents the left-hand side.
6	Column 0 represents the top, and row 0 represents the right-hand side.
7	Column 0 represents the bottom, and row 0 represents the right-hand side.
8	Column 0 represents the bottom, and row 0 represents the left-hand side.

Warning

Not all TIFF readers honor the value of the ORIENTATION field. IDL writes the value into the file, but some readers are known to ignore this value. In such cases, we recommend that you convert the image to top-to-bottom order with the REVERSE function and then set ORIENTATION to 1. If your image is a True Color three-channel image, which is pixel- or line-interleaved, then set the REVERSE call's optional 'Subscript_Index' argument to 3. If your image is band-interleaved or is a one-channel image, set that argument to 2.

Note

Setting the ORIENTATION keyword does not alter the way the image data is stored. The raw data is not rotated prior to being written to disk.

PHOTOSHOP

Set this keyword to a byte array containing the TIFF PHOTOSHOP tag value, as returned by the READ_TIFF routine.

Note

The PHOTOSHOP tag is an opaque byte array. It is assumed that the tag will be read from an existing file, and written out to a new file without modification.

PLANARCONFIG

This keyword determines the order in which a multi-channel image is stored and written. It has no effect with a single-channel image. Set this keyword to 2 to if the Image parameter is interleaved by "plane", or band, and its dimensions are (*Columns*, *Rows*, *Channels*). The default value is 1, indicating that multi-channel images are interleaved by color, also called channel, and its dimensions are (*Channels*, *Columns*, *Rows*).

As a special case, this keyword may be set to 2 to write an RGB image that is contained in three separate arrays (color planes), stored in the variables specified by the RED, GREEN, and BLUE keywords. Otherwise, omit this parameter (or set it to 1).

Note

Many TIFF readers can read only one- or three-channel images.

RED

GREEN

BLUE

If you are writing a Palette color image, set these keywords equal to the color table vectors, scaled from 0 to 255.

If you are writing an RGB interleaved image (i.e., if the PLANARCONFIG keyword is set to 2), set these keywords to the names of the variables containing the three image components.

SHORT

Set this keyword to write the pixel components as unsigned 16-bit entities (the default is 8-bit).

UNITS

Set this keyword to one of the following values to specify the units used for the values specified by the XRESOL and YRESOL keywords:

1	No units
2	Inches (the default)
3	Centimeters

VERBOSE

Set this keyword to produce additional diagnostic output during the write.

XPOSITION

Set this keyword to the X offset relative to the left side of the image, in units specified by the UNITS keyword. XPOSITION must be nonnegative. If XPOSITION is not specified then this tag is not written to the file.

Note ───
The XPOSITION tag is usually ignored by most TIFF readers.

───

XRESOL

Set this keyword to the horizontal resolution, in pixels per unit, where the unit is specified by the value of the UNITS keyword (inches, by default). The default value of XRESOL is 100. Note that while this value is stored in the TIFF file, it may be interpreted by the TIFF reader in a variety of ways, or ignored.

YPOSITION

Set this keyword to the Y offset relative to the top of the image (with positive Y increasing downwards), in units specified by the UNITS keyword. YPOSITION must be nonnegative. If YPOSITION is not specified then this tag is not written to the file.

Note ───
The YPOSITION tag is usually ignored by most TIFF readers.

───

YRESOL

Set this keyword to the vertical resolution, in pixels per unit, where the unit is specified by the value of the UNITS keyword (inches, by default). The default value of YRESOL is 100. Note that while this value is stored in the TIFF file, it may be interpreted by the TIFF reader in a variety of ways, or ignored.

Examples

Example 1

Create a pseudo screen dump from the current window. Note that this works only on a PseudoColor (8-bit) display:

```
WRITE_TIFF, 'test.tiff', TVRD()
```

Example 2

Write a three-channel image from three one-channel (two-dimensional) arrays, contained in the variables Red, Green, and Blue:

```
WRITE_TIFF, 'test.tif', RED=Red, GREEN=Green, BLUE=Blue, $
    PLANARCONFIG=2
```

Example 3

Write and read a multi-image TIFF file. The first image is a 16-bit single channel image stored using compression. The second image is an RGB image stored using 32-bits/channel uncompressed.

```
; Write the image data:
data = FIX(DIST(256))
rgbdata = LONARR(3,320,240)
WRITE_TIFF,'multi.tif',data,COMPRESSION=1,/SHORT
WRITE_TIFF,'multi.tif',rgbdata,/LONG,/APPEND
; Read the image data back
ok = QUERY_TIFF('multi.tif',s)
IF (ok) THEN BEGIN
   FOR i=0,s.NUM_IMAGES-1 DO BEGIN
      imp = QUERY_TIFF('multi.tif',t,IMAGE_INDEX=i)
      img = READ_TIFF('multi.tif',IMAGE_INDEX=i)
      HELP,t,/STRUCTURE
      HELP,img
   ENDFOR
ENDIF
```

Version History

5.0	Introduced
5.5	Deprecated *Order* argument.
5.6	Added ITIFF support
6.1	Added CMYK, DESCRIPTION, DOCUMENT_NAME, DOT_RANGE, ICC_PROFILE, PHOTOSHOP, XPOSITION, and YPOSITION keywords

For information on obsolete keywords, see Appendix I, "Obsolete Features".

READ_TIFF, QUERY_* Routines

WRITE_WAV

The WRITE_WAV procedure writes the audio stream to the named .WAV file.

Syntax

WRITE_WAV, *Filename*, *Data*, *Rate*

Arguments

Filename

A scalar string containing the full pathname of the .WAV file to write.

Data

The array to write into the new .WAV file. The array can be a one- or two-dimensional array. A two-dimensional array is written as a multi-channel audio stream where the leading dimension of the IDL array is the number of channels. If the input array is in BYTE format, the data is written as 8-bit samples, otherwise, the data is written as signed 16-bit samples.

Rate

The sampling rate for the data array in samples per second.

Keywords

None

Version History

5.3	Introduced

WRITE_WAVE

The WRITE_WAVE procedure writes a three dimensional IDL array to a `.wave` or `.bwave` file for use with the Wavefront Advanced Data Visualizer. Note that this routine only writes one scalar field for each Wavefront file that it creates.

This routine is written in the IDL language. Its source code can be found in the file `write_wave.pro` in the `lib` subdirectory of the IDL distribution.

Syntax

WRITE_WAVE, *File*, *Array* [, /BIN] [, DATANAME=*string*]
　　[, MESHNAME=*string*] [, /NOMESHDEF] [, /VECTOR]

Arguments

File

A scalar string containing the full path name of the Wavefront file to write.

Array

A 3D array to be written to the file.

Keywords

BIN

Set this keyword to create a binary file. By default, text files are created.

DATANAME

Set this keyword to the name of the data inside of the Wavefront file. If not specified, the name used is "idldata".

MESHNAME

Set this keyword to the name of the mesh used in the Wavefront file. If not specified, the name used is "idlmesh".

NOMESHDEF

Set this keyword to *omit* the mesh definition from the Wavefront file.

VECTOR

Set this keyword to write the variable as a vector. The data is written as an array of 3-space vectors. The array may contain any number of dimensions but must have a leading dimension of 3. If the leading array dimension is not 3, this keyword is ignored.

Version History

Pre-4.0	Introduced

READ_WAVE

WRITEU

The WRITEU procedure writes unformatted binary data from an expression into a file. This procedure performs a direct transfer with no processing of any kind being done to the data.

Syntax

WRITEU, *Unit*, *Expr$_1$ ...*, *Expr$_n$* [, TRANSFER_COUNT=*variable*]

Arguments

Unit

The IDL file unit to which the output is sent.

Expr$_i$

The expressions to be output. For non-string variables, the number of bytes implied by the data type is output. When WRITEU is used with a variable of type string, IDL outputs exactly the number of bytes contained in the existing string.

Keywords

TRANSFER_COUNT

Set this keyword to a named variable in which to return the number of elements transferred by the output operation. Note that the number of elements is not the same as the number of bytes (except in the case where the data type being transferred is bytes). For example, transferring 256 floating-point numbers yields a transfer count of 256, not 1024 (the number of bytes transferred).

This keyword is useful with files opened with the RAWIO keyword to the OPEN routines. Normally, writing more data than an output device will accept causes an error. Files opened with the RAWIO keyword will not generate such an error. Instead, the programmer must keep track of the transfer count to judge the success or failure of a WRITEU operation.

Examples

```
; Create some data to store in a file:
D = BYTSCL(DIST(200))
; Open a new file for writing as IDL file unit number 1:
OPENW, 1, 'newfile'
; Write the data in D to the file:
WRITEU, 1, D
; Close file unit 1:
CLOSE, 1
```

Version History

Original	Introduced
Pre-6.2	Deprecated REWRITE keyword

For information on obsolete keywords, see Appendix I, "Obsolete Features".

OPENR/OPENU/OPENW, READU, Chapter 18, "Files and Input/Output"
(*Application Programming*), and "Unformatted Input/Output with Structures"
(Chapter 16, *Application Programming*).

WSET

The WSET procedure selects the current window. Most IDL graphics routines do not explicitly require the IDL window to be specified. Instead, they use the window known as the current window. The window index number of the current window is contained in the read-only system variable !D.WINDOW. WSET only works with devices that have windowing systems.

Syntax

WSET [, *Window_Index*]

Arguments

Window_Index

This argument specifies the window index of the window to be made current. If this argument is not specified, a default of 0 is used.

If you set *Window_Index* equal to -1, IDL will try to locate an existing window to make current, ignoring any managed draw widgets that may exist. If there is no window to make current, WSET changes the value of the WINDOW field of the !D system variable to -1, indicating that there are no current windows.

If there are no existing IDL windows, and you call WSET without the *Window_Index* argument or with a *Window_Index* of 0, a new window with the index 0 is opened. Calling WSET with a *Window_Index* for a window that does not exist, except for window 0, results in a "Window is closed and unavailable" error message.

Keywords

None

Examples

Create IDL windows 1 and 2 by entering:

```
WINDOW, 1 & WINDOW, 2
```

Set the current window to window 1 and display an image by entering:

```
WSET, 1 & TVSCL, DIST(100)
```

Set the current window to window 2 and display an image by entering:

```
WSET, 2 & TVSCL, DIST(100)
```

Version History

Original	Introduced

See Also

WDELETE, WINDOW, WSHOW

WSHOW

The WSHOW procedure exposes or hides the designated window.

Syntax

WSHOW [, *Window_Index* [, *Show*]] [, /ICONIC]

Arguments

Window_Index

The window index of the window to be hidden or exposed. If this argument is not specified, the current window is assumed. If this index is the window ID of a draw widget, the widget base associated with that drawable is brought to the front of the screen.

Show

Set *Show* to 0 to hide the window. Omit this argument or set it to 1 to expose the window.

Keywords

ICONIC

Set this keyword to iconify the window. Set ICONIC to 0 to de-iconify the window.

Under windowing systems, iconification is the task of the window manager, and client applications such as IDL have no direct control over it. The ICONIC keyword serves as a hint to the window manager, which is free to iconify the window or ignore the request as it sees fit.

Examples

To bring IDL window number 0 to the front, enter:

```
WSHOW, 0
```

WDELETE, WINDOW, WSET

WTN

The WTN function returns a multi-dimensional discrete wavelet transform of the input array *A*. The transform is based on a Daubechies wavelet filter.

WTN is based on the routine `wtn` described in section 13.10 of *Numerical Recipes in C: The Art of Scientific Computing* (Second Edition), published by Cambridge University Press, and is used by permission.

Syntax

Result = WTN(*A*, *Coef* [, /COLUMN] [, /DOUBLE] [, /INVERSE]
   [, /OVERWRITE])

Return Value

Returns an output array of the same dimensions as *A*, containing the discrete wavelet transform over each dimension.

Arguments

A

The input vector or array. The dimensions of *A* must all be powers of 2.

Note
   If WTN is complex then only the real part is used for the computation.

Coef

An integer that specifies the number of wavelet filter coefficients. The allowed values are 4, 12, or 20. When *Coef* is 4, the `daub4()` function (see *Numerical Recipes*, section 13.10) is used. When *Coef* is 12 or 20, `pwt()` is called, preceded by `pwtset()` (see *Numerical Recipes*, section 13.10).

Keywords

COLUMN

Set this keyword if the input array *A* is in column-major format (composed of column vectors) rather than in row-major format (composed of row vectors).

DOUBLE

Set this keyword to force the computation to be done in double-precision arithmetic.

INVERSE

If the INVERSE keyword is set, the inverse transform is computed. By default, WTN performs the forward wavelet transform.

OVERWRITE

Set the OVERWRITE keyword to perform the transform "in place." The result overwrites the original contents of the array.

Examples

> **Note** ──
> Also see "Transforming Between Domains with Wavelets" (Chapter 7, *Image Processing in IDL*).
> ──

This example demonstrates the use of IDL's discrete wavelet transform and sparse array storage format to compress and store an 8-bit gray-scale digital image. First, an image selected from the people.dat data file is transformed into its wavelet representation and written to a separate data file using the WRITEU procedure.

Next, the transformed image is converted, using the SPRSIN function, to row-indexed sparse storage format retaining only elements with an absolute magnitude greater than or equal to a specified threshold. The sparse image is written to a data file using the WRITE_SPR procedure.

Finally, the transformed image is reconstructed from the storage file and displayed alongside the original.

```
; Begin by choosing the number of wavelet coefficients to use and a
; threshold value:
coeffs = 12 & thres = 10.0

; Open the people.dat data file, read an image using associated
; variables, and close the file:
OPENR, 1, FILEPATH('people.dat', SUBDIR = ['examples','data'])
images = assoc(1, bytarr(192, 192, /NOZERO))
image_1 = images[0]
close, 1

; Expand the image to the nearest power of two using cubic
; convolution, and transform the image into its wavelet
```

```
; representation using the WTN function:
pwr = 256
image_1 = CONGRID(image_1, pwr, pwr, /CUBIC)
wtn_image = WTN(image_1, coeffs)

; Write the image to a file using the WRITEU procedure and check
; the size of the file (in bytes) using the FSTAT function:
OPENW, 1, 'original.dat'
WRITEU, 1, wtn_image
status = FSTAT(1)
CLOSE, 1
PRINT, 'Size of the file is ', status.size, ' bytes.'

; Now, we convert the wavelet representation of the image to a
; row-indexed sparse storage format using the SPRSIN function,
; write the data to a file using the WRITE_SPR procedure, and check
; the size of the "compressed" file:
sprs_image = SPRSIN(wtn_image, THRES = thres)
WRITE_SPR, sprs_image, 'sparse.dat'
OPENR, 1, 'sparse.dat'
status = FSTAT(1)
CLOSE, 1
PRINT, 'Size of the compressed file is ', status.size, ' bytes.'

; Determine the number of elements (as a percentage of total
; elements) whose absolute magnitude is less than the specified
; threshold. These elements are not retained in the row-indexed
; sparse storage format:
PRINT, 'Percentage of elements under threshold: ',$
   100.*N_ELEMENTS(WHERE(ABS(wtn_image) LT thres, $
   count)) / N_ELEMENTS(image(1)

; Next, read the row-indexed sparse data back from the file
; sparse.dat using the READ_SPR function and reconstruct the
; image from the non-zero data using the FULSTR function:
sprs_image = READ_SPR('sparse.dat')
wtn_image = FULSTR(sprs_image)

; Apply the inverse wavelet transform to the image:
image_2 = WTN(wtn_image, COEFFS, /INVERSE)

; Calculate and print the amount of data used in reconstruction of
; the image:
PRINT, 'The image on the right is reconstructed from:', $
   100.0 - (100.* count/N_ELEMENTS(image_1)),$
   '% of original image data.'

; Finally, display the original and reconstructed images side by
; side:
```

```
WINDOW, 1, XSIZE = pwr*2, YSIZE = pwr, $
   TITLE = 'Wavelet Image Compression and File I/O'
TV, image_1, 0, 0
TV, image_2, pwr - 1, 0
```

IDL Output

```
Size of the file is   262144 bytes.
Size of the compressed file is   69600 bytes.
Percentage of elements under threshold:   87.0331
The image on the right is reconstructed from: 12.9669% of original
image data.
```

The sparse array contains only 13% of the elements contained in the original array. The following figure is created from this example. The image on the left is the original 256 by 256 image. The image on the right was compressed by the above process and was reconstructed from 13% of the original data. The size of the compressed image's data file is 26.6% of the size of the original image's data file. Note that due to limitations in the printing process, differences between the images may not be as evident as they would be on a high-resolution printer or monitor.

*Figure 25-14: Original image (left) and image reconstructed
from 13% of the data (right).*

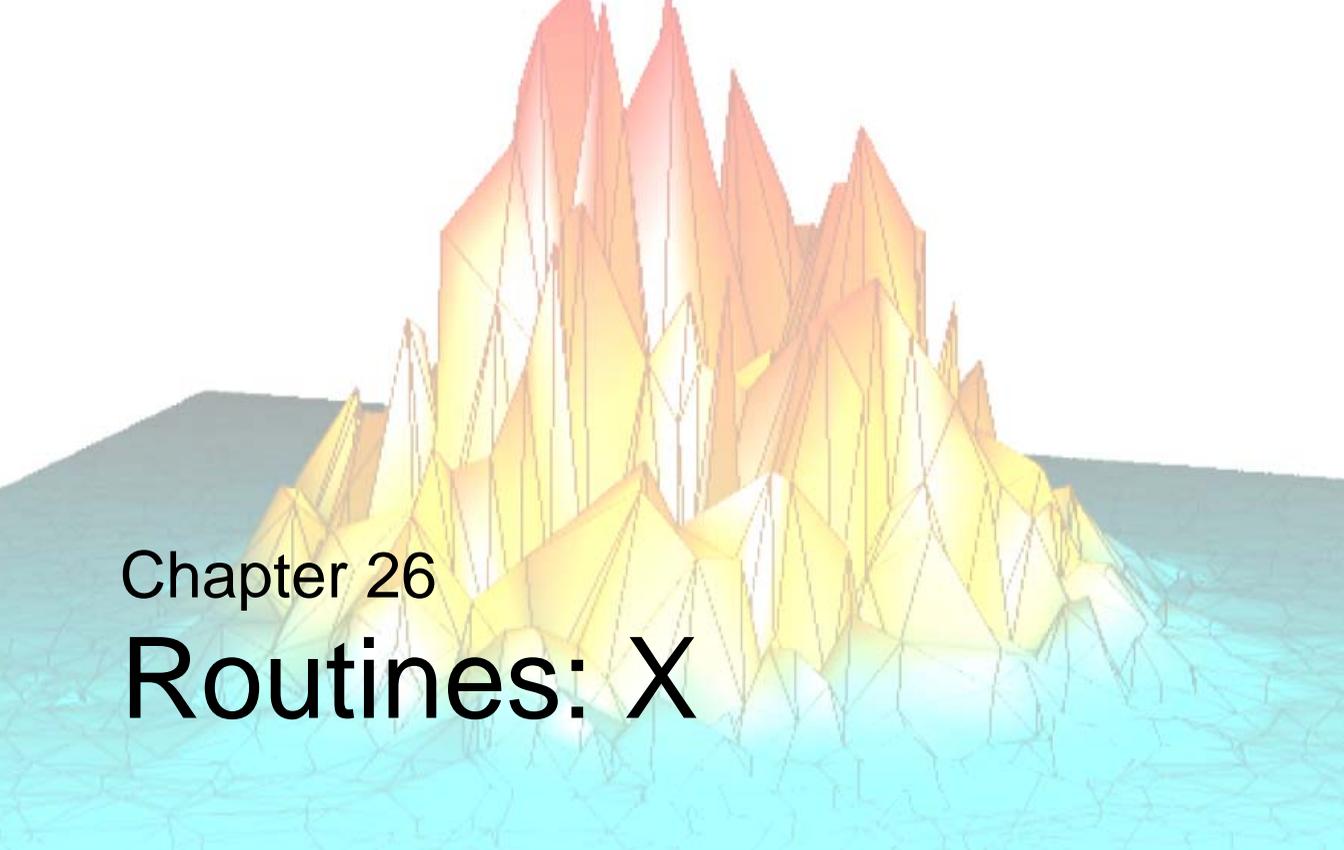
WV_* Routines

For information, see the *Chapter 1, "Introduction to the IDL Wavelet Toolkit"* (*IDL Wavelet Toolkit*).


Chapter 26
Routines: X

XBM_EDIT

The XBM_EDIT procedure is a utility for creating and editing icons for use with IDL widgets as bitmap labels for widget buttons.

The icons created with XBM_EDIT can be saved in two different file formats. IDL "array definition files" are text files that can be inserted into IDL programs. "Bitmap array files" are data files that can be read into IDL programs. Bitmap array files should be used temporarily until the final icon design is determined and then they can be saved as IDL array definitions for inclusion in the final widget code. This routine does not check the file types of the files being read and assumes that they are of the correct size and type for reading. XBM_EDIT maintains its state in a common block so it is restricted to one working copy at a time.

This routine is written in the IDL language. Its source code can be found in the file xbm_edit.pro in the lib/utilities subdirectory of the IDL distribution.

Syntax

XBM_EDIT [, /BLOCK] [, FILENAME=*string*] [, GROUP=*widget_id*]
   [, XSIZE=*pixels*] [, YSIZE=*pixels*]

Arguments

None

Keywords

BLOCK

Set this keyword to have XMANAGER *block* when this application is registered. By default, BLOCK is set equal to zero, providing access to the command line if active command line processing is available. Note that setting BLOCK=1 will cause *all* widget applications to block, not just this application. For more information, see the documentation for the NO_BLOCK keyword to XMANAGER.

Note

Only the outermost call to XMANAGER can block. Therefore, to have XBM_EDIT block, any earlier calls to XMANAGER must have been called with the NO_BLOCK keyword. See the documentation for the NO_BLOCK keyword to XMANAGER for an example.

FILENAME

Set this keyword to a scalar string that contains the filename to be used for the new icon. If this argument is not specified, the name "idl.bm" is used. The filename can be changed in XBM_EDIT by editing the "Filename" field before selecting a file option.

GROUP

The widget ID of the widget that calls XBM_EDIT. When this ID is specified, the death of the caller results in the death of XBM_EDIT.

XSIZE

The number of pixels across the bitmap is in the horizontal direction. The default value is 16 pixels.

YSIZE

The number of pixels across the bitmap is in the vertical direction. The default value is 16 pixels.

WIDGET_BUTTON

XDISPLAYFILE

The XDISPLAYFILE procedure is a utility for displaying ASCII text files using a widget interface. In addition to allowing users to read and optionally edit text files, the utility allows you programmatically interact with the text widget.

This routine is written in the IDL language. Its source code can be found in the file xdisplayfile.pro in the lib/utilities subdirectory of the IDL distribution.

Syntax

XDISPLAYFILE, *Filename* [, /BLOCK] [, DONE_BUTTON=*string*]
   [, /EDITABLE] [, FONT=*string*] [, GROUP=*widget_id*]
   [, /GROW_TO_SCREEN] [, HEIGHT=*lines*] [, /MODAL]
   [, RETURN_ID=*variable*] [, TEXT=*string or string array*] [, TITLE=*string*]
   [, WIDTH=*characters*] [, WTEXT=*variable*]

Arguments

Filename

A scalar string that contains the filename of the file to display. *Filename* can include a path to that file.

Keywords

BLOCK

Set this keyword to have XMANAGER *block* when this application is registered. By default, BLOCK is set equal to zero, providing access to the command line if active command line processing is available. Note that setting BLOCK=1 will cause *all* widget applications to block, not just this application. For more information, see the documentation for the NO_BLOCK keyword to XMANAGER.

Note

Only the outermost call to XMANAGER can block. Therefore, to have XDISPLAYFILE block, any earlier calls to XMANAGER must have been called with the NO_BLOCK keyword. See the documentation for the NO_BLOCK keyword to XMANAGER for an example.

DONE_BUTTON

Set this keyword to a string containing the text to use for the Done button label. If omitted, the text "Done with <filename>" is used.

EDITABLE

Set this keyword to allow modifications to the text displayed in XDISPLAYFILE. Setting this keyword also adds a "Save" button in addition to the Done button.

FONT

A string containing the name of the font to use. The font specified is a device font (an X Windows font on Motif systems; a TrueType or PostScript font on Windows systems). See "About Device Fonts" on page 5580 for details on specifying names for device fonts. If this keyword is omitted, the default font is used.

GROUP

The widget ID of the widget that calls XDISPLAYFILE. If this keyword is specified, the death of the group leader results in the death of XDISPLAYFILE.

GROW_TO_SCREEN

Set this keyword to cause XDISPLAYFILE to display as many lines of text as possible without making the display too tall to fit on the screen. If this keyword is set, the value specified by the HEIGHT keyword is taken to be the minimum number of lines to display.

HEIGHT

The number of text lines that the widget should display at one time. If this keyword is not specified, 24 lines is the default.

MODAL

Set this keyword to create the XDISPLAYFILE dialog as a modal dialog. Setting the MODAL keyword allows you to call XDISPLAYFILE from another modal dialog.

RETURN_ID

Set this keyword equal to a named variable that will contain the widget ID of the top level base created by XDISPLAYFILE.

TEXT

A string or string array to be displayed in the widget instead of the contents of a file. If this keyword is present, the *Filename* input argument is ignored (but is still required). String arrays are displayed one element per line.

TITLE

A string to use as the widget title rather than the file name or "XDisplayFile".

WIDTH

The width of the widget display in characters. If this keyword is not specified, 80 characters is the default.

WTEXT

Set this keyword to a named variable that will contain the widget ID of the text widget. This allows setting text selections and cursor positions programmatically. For example, the following code opens the XDISPLAYFILE widget and selects the first 10 characters of the file displayed in the text widget:

```
XDISPLAYFILE, 'myfile.txt', /EDITABLE, WTEXT=w
WIDGET_CONTROL, w, SET_TEXT_SELECT=[0, 10]
```

XDXF

The XDXF procedure is a utility for displaying and interactively manipulating DXF objects. It also displays a dialog that contains block and layer information for the DXF file, allowing the user to turn on and off the display of individual layers.

Using XDXF

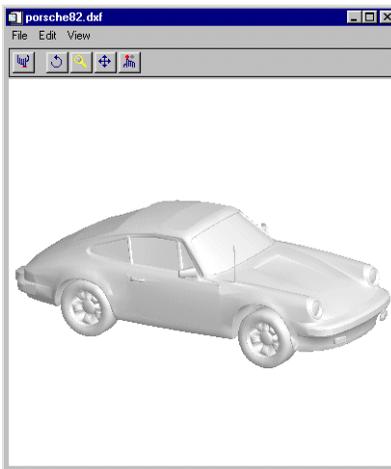
XDXF displays a resizeable top-level base with a menu and draw widget used to display and manipulate the orientation of a DXF object.


Figure 26-1: The XDXF Utility

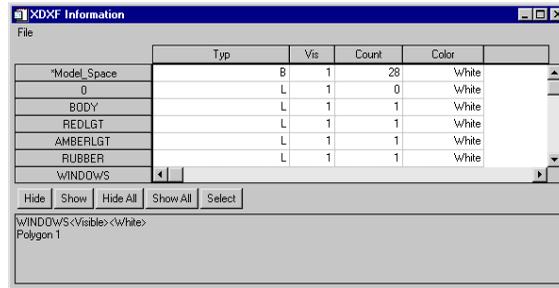
XDXF also displays a dialog that contains block and layer information and allows the user to turn on and off the display of individual layers.


Figure 26-2: The XDXF Information Dialog

The XDXF Toolbar

The XDXF toolbar contains the following buttons:

Button	Tool Name	Function
	Reset	Resets rotation, scaling, and panning.
	Rotate	Click the left mouse button on the object and drag to rotate.
	Pan	Click the left mouse button on the object and drag to pan.
	Zoom	Click the left mouse button on the object and drag to zoom in or out.
	Select	Click on the object. The name of the selected object is displayed, if the object has a name, otherwise its class is displayed.

Table 26-1: XDXF Toolbar Buttons

The XDXF Information Dialog

The XDXF Information dialog displays information about the blocks and layers contained in the currently displayed object, and allows you to turn on and off the display of each layer.

To show or hide layers in the DXF object, select the layer from the list of layers on the left of the dialog, and click the **Show** or **Hide** button. Alternatively, you can click in the "Vis" field for the desired layer. To show or hide all layers, click the **Show All** or **Hide All** buttons.

If the **View Block Outlines** checkbox is selected, a green box will be displayed around the currently selected block, if any.

Syntax

XDXF [, *Filename*] [, /BLOCK] [, GROUP=*widget_id*] [, SCALE=*value*] [, /TEST] [*keywords to XOBJVIEW*]

Arguments

Filename

A string specifying the name of the DXF file to display. If this argument is not specified, a file selection dialog is opened.

Keywords

XDXF accepts the keywords to XOBJVIEW. (Note, however, that specifying the XOBJVIEW keyword MODAL is interpreted by XDXF as a call to the BLOCK keyword.) In addition, XDXF supports the following keywords:

BLOCK

Set this keyword to have XMANAGER block when this application is registered. By default, BLOCK is set equal to zero, providing access to the command line if active command line processing is available. Note that setting the BLOCK keyword causes all widget applications to block, not just this application. For more information, see the documentation for the NO_BLOCK keyword to XMANAGER.

Note ───

Only the outermost call to XMANAGER can block. Therefore, to have XDXF block, any earlier calls to XMANAGER must have been called with the NO_BLOCK keyword. See the documentation for the NO_BLOCK keyword to XMANAGER for an example.

───

GROUP

The widget ID of the widget that calls XDXF. When this ID is specified, the death of the caller results in the death of XDXF.

SCALE

Set this keyword to the zoom factor for the initial view. The default is 1/SQRT(3). This default value provides the largest possible view of the object, while ensuring that no portion of the object will be clipped by the XDXF window, regardless of the object's orientation.

TEST

If this keyword is set, the file heart.dxf in the IDL distribution is automatically opened in XDXF.

Examples

Display the file heart.dxf, contained in the IDL distribution:

```
XDXF, FILEPATH('heart.dxf', $
   SUBDIR=['examples', 'data'])
```

IDLffDXF

XFONT

The XFONT function is a utility that creates a modal widget for selecting and viewing an X Windows font.

Calling XFONT resets the current X Windows font.

Note ———

 This routine is only available on UNIX platforms.

———

This routine is written in the IDL language. Its source code can be found in the file xfont.pro in the lib/utilities subdirectory of the IDL distribution.

Syntax

Result = XFONT([, GROUP=*widget_id*] [, /PRESERVE_FONT_INFO])

Return Value

The function returns a string containing the name of the last selected font. If no font is selected, or the "Cancel" button is clicked, a null string is returned.

Arguments

None.

Keywords

GROUP

The widget ID of the widget that calls XFONT. When this ID is specified, the death of the caller results in the death of XFONT.

PRESERVE_FONT_INFO

Set this keyword to make XFONT save the server font directory in common blocks so that subsequent calls to XFONT start-up much faster. If this keyword is not set, the common block is cleaned.

Version History

Pre-4.0	Introduced

EFONT, SHOWFONT

XINTERANIMATE

The XINTERANIMATE procedure is a utility for displaying an animated sequence of images using off-screen pixmaps or memory buffers. The speed and direction of the display can be adjusted using the widget interface.

Warning ──

On Microsoft Windows systems, the number of pixmap windows that can be created (and thus the number of images in an animation sequence) is limited by system GDI resources. The number of pixmap windows IDL can create is constrained by the total amount of GDI memory, the amount of GDI memory used by other applications, and the size of the IDL pixmap windows.

──

Only a single copy of XINTERANIMATE can run at a time. If you need to run multiple instances of the animation widget concurrently, use the CW_ANIMATE compound widget.

MPEG Support

MPEG animation files can be created either programmatically using keywords to open and save a file, or interactively using the widget interface. Note that the MPEG standard does not allow movies with odd numbers of pixels to be created.

Note ───

MPEG support in IDL requires a special license. For more information, contact your ITT Visual Information Solutions sales representative or technical support.

The IDLffMJPEG2000 object creates and reads Motion JPEG2000 (MJ2) files, and provides more functionality than the MPEG_* routines. No special license is required and animations can consist of monochrome, RGB or multi-component frames that display individual components, tiles or regions. See "Overview of Motion JPEG2000" (Chapter 6, *Using IDL*) for more information on creating MJ2 files and using the pre-built MJ2 player provided with IDL.

──

This routine is written in the IDL language. Its source code can be found in the file xinteranimate.pro in the lib/utilities subdirectory of the IDL distribution.

Using XINTERANIMATE

Displaying an animated series of images using XINTERANIMATE requires at least three calls to the routine: one to initialize the animation widget, one to load images, and one to display the images. When initialized using the SET keyword,

XINTERANIMATE creates an approximately square pixmap or memory buffer, large enough to contain the requested number of frames of the requested size. Images are loaded using the IMAGE and FRAME keywords. Finally, images are displayed by copying them from the pixmap or memory buffer to the visible draw widget.

See CW_ANIMATE for a description of the widget interface controls used by XINTERANIMATE.

Syntax

XINTERANIMATE [, *Rate*]

Keywords for initialization: [, SET=*[sizex*, *sizey*, *nframes]*] [, /BLOCK]
   [, /CYCLE] [, GROUP=*widget_id*] [, /MODAL] [, MPEG_BITRATE=*value*]
   [, MPEG_FORMAT=*value*] [, MPEG_IFRAME_GAP=*integer value*]
   [, MPEG_MOTION_VEC_LENGTH={1 | 2 | 3}]
   [, /MPEG_OPEN, MPEG_FILENAME=*string*]
   [MPEG_QUALITY=*value*{0 to 100}] [, /SHOWLOAD] [, /TRACK]
   [, TITLE=*string*]

Keywords for loading images: [, FRAME=*value*{0 to (*nframes*-1)}
   [, IMAGE=*value*]] [, /ORDER] [, WINDOW=*[window_num* [, *x0*, *y0*, *sx*, *sy*]*]*]

Keywords for running animations: [, /CLOSE] [, /KEEP_PIXMAPS]
   [, /MPEG_CLOSE] [, XOFFSET=*pixels*] [, YOFFSET=*pixels*]

Arguments

Rate

A value between 0 and 100 that represents the speed of the animation as a percentage of the maximum display rate. The fastest animation is with a value of 100 and the slowest is with a value of 0. The default animation rate is 100. The animation must be initialized using the SET keyword before calling XINTERANIMATE with a rate value.

Keywords: Initialization

The following keywords are used to initialize the animation display. The SET keyword *must* be provided. Other keywords described in this section are optional; note that they work only when SET is specified.

SET

Set this keyword to a three-element vector [*Sizex*, *Sizey*, *Nframes*] to initialize XINTERANIMATE. *Sizex* and *Sizey* represent the width and height of the images to be displayed, in pixels. *Nframes* is the number of frames in the animation sequence. Note that *Nframes* must be at least 2 frames.

BLOCK

Set this keyword to have XMANAGER *block* when this application is registered. By default, BLOCK is set equal to zero, providing access to the command line if active command line processing is available. Note that setting BLOCK=1 will cause *all* widget applications to block, not just this application. For more information, see the documentation for the NO_BLOCK keyword to XMANAGER.

Note ———————————————————————————————

Only the outermost call to XMANAGER can block. Therefore, to have XINTERANIMATE block, any earlier calls to XMANAGER must have been called with the NO_BLOCK keyword. See the documentation for the NO_BLOCK keyword to XMANAGER for an example.

———————————————————————————————————————

CYCLE

Normally, frames are displayed going either forward or backwards. If the CYCLE keyword is set, the animation reverses direction after the last frame in either direction is displayed.

GROUP

Set this keyword to the widget ID of the widget that calls XINTERANIMATE. When GROUP is specified, the death of the calling widget results in the death of XINTERANIMATE.

MODAL

Set this keyword to block processing of events from other widgets until the user quits XINTERANIMATE. A group leader must be specified (via the GROUP keyword) for the MODAL keyword to have any effect. By default, XINTERANIMATE does not block event processing.

MPEG_BITRATE

Set this keyword to a double-precision value to specify the MPEG movie bit rate. Higher bit rates will create higher quality MPEGs but will increase file size. The following table describes the valid values:

MPEG Version	Range
MPEG 1	0.1 to 104857200.0
MPEG 2	0.1 to 429496729200.0

Table 26-2: BITRATE Value Range

If you do not set this keyword, IDL computes the MPEG_BITRATE value based upon the value you have specified for the MPEG_QUALITY keyword.

Note

Only use the MPEG_BITRATE keyword if changing the MPEG_QUALITY keyword value does not produce the desired results. It is highly recommended to set the MPEG_BITRATE to at least several times the frame rate to avoid unusable MPEG files or file generation errors.

MPEG_FILENAME

Set this keyword equal to a string specifying the name of the MPEG file. If no file name is specified, the default value (idl.mpg) is used.

MPEG_FORMAT

Set this keyword to a boolean value that specifies the type of MPEG encoding to use:

- 0 = MPEG1 (the default)
- 1 = MPEG2

MPEG_IFRAME_GAP

Set this keyword to a positive integer value that specifies the number of frames between I frames to be created in the MPEG file. I frames are full-quality image frames that may have a number of predicted or interpolated frames between them.

If you do not specify this keyword, IDL computes the MPEG_IFRAME_GAP value based upon the value you have specified for the MPEG_QUALITY keyword.

Note

Only use the MPEG_IFRAME_GAP keyword if changing the MPEG_QUALITY keyword value does not produce the desired results.

MPEG_MOTION_VEC_LENGTH

Set this keyword to an integer value specifying the length of the motion vectors to be used to generate predictive frames. Valid values include:

1	Small motion vectors
2	Medium motion vectors
3	Large motion vectors

If you do not set this keyword, IDL computes the MPEG_MOTION_VEC_LENGTH value based upon the value you have specified for the MPEG_QUALITY keyword.

Note

Only use the MPEG_MOTION_VEC_LENGTH keyword if changing the MPEG_QUALITY value does not produce the desired results.

MPEG_OPEN

Set this keyword to open an MPEG file.

MPEG_QUALITY

Set this keyword to an integer value between 0 (low quality) and 100 (high quality) inclusive to specify the quality at which the MPEG stream is to be stored. Higher quality values result in lower rates of time compression and less motion prediction which provide higher quality MPEGs but with substantially larger file size. Lower quality factors may result in longer MPEG generation times. The default is 50.

Note

Since MPEG uses JPEG (lossy) compression, the original picture quality can't be reproduced even when setting QUALITY to its highest setting.

SHOWLOAD

Set this keyword to display each frame and update the frame slider as frames are loaded.

TRACK

Set this keyword to cause the frame slider to track the current frame when the animation is in progress. The default is not to track.

TITLE

Use this keyword to specify a string to be used as the title of the animation widget. If TITLE is not specified, the title is set to "XInterAnimate."

Keywords: Loading Images

The following keywords are used to load images into the animation display. They have no effect when initializing or running animations.

FRAME

Use this keyword to specify the frame number when loading frames. FRAME must be set to a number in the range 0 to *Nframes*-1.

IMAGE

Use this keyword to specify a single image to be loaded at the animation position specified by the FRAME keyword. (FRAME *must* also be specified.)

ORDER

Set this keyword to display images from the top down instead of the default bottom up.

WINDOW

When this keyword is specified, an image is copied from an existing window to the animation pixmap or memory buffer. (When using some windowing systems, using this keyword is much faster than reading from the display and then calling XINTERANIMATE with a 2-D array.)

The value of this parameter is either an IDL window number (in which case the entire window is copied), or a vector containing the window index and the rectangular bounds of the area to be copied. For example:

```
WINDOW = [Window_Number, X0, Y0, Sx, Sy]
```

Keywords: Running Animations

The following keywords are used when running the animation. They have no effect when initializing the animation or loading images.

CLOSE

Set this keyword to delete the offscreen pixmaps or buffers and the animation widget itself. This also takes place automatically when the user presses the "Done With Animation" button or closes the window with the window manager.

KEEP_PIXMAPS

If this keyword is set, XINTERANIMATE will not destroy the animation pixmaps or buffers when it is killed. Calling XINTERANIMATE again without going through the SET and LOAD steps will play the same animation without the overhead of creating the pixmaps.

MPEG_CLOSE

Set this keyword to close and save the MPEG file. This keyword has no effect if MPEG_OPEN was not used during initialization.

XOFFSET

Use this keyword to specify the horizontal offset, in pixels from the left of the frame, of the image in the destination window.

YOFFSET

Use this keyword to specify the vertical offset, in pixels from the bottom of the frame, of the image in the destination window.

Examples

Enter the following commands to open the file ABNORM.DAT (a series of images of a human heart) and animate the images it contains using XINTERANIMATE.

```
OPENR, unit, FILEPATH('abnorm.dat', SUBDIR=['examples','data']), $
   /GET_LUN
H = BYTARR(64, 64, 16, /NOZERO)
READU, unit, H
CLOSE, unit

; Read the images into variable H:
```

```
H = REBIN(H, 128, 128, 16)

; Initialize XINTERANIMATE:
XINTERANIMATE, SET=[128, 128, 16], /SHOWLOAD

; Load the images into XINTERANIMATE:
FOR I=0,15 DO XINTERANIMATE, FRAME = I, IMAGE = H[*,*,I]

; Play the animation:
XINTERANIMATE, /KEEP_PIXMAPS
```

Note ───

Since the KEEP_PIXMAPS keyword was supplied, the same animation can be replayed (after the animation widget has been destroyed) with the single command `XINTERANIMATE`.

───

Also see T3D for an example that draws and rotates a simple house.

Version History

Pre-4.0	Introduced
6.4	Added MPEG_FORMAT keyword.

CW_ANIMATE

XLOADCT

The XLOADCT procedure is a utility that provides a graphical widget interface to the LOADCT procedure. XLOADCT displays the current Direct Graphics color table and shows a list of available predefined color tables. Clicking on the name of a color table causes that color table to become IDL's current color table. IDL maintains a color table on PseudoColor displays or when the DECOMPOSED keyword to the DEVICE command is set to zero (DEVICE, DECOMPOSED = 0) on TrueColor displays. Many other options, such as Gamma correction, stretching, and transfer functions can also be applied to the colortable.

This routine is written in the IDL language. Its source code can be found in the file xloadct.pro in the lib/utilities subdirectory of the IDL distribution.

Syntax

XLOADCT [, /BLOCK] [, BOTTOM=*value*] [, FILE=*string*] [, GROUP=*widget_id*]
   [, /MODAL] [, NCOLORS=*value*] [, /SILENT]
   [, UPDATECALLBACK='*procedure_name*' [, UPDATECBDATA=*value*]]
   [, /USE_CURRENT]

Arguments

None.

Keywords

BLOCK

Set this keyword to have XMANAGER *block* when this application is registered. By default, BLOCK is set equal to zero, providing access to the command line if active command line processing is available. Note that setting BLOCK=1 will cause *all* widget applications to block, not just this application. For more information, see the documentation for the NO_BLOCK keyword to XMANAGER.

Note ———

Only the outermost call to XMANAGER can block. Therefore, to have XLOADCT block, any earlier calls to XMANAGER must have been called with the NO_BLOCK keyword. See the documentation for the NO_BLOCK keyword to XMANAGER for an example.

——

BOTTOM

The first color index to use. XLOADCT will use color indices from BOTTOM to BOTTOM+NCOLORS-1. The default is BOTTOM=0.

FILE

Set this keyword to a string representing the name of the file to be used instead of the file colors1.tbl in the IDL directory.

GROUP

The widget ID of the widget that calls XLOADCT. When this ID is specified, a death of the caller results in a death of XLOADCT.

MODAL

Set this keyword to block processing of events from other widgets until the user quits XLOADCT. A group leader must be specified (via the GROUP keyword) for the MODAL keyword to have any effect. By default, XLOADCT does not block event processing.

NCOLORS

The number of colors to use. Use color indices from 0 to the smaller of !D.TABLE_SIZE-1 and NCOLORS-1. The default is all available colors (!D.TABLE_SIZE).

SILENT

Normally, no informational message is printed when a color map is loaded. If this keyword is set to zero, the message is printed.

UPDATECALLBACK

Set this keyword to a string containing the name of a user-supplied procedure that will be called when the color table is updated by XLOADCT. The procedure may optionally accept a keyword called DATA, which will be automatically set to the value specified by the optional UPDATECBDATA keyword.

UPDATECBDATA

Set this keyword to a value of any type. It will be passed via the DATA keyword to the user-supplied procedure specified via the UPDATECALLBACK keyword, if any. If the UPDATECBDATA keyword is not set the value accepted by the DATA keyword to the procedure specified by UPDATECALLBACK will be undefined.

USE_CURRENT

Set this keyword to use the current color tables, regardless of the contents of the COLORS common block.

Examples

The XLOADCT utility allows you to load one of IDL's 41 pre-defined color tables and change that color table if necessary.

Using the XLOADCT Utility

The following example shows how to use XLOADCT to load a color table and then change that table to highlight specific features of an image. The indexed image used in this example is a computed tomography (CT) scan of a human thoracic cavity and is contained (without a default color table) within the `ctscan.dat` file in IDL's `examples/data` directory. Complete the following steps for a detailed description of the process.

Example Code

See `usingxloadct.pro` in the `examples/doc/image` subdirectory of the IDL installation directory for code that duplicates this example. Run the example procedure by entering `usingxloadct` at the IDL command prompt or view the file in an IDL Editor window by entering `.EDIT usingxloadct.pro`. The BLOCK keyword is set when using XLOADCT to force the example routine to wait until the **Done** button is pressed to continue. If the BLOCK keyword was not set, the example routine would produce all of the displays at once and then end.

1. Determine the path to the `ctscan.dat` binary file:

   ```
   ctscanFile = FILEPATH('ctscan.dat', $
      SUBDIRECTORY = ['examples', 'data'])
   ```

2. Initialize the image size parameter:

   ```
   ctscanSize = [256, 256]
   ```

3. Import the image from the file:

```
ctscanImage = READ_BINARY(ctscanFile, $
   DATA_DIMS = ctscanSize)
```

4. If you are running IDL on a TrueColor display, set the DECOMPOSED keyword of the DEVICE command to zero before your first color table related routine is used within an IDL session or program.

```
DEVICE, DECOMPOSED = 0
```

Since the imported image does not have an associated color table, you need to apply a pre-defined color table to display the image.

5. Initialize the display by applying the B-W LINEAR color table (index number 0):

```
LOADCT, 0
WINDOW, 0, TITLE = 'ctscan.dat', $
    XSIZE = ctscanSize[0], YSIZE = ctscanSize[1]
```

6. Display the image using this color table:

```
TV, ctscanImage
```

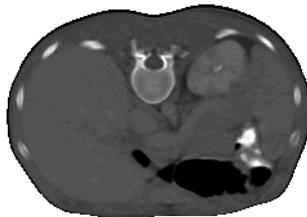
As the following figure shows, the B-W LINEAR color table does not highlight all of the aspects of this image. The XLOADCT utility can be used to change the color table to highlight more features.


Figure 26-3: CT Scan Image with Grayscale Color Table

7. Open the XLOADCT utility:

   XLOADCT

   Select Rainbow + white and click **Done** to apply the color table.

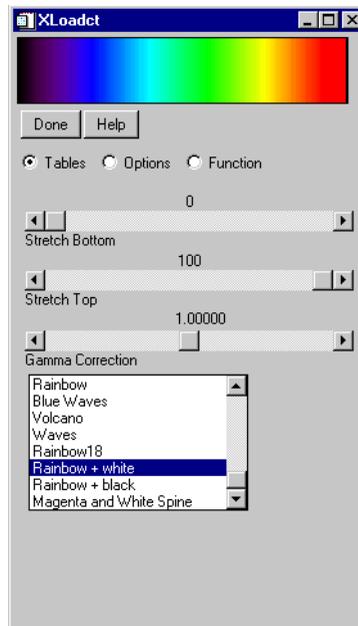
   The following figure shows the resulting XLOADCT display.


Figure 26-4: Selecting Rainbow + white Color Table in XLOADCT Utility

After applying the new color table, you can now see the spine, liver, and kidney within the image, as shown in the following figure. However, the separations between the skin, the organs, and the cartilage and bone within the spine are hard to distinguish.

8. Now re-display the image to show it on the Rainbow + white color table:

    ```
    TV, ctscanImage
    ```

    Note ──

    You do not have to perform the previous step on a PseudoColor display.
    Changes to the current color table automatically show in the current image
    window within a PseudoColor display.

    ──

    The following figure shows the CT scan image with the Ranbow+white color
    table.
    Figure 26-5: CT Scan Image with the Rainbow + white Color Table

9. Redisplay the color table with the XLOADCT utility:

    ```
    XLOADCT
    ```

    Comparing the image to the color table, you can see that most image pixels are
    not within the black to purple range. Therefore the black to purple pixels in the
    image can be replaced by black. The black range can be stretched to move the
    purple range to help highlight more features.

    The **Stretch Bottom** slider in the XLOADCT utility increases the range of the
    lowest color index. For example, if black was the color of the lowest index and
    you increased the bottom stretch by 50 percent, the lower half of the color table
    would become all black. The remaining part of the color table will contain a
    scaled version of all the previous color ranges.

10. Within XLOADCT, stretch the bottom part of the color table by 20 percent by moving the slider as shown in the following figure:

```
TV, ctscanImage
```

Note ———

Remember to click on the **Done** button after changing the **Stretch Bottom** slider, then use TV to re-display the image to include the last changing made in the XLOADCT utility.

——

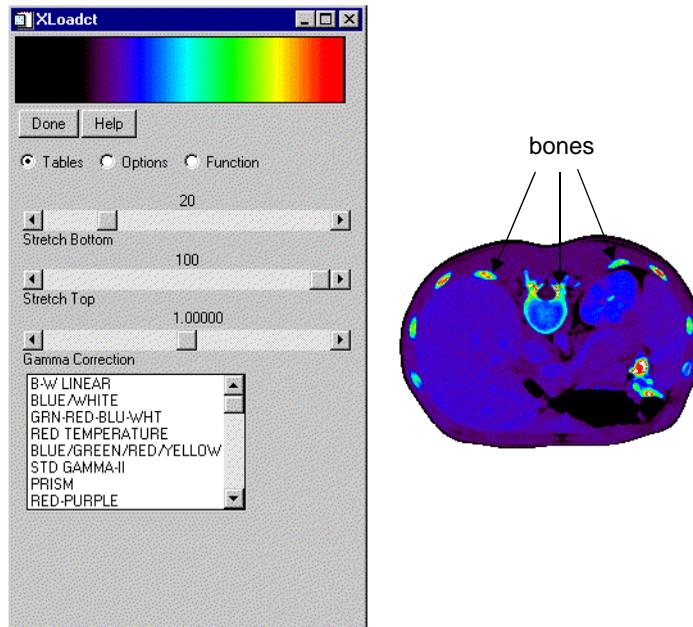
In the following figure, you can now see the difference between skin and organs. You can also see where cartilage and bone is located within the spine, but now organs are hard to see. Most of the values in the top (the yellow to red to white ranges) of the color table show just the bones. You can use less of these ranges to show bones by stretching the top of the color table.


Figure 26-6: CT Scan Image with Bottom Stretched by 20%

The **Stretch Top** slider in the XLOADCT utility allows you increase the range of the highest color index. For example, if white was the color of the highest index and you increased the top stretch by 50 percent, the higher half of the color table would become all white. The remaining part of the color table will contain a scaled version of all the previous color ranges.

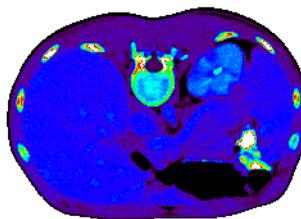
11. Open XLOADCT:

```
XLOADCT
```

Stretch the bottom part of the color table by 20 percent and stretch the top part of the color table by 20 percent (changing it from 100 to 80 percent).

Click **Done** and redisplay the image:

```
TV, ctscanImage
```

The following figure shows that the organs are more distinctive, but now the liver and kidneys are not clearly distinguished. These features occur in the blue range. You can shift the green range more toward the values of these organs with a gamma correction.


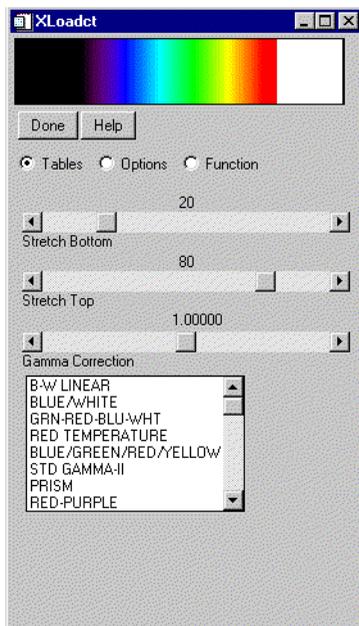


Figure 26-7: CT Scan Image with Bottom and Top Stretched by 20%

With the **Gamma Correction** slider in the XLOADCT utility you can change the contrast within the color table. A value of 1.0 indicates a linear ramp (no gamma correction). Values other than 1.0 indicate a logarithmic ramp. Higher values of gamma give more contrast. Values less than 1.0 yield lower contrast.

12. Within XLOADCT, stretch the bottom part of the color table by 20 percent, stretch the top part of the color table by 20 percent (change it from 100 percent to 80 percent), and decrease the Gamma Correction factor to 0.631:

```
XLOADCT
```

Redisplay the image:

```
TV, ctscanImage
```

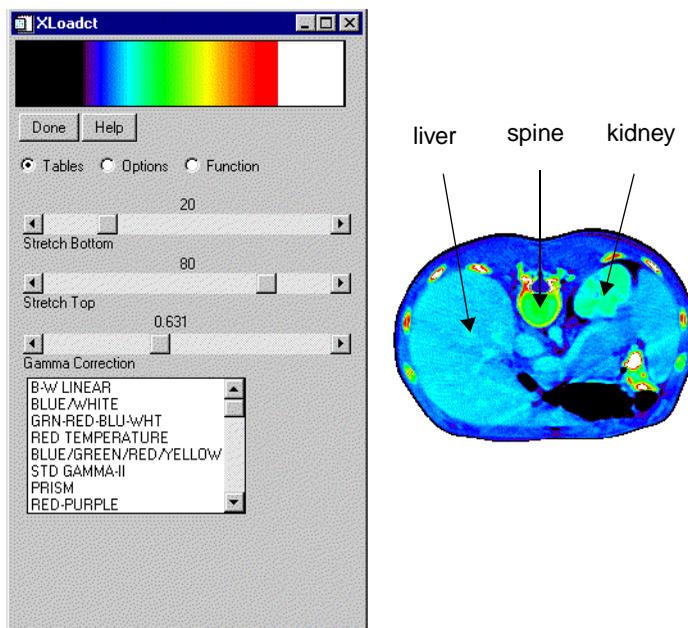
All the features are now highlighted within the image as shown in the following figure:


Figure 26-8: CT Scan Image with Bottom and Top Stretched by 20% and Gamma Correction at 0.631

The previous steps showed how to use the **Tables** section of the XLOADCT utility. XLOADCT also contains two other sections: **Options** and **Function**.

The **Options** section allows you to change what the sliders represent and how they are used. When the **Gang** option is selected, the sliders become dependent upon each other. When either the **Stretch Bottom** or **Stretch Top** sliders are moved, the other ones reset to their default values (0 or 100, respectively). With the **Chop** option, you can chop off the top of the color table (the range of the **Stretch Top** is now black instead of the color at the original highest index). With the **Intensity** option, you can change the slider to control the intensity instead of the index location. The **Stretch Bottom** slider will darken the color table and the **Stretch Top** slider will brighten the color table.

The **Function** section allows you to place control points which you can use to change the color table with respect to the other colors in that table. The color table function is shown as a straight line increasing from the lowest index (0) to the highest index (255). The x-axis ranges from 0 to 255 and the y-axis ranges from 0 to 255. Moving a control point in the x-direction has the same effects as the previous sliders. Moving a control point in the y-direction changes the color of that index to another color within the color table. For example, if a control point is red at an index of 128 and the color table is green at an index of 92, when the control point is moved in the y-direction to an index of 92, the color at that x-location will become green. To understand how the **Function** section work, you can use it to highlight just the bones with the CT scan image.

13. Open XLOADCT:

        XLOADCT

Select the Rainbow + white color table.

Switch to the **Function** section by selecting that option.

Select the **Add Control Point** button, and drag this new center control point one half of the way to the right and one quarter of the way down as shown in the following figure.

Click **Done** and redisplay the image:

        TV, ctscanImage

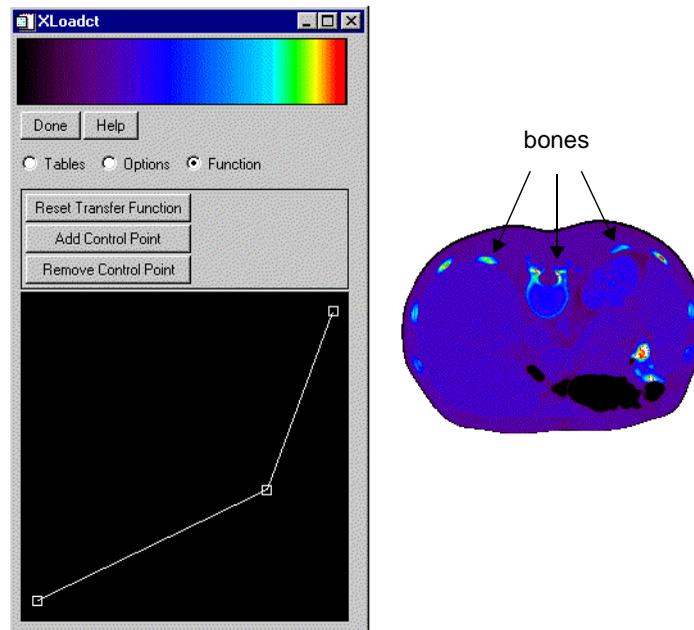
The bones in the image are now highlighted.


Figure 26-9: CT Scan Image with Central Control Point Moved One Half to the Right and One Quarter Down

XMANAGER

The XMANAGER procedure provides the main event loop and management for widgets created using IDL. Calling XMANAGER "registers" a widget program with the XMANAGER event handler. XMANAGER takes control of event processing until all widgets have been destroyed.

Beginning with IDL version 5.0, IDL supports an *active command line* that allows the IDL command line to continue accepting input while properly configured widget applications are running. See "A Note About Blocking in XMANAGER" on page 3032 for a more detailed explanation of the active command line.

This routine is written in the IDL language. Its source code can be found in the file xmanager.pro in the lib subdirectory of the IDL distribution.

Warning ───

Although this routine is written in the IDL language, it may change in the future in its internal implementation. For future upgradability, it is best not to modify or even worry about what this routine does internally.

───

Syntax

XMANAGER [, *Name*, *ID*] [, /CATCH] [, CLEANUP=*string*]
    [, EVENT_HANDLER='*procedure_name*'] [, GROUP_LEADER=*widget_id*]
    [, /JUST_REG] [, /NO_BLOCK]

Arguments

Name

A string that contains the name of the routine that creates the widget (i.e., the name of the widget creation routine that is calling XMANAGER).

Note ──

The *Name* argument is stored in a COMMON block for use by the XREGISTERED routine. The stored name is case-sensitive.

───

ID

The widget ID of the top-level base that is the root of the widget hierarchy being to be managed.

Keywords

CATCH

Set this keyword to cause XMANAGER to catch any errors, using the CATCH procedure, when dispatching widget events. If the CATCH keyword is set equal to zero, execution halts and IDL provides traceback information when an error is detected. This keyword is set by default (errors are caught and processing continues).

Do not specify either the *Name* or *ID* argument to XMANAGER when specifying the CATCH keyword (they are ignored). CATCH turns error catching on and off for *all* applications managed by XMANAGER. When CATCH is specified, XMANAGER changes its error-catching behavior and returns immediately, without taking any other action.

Note _____

Beginning with IDL version 5.0, the default behavior of XMANAGER is to catch errors and continue processing events. In versions of IDL prior to version 5.0, XMANAGER halted when an error was detected. This change in default behavior was necessary in order to allow multiple widget applications (all being managed by XMANAGER) to coexist peacefully. When CATCH is set equal to zero, (the old behavior), any error halts XMANAGER, and thus halts event processing for all running widget applications.

Note also that CATCH is only effective if XMANAGER is blocking to dispatch errors. If event dispatching for an active IDL command line is in use, the CATCH keyword has no effect.

The CATCH=0 setting (errors are not caught and processing halts in XMANAGER when an error is detected) is intended as a debugging aid. Finished programs should not set CATCH=0.

_____

CLEANUP

Set this keyword to a string that contains the name of the routine to be called when the widget program dies. If this keyword is not specified, the routine (if any) specified for the program's top-level base by the KILL_NOTIFY keyword to WIDGET_BASE or WIDGET_CONTROL is used.

The routine specified by CLEANUP becomes the KILL_NOTIFY routine for the widget application, overriding any cleanup routines that have been set previously via the KILL_NOTIFY keyword to WIDGET_BASE or WIDGET_CONTROL.

Note ──

Specifying a routine for the widget application's top-level base via the
KILL_NOTIFY keyword to WIDGET_CONTROL *after* the call to XMANAGER
will override the value of the CLEANUP keyword.

──

The cleanup routine is called with the widget identifier as its only argument.

EVENT_HANDLER

Set this keyword to a string that contains the name of a routine to be called when a
widget event occurs in the widget program being registered. If this keyword is not
supplied, XMANAGER will construct a default name by adding the "_event" suffix
to the *Name* argument. See the example below for a more detailed explanation.

GROUP_LEADER

The widget ID of the group leader for the widget being processed. When the leader
dies either by the users actions or some other routine, all widgets that have that leader
will also die.

For example, a widget that views a help file for a demo widget would have that demo
widget as its leader. When the help widget is registered, it sets the keyword
GROUP_LEADER to the widget ID of the demo widget. If the demo widget were
destroyed, the help widget led by it would be killed by the XMANAGER.

JUST_REG

Set this keyword to indicate that XMANAGER should just register the widget and
return immediately. This keyword is useful if you want to register a group of related
top-level widgets before beginning event processing and one or more of the registered
widgets requests that XMANAGER block event processing. (Note that in this case a
later call to XMANAGER without the JUST_REG keyword is necessary to begin
blocking.)

(See "A Note About Blocking in XMANAGER" on page 3032 for further discussion
of the active command line.)

Warning ──

JUST_REG is not the same as NO_BLOCK. See "JUST_REG vs. NO_BLOCK"
on page 3032 for additional details.

──

NO_BLOCK

Set this keyword to tell XMANAGER that the registering client does not require XMANAGER to block if active command line event processing is available. If active command line event processing is available *and* every current XMANAGER client specifies NO_BLOCK, then XMANAGER will not block and the user will have access to the command line while widget applications are running.

It is important to understand the result of making nested calls to XMANAGER. XMANAGER can only block event processing for one client at a time. In applications involving multiple calls to XMANAGER (either directly or via calls to other routines that call XMANAGER, such as XLOADCT), blocking occurs only for the outermost call to XMANAGER, unless XMANAGER is told not to block in that call. If an application contains two calls to XMANAGER, the second call cannot block unless the first call sets the NO_BLOCK keyword. If an application contains a call to XMANAGER, followed by a call to XLOADCT, XLOADCT will not block unless the NO_BLOCK keyword was set in the call to XMANAGER (and the BLOCK keyword to XLOADCT is set). Consider the following example:

```
PRO blocking_example_event, event
   ; The following call blocks only if the NO_BLOCK keyword to
   ; XMANAGER is set:
   XLOADCT, /BLOCK
END

PRO blocking_example
   base=WIDGET_BASE(/COLUMN)
   button1=WIDGET_BUTTON(base,VALUE='Run XLOADCT')
   WIDGET_CONTROL,base, /REALIZE
   XMANAGER,'blocking_example', base, /NO_BLOCK
END
```

If the NO_BLOCK keyword to XMANAGER was not set in the above example, XLOADCT would not block, even though the BLOCK keyword was set. Setting the NO_BLOCK keyword to XMANAGER prevents XMANAGER from blocking, thereby allowing the subsequent call to XMANAGER (via XLOADCT) to block.

Warning ──

NO_BLOCK is not the same as JUST_REG. See "JUST_REG vs. NO_BLOCK" on page 3032 for additional details.

──

A Note About Blocking in XMANAGER

By default, IDL widget application blocking is *enabled*. Unless you take the appropriate steps, widget applications will block all other processing from occurring in IDL. Keeping the following issues in mind when writing widget applications will give you the best chance to create applications that coexist with other applications and the IDL command line.

Active Command Line

Beginning with IDL version 5.0, most versions of IDL's command-processing front-end are able to support an *active command line* while running properly constructed widget applications. What this means is that—provided the widget application is properly configured—the IDL command line is available for input while a widget application is running and widget events are being processed.

There are currently 3 separate IDL command-processing front-end implementations:

- Microsoft Windows workbench
- Motif workbench (UNIX)
- UNIX plain tty

Note that widget applications must be well-behaved with respect to blocking widget event processing. Since in most cases XMANAGER is used to handle widget event processing, this means that in order for the command line to remain active, all widget applications must be run with the NO_BLOCK keyword to XMANAGER set. (Note that since NO_BLOCK is *not* the default, it is quite likely that some application will block.) If a single application runs in blocking mode, the command line will be inaccessible until the blocking application exits. When a blocking application exits, the IDL command line will once again become active.

JUST_REG vs. NO_BLOCK

Although their names imply a similar function, the JUST_REG and NO_BLOCK keywords perform very different services. It is important to understand what they do and how they differ.

The JUST_REG keyword tells XMANAGER that it should simply register a client and then return immediately. The result is that the client becomes known to XMANAGER, and that future calls to XMANAGER will take this client into account. Therefore, JUST_REG only controls how the registering call to XMANAGER should behave. The client can still be registered as requiring

XMANAGER to block by setting NO_BLOCK=0. In this case, *future* calls to XMANAGER will block.

The NO_BLOCK keyword tells XMANAGER that the registered client does not require XMANAGER to block if the command-processing front-end is able to support active command line event processing. XMANAGER remembers this attribute of the client until the client exits, even after the call to XMANAGER that registered the client returns. NO_BLOCK is just a "vote" on how XMANAGER should behave—the final decision is made by XMANAGER by considering the NO_BLOCK attributes of *all* of its current clients as well as the ability of the command-processing front-end in use to support the active command line.

Blocking vs. Non-blocking Applications

The issue of blocking in XMANAGER requires some explanation. IDL widget events are not processed until the WIDGET_EVENT function is called to handle them. Otherwise, they are queued by IDL indefinitely. Knowing how and when to call WIDGET_EVENT is the primary service provided by XMANAGER.

There are two ways blocking is typically handled:

1. The first call to XMANAGER processes events by calling WIDGET_EVENT as necessary until no managed widgets remain on the screen. This is referred to as "blocking" because XMANAGER does not return to the caller until it is done, and the IDL command line is not available.

2. XMANAGER does not block, and instead, the part of IDL that reads command input also watches for widget events and calls WIDGET_EVENT as necessary while also reading command input. This is referred to as "non-blocking" or "active command line" mode.

XMANAGER will block unless the following conditions are met:

- All registered widget applications have the NO_BLOCK keyword to XMANAGER set.

- No modal dialogs are displayed. (Modal dialogs always block until dismissed.)

In general, we suggest that new widget applications be written with XMANAGER blocking disabled (that is, with the NO_BLOCK keyword set).

Since a widget application that does block event processing for itself will block event processing for all other widget applications (and the IDL command line) as well, we suggest that older widget applications be upgraded to take advantage of the new, non-blocking behavior by adding the NO_BLOCK keyword to most calls to XMANAGER.

Examples

The following code creates a widget named EXAMPLE that is just a base widget with a "Done" button and registers it with the XMANAGER. Widgets being registered with the XMANAGER must provide at least two routines. The first routine creates the widget and registers it with the manager and the second routine processes the events that occur within that widget. An example widget is supplied below that uses only two routines. A number of other "Simple Widget Examples", can be viewed by entering WEXMASTER at the IDL prompt. These simple programs demonstrate many aspects of widget programming.

The following lines of code would be saved in a single file, named example.pro:

```
; Begin the event handler routine for the EXAMPLE widget:
PRO example_event, ev

; The uservalue is retrieved from a widget when an event occurs:
WIDGET_CONTROL, ev.id, GET_UVALUE = uv

; If the event occurred in the Done button, kill the widget
; example:
if (uv eq 'DONE') THEN WIDGET_CONTROL, ev.top, /DESTROY

; End of the event handler part:
END

; This is the routine that creates the widget and registers it with
; the XMANAGER:
PRO example

; Create the top-level base for the widget:
base = WIDGET_BASE(TITLE='Example')

; Create the Done button and set its uservalue to "DONE":
done = WIDGET_BUTTON(base, VALUE = 'Done', UVALUE = 'DONE')
; Realize the widget (i.e., display it on screen):
WIDGET_CONTROL, base, /REALIZE

; Register the widget with the XMANAGER, leaving the IDL command
; line active:
XMANAGER, 'example', base, /NO_BLOCK

; End of the widget creation part:
END
```

First the event handler routine is listed. The handler routine has the same name as the main routine with the characters "_event" added. If you would like to use another event handler name, you would need to pass its name to XMANAGER using the EVENT_HANDLER keyword.

Notice that the event routine is listed before the main routine. If you include both the event routine and the main routine in a single .pro file with the name of the main routine (a common practice), this is necessary to ensure that the event routine is compiled. If the event routine were placed after the main routine in the file, IDL would compile and execute the main routine — and the compiler would exit — before the event routine was compiled. Alternatively, you can save your event routine in its own file with its own name (which in the above example would be example_event.pro), and IDL will compile the routine when it is required.

Notice also the NO_BLOCK keyword to XMANAGER has been included. This allows IDL to continue processing events and accepting input at the command prompt while the example widget application is running.

Version History

Pre-4.0	Introduced
Pre-6.2	Deprecated BACKGROUND and MODAL

For information on obsolete keywords, see Appendix I, "Obsolete Features".

XMTOOL, XREGISTERED, Chapter 2, "Creating Widget Applications" (*Widget Application Programming*).

XMNG_TMPL

The XMNG_TMPL procedure is a template for widgets that use the XMANAGER. Use this template instead of writing your widget applications from "scratch". This template can be found in the file `xmng_tmpl.pro` in the `lib` subdirectory of the IDL distribution.

The documentation header should be altered to reflect the actual implementation of the XMNG_TMPL widget. Use a global search and replace to replace the word `XMNG_TMPL` with the name of the routine you would like to use. All the comments with a "`***`" in front of them should be read, decided upon and removed from the final copy of your new widget routine.

Syntax

XMNG_TMPL [, /BLOCK] [, GROUP=*widget_id*]

Arguments

None

Keywords

BLOCK

Set this keyword to have XMANAGER *block* when this application is registered. By default, BLOCK is set equal to zero, providing access to the command line if active command line processing is available. Note that setting BLOCK=1 will cause *all* widget applications to block, not just this application. For more information, see the documentation for the NO_BLOCK keyword to XMANAGER.

Note ——

Only the outermost call to XMANAGER can block. Therefore, to have XMNG_TMPL block, any earlier calls to XMANAGER must have been called with the NO_BLOCK keyword. See the documentation for the NO_BLOCK keyword to XMANAGER for an example.

——

GROUP

The widget ID of the widget that calls XMNG_TMPL. When this ID is specified, the death of the caller results in the death of XMNG_TMPL.

Version History

Pre-4.0	Introduced

CW_TMPL

XMTOOL

The XMTOOL procedure displays a tool for viewing widgets currently being managed by the XMANAGER. Only one instance of the XMTOOL can run at one time.

This routine is written in the IDL language. Its source code can be found in the file xmtool.pro in the lib/utilities subdirectory of the IDL distribution.

Syntax

XMTOOL [, /BLOCK] [, GROUP=*widget_id*]

Arguments

None.

Keywords

BLOCK

Set this keyword to have XMANAGER *block* when this application is registered. By default, BLOCK is set equal to zero, providing access to the command line if active command line processing is available. Note that setting BLOCK=1 will cause *all* widget applications to block, not just this application. For more information, see the documentation for the NO_BLOCK keyword to XMANAGER.

Note
Only the outermost call to XMANAGER can block. Therefore, to have XMTOOL block, any earlier calls to XMANAGER must have been called with the NO_BLOCK keyword. See the documentation for the NO_BLOCK keyword to XMANAGER for an example.

GROUP

The widget ID of the widget that calls XMTOOL. If the calling widget is destroyed, the XMTOOL is also destroyed.

XMANAGER

XOBJVIEW

The XOBJVIEW procedure is a utility used to quickly and easily view and manipulate IDL Object Graphics on screen. It displays given objects in an IDL widget with toolbar buttons and menus providing functionality for manipulating, printing, and exporting the resulting graphic. The mouse can be used to rotate, scale, or translate the overall model shown in a view, or to select graphic objects in a view.

This routine is written in the IDL language. Its source code can be found in the file `xobjview.pro` in the `lib/utilities` subdirectory of the IDL distribution.

Note ───

Two routines associated with the XOBJVIEW utility — XOBJVIEW_ROTATE and XOBJVIEW_WRITE_IMAGE — do not provide a graphical interface themselves, but act on an existing instance of the XOBJVIEW utility.

──

Using XOBJVIEW

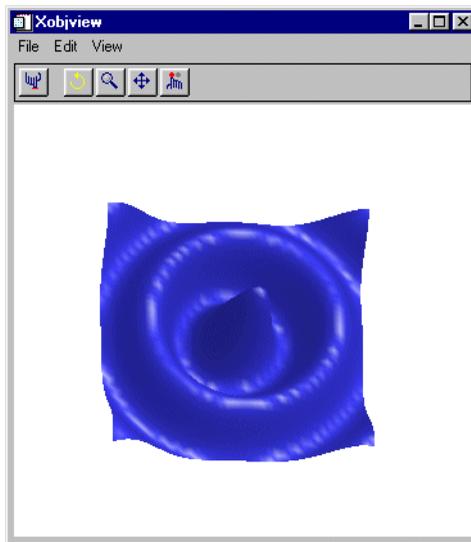
XOBJVIEW displays a resizeable top-level base with a menu, toolbar and draw widget, as shown in the following figure:


Figure 26-10: The XOBJVIEW widget

The XOBJVIEW Toolbar

The XOBJVIEW toolbar contains the following buttons:

Button	Tool Name	Function
	Reset	Resets the display to its original position, orientation, scale, and aspect ratio. Changes to the size of the XOBJVIEW window itself are *not* reset.
	Rotate	Click the left mouse button on the object and drag to rotate.
	Pan	Click the left mouse button on the object and drag to pan.
	Zoom	Click the left mouse button on the object and drag to zoom in or out.
	Select	Click on the object. The name of the selected object is displayed, if the object has a name, otherwise its class is displayed.

Table 26-3: XOBJVIEW Toolbar Buttons

Syntax

XOBJVIEW, *Obj* [, BACKGROUND=*[r, g, b]*] [, /BLOCK] [, /DOUBLE_VIEW]
   [, GROUP=*widget_id*] [, /JUST_REG] [, /MODAL] [, REFRESH=*widget_id*]
   [, RENDERER={0 | 1}] [, SCALE=*value*] [, STATIONARY=*objref(s)*] [, /TEST]
   [, TITLE=*string*] [, TLB=*variable*] [, XOFFSET=*value*] [, XSIZE=*pixels*]
   [, YOFFSET=*value*] [, YSIZE=*pixels*]

Arguments

Obj

A reference to an atomic graphics object, an IDLgrModel, or an array of such references. If *Obj* is an array, the array can contain a mixture of such references. Also, if *Obj* is an array, all object references in the array must be unique (i.e. no two references in the array can refer to the same object).

Obj is not destroyed when XOBJVIEW is quit or killed.

Keywords

BACKGROUND

Set this keyword to a three-element [r, g, b] color vector specifying the background color of the XOBJVIEW window.

BLOCK

Set this keyword to have XMANAGER block when this application is registered. By default, BLOCK is set equal to zero, providing access to the command line if active command line processing is available. Note that setting the BLOCK keyword causes all widget applications to block, not just this application. For more information, see the documentation for the NO_BLOCK keyword to XMANAGER.

Note

Only the outermost call to XMANAGER can block. Therefore, to have XOBJVIEW block, any earlier calls to XMANAGER must have been called with the NO_BLOCK keyword. See the documentation for the NO_BLOCK keyword to XMANAGER for an example.

DOUBLE_VIEW

Set this keyword to cause XOBJVIEW to set the DOUBLE property on the IDLgrView that it uses to display graphical data.

GROUP

The widget ID of the widget that calls XOBJVIEW. When this ID is specified, the death of the caller results in the death of XOBJVIEW.

JUST_REG

Set this keyword to indicate that the XOBJVIEW utility should just be registered and return immediately. This is useful if you want to register XOBJVIEW before beginning event processing and one or more widgets requests that XMANAGER block event processing. See "JUST_REG vs. NO_BLOCK" on page 3032 for additional details.

MODAL

Set this keyword to block processing of events from other widgets until the user quits XOBJVIEW. The MODAL keyword does not require a group leader to be specified.

If no group leader is specified, and the MODAL keyword is set, XOBJVIEW fabricates an invisible group leader for you.

Note

To be modal, XOBJVIEW does not require that its caller specify a group leader. This is unlike other IDL widget procedures such as XLOADCT, which, to be modal, do require that their caller specify a group leader. These other procedures were implemented this way to encourage the caller to create a modal widget that will be well-behaved with respect to layering and iconizing. (See "Iconizing, Layering, and Destroying Groups of Top-Level Bases" on page 2653 for more information.)

To provide a simple means of invoking XOBJVIEW as a modal widget in applications that contain no other widgets, XOBJVIEW can be invoked as MODAL without specifying a group leader, in which case XOBJVIEW fabricates an invisible group leader for you. For applications that contain multiple widgets, however, it is good programming practice to supply an appropriate group leader when invoking XOBJVIEW, /MODAL. As with other IDL widget procedures with names prefixed with "X", specify the group leader via the GROUP keyword.

REFRESH

Set this keyword to the widget ID of the XOBJVIEW instance to be refreshed. To retrieve the widget ID of an instance of XOBJVIEW, first call XOBJVIEW with the TLB keyword. To refresh that instance of XOBJVIEW, call XOBVIEW again and set REFRESH to the value retrieved by the TLB keyword in the earlier call to XOBJVIEW. For example, in the initial call to XOBJVIEW, use the TLB keyword as follows:

```
XOBJVIEW, myobj, TLB=tlb
```

If the properties of myobj are changed in your application or at the IDL command line, refresh the view in XOBJVIEW by calling XOBJVIEW again with the REFRESH keyword:

```
XOBJVIEW, REFRESH=tlb
```

For an example application demonstrating the use of the REFRESH keyword, see "Example 3" on page 3047.

Note ───

Currently, the REFRESH keyword can only be used to refresh the object itself. All other keywords and arguments to XOBJVIEW are ignored when REFRESH is specified, therefore, properties such as the background color and scale are not affected.

───

RENDERER

Set this keyword to an integer value indicating which graphics renderer to use when drawing objects in the XOBJVIEW draw window. Valid values are:

- 0 = Platform native OpenGL
- 1 = IDL's software implementation

By default, your platform's native OpenGL implementation is used. If your platform does not have a native OpenGL implementation, IDL's software implementation is used regardless of the value of this property. See "Hardware vs. Software Rendering" (Chapter 2, *Object Programming*) for details. Your choice of renderer may also affect the maximum size of the XOBJVIEW draw window. See "IDLgrWindow" on page 4960 for details.

SCALE

Set this keyword to the zoom factor for the initial view. The default is 1/SQRT(3). This default value provides the largest possible view of the object, while ensuring that no portion of the object will be clipped by the XOBJVIEW window, regardless of the object's orientation.

STATIONARY

Set this keyword to a reference to an atomic graphics object, an IDLgrModel, or an array of such references. If this keyword is an array, the array can contain a mixture of such references. Also, if this keyword is an array, all object references in the array must be unique (i.e., no two references in the array can refer to the same object). Objects passed to XOBJVIEW via this keyword will not scale, rotate, or translate in response to mouse events. Default stationary objects are two lights. These two lights are replaced if one or more lights are supplied via this keyword. Objects specified via this keyword are not destroyed by XOBJVIEW when XOBJVIEW is quit or killed.

For example, to change the default lights used by XOBJVIEW, you could specify your own lights using the STATIONARY keyword as follows:

```
mylight1 = OBJ_NEW('IDLgrLight', TYPE=0, $
   COLOR=[255,0,0]) ; Ambient red
```

```
mylight2 = OBJ_NEW('IDLgrLight', TYPE=2, $
   COLOR=[255,0,0], LOCATION=[2,2,5]) ; Directional red

mymodel = OBJ_NEW('IDLgrModel')
mymodel->Add, mylight1
mymodel->Add, mylight2

XOBJVIEW, /TEST, STATIONARY=mymodel
```

TEST

If set, the *Obj* argument is not required (and is ignored if provided). A blue sinusoidal surface is displayed. This allows you to test code that uses XOBJVIEW without having to create an object to display.

TITLE

Set this keyword to the string that appears in the XOBJVIEW title bar.

TLB

Set this keyword to a named variable that upon return will contain the widget ID of the top level base.

XOFFSET

The horizontal offset of the widget in units specified by the UNITS keyword (pixels are the default) relative to its parent.

Specifying an offset relative to a row-major or column-major base widget does not work because those widgets enforce their own layout policies. This keyword is primarily of use relative to a plain base widget. Note that it is best to avoid using this style of widget layout.

XSIZE

Set this keyword to the width of the drawable area in pixels. The default is 400.

YOFFSET

The vertical offset of the widget in units specified by the UNITS keyword (pixels are the default) relative to its parent. This offset is specified relative to the upper left corner of the parent widget.

Specifying an offset relative to a row-major or column-major base widget does not work because those widgets enforce their own layout policies. This keyword is

primarily of use relative to a plain base widget. Note that it is best to avoid using this style of widget layout.

YSIZE

Set this keyword to the height of the drawable area in pixels. The default is 400.

Examples

Example 1

This example displays a simple IDLgrSurface object using XOBJVIEW:

```
oSurf = OBJ_NEW('IDLgrSURFACE', DIST(20))
XOBJVIEW, oSurf
```

Example 2

This example displays an IDLgrModel object consisting of two separate objects:

```
; Create contour object:
oCont = OBJ_NEW('IDLgrContour', DIST(20), N_LEVELS=10)

; Create surface object:
oSurf = OBJ_NEW('IDLgrSurface', $
   DIST(20),INDGEN(20)+20, INDGEN(20)+20)

; Create model object:
oModel = OBJ_NEW('IDLgrModel')

; Add contour and surface objects to model:
oModel->Add, oCont
oModel->Add, oSurf

; View model:
XOBJVIEW, oModel
```

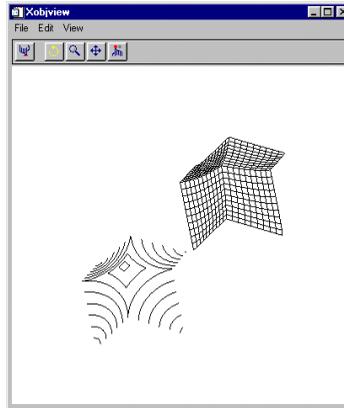
This code results in the following view in the XOBJVIEW widget:


Figure 26-11: Using XOBJVIEW to view a model consisting of two objects

Note that when you click the Select button, and then click on an object, the class of that object appears next to the Select button. If the selected object has a non-null NAME property associated with it, that string value will be displayed, otherwise the name of the selected object's class will be displayed.

If you want the class of the model to appear when you click over any object in the model, you can set the SELECT_TARGET property of the model as follows:

```
oModel->SetProperty, /SELECT_TARGET
```

Also note that it is not necessary to create a model to view more than one object using XOBJVIEW. We could view the oCont and oSurf objects created in the above example by placing them in an array as follows:

```
XOBJVIEW, [oCont, oSurf]
```

Example 3

This example demonstrates how the REFRESH keyword can be used to refresh the object displayed in an instance of XOBJVIEW.

```
PRO xobjview_refresh_event, event
   WIDGET_CONTROL, event.id, GET_UVALUE=uval
   WIDGET_CONTROL, event.top, GET_UVALUE=state
```

```
            CASE uval OF
               'red': BEGIN
                   WIDGET_CONTROL, event.id, GET_VALUE=val
                   state.myobj->GetProperty, COLOR=c
                   state.myobj->SetProperty, COLOR=[val,c[1],c[2]]
                   XOBJVIEW, REFRESH=state.tlb
                   END
               'green':  BEGIN
                   WIDGET_CONTROL, event.id, GET_VALUE=val
                   state.myobj->GetProperty, COLOR=c
                   state.myobj->SetProperty, COLOR=[c[0],val,c[2]]
                   XOBJVIEW, REFRESH=state.tlb
                   END
               'blue': BEGIN
                   WIDGET_CONTROL, event.id, GET_VALUE=val
                   state.myobj->GetProperty, COLOR=c
                   state.myobj->SetProperty, COLOR=[c[0],c[1],val]
                   XOBJVIEW, REFRESH=state.tlb
                   END
            ENDCASE
         END

         PRO xobjview_refresh_cleanup, wID
            WIDGET_CONTROL, wID, GET_UVALUE=state
            OBJ_DESTROY, state.myobj
         END

         PRO xobjview_refresh
            base = WIDGET_BASE(/COLUMN, TITLE='Adjust Object Color', $
               XOFFSET=420, XSIZE=200)

            myobj = OBJ_NEW('IDLgrSurface', $
               BESELJ(SHIFT(DIST(40), 20, 20) / 2,0) * 20, $
               COLOR=[255, 60, 60], STYLE=2, SHADING=1)
            XOBJVIEW, myobj, TLB=tlb, GROUP=base, BACKGROUND=[0,0,0]

            red = WIDGET_SLIDER(base, /DRAG, MIN=0, MAX=255, TITLE='Red', $
               UVALUE='red', VALUE=255)
            green = WIDGET_SLIDER(base, /DRAG, MIN=0, MAX=255, $
               TITLE='Green', UVALUE='green', VALUE=60)
            blue = WIDGET_SLIDER(base, /DRAG, MIN=0, MAX=255, $
               TITLE='Blue', UVALUE='blue', VALUE=60)

            WIDGET_CONTROL, base, /REALIZE

XOBJVIEW_ROTATE, XOBJVIEW_WRITE_IMAGE

XOBJVIEW_ROTATE

The XOBJVIEW_ROTATE procedure is used to programmatically rotate the object currently displayed in XOBJVIEW. XOBJVIEW must be called prior to calling XOBJVIEW_ROTATE. This procedure can be used to create animations of object displays.

This routine is written in the IDL language. Its source code can be found in the file `xobjview_rotate.pro` in the `lib/utilities` subdirectory of the IDL distribution.

Syntax

XOBJVIEW_ROTATE, *Axis*, *Angle* [, /PREMULTIPLY]

Arguments

Axis

A 3-element vector of the form [*x*, *y*, *z*] describing the axis about which the model is to be rotated.

Angle

The amount of rotation, measured in degrees.

Keywords

PREMULTIPLY

Set this keyword to cause the rotation matrix specified by *Axis* and *Angle* to be pre-multiplied to the model's transformation matrix. By default, the rotation matrix is post-multiplied.

Examples

The following example creates an animation of the test object (a surface) currently displayed in XOBJVIEW. It does this by rotating the surface through 360 degrees in increments of 10 degrees using XOBJVIEW_ROTATE, and writing the display image to a BMP file for each increment using XOBJVIEW_WRITE_IMAGE.

```
PRO RotateAndWriteObject

XOBJVIEW, /TEST
FOR i = 0, 359 DO BEGIN
   XOBJVIEW_ROTATE, [0, 1, 0], 1, /PREMULTIPLY;
   XOBJVIEW_WRITE_IMAGE, 'img' + $
   STRCOMPRESS(i, /REMOVE_ALL) + '.bmp', 'bmp'
ENDFOR

END
```

Version History

5.5	Introduced

See Also

XOBJVIEW, XOBJVIEW_WRITE_IMAGE

XOBJVIEW_WRITE_IMAGE

The XOBJVIEW_WRITE_IMAGE procedure is used to write the object currently displayed in XOBJVIEW to an image file with the specified name and file format. XOBJVIEW must be called prior to calling XOBJVIEW_WRITE_IMAGE.

This routine is written in the IDL language. Its source code can be found in the file `xobjview_write_image.pro` in the `lib/utilities` subdirectory of the IDL distribution.

Syntax

XOBJVIEW_WRITE_IMAGE, *Filename*, *Format* [, DIMENSIONS=*[x, y]*]

Arguments

Filename

A scalar string containing the name of the file to write.

Format

A scalar string containing the name of the file format to write. See WRITE_IMAGE for a list of supported formats.

Keywords

DIMENSIONS

Set this keyword to a 2-element vector of the form [*x*, *y*] specifying the size of the output image, in pixels. If this keyword is not specified, the image will be written using the dimensions of the current XOBJVIEW draw widget.

Examples

See XOBJVIEW_ROTATE.

Version History

5.5	Introduced

XOBJVIEW, XOBJVIEW_ROTATE

XPALETTE

The XPALETTE procedure is a utility that displays a widget interface that allows interactive creation and modification of color tables using the RGB, CMY, HSV, or HLS color systems. This procedure can interpolate the space between color indices (to create smooth color transitions) or edit individual colors.

This routine is written in the IDL language. Its source code can be found in the file xpalette.pro in the lib/utilities subdirectory of the IDL distribution.

Using the XPALETTE Interface

Calling XPALETTE causes a graphical interface to appear. The elements of this interface are described below.

Plots on Left Side of Interface

Three plots show the current red, green, and blue vectors.

Status Region

The center of the XPALETTE widget is a status region containing:

- The total number of colors.

- The current color index. XPALETTE allows changing one color at a time. This color is known as the "current color" and is indicated in the color spectrum display with a special marker.

- The current mark index. The mark is used to remember a color index. Click the "Set Mark Button" to make the current color index the mark index.

- A sample of the current color. The special marker used in the color spectrum display prevents the user from seeing the color of the current index, but it is visible here.

Control Panel

A panel of 8 buttons control common XPALETTE functions:

- **Done:** Click this button to exit XPALETTE. The new color tables are saved in the COLORS common block and loaded to the display.

- **Predefined:** Click this button to start XLOADCT, allowing selection of one of the predefined color tables. Note that when you change the color map via XLOADCT, XPALETTE is not always able to keep its display accurate. This problem can be overcome by pressing the XPALETTE "Redraw" button after changing the colortable via XLOADCT.

- **Help:** Click this button to display help information.

- **Redraw:** Click this button to redraw the display using the current state of the color map.

- **Set Mark:** Click this button to set the value of the mark index to the current color index.

- **Switch Mark:** Click this button to exchange the mark and the current index.

- **Copy Current:** Click this button to make every color lying between the current index and the mark index (inclusive) the same color as the current color.

- **Interpolate:** Click this button to smoothly interpolate colors between the current index and the mark index.

Color System Control

This section of the interface allows you to select the color system used to modify individual colors. The "Select Color System" pulldown menu lets you select from four different systems—RGB, CMY, HSV, and HLS. Depending upon the current system, 3 sliders below the pulldown menu allow you to alter the current color.

Right Side Color Spectrum Display

A display on the right side of the XPALETTE interface shows the current color map as a series of squares. Color index 0 is at the upper left. The color index increases monotonically by rows going left to right and top to bottom. The current color index is indicated by a special marker symbol. There are 4 ways to change the current color:

- Click on any square in the color map display.

- Use the "By Index" slider to move to the desired color index.

- Use the "Row" Slider to move the marker vertically.

- Use the "Column" Slider to move the marker horizontally.

A Note about the Colors Used in the Interface

XPALETTE uses two colors from the current color table as drawing foreground and background colors. These are used for the RGB plots on the left, and the current index marker on the right. This means that if the user set these two colors to the same value, the XPALETTE display could become unreadable (like writing on black paper with black ink). XPALETTE minimizes this possibility by noting changes to the color map and always using the brightest available color for the foreground color and the darkest for the background. Thus, the only way to make XPALETTE's display

unreadable is to set the entire color map to a single color, which is highly unlikely. The only side effect of this policy is that you may notice XPALETTE redrawing the entire display after you've modified the current color. This simply means that the change has made XPALETTE pick new drawing colors.

Syntax

XPALETTE [, /BLOCK] [, GROUP=*widget_id*]
   [, UPDATECALLBACK='*procedure_name*' [, UPDATECBDATA=*value*]]

Arguments

None

Keywords

BLOCK

Set this keyword to have XMANAGER *block* when this application is registered. By default, BLOCK is set equal to zero, providing access to the command line if active command line processing is available. Note that setting BLOCK=1 will cause *all* widget applications to block, not just this application. For more information, see the documentation for the NO_BLOCK keyword to XMANAGER.

Note ───

Only the outermost call to XMANAGER can block. Therefore, to have XPALETTE block, any earlier calls to XMANAGER must have been called with the NO_BLOCK keyword. See the documentation for the NO_BLOCK keyword to XMANAGER for an example.

───

GROUP

The widget ID of the widget that calls XPALETTE. When this ID is specified, a death of the caller results in a death of XPALETTE.

UPDATECALLBACK

Set this keyword to a string containing the name of a user-supplied procedure that will be called when the color table is updated by XLOADCT. The procedure may optionally accept a keyword called DATA, which will be automatically set to the value specified by the optional UPDATECBDATA keyword.

UPDATECBDATA

Set this keyword to a value of any type. It will be passed via the DATA keyword to the user-supplied procedure specified via the UPDATECALLBACK keyword, if any. If the UPDATECBDATA keyword is not set the value accepted by the DATA keyword to the procedure specified by UPDATECALLBACK will be undefined.

Examples

This example uses a single color (orange) to highlight pixels within the spine of the CT scan image. Then, starting with the entry that was changed to orange, a range of entries is selected and replaced with a ramp from orange to white to highlight the bones within this image. Complete the following steps for a detailed description of the process.

Example Code

See `usingxpalette.pro` in the `examples/doc/image` subdirectory of the IDL installation directory for code that duplicates this example. Run the example procedure by entering `usingxpalette` at the IDL command prompt or view the file in an IDL Editor window by entering `.EDIT usingxpalette.pro`. The BLOCK keyword is set when using XPALETTE to force the example routine to wait until the **Done** button is pressed to continue. If the BLOCK keyword was not set, the example routine would produce all of the displays at once and then end.

1. Determine the path to the `ctscan.dat` binary file:

   ```
   ctscanFile = FILEPATH('ctscan.dat', $
      SUBDIRECTORY = ['examples', 'data'])
   ```

2. Initialize the image size parameter:

   ```
   ctscanSize = [256, 256]
   ```

3. Import the image from the file:

   ```
   ctscanImage = READ_BINARY(ctscanFile, $
      DATA_DIMS = ctscanSize)
   ```

4. If you are running IDL on a TrueColor display, set the DECOMPOSED keyword to the DEVICE command to zero before your first color table related routine is used within an IDL session or program.

   ```
   DEVICE, DECOMPOSED = 0
   ```

5. Display the image from the `ctscan.dat` file with the B-W LINEAR color
    table:

    ```
    LOADCT, 0
    WINDOW, 0, TITLE = 'ctscan.dat', $
       XSIZE = ctscanSize[0], YSIZE = ctscanSize[1]
    TV, ctscanImage
    ```

    As shown in the following figure, the B-W LINEAR color table does not
    distinguish all of the aspects of this image. The XPALETTE utility can be used
    to change the color table.
    Figure 26-12: CT Scan Image with Grayscale Color Table

6. Open the XPALETTE utility:

    ```
    XPALETTE
    ```

    Select the **Predefined** button in the XPALETTE utility to change the color
    table to Rainbow + white.

    Click on the **Done** button after you select the Rainbow + white color table in
    XLOADCT and then click on the **Done** button in XPALETTE.

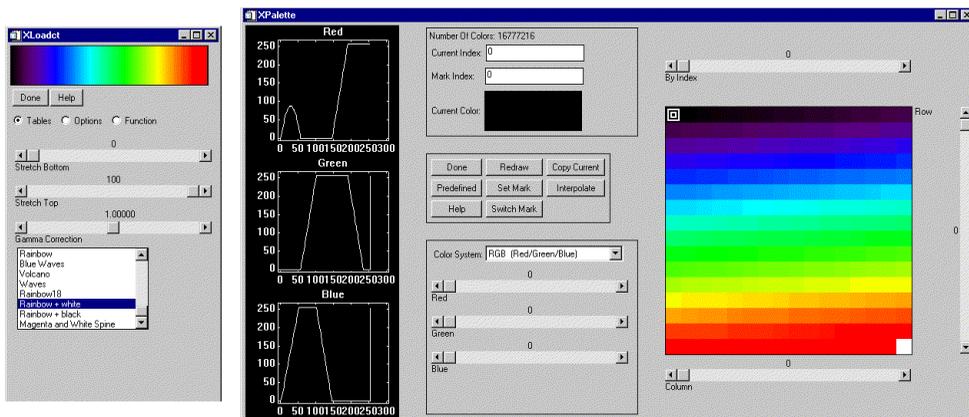
The following figure shows the resulting XPALETTE and XLOADCT displays.


Figure 26-13: Selecting Rainbow + white Color Table in XPALETTE Utility

7. Now redisplay the image to show it with the Rainbow + white color table:

```
TV, ctscanImage
```

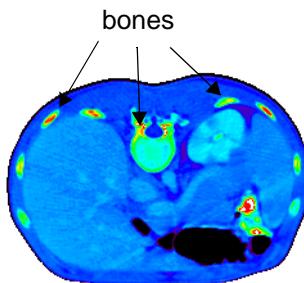
Your display should be similar to the following figure.


Figure 26-14: CT Scan Image with the Rainbow + white Color Table

You can use XPALETTE to change a single color within the current color table. For example, you can change the color at index number 115 to orange.

8. Open XPALETTE and click on the 115th index (in column 3 and row 7):

    XPALETTE

    Change its color to orange by moving the RGB (red, green, and blue) sliders
    (Orange is made up of 255 red, 128 green, and 0 blue)

    Click on the **Done** button after changing the **Red**, **Green**, and **Blue** sliders.

    Use TV to redisplay the image to include the last changes made in the
    XPALETTE utility:

    TV, ctscanImage

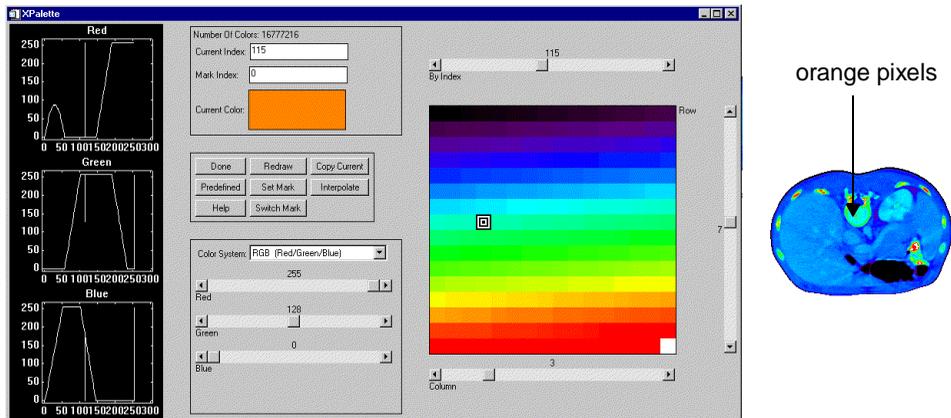
    The orange values now highlight some areas of the spine, kidney, and bones as
    shown in the following figure.


Figure 26-15: CT Scan Image with Orange Added to the Color Table

You can highlight the bones even further by interpolating a new range in
between the orange and white indices.

9. Open XPALETTE:

    Click on the 115th index and select the S**et Mark** button.

    Click on the highest index (which is usually 255 but it could be less) and then
    select the **Interpolate** button.

    To see the result of this interpolation within XPALETTE, click on the **Redraw**
    button.

Click **Done** and redisplay the image:

```
TV, ctscanImage
```

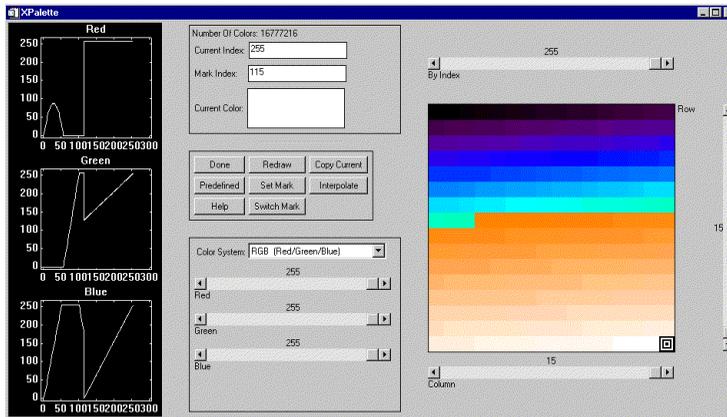
The following figure displays the image using the modified color table.


Figure 26-16: CT Scan Image with Orange to White Range Added

Note
You can add this modified color table to the list of pre-defined color tables using MODIFYCT. See the "Examples" section of "MODIFYCT" on page 1665.

XPCOLOR

The XPCOLOR procedure is a utility that allows you to adjust the value of the current Direct Graphics plotting color (foreground) using sliders, and store the desired color in the global system variable, !P.COLOR.

When XPCOLOR is called from the IDL input command line, the **Set Plot Color** dialog box appears. The dialog has two buttons (**Done** and **Help**) a single color swatch window, three sliders, and a pulldown menu with the four color systems: red, green, blue (RGB); cyan, magenta, yellow (CMY); hue, saturation, value (HSV); and hue, lightness, and saturation (HLS).

When you have chosen the color system and adjusted the sliders to your liking, click **Done** to store the color selected in the !P.COLOR system variable. Any plots generated in IDL afterwards use the color selected as the plotting (foreground) color until !P.COLOR is changed again.

Note

For a more flexible color editor, use the XPALETTE User Library routine.

This routine is written in the IDL language. Its source code can be found in the file xpcolor.pro in the lib/utilities subdirectory of the IDL distribution.

Syntax

XPCOLOR [, GROUP=*widget_id*]

Arguments

None

Keywords

GROUP

Set this keyword to the group leader widget ID as passed to XMANAGER.

Version History

4.0	Introduced

XPLOT3D

The XPLOT3D procedure is a utility for creating and interactively manipulating 3-D plots.

This routine is written in the IDL language. Its source code can be found in the file `xplot3d.pro` in the `lib/utilities` subdirectory of the IDL distribution.

Using XPLOT3D

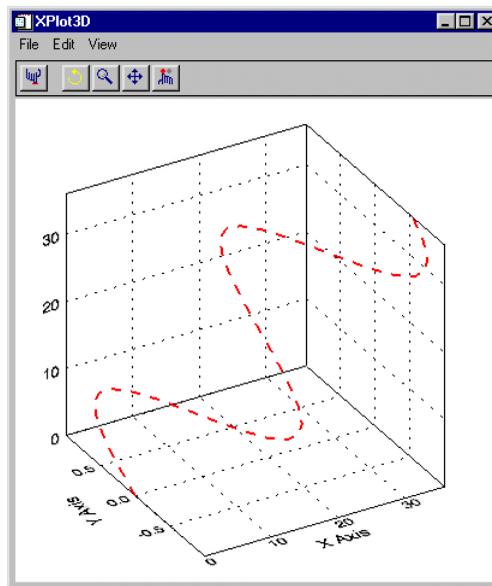
XPLOT3D displays a resizeable top-level base with a menu, toolbar and draw widget, as shown in the following figure:


Figure 26-17: The XPLOT3D Utility

The XPLOT3D Toolbar

The XPLOT3D toolbar contains the following buttons:

Button	Tool Name	Function
	Reset	Resets rotation, scaling, and panning.
	Rotate	Click the left mouse button on the object and drag to rotate.
	Pan	Click the left mouse button on the object and drag to pan.
	Zoom	Click the left mouse button on the object and drag to zoom in or out.
	Select	Click on the object. The name of the selected object is displayed, if the object has a name, otherwise its class is displayed.

Table 26-4: XPLOT3D Toolbar Buttons

Projecting Data onto Plot "Walls"

To turn on or off the projection of data onto the walls of the box enclosing the 3-D plot, select **All On**, **All Off**, **XY**, **YZ**, or **XZ** from the **View → 2D Projection** menu.

Changing the Axis Type

The **View → Axes** menu allows you to select one of the following types of axes:

- Simple Axes — displays the X, Y, and Z axes as lines.

- Box Axes — displays the X, Y, and Z axes as planes.

- No Axes — turns off the display of axes.

Syntax

XPLOT3D, *X*, *Y*, *Z* [, /BLOCK] [, COLOR=*[r,g,b]*] [, /DOUBLE_VIEW]
   [, GROUP=*widget_id*] [, LINESTYLE={0 | 1 | 2 | 3 | 4 | 5 | 6}] [, /MODAL]
   [, NAME=*string*] [, /OVERPLOT] [, SYMBOL=*objref(s)*] [, /TEST]
   [, THICK=*points*{1.0 to 10.0}] [, TITLE=*string*] [, XRANGE=*[min, max]*]
   [, XTITLE=*string*] [, YRANGE=*[min, max]*] [, YTITLE=*string*]
   [, ZRANGE=*[min, max]*] [, ZTITLE=*string*]

Arguments

X

A vector of X data values.

Y

A vector of Y data values.

Z

A vector of Z data values.

Keywords

BLOCK

Set this keyword to have XMANAGER block when this application is registered. By default, BLOCK is set equal to zero, providing access to the command line if active command line processing is available. Note that setting the BLOCK keyword causes all widget applications to block, not just this application. For more information, see the documentation for the NO_BLOCK keyword to XMANAGER.

Note

Only the outermost call to XMANAGER can block. Therefore, to have XPLOT3D block, any earlier calls to XMANAGER must have been called with the NO_BLOCK keyword. See the documentation for the NO_BLOCK keyword to XMANAGER for an example.

COLOR

Set this keyword to an [*r*, *g*, *b*] triplet specifying the color of the curve.

DOUBLE_VIEW

Set this keyword to cause XPLOT3D to set the DOUBLE property on the IDLgrView that it uses to display the plot.

GROUP

Set this keyword to the widget ID of the widget that calls XPLOT3D. When this keyword is specified, the death of the caller results in the death of XPLOT3D.

LINESTYLE

Set this keyword to a value indicating the line style that should be used to draw the curve. The value can be either an integer value specifying a pre-defined line style, or a 2-element vector specifying a stippling pattern.

To use a pre-defined line style, set the LINESTYLE keyword to one of the following integer values:

0	Solid line (default)
1	Dotted
2	Dashed
3	Dash-dot
4	Dash-dot-dot-dot
5	Long dash
6	No line drawn

To define your own stippling pattern, specify a two-element vector [*repeat*, *bitmask*], where repeat indicates the number of times consecutive runs of 1s or 0s in the bitmask should be repeated. (That is, if three consecutive 0s appear in the bitmask and the value of repeat is 2, then the line that is drawn will have six consecutive bits turned off.) The value of repeat must be in the range $1 \leq repeat \leq 255$.

The bitmask indicates which pixels are drawn and which are not along the length of the line. The bitmask is most conveniently specified as a 16-bit hexadecimal value.

For example, LINESTYLE = [2, 'F0F0'X] describes a dashed line (8 bits on, 8 bits off, 8 bits on, 8 bits off).

MODAL

Set this keyword to block processing of events from other widgets until the user quits XPLOT3D. The MODAL keyword does not require a group leader to be specified. If no group leader is specified, and the MODAL keyword is set, XPLOT3D fabricates an invisible group leader for you.

Note ───

To be modal, XPLOT3D does not require that its caller specify a group leader. This is unlike other IDL widget procedures such as XLOADCT, which, to be modal, do require that their caller specify a group leader. These other procedures were implemented this way to encourage the caller to create a modal widget that will be well-behaved with respect to layering and iconizing. (See "Iconizing, Layering, and Destroying Groups of Top-Level Bases" on page 2653 for more information.)

To provide a simple means of invoking XPLOT3D as a modal widget in applications that contain no other widgets, XPLOT3D can be invoked as MODAL without specifying a group leader, in which case XPLOT3D fabricates an invisible group leader for you. For applications that contain multiple widgets, however, it is good programming practice to supply an appropriate group leader when invoking XPLOT3D, /MODAL. As with other IDL widget procedures with names prefixed with "X", specify the group leader via the GROUP keyword.

───

NAME

Set this keyword to a string specifying the name for the data curve being plotted. The name is displayed on the XPLOT3D toolbar when the curve is selected with the mouse. (To select the curve with the mouse, XPLOT3D must be in select mode. You can put XPLOT3D in select mode by clicking on the rightmost button on the XPLOT3D toolbar.)

OVERPLOT

Set this keyword to draw the curve in the most recently created view. The TITLE, [XYZ]TITLE, [XYZ]RANGE, and MODAL keywords are ignored if this keyword is set.

SYMBOL

Set this keyword to a vector containing one or more instances of the IDLgrSymbol object class to indicate the plotting symbols to be used at each vertex of the polyline. If there are more vertices than elements in SYMBOL, the elements of the SYMBOL vector are cyclically repeated. By default, no symbols are drawn. To remove symbols from a polyline, set SYMBOL to a scalar.

TEST

If set, the *X*, *Y*, and *Z* arguments are not required (and are ignored if provided). A sinusoidal curve is displayed instead. This allows you to test code that uses XPLOT3D without having to specify plot data.

THICK

Set this keyword to a value between 1.0 and 10.0, specifying the line thickness to be used to draw the polyline, in points. The default is 1.0 points.

TITLE

Set this keyword to a string to appear in the XPLOT3D title bar.

XRANGE

Set this keyword to a 2-element array of the form [*min*, *max*] specifying the X-axis range.

XTITLE

Set this keyword to a string specifying the title for the X axis of the plot.

YRANGE

Set this keyword to a 2-element array of the form [*min*, *max*] specifying the Y-axis range.

YTITLE

Set this keyword to a string specifying the title for the Y axis of the plot.

ZRANGE

Set this keyword to a 2-element array of the form [*min*, *max*] specifying the Z-axis range.

ZTITLE

Set this keyword to a string specifying the title for the Z axis of the plot.

Examples

The following example displays two curves in XPLOT3D, using a custom plotting symbol for one of the curves:

```
;Define plot data:
X = INDGEN(20)
Y1 = SIN(X/3.)
Y2 = COS(X/3.)
Z = X

;Display curve 1 in XPLOT3D:
XPLOT3D, X, Y1, Z, NAME='Curve1', THICK=2

;Define custom plotting symbols:
oOrb = OBJ_NEW('orb', COLOR=[0, 0, 255])
oOrb->Scale, .75, .1, .5
oSymbol = OBJ_NEW('IDLgrSymbol', oOrb)

;Overplot curve 2 in XPLOT3D:
XPLOT3D, X, Y2, Z, COLOR=[0,255,0], NAME='Curve2', $
   SYMBOL=oSymbol, THICK=2, /OVERPLOT
```

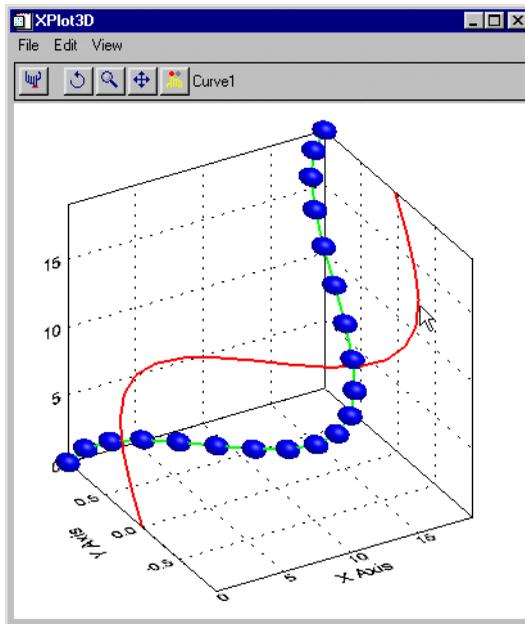
This code results in the following:


Figure 26-18: Two curves displayed in XPLOT3D

IPLOT

XREGISTERED

The XREGISTERED function returns the number of instances of the widget named as its argument that are registered with XMANAGER in the current IDL session. The registered widget is brought to the front of the desktop unless the NOSHOW keyword is set.

If the specified widget is not currently registered with XMANAGER, XREGISTERED returns zero.

This routine is written in the IDL language. Its source code can be found in the file xregistered.pro in the lib subdirectory of the IDL distribution.

Syntax

Result = XREGISTERED(*Name* [, /NOSHOW])

Return Value

The result is an integer containing the number of instances of the named widget that are registered with XMANAGER in the current IDL session.

Arguments

Name

A string containing the name of the widget in question.

Note

XREGISTERED checks for *Name* in a COMMON block created by XMANAGER. The stored name is case-sensitive.

Keywords

NOSHOW

If the widget in question is registered, it is brought to the front of all the other windows by default. Set this keyword to keep the widget from being brought to the front.

Examples

Suppose that you have a widget program that registers itself with the XMANAGER with the command:

```
XMANAGER, 'mywidget', base
```

You could limit this widget to one instantiation by adding the following line as the first line (after the procedure definition statement) of the widget creation routine:

```
IF ( XREGISTERED('mywidget') NE 0 ) THEN RETURN
```

Version History

Pre-4.0	Introduced

XMANAGER

XROI

The XROI procedure is a utility for interactively defining regions of interest (ROIs), and obtaining geometry and statistical data about these ROIs.

This routine is written in the IDL language. Its source code can be found in the file `xroi.pro` in the `lib/utilities` subdirectory of the IDL distribution.

Note

See "Using XROI" on page 3079, for detailed information describing importing images, modifying image and ROI colors, retrieving ROI information and growing regions.

Syntax

XROI [, *ImageData*] [, *R*] [, *G*] [, *B*] [, /BLOCK]
    [[, /FLOATING] , GROUP=*widget_ID*] [, /MODAL] [, REGIONS_IN=*value*]
    [, REGIONS_OUT=*value*] [, REJECTED=*variable*] [, RENDERER={0 | 1}]
    [, ROI_COLOR=*[r, g, b] or variable*] [, ROI_GEOMETRY=*variable*]
    [, ROI_SELECT_COLOR=*[r, g, b] or variable*] [, STATISTICS=*variable*]
    [, TITLE=*string*] [, TOOLS=*string/string array* {valid values are
    'Translate-Scale', 'Rectangle', 'Ellipse', 'Freehand Draw', 'Polygon Draw', and
    'Selection'}] [, X_SCROLL_SIZE=*value*] [, Y_SCROLL_SIZE=*value*]

Arguments

ImageData

ImageData is both an input and output argument. It is an array representing an 8-bit or 24-bit image to be displayed. *ImageData* can be any of the following:

- [*m*, *n*]   — 8-bit image
- [3, *m*, *n*] — 24-bit image
- [*m*, 3, *n*] — 24-bit image
- [*m*, *n*, 3] — 24-bit image

If *ImageData* is not supplied, the user will be prompted for a file via DIALOG_PICKFILE. On output, *ImageData* will be set to the current image data. (The current image data can be different than the input image data if the user imported an image via the **File → Import Image** menu item.)

R, G, B

R, *G*, and *B* are arrays of bytes representing red, green, or blue color table values, respectively. *R*, *G*, and *B* are both input and output arguments. On input, these values are applied to the image if the image is 8-bit. To get the red, green, or blue color table values for the image on output from XROI, specify a named variable for the appropriate argument. (If the image is 24-bit, this argument will output a 256-element byte array containing the values given at input, or BINDGEN(256) if the argument was undefined on input.)

Keywords

BLOCK

Set this keyword to have XMANAGER block when this application is registered. By default, BLOCK is set equal to zero, providing access to the command line if active command line processing is available. Note that setting the BLOCK keyword causes all widget applications to block, not just this application. For more information, see the documentation for the NO_BLOCK keyword to XMANAGER.

Note ───

Only the outermost call to XMANAGER can block. Therefore, to have XROI block, any earlier calls to XMANAGER must have been called with the NO_BLOCK keyword. See the documentation for the NO_BLOCK keyword to XMANAGER for an example.

───

FLOATING

Set this keyword, along with the GROUP keyword, to create a floating top-level base widget. If the windowing system provides Z-order control, floating base widgets appear above the base specified as their group leader. If the windowing system does not provide Z-order control, the FLOATING keyword has no effect.

Note ───

Floating widgets must have a group leader. Setting this keyword without also setting the GROUP keyword causes an error.

───

GROUP

Set this keyword to the widget ID of the widget that calls XROI. When this keyword is specified, the death of the caller results in the death of XROI.

MODAL

Set this keyword to block other IDL widgets from receiving events while XROI is active.

REGIONS_IN

Set this keyword to an array of IDLgrROI references. This allows you to open XROI with previously defined regions of interest (see Example: Save ROI Data). This is also useful when using a loop to open multiple images in XROI. By using the same named variable for both the REGIONS_IN and REGIONS_OUT keywords, you can reuse the same ROIs in multiple images (see Example: Preserving ROIs Among Images). This keyword also accepts –1, or OBJ_NEW() (Null object) to indicate that there are no ROIs to read in. This allows you to assign the result of a previous REGIONS_OUT to REGIONS_IN without worrying about the case where the previous REGIONS_OUT is undefined.

REGIONS_OUT

Set this keyword to a named variable that will contain an array of IDLgrROI references. This keyword is assigned the null object reference if there are no ROIs defined. By using the same named variable for both the REGIONS_IN and REGIONS_OUT keywords, you can reuse the same ROIs in multiple images (see Example: Preserving ROIs Among Images).

Note ───────────────────────────────────────

This keyword must be used in conjunction with the BLOCK keyword.

───

REJECTED

Set this keyword to a named variable that will contain those REGIONS_IN that are not in REGIONS_OUT. The objects defined in the variable specified for REJECTED can be destroyed with a call to OBJ_DESTROY, allowing you to perform cleanup on objects that are not required (see Example: Preserving ROIs Among Images). This keyword is assigned the null object reference if no REGIONS_IN are rejected by the user.

Note ───────────────────────────────────────

This keyword must be used in conjunction with the BLOCK keyword.

───

RENDERER

Set this keyword to an integer value to indicate which graphics renderer to use when drawing objects within the window. Valid values are:

- 0 = Platform native OpenGL
- 1 = IDL's software implementation (the default)

ROI_COLOR

This keyword is both an input and an output parameter. Set this keyword to a 3-element byte array, [*r*, *g*, *b*], indicating the color of ROI outlines when they are not selected. This color will be used by XROI unless and until the color is changed by the user via the "Unselected Outline Color" portion of the "ROI Outline Colors" dialog (which is accessed by selecting **Edit → ROI Outline Colors**). If this keyword is assigned a named variable, that variable will be set to the current [*r*, *g*, *b*] value at the time that XROI returns.

ROI_GEOMETRY

Set this keyword to a named variable that will contain an array of anonymous structures, one for each ROI that is valid when this routine returns. The structures will contain the following fields:

Field	Description
area	The area of the region of interest, in square pixels.
centroid	The coordinates (*x*, *y*, *z*) of the centroid of the region of interest, in pixels.
perimeter	The perimeter of the region of interest, in pixels.

Table 26-5: Fields of the structure returned by ROI_GEOMETRY

If there are no valid regions of interest when this routine returns, ROI_GEOMETRY will be undefined.

Note
If there are no REGIONS_IN, XROI must either be modal or must block control flow in order for ROI_GEOMETRY to be defined upon exit from XROI. Otherwise, XROI will return before an ROI can be defined, and ROI_GEOMETRY will therefore be undefined.

Note ───
This keyword must be used in conjunction with the BLOCK keyword.
──

ROI_SELECT_COLOR

This keyword is both an input and an output parameter. Set this keyword to a
3-element byte array, [*r*, *g*, *b*], indicating the color of ROI outlines when they are
selected. This color will be used by XROI unless and until the color is changed by the
user via the "Selected Outline Color" portion of the "ROI Outline Colors" dialog
(which is accessed by selecting **Edit → ROI Outline Colors**). If this keyword is
assigned a named variable, that variable will be set to the current [*r*, *g*, *b*] value at the
time that XROI returns.

STATISTICS

Set this keyword to a named variable to receive an array of anonymous structures, one
for each ROI that is valid when this routine returns. The structures will contain the
following fields:

Field	Description
count	Number of pixels in region.
minimum	Minimum pixel value.
maximum	Maximum pixel value.
mean	Mean pixel value.
stddev	Standard deviation of pixel values.

Table 26-6: Fields of the structure returned by STATISTICS

If *ImageData* is 24-bit, or if there are no valid regions of interest when the routine
exits, STATISTICS will be undefined.

Note ───
If there are no REGIONS_IN, XROI must either be modal or must block control
flow in order for STATISTICS to be defined upon exit from XROI. Otherwise,
XROI will return before an ROI can be defined, and STATISTICS will therefore be
undefined.
──

TITLE

Set this keyword to a string to appear in the XROI title bar.

TOOLS

Set this keyword a string or vector of strings from the following list to indicate which ROI manipulation tools should be supported when XROI is run:

- 'Translate-Scale' — Translation and scaling of ROIs. Mouse down inside the bounding box selects a region, mouse motion translates (repositions) the region. Mouse down on a scale handle of the bounding box enables scaling (stretching, enlarging and shrinking) of the region according to mouse motion. Mouse up finishes the translation or scaling.

- 'Rectangle' — Rectangular ROI drawing. Mouse down positions one corner of the rectangle, mouse motions creates the rectangle, positioning the rectangle's opposite corner, mouse up finishes the rectangular region.

- 'Ellipse' — Elliptical ROI drawing. Mouse down positions the center of the ellipse, mouse motion positions the corner of the ellipse's imaginary bounding box, mouse up finishes the elliptical region.

- 'Freehand Draw' — Freehand ROI drawing. Mouse down begins a region, mouse motion adds vertices to the region (following the path of the mouse), mouse up finishes the region.

- 'Polygon Draw' — Polygon ROI drawing. Mouse down begins a region, subsequent mouse clicks add vertices, double-click finishes the region.

- 'Selection' — ROI selection. Mouse down/up selects the nearest region. The nearest vertex in that region is identified with a crosshair symbol.

If more than one string is specified, a series of bitmap buttons will appear at the top of the XROI widget in the order specified (to the right of the fixed set of bitmap buttons used for saving regions, displaying region information, copying to clipboard, and flipping the image). If only one string is specified, no additional bitmap buttons will appear, and the manipulation mode is implied by the given string. If this keyword is not specified, bitmap buttons for all three manipulation tools are included on the XROI toolbar.

X_SCROLL_SIZE

Set this keyword to the width of the scroll window. If this keyword is larger than the image width then it will be set to the image width. The default is to use the image width or the screen width, whichever is smaller.

Y_SCROLL_SIZE

Set this keyword to the height of the scroll window. If this keyword is larger than the image height then it will be set to the image height. The default is to use the image height or the screen height, whichever is smaller.

Using XROI

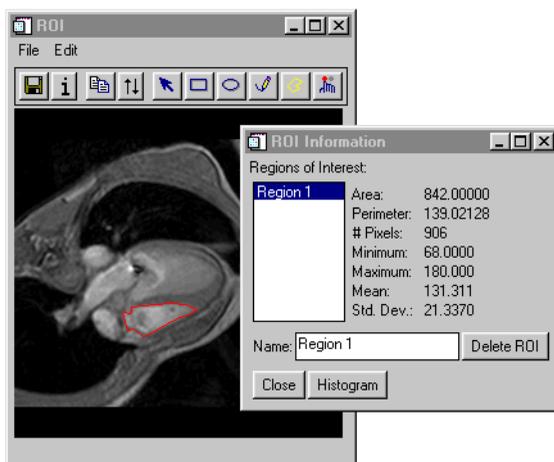
XROI displays a top-level base with a menu, toolbar and draw widget. After defining an ROI, the **ROI Information** window appears, as shown in the following figure:


Figure 26-19: The XROI Utility

As you move the mouse over an image, the x and y pixel locations are shown in the status line on the bottom of the XROI window. For 8-bit images, the data value (z) is also shown. If an ROI is defined, the status line also indicates the mouse position relative to the ROI using the text "Inside", "Outside", "On Edge," or "On Vertex."

The XROI Toolbar

The XROI toolbar contains the following buttons:

	Save:	Opens a file selection dialog for saving the currently defined ROIs to a save file.
	Info:	Opens the **ROI Information** window.

| | **Copy:** | Copies the contents of the display area to the clipboard. |
| | **Flip:** | Flips image vertically. Note that only the image is flipped; any ROIs that have been defined do not move. |

Depending on the value of the TOOLS keyword, the XROI toolbar may also contain the following buttons:

	Translate/ Scale:	Click this button to translate or scale ROIs. Mouse down inside the bounding box selects a region, mouse motion translates (repositions) the region. Mouse down on a scale handle of the bounding box enables scaling (stretching, enlarging and shrinking) of the region according to mouse motion. Mouse up finishes the translation or scaling.
	Draw Rectangle:	Click this button to draw rectangular ROIs. Mouse down positions one corner of the rectangle, mouse motions creates the rectangle, positioning the rectangle's opposite corner, mouse up finishes the rectangular region.
	Draw Ellipse:	Click this button to draw elliptical ROIs. Mouse down positions the center of the ellipse, mouse motion positions the corner of the ellipse's imaginary bounding box, mouse up finishes the elliptical region.
	Draw Freehand:	Click this button to draw freehand ROIs. Mouse down begins a region, mouse motion adds vertices to the region (following the path of the mouse), mouse up finishes the region.
	Draw Polygon:	Click this button to draw polygon ROIs. Mouse down begins a region, subsequent mouse clicks add vertices, double-click finishes the region.
	Select:	Click this button to select an ROI region. Clicking the image causes a cross hairs symbol to be drawn at the nearest vertex of the selected ROI.

Importing an Image into XROI

To import an image into XROI, select **File → Import Image**. This opens a DIALOG_READ_IMAGE dialog, which can be used to preview and select an image.

Changing the Image Color Table

To change the color table properties for the current image, select **Edit → Image Color Table**. This opens the CW_PALETTE_EDITOR dialog, which is a compound widget used to edit color palettes. See CW_PALETTE_EDITOR for more information. This menu item is grayed out if the image does not have a color palette.

Changing the ROI Outline Colors

To change the outline colors for selected and unselected ROIs, select **Edit → ROI Outline Colors**. This opens the **ROI Outline Colors** dialog, which consists of two CW_RGBSLIDER widgets for interactively adjusting the ROI outline colors. The left widget is used to define the color for the selected ROI, and the right widget is used to define the color of unselected ROIs. You can select the RGB, CMY, HSV, or HLS color system from the **Color System** drop-down list.

Viewing ROI Information

To view geometry and statistical data about the currently selected ROI, click the **Info** button or select **Edit → ROI Information**. This opens the **ROI Information** dialog, which displays area, perimeter, number of pixels, minimum and maximum pixel values, mean, and standard deviation. Values for statistical information (minimum, maximum, mean, and standard deviation) appear as "N/A" for 24-bit images.

Viewing a Histogram Plot for an ROI

To view a histogram for an ROI, use either the shortcut menu or the ROI Information dialog.

To view an ROI's histogram plot using the shortcut menu:

1. Position the cursor on the line defining the boundary of an ROI in the drawing window and click the right mouse button. This selects the region and brings up its shortcut menu.

2. Select the **Plot Histogram** menu option from the shortcut menu.

To view an ROI's histogram plot using the ROI Information dialog:

1. Open the ROI Information dialog by clicking the **Info** button or selecting **Edit → ROI Information**.

2. Select a region from the list and click the **Histogram** button on the ROI Information dialog.

Either of the previous methods opens an iTool showing the ROI's histogram that can be used to interactively control the plot properties.

Note

XROI's histogram plot feature now supports RGB images.

Growing an ROI

Once a region has been created, it may be used as a source ROI for region growing. Region growing is a process of generating one or more new ROIs based upon the image pixel values that fall within the source ROI and the values of the neighboring pixels. New pixels are added to the new grown region if those image pixel values fall within a specified threshold.

Note

This option is an interactive implementation of the REGION_GROW function.

To create a new, grown region, do the following:

1. Within the draw area, click the right mouse button on the ROI that is to be grown. This will select the region and bring up its shortcut menu.

2. Select **Grow Region → By threshold** or select **Grow Region → By std. dev. multiple** from the shortcut menu to control how the region is grown.

   The **By threshold** option grows the region to include all neighboring pixels that fall within a specified threshold range. By default, the range is defined by the minimum and maximum pixel values occurring within the original region. To specify a different threshold range, see Using the Region Grow Properties Dialog in the following section.

   The **By std. dev. multiple** option grows a region to include all neighboring pixels that fall within the range of:

   ```
   Mean +/- StdDevMultiplier * StdDev
   ```

   where `Mean` is the mean value of the pixel values within the source ROI, `StdDevMultiplier` is a multiplier that is set using the Region Grow Properties dialog (described below), and `StdDev` is the sample standard deviation of the pixel values within the original region.

Using the Region Grow Properties Dialog

The Region Grow Properties dialog allows you to view and edit the properties associated with a region growing process. To bring up the Region Grow Properties dialog, do one of the following:

- Click the right mouse button on an ROI in the drawing window and select **Grow Region → Properties...** shortcut menu option.

- Select **Edit → Region Grow Properties**... from the XROI menu bar.

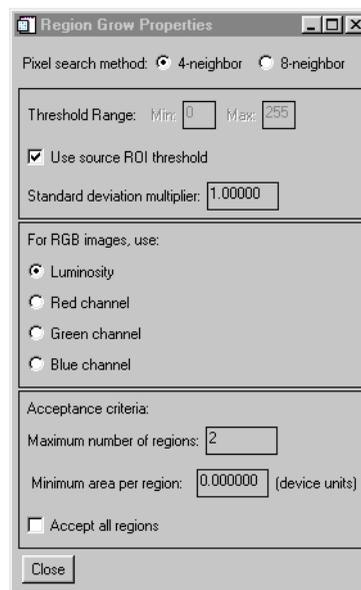
This brings up the Region Grow Properties dialog, shown in the following figure.


Figure 26-20: XROI's Region Grow Properties Dialog

The Region Grow Properties dialog offers the following options:

Option	Description
Pixel search method:	Describes which pixels are searched when growing the original ROI. The option are: • **4-neighbor** — Searches only the four neighboring pixels that share a common edge with the current pixel. This is the default. • **8-neighbor** — Searches all eight neighboring pixels, including those that are located diagonally relative to the original pixel and share a common corner.
Threshold range:	Represents the minimum and maximum image pixel values that are to be included in the grown region when using the **Grow Region → By threshold** option (described in "Growing an ROI" on page 3082). By default, the range of pixel values used are those occurring in the ROI to be grown. To change the threshold values, uncheck **Use source ROI threshold** and enter the minimum and maximum threshold values in the **Min:** and **Max:** fields provided.
Standard deviation multiplier:	Represents the factor by which the sample standard deviation of the original ROI's pixel values is multiplied. This factor only applies when the **Grow Region → By std. dev. multiple** option (described in "Growing an ROI" on page 3082) is used. Change the multiplier value by typing the value into the **Standard deviation multiplier** field provided.

Table 26-7: Options of the Region Grow Properties Dialog

Option	Description
For RGB image, use:	Determines the basis of region growing for an RGB (rather than indexed) image. The image data values used when growing a RGB region can be one of the following: • **Luminosity** — Uses the luminosity values associated with an RGB image. This is the default method. Luminosity is computed as: Luminosity = (0.3 * Red) + (0.59 * Green) + (0.11 * Blue) • **Red Channel**, **Green Channel** or **Blue Channel** — Uses the ROI's red, green or blue channel as a basis for region growing. Click the channel's associated button to specify the channel to be used. **Note -** For indexed images, the image data itself is always used for region growing.
Acceptance criteria:	Determines which contours of the grown region are accepted as new regions, (which will also be displayed in the draw area and in the ROI Information dialog list of regions). The region growing process can result in a large number of contours, some of which may be considered insignificant. By default, no more than two regions (those with the greatest geometrical area) are accepted. Modify the acceptance criteria by altering the following values: • **Maximum number of regions:** — Specifies the upper limit of the number of regions to create when growing an ROI. • **Minimum area per region:** — Specifies that only contours having a geometric area (computed in device coordinates) of at least the value stated are accepted and displayed. • **Accept all regions:** — Select this option to accept all generated contours, regardless of count or area.

Table 26-7: Options of the Region Grow Properties Dialog (Continued)

Deleting an ROI

An ROI can be deleted using either the shortcut menu or using the ROI Information dialog.

To delete an ROI using the shortcut menu:

1. Click the right mouse button on the line defining the boundary of the ROI in the drawing area that you wish to delete. This selects the region and bring up the shortcut menu.

2. Select the **Delete** menu option from the shortcut menu.

To delete an ROI using the ROI Information dialog:

1. Click the **Info** button or select **Edit → ROI Information**. This opens the **ROI Information** dialog.

2. In the **ROI Information** dialog, select the ROI you wish to delete from the list of ROIs. You can also select an ROI by clicking the **Select** button on the XROI toolbar, then clicking on an ROI on the image.

3. Click the **Delete ROI** button.

Examples

See the following examples:

- "Example: Open Image File in XROI"
- "Example: Preserving ROIs Among Images" on page 3087
- "Example: Save ROI Data" on page 3088
- "Example: Save the XROI Utility with ROI Data" on page 3088

Example: Open Image File in XROI

This example opens a single image in XROI:

```
image = READ_PNG(FILEPATH('mineral.png', $
   SUBDIR=['examples', 'data']))
XROI, image
```

Example: Preserving ROIs Among Images

This example reads 3 images from the file `mr_abdomen.dcm`, and calls XROI for each image. A single list of regions is maintained, saving the user from having to redefine regions on each image:

```
PRO docs_xroi_maintain_rois

; Read 3 images from mr_abdomen.dcm and open each one in XROI:
FOR i=0,2 DO BEGIN
   image = READ_DICOM(FILEPATH('mr_abdomen.dcm',$
      SUBDIR=['examples', 'data']), IMAGE_INDEX=i)
   XROI, image, r, g, b, REGIONS_IN = regions, $
      REGIONS_OUT = regions, $
      ROI_SELECT_COLOR = roi_select_color, $
      ROI_COLOR = roi_color, REJECTED = rejected, /BLOCK
   OBJ_DESTROY, rejected
ENDFOR

OBJ_DESTROY, regions

END
```

Perform the following steps:

1. Run the example code and draw an ROI on the first image, then close that XROI window. Note that the next image contains the ROI defined in the first image. This is accomplished by setting REGIONS_IN and REGIONS_OUT to the same named variable in the FOR loop of the above code.

2. Draw another ROI on the second image.

3. Click the **Select** button and select the first ROI. Then click the **Info** button to open the **ROI Information** window, and click the **Delete ROI** button.

4. Close the second XROI window. Note that the third image contains the ROI defined in the second image, but not the ROI deleted on the second image. This example sets the REJECTED keyword to a named variable, and calls OBJ_DESTROY on that variable. Use of the REJECTED keyword is not necessary to prevent deleted ROIs from appearing on subsequent images, but allows you perform cleanup on objects that are no longer required.

Example: Save ROI Data

XROI's **File → Save ROIs** option allows you to save selected regions of interest. This example shows how to restore such a save file. Suppose you have a file named `mineralRoi.sav` that contains regions of interest selected in the `mineral.png` image file. You would need to complete the following steps to restore the file:

1. First, restore the file, `mineralRoi.sav`. Provide a value for the RESTORE procedure's RESTORED_OBJECTS keyword. Using the scenario stated above, you could enter the following:

```
RESTORE, 'mineralRoi.sav', RESTORED_OBJECTS = myRoi
```

2. Pass the restored object data containing your regions of interest into XROI by specifying `myRoi` as the value for REGIONS_IN as follows:

```
XROI, READ_PNG(FILEPATH('mineral.png', SUBDIRECTORY = $
   ['examples', 'data'])), REGIONS_IN = myRoi
```

This opens the previously selected regions of interest in the XROI utility.

Example: Save the XROI Utility with ROI Data

You can easily share your own IDL routines or utilities with other IDL users by using the SAVE routine to create a binary file of your compiled code. The following example creates a SAVE file of the XROI utility (a `.pro` file) and from within this file, restores a secondary SAVE file containing selected regions of interest.

1. Type `XROI` at the command line to open the XROI utility.

2. In the file selection dialog, select `mineral.png` from the `examples/data` subdirectory of the IDL distribution.

3. Select the **Draw Polygon** toolbar button and roughly outline the three large, angular areas of the image.

4. Select **File → Save ROIs** and name the file `mineralROI.sav`. This creates a SAVE file containing the regions of interest selected within the image.

5. In the IDL Editor or any text editor, enter the following routine:

```
PRO myXRoi

; Restore ROI object data by specifying a value for the
; RESTORED_OBJECTS keyword.
RESTORE, 'mineralROI.sav', RESTORED_OBJECTS = myROI
```

```
; Open XROI, specifying the previously defined value for the
; restored object data as the value for "REGIONS_IN".
XROI, READ_PNG(FILEPATH('mineral.png', $
   SUBDIRECTORY = ['examples', 'data'])), $
   REGIONS_IN = myROI, /BLOCK

END
```

Save the routine as `myXRoi.pro`

6. Exit and restart IDL or enter `.FULL_RESET_SESSION` at the IDL command line before creating a SAVE file to avoid saving unwanted session information.

7. Compile the program you just created:

```
.COMPILE myXRoi.pro
```

8. Use RESOLVE_ALL to iteratively compile any uncompiled user-written or library procedures or functions that are called in any already-compiled procedure or function:

```
RESOLVE_ALL
```

Note

RESOLVE_ALL does not resolve procedures or functions that are called via quoted strings such as CALL_PROCEDURE, CALL_FUNCTION, or EXECUTE, or in keywords that can contain procedure names such as TICKFORMAT or EVENT_PRO. You must manually compile these routines.

9. Create a SAVE file named `myXRoi.sav`, containing all of the XROI utility routines. When the SAVE procedure is called with the ROUTINES keyword and no arguments, it creates a SAVE file containing all currently compiled routines. Because the routines associated with the XROI utility are the only ones that are currently compiled in our IDL session, we can create a SAVE file as follows:

```
SAVE, /ROUTINES, FILENAME='myXRoi.sav'
```

10. It is not necessary to use RESTORE to open `myXRoi.sav`. If the SAVE file uses the `.sav` extension and has the same base name as the main level routine, and all necessary files (in this case, `mineralROI.sav` and `myXRoi.sav`) are stored in the current working directory, simply type the name of the file, minus the `.sav` extension, at the command line:

```
myXRoi
```

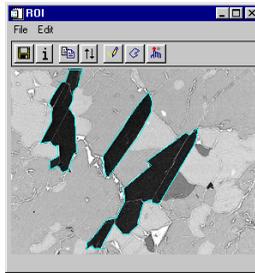
The following figure will appear, showing the selected regions of interest.


Figure 26-21: Example of Restoring the XROI Utility and ROI Image Data

XSQ_TEST

The XSQ_TEST function computes the chi-square goodness-of-fit test between observed frequencies and the expected frequencies of a theoretical distribution.

Expected frequencies of magnitude less than 5 are combined with adjacent elements resulting in a reduction of cells used to formulate the chi-squared test statistic. If the observed frequencies differ significantly from the expected frequencies, the chi-square test statistic will be large and the fit is poor. This situation requires the rejection of the hypothesis that the given observed frequencies are an accurate approximation to the expected frequency distribution.

This routine is written in the IDL language. Its source code can be found in the file xsq_test.pro in the lib subdirectory of the IDL distribution.

Syntax

Result = XSQ_TEST(*Obfreq*, *Exfreq* [, EXCELL=*variable*] [, OBCELL=*variable*] [, RESIDUAL=*variable*])

Return Value

The result is a two-element vector containing the Chi-square test statistic X2 and the one-tailed probability of obtaining a value of X2 or greater.

Arguments

Obfreq

An *n*-element integer, single-, or double-precision floating-point vector containing observed frequencies.

Exfreq

An *n*-element integer, single-, or double-precision floating-point vector containing expected frequencies.

Keywords

EXCELL

Set this keyword to a named variable that will contain a vector of expected frequencies used to formulate the chi-square test statistic. If each of the expected frequencies contained in *Exfreq*, has a magnitude of 5 or greater, then this vector is identical to *Exfreq*. If *Exfreq* contains elements of magnitude less than 5, adjacent expected frequencies are combined. The identical combinations are performed on the corresponding elements of *Obfreq*.

OBCELL

Set this keyword to a named variable that will contain a vector of observed frequencies used to formulate the chi-square test statistic. The elements of this vector are often referred to as the "cells" of the observed frequencies. The length of this vector is determined by the length of EXCELL described below.

RESIDUAL

Set this keyword to a named variable that will contain a vector of signed differences between corresponding cells of observed frequencies and expected frequencies.

```
RESIDUAL[i] = OBCELL[i] - EXCELL[i].
```

The length of this vector is determined by the length of EXCELL described above.

Examples

```
; Define the vectors of observed and expected frequencies:
obfreq = [2, 1, 4, 15, 10, 5, 3]
exfreq = [0.5, 2.1, 5.9, 10.3, 10.7, 7.0, 3.5]

; Test the hypothesis that the given observed frequencies are an
; accurate approximation to the expected frequency distribution:
result = XSQ_TEST(obfreq, exfreq)
PRINT, result
```

IDL Output

```
3.05040        0.383920
```

Since the vector of expected frequencies contains elements of magnitude less than 5, adjacent expected frequencies are combined resulting in fewer cells. The identical combinations are performed on the corresponding elements of observed frequencies.

The computed value of 0.383920 indicates that there is no reason to reject the proposed hypothesis at the 0.05 significance level.

CTI_TEST

XSURFACE

The XSURFACE procedure is a utility that provides a graphical interface to the SURFACE and SHADE_SURF commands. Different controls are provided to change the viewing angle and other plot parameters. The command used to generate the resulting surface plot is shown in a text window. Note that this procedure does not accept SURFACE or SHADE_SURF keywords. Because XSURFACE relies on IDL direct graphics rather than object graphics, the image manipulation facilities are less sophisticated than those of XOBJVIEW.

This routine is written in the IDL language. Its source code can be found in the file xsurface.pro in the lib/utilities subdirectory of the IDL distribution.

Syntax

XSURFACE, *Data* [, /BLOCK] [, GROUP=*widget_id*]

Arguments

Data

The two-dimensional array to display as a wire-mesh or shaded surface.

Keywords

BLOCK

Set this keyword to have XMANAGER *block* when this application is registered. By default, BLOCK is set equal to zero, providing access to the command line if active command line processing is available. Note that setting BLOCK=1 will cause *all* widget applications to block, not just this application. For more information, see the documentation for the NO_BLOCK keyword to XMANAGER.

Note
Only the outermost call to XMANAGER can block. Therefore, to have XSURFACE block, any earlier calls to XMANAGER must have been called with the NO_BLOCK keyword. See the documentation for the NO_BLOCK keyword to XMANAGER for an example.

GROUP

Set this keyword to the widget ID of the widget that calls XSURFACE. When GROUP is specified, the death of the calling widget results in the death of XSURFACE.

Examples

```
; Make a 2-D array:
z = DIST(30)

; Call XSURFACE. The XSURFACE widget appears:
XSURFACE, z
```

XVAREDIT

The XVAREDIT procedure is a utility that provides a widget-based editor for any IDL variable. Use the input fields to change desired values of the variable or array. Click "Accept" to write the new values into the variable. Click "Cancel" to exit XVAREDIT without saving changes.

Note

When XVAREDIT runs in the IDL Virtual Machine, variable values can be displayed, but not edited.

This routine is written in the IDL language. Its source code can be found in the file xvaredit.pro in the lib/utilities subdirectory of the IDL distribution.

Syntax

XVAREDIT, *Var* [, NAME='*variable_name*'{ignored if variable is a structure}]
   [, GROUP=*widget_id*] [, X_SCROLL_SIZE=*columns*]
   [, Y_SCROLL_SIZE=*rows*]

Arguments

Var

The variable to be edited. On output, this variable contains the edited value if the user selects the "Accept" button, or the original value if the user selects the "Cancel" button.

Keywords

NAME

The NAME of the variable. This keyword is overwritten with the structure name if the variable is a structure.

GROUP

The widget ID of the widget that calls XVAREDIT. When this ID is specified, a death of the caller results in a death of XVAREDIT.

X_SCROLL_SIZE

Set this keyword to the column width of the scrolling viewport. The default is 4.

Y_SCROLL_SIZE

Set this keyword to the row width of the scrolling viewport. The default is 4.

XVOLUME

The XVOLUME procedure is a utility for viewing and interactively manipulating volumes and isosurfaces. The utility provides a graphical interface for manipulating the volume orientation, adjusting the color table and opacity, viewing image planes and contours, and adjusting the color, opacity, and threshold value of an isosurface.

This routine is written in the IDL language. Its source code can be found in the file `xvolume.pro` in the `lib/utilities` subdirectory of the IDL distribution.

Tip ———————————————————————————————————

The XVOLUME_ROTATE and XVOLUME_WRITE_IMAGE procedures, which can be called only after a call to XVOLUME, can be used to easily create animations of volumes and isosurfaces displayed in XVOLUME. See XVOLUME_ROTATE for an example.

———————————————————————————————————————

Note ——————————————————————————————————

IDL converts and stores volume data in a BYTE array. Thus, all incoming volume data is converted to BYTE type. This could alter the volume data values if the incoming data cannot accurately be stored as BYTE data.

———————————————————————————————————————

Using XVOLUME

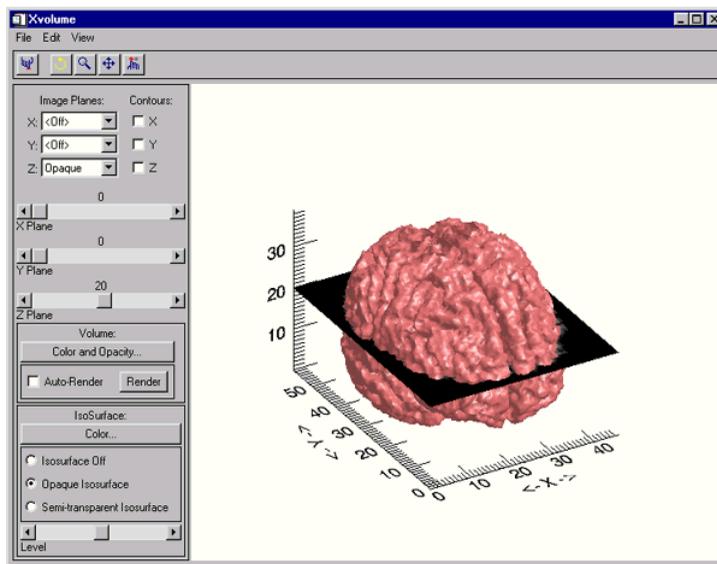
XVOLUME displays a resizeable top-level base with a toolbar, a menu, a graphical interface for controlling volume and isosurface properties, and a draw widget for displaying and manipulating the volume, as shown in the following figure:


Figure 26-22: The XVOLUME Utility

The XVOLUME Toolbar

The XVOLUME toolbar contains the following buttons.

Note

If you have the **Auto-Render** option selected, the Rotate, Zoom, and Pan features may be more difficult to use. For the best performance while manipulating the orientation of a volume using these features, uncheck the **Auto-Render** option.

Button	Tool Name	Function
	Reset	Resets rotation, scaling, and panning.
	Rotate	Click the left mouse button on the object and drag to rotate.
	Pan	Click the left mouse button on the object and drag to pan.
	Zoom	Click the left mouse button on the object and drag to zoom in or out.
	Select	Click on the object. The name of the selected object is displayed, if the object has a name, otherwise its class is displayed.

Table 26-8: XVOLUME Toolbar Buttons

The XVOLUME Interface

The XVOLUME interface provides the following elements for controlling the display of image planes and contours, volumes, and isosurfaces:

Image Planes and Contours

Image planes and contours allow you to visualize the values associated with the volume or isosurface at a specified X, Y, or Z plane.

- **Image Planes** — Select one of the following options from the drop-down list for each dimension to control the display of image planes:

  - **Off**: Turns off the image plane display.

  - **Opaque**: Displays an opaque image plane at the location specified by the corresponding plane slider.

  - **Transparent**: Displays a transparent image plane at the location specified by the corresponding plane slider. The transparency value of the plane is taken from the volume at the current location of the image plane.

- **Contours** — Check this option to display contours on the specified plane at the location specified by corresponding the plane slider.

- **Plane Sliders** — Move these sliders to change the position of the plane in each dimension.

Volume

- **Color and Opacity**: Click this button to change the color and/or opacity of the current volume. This opens a CW_PALETTE_EDITOR dialog, which is a compound widget used to edit color palettes. See CW_PALETTE_EDITOR for more information.

- **Auto-Render**: Select this option to have rendering executed automatically after each change you make to the volume. If **Auto-Render** is unchecked, you must manually click the **Render** button to see changes you have made to the volume. If **Auto-Render** is checked, the **Render** button will be grayed out.

- **Render**: Click on this button to execute rendering computations and display the current volume. If **Auto-Render** is checked, this button will be grayed out.

Isosurface

An isosurface is a 3-D surface on which the data values are constant along the entire surface. Use the following elements to control the appearance of the isosurface:

- **Color**: Click this button to change the color system and/or values for the current isosurface. This opens a CW_RGBSLIDER dialog, which is a compound widget that provides a drop-down list for selecting the RGB, CMY, HSV, or HLS color system, and three sliders for adjusting the values associated with each color system.

- **Isosurface Off**: Select this option to turn off the isosurface display.

- **Opaque Isosurface**: Select this option to display an opaque isosurface.

- **Semi-transparent Isosurface**: Select this option to display a semi-transparent isosurface.

- **Level**: Use this slider to adjust the threshold value of the isosurface.

Syntax

XVOLUME, *Vol*, [, /BLOCK] [, GROUP=*widget_id*] [, /INTERPOLATE]
[, /MODAL] [, RENDERER={0 | 1}] [, /REPLACE] [, SCALE=*value*] [, /TEST]
[, XSIZE=*pixels*] [, YSIZE=*pixels*]

Arguments

Vol

A 3-dimensional array of the form [*x*, *y*, *z*] that specifies a data volume.

Keywords

BLOCK

Set this keyword to have XMANAGER block when this application is registered. By default, BLOCK is set equal to zero, providing access to the command line if active command line processing is available. Note that setting the BLOCK keyword causes all widget applications to block, not just this application. For more information, see the documentation for the NO_BLOCK keyword to XMANAGER.

Note

Only the outermost call to XMANAGER can block. Therefore, to have XVOLUME block, any earlier calls to XMANAGER must have been called with the NO_BLOCK keyword. See the documentation for the NO_BLOCK keyword to XMANAGER for an example.

GROUP

Set this keyword to the widget ID of the widget that calls XVOLUME. When this keyword is specified, the death of the caller results in the death of XVOLUME.

INTERPOLATE

Set this keyword to indicate that trilinear interpolation is to be used when rendering the volume and the image planes. Setting this keyword improves the quality of images produced, at the cost of more computing time, especially when the volume has low resolution with respect to the size of the viewing plane. Nearest neighbor sampling is used by default.

MODAL

Set this keyword to block processing of events from other widgets until the user quits XVOLUME. The MODAL keyword does not require a group leader to be specified. If no group leader is specified, and the MODAL keyword is set, XVOLUME fabricates an invisible group leader for you.

Note ────────────────────────────────────

To be modal, XVOLUME does not require that its caller specify a group leader. This is unlike other IDL widget procedures such as XLOADCT, which, to be modal, do require that their caller specify a group leader. These other procedures were implemented this way to encourage the caller to create a modal widget that will be well-behaved with respect to layering and iconizing. (See "Iconizing, Layering, and Destroying Groups of Top-Level Bases" on page 2653 for more information.)

To provide a simple means of invoking XVOLUME as a modal widget in applications that contain no other widgets, XVOLUME can be invoked as MODAL without specifying a group leader, in which case XVOLUME fabricates an invisible group leader for you. For applications that contain multiple widgets, however, it is good programming practice to supply an appropriate group leader when invoking XVOLUME, /MODAL. As with other IDL widget procedures with names prefixed with "X", specify the group leader via the GROUP keyword.

────────────────────────────────────

RENDERER

Set this keyword to an integer value indicating which graphics renderer to use when drawing objects within the window. Valid values are:

- 0 = Platform native OpenGL (the default)

- 1 = IDL's software implementation

REPLACE

If this keyword is set, and there is a current instance of XVOLUME running, the volume displayed in XVOLUME is replaced with the volume specified by *Vol*. For example, display volume1 using the command

```
XVOLUME, volume1
```

To replace volume1 with volume2, you would use the command

```
XVOLUME, volume2, /REPLACE
```

SCALE

Set this keyword to the zoom factor for the initial view. The default is 1/SQRT(3). This default value provides the largest possible view of the volume, while ensuring that no portion of the volume will be clipped by the XVOLUME window, regardless of the volume's orientation.

When using the SCALE keyword for XVOLUME, you can scale with a 3-element array of values [x, y, z].

TEST

If set, the *Vol* argument is not required (and is ignored if provided). A volume of random numbers is displayed instead. This allows you to test code that uses XVOLUME without having to specify volume data.

XSIZE

The width of the drawable area in pixels.

YSIZE

The height of the drawable area in pixels.

Examples

Create a volume and display using XVOLUME:

```
; Create a volume:
vol = BYTSCL(RANDOMU((SEED=0),5,5,5))
vol = CONGRID(vol, 30,30,30)

; Display volume:
XVOLUME, vol
```

Displaying Volumes Using XVOLUME

Unlike SLICER3, the IDL Object Graphics procedure, XVOLUME, allows you to interactively manipulate 3D volumes and isosurfaces. While the following example requires more processing time to display the same data (head.dat) as that previously displayed with SLICER3, remember that the output is not the same. The XVOLUME example is rendering an opaque volume of the data set whereas the previous SLICER3 example simply displayed an isosurface. Although Object Graphics display methods can require more processing time, they also offer significant advantages including greater interactivity, true volume rendering with the ability to specify opacities, and finer control over image and volumetric data.

Complete the following steps to load the head.dat volume into the XVOLUME application.

Example Code ───

See displayxvolume.pro in the examples/doc/image subdirectory of the IDL installation directory for code that duplicates this example. Run the example

procedure by entering `displayxvolume` at the IDL command prompt or view the file in an IDL Editor window by entering `.EDIT displayxvolume.pro`.

1. Select the file and read in the data, specifying known data dimensions:

   ```
   file = FILEPATH('head.dat', SUBDIRECTORY = ['examples',
   'data'])
   volume = READ_BINARY(file, DATA_DIMS = [80, 100, 57])
   ```

2. Reduce the size of the original array to speed up processing:

   ```
   smallVol = CONGRID(volume, 40, 50, 27)
   ```

3. Using the INTERPOLATE keyword to smooth the data, display the volume using the XVOLUME procedure:

   ```
   XVOLUME, smallVol, /INTERPOLATE
   ```

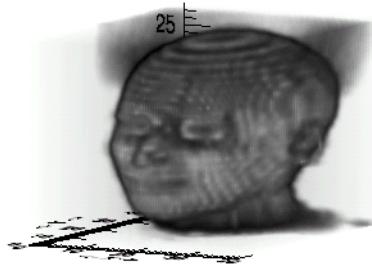
   After the data is passed to the XVOLUME application, an image similar to the following figure appears.


Figure 26-23: Visualizing a Volume with XVOLUME

Manipulating Volumetric Data Using XVOLUME

Once data has been loaded into the XVOLUME application, you can create color coded contoured slices of data. Complete the following steps to create x-, y- and z-dimensional contours of the `head.dat` volume.

1. Rotate the image of the head so that the nose is facing toward the right. Click in the display window and, with your mouse button depressed, drag the mouse cursor to reposition the image display.

2. Select the **X**, **Y**, and **Z** "Contours" options, located on the upper-left portion of the XVOLUME interface.

   Note ───

   Turning off the XVOLUME "Auto-Render" feature produces faster responses to processing requests.

   ──

3. Move the **X Plane** slider to a value of 22. A contour line appears in the display window, running down the center of the image of the head. When you click in the display window, the planar slice is visible.

4. Move the **Y Plane** slider to a value of 27. A contour line appears along the middle of the y-dimension.

5. Move the **Z Plane** slider to a value of 12. Another contour line appears near the middle of the z-dimension.

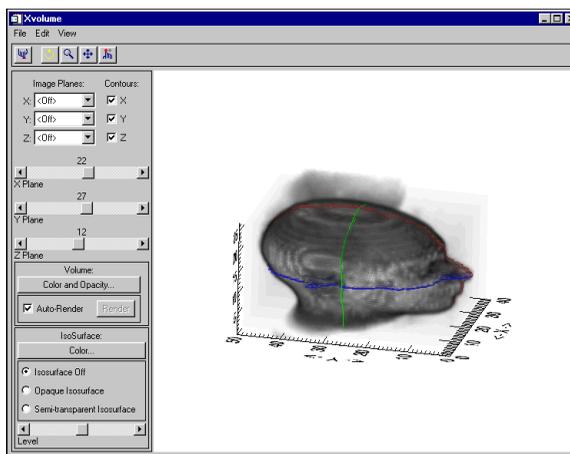
The XVOLUME interface should appear similar to the following figure.


Figure 26-24: Creating Dimensional Contours Using XVOLUME

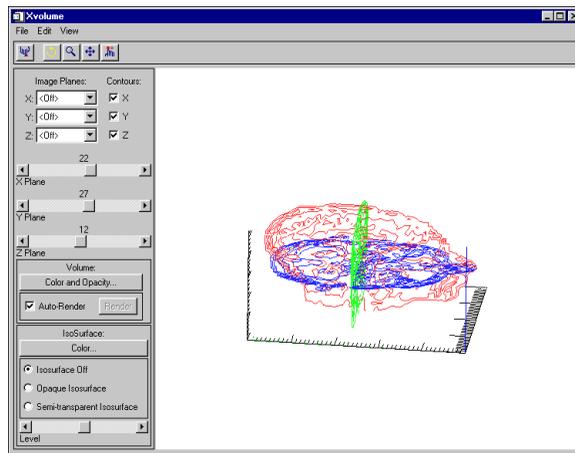
Click in the image display window to show the contour lines.


Figure 26-25: Displaying Contours of Planar Slices Using XVOLUME

Tip

After a volumetric array has been loaded into the XVOLUME application, it can be animated using the XVOLUME_ROTATE procedure. To rotate the image above, run the example program for XVOLUME_ROTATE.

IVOLUME, XVOLUME_ROTATE, XVOLUME_WRITE_IMAGE, IDLgrVolume, INTERPOLATE, ISOSURFACE, SHADE_VOLUME, SLICER3, "Creating a Volume Object" (Chapter 7, *Object Programming*).

XVOLUME_ROTATE

The XVOLUME_ROTATE procedure is used to programmatically rotate the volume currently displayed in XVOLUME. XVOLUME must be called prior to calling XVOLUME_ROTATE. This procedure can be used to create animations of volumes and isosurfaces.

This routine is written in the IDL language. Its source code can be found in the file xvolume_rotate.pro in the lib/utilities subdirectory of the IDL distribution.

Syntax

XVOLUME_ROTATE, *Axis*, *Angle* [, /PREMULTIPLY]

Arguments

Axis

A 3-element vector of the form [*x*, *y*, *z*] describing the axis about which the model is to be rotated.

Angle

The amount of rotation, measured in degrees.

Keywords

PREMULTIPLY

Set this keyword to cause the rotation matrix specified by *Axis* and *Angle* to be pre-multiplied to the model's transformation matrix. By default, the rotation matrix is post-multiplied.

Examples

The following example creates an animation of the volume currently displayed in XVOLUME. It does this by rotating the volume through 360 degrees in increments of 10 degrees using XVOLUME_ROTATE, and writing the volume to a BMP file for each increment using XVOLUME_WRITE_IMAGE. It then loops through the images and uses TV to display each image.

First, display a volume as follows:

```
; Create a volume:
vol = BYTSCL(RANDOMU((SEED=0),5,5,5))
vol = CONGRID(vol, 30,30,30)

; Display volume:
XVOLUME, vol
```

Now, use the XVOLUME interface to modify the orientation and appearance of the volume or isosurface as desired. Once you have the volume or isosurface displayed the way you want it, run the following program:

```
PRO spin_volume

    inc = 10. ; degrees.
    ; Create images
    FOR i=0,(360./inc)-2 DO BEGIN
       XVOLUME_WRITE_IMAGE, $
          'spin' + STRCOMPRESS(i, /REMOVE_ALL) + '.bmp', 'bmp'
       XVOLUME_ROTATE, [0,0,1], inc, /PREMULTIPLY
    ENDFOR
    XVOLUME_ROTATE, [0,0,1], inc, /PREMULTIPLY

    ; Read images
    img = READ_BMP('spin0.bmp')
    siz = SIZE(img, /DIM)
    arr = BYTARR(3, siz[1], siz[2], 360./inc-1)
    FOR i=0,360./inc-2 DO BEGIN
       img = READ_BMP( $
          'spin' + STRCOMPRESS(i, /REMOVE_ALL) + '.bmp', /RGB)
       arr[0,0,0, i] = img
       PRINT, i
    ENDFOR

    ; Display animation
    FOR i=0,2 DO BEGIN ; num rotations
       FOR j=0,(360./inc)-2 DO BEGIN
          TV, arr[*,*,*,j], /TRUE
       ENDFOR
    ENDFOR

    TV, arr[*,*,*,0], /TRUE

END
```

XVOLUME, XVOLUME_WRITE_IMAGE

XVOLUME_WRITE_IMAGE

The XVOLUME_WRITE_IMAGE procedure is used to write the volume currently displayed in XVOLUME to an image file with the specified name and file format. XVOLUME must be called prior to calling XVOLUME_WRITE_IMAGE.

This routine is written in the IDL language. Its source code can be found in the file `xvolume_write_image.pro` in the `lib/utilities` subdirectory of the IDL distribution.

Syntax

XVOLUME_WRITE_IMAGE, *Filename*, *Format* [, DIMENSIONS=*[x, y]*]

Arguments

Filename

A scalar string containing the name of the file to write.

Format

A scalar string containing the name of the file format to write. See QUERY_IMAGE for a list of supported formats.

Keywords

DIMENSIONS

Set this keyword to a 2-element vector of the form [*x*, *y*] specifying the size of the output image, in pixels. If this keyword is not specified, the image will be written using the dimensions of the current XVOLUME draw widget.

Examples

See XVOLUME_ROTATE.

XVOLUME, XVOLUME_ROTATE

XYOUTS

The XYOUTS procedure draws text on the currently-selected graphics device starting at the designated coordinate.

Arguments *X*, *Y*, and *String* can be any combination of scalars or arrays. If the arguments are arrays, multiple strings are output.

If the optional *X* and *Y* arguments are omitted, the text is positioned at the end of the most recently output text string.

Important keywords that control the appearance and positioning of the text include: ALIGNMENT, the justification of the text; CHARSIZE, the size of the text; FONT, chooses between vector drawn and hardware fonts; COLOR, the color of the text; and ORIENTATION, the angle between the baseline of the text and the horizontal. With hardware fonts, most of the text attributes, (e.g., size and orientation), are predetermined and not changeable.

Note

Specify the Z coordinate with the Z keyword when positioning text in three dimensions.

Syntax

XYOUTS, [*X*, *Y*,] *String* [, ALIGNMENT=*value*{0.0 to 1.0}] [, CHARSIZE=*value*]
  [, CHARTHICK=*value*] [, TEXT_AXES={0 | 1 | 2 | 3 | 4 | 5}]
  [, WIDTH=*variable*]

Graphics Keywords:[, CLIP=*[X$_0$, Y$_0$, X$_1$, Y$_1$]*] [, COLOR=*value*][, /DATA | ,
  /DEVICE | , /NORMAL] [, FONT=*integer*]
  [, ORIENTATION=*ccw_degrees_from_horiz*] [, /NOCLIP] [, /T3D] [, Z=*value*]

Arguments

X, Y

The horizontal and vertical coordinates used to position the string(s). *X* and *Y* are normally interpreted in data coordinates. The DEVICE and NORMAL keywords can be used to specify the coordinate units.

X and *Y* can be arrays of positions if *String* is an array.

String

The string(s) to be output. This argument can be a scalar string or an array of strings. If this argument is not a string, it is converted prior to use using the default formatting rules. If *String* is an array, *X*, *Y*, and the COLOR keyword can also be arrays so that each string can have a separate location and color.

Keywords

ALIGNMENT

Specifies the alignment of the text baseline. An alignment of 0.0 (the default) aligns the left edge of the text baseline with the given (*x*, *y*) coordinate. An alignment of 1.0 right-justifies the text, while 0.5 results in text centered over the point (*x*, *y*).

CHARSIZE

The overall character size for the annotation. A CHARSIZE of 1.0 is normal. Setting CHARSIZE = -1 suppresses output of the text string. This keyword has no effect when used with the hardware drawn fonts; for exceptions, see "Scaled Hardware Fonts" on page 3117.

CHARTHICK

The line thickness of the vector drawn font characters. This keyword has no effect when used with the hardware drawn fonts; for exceptions, see "Scaled Hardware Fonts" on page 3117. The default value is 1.0.

TEXT_AXES

This keyword specifies the plane of vector drawn text when three-dimensional plotting is enabled. By default, text is drawn in the plane of the XY axes. The horizontal text direction is in the X plane, and the vertical text direction is in the Y plane. Values for this keyword can range from 0 to 5, with the following effects: 0 for XY, 1 for XZ, 2 for YZ, 3 for YX, 4 for ZX, and 5 for ZY. The notation ZY means that the horizontal direction of the text lies in the Z plane, and the vertical direction of the text is drawn in the Y plane.

WIDTH

Set this keyword to a named variable in which to return the width of the text string, in normalized coordinate units.

Graphics Keywords Accepted

See Appendix B, "Graphics Keywords" for the description of the following graphics and plotting keywords:

CLIP, COLOR, DATA, DEVICE, FONT, NOCLIP, NORMAL, ORIENTATION, T3D, Z

Examples

Print the string "This is text" at device coordinate position (100,100):

```
XYOUTS, 100, 100, 'This is text', /DEVICE
```

Print an array of strings with each element of the array printed at a different location. Use larger text than in the previous example:

```
XYOUTS, [0, 200, 250], [200, 50, 100], $
   ['This', 'is', 'text'], CHARSIZE = 3, /DEVICE
```

Determine the text size for a window device before opening an on-screen window:

```
WINDOW, /FREE, /PIXMAP, XSIZE=myWinXSize, YSIZE=myWinYSize
XYOUTS, 'Check this out', WIDTH=w
WDELETE
```

myWinXSize and *myWinYSize* are chosen to match your onscreen window. Since we can not know the characteristics of a given device (such as character size) until a window has been opened, the PIXMAP keyword to WINDOW allows you to compute appropriate dimensions for text with an invisible window before displaying a window on your screen.

Labeling Lines of Data in a Plot

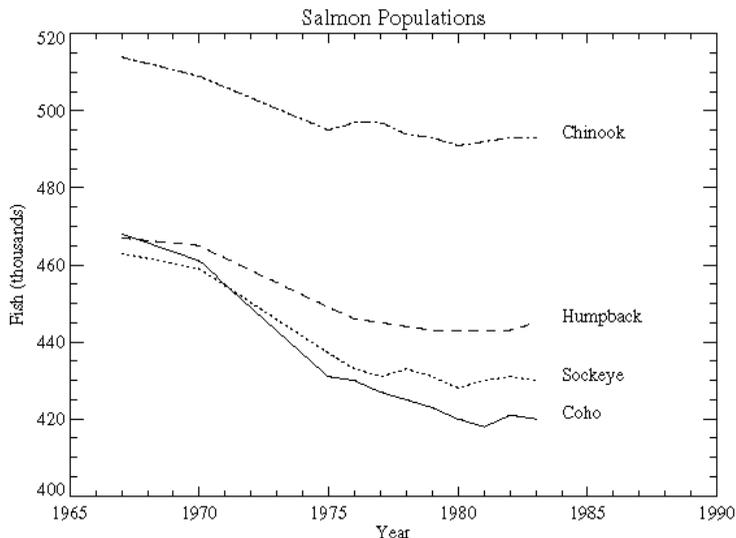
This example adds to the example shown in OPLOT by annotating each graph with its name. This plot is exactly the same as the OPLOT example except that the *x*-axis range is extended to the year 1990 to allow room for the titles. To accomplish this, the keyword parameter XRANGE = [1967, 1990] was added to the call to PLOT. A string vector, NAMES, containing the names of each sample population also is defined.


Figure 26-26: Example of Annotating Each Line

First, we define an array containing names for each of the lines plotted. (This array is also defined by the plot01 batch file.)

```
NAMES=['Coho','Sockeye','Humpback','Chinook']
```

The plot was produced with the following statements:

```
; Define variables:
@plot01
; Index of last point:
N1 = N_ELEMENTS(YEAR) - 1
; Plot first graph. Set the y-axis min and max
; from the min and max of all data sets. Default linestyle is 0.
PLOT, YEAR, COHO, YRANGE = [MIN(ALLPTS), MAX(ALLPTS)], $
    TITLE='Salmon Populations', XTITLE = 'Year', $
    YTITLE = 'Fish (thousands)', XRANGE = [1965, 1990], $
    /XSTYLE
; Loop for the three remaining scores, varying the linestyle:
FOR I = 1, 3 DO OPLOT, YEAR, ALLPTS[*, I], LINE = I
; Append the title of each graph on the right:
FOR I = 0, 3 DO XYOUTS, 1984, ALLPTS[N1, I], NAMES[I]
```

Note ───

If IDL does not find the batch file, the required directory may not be in your IDL search path. All of the files mentioned are located in the `examples/doc/plot` subdirectory of the IDL distribution. By default, this directory is part of IDL's path; if you have not changed your path, you will be able to run the examples as described here. See !PATH for information on modifying IDL's path.

───

Font Selection

The previous example illustrates the use of a PostScript font (Times-Roman, in this case) for the titles and annotations. Note that PostScript fonts can only be used when the current graphics devices is set to PostScript.

This font was selected by first setting the default font, controlled by the system variable !P.FONT, to the hardware-font index of zero, and then calling the DEVICE procedure to set the Times-Roman font.

Example Code ─────────────────────────────────────

To recreate the plot using this font on your system enter `@plot02` at the IDL command prompt. You can also inspect the batch file `plot02`, located in the `examples/doc/plot` subdirectory of the IDL distribution. Running this batch files creates a PostScript file named `plot.ps` in your current working directory.

───

Warning ──

Because not all devices have selectable hardware fonts, default hardware fonts vary. Use of other PostScript fonts and their bold, italic, oblique, and other variants is described in Appendix H, "Fonts".

───

Scaled Hardware Fonts

One example of hardware fonts which can be scaled are PostScript fonts. If you are using PostScript fonts, the keywords CHARTHICK and CHARSIZE will have an effect on a call to XYOUTS. Of the devices we provide that support hardware fonts, only the PostScript device uses scalable PostScript fonts for its "hardware" font system. All other devices use a bitmapped font technology.

Scaling is related to whether or not a device supports Hershey formatting commands when hardware fonts are used. Formatting requires the ability to scale the text on a per-character basis (i.e. for subscripting). To see if a given device supports Hershey formatting when hardware fonts are used, look at bit 12 of !D.FLAGS. You can also use this indicator to determine whether or not the hardware fonts will be scaled.

Chapter 27
Routines: Z

ZOOM

The ZOOM procedure displays part of an image from the current window enlarged in a new ("zoom") window. The cursor is used to mark the center of the zoom area, and different zoom factors can be specified interactively.

Note ——————————————————————————————————

ZOOM only works with color systems.

——

This routine is written in the IDL language. Its source code can be found in the file zoom.pro in the lib subdirectory of the IDL distribution.

Using ZOOM

After calling ZOOM, place the mouse cursor over an image in an IDL graphics window. Click the left mouse button to display a magnified version of the image in a new window. The zoomed image is centered around the pixel selected in the original window. Click the middle mouse button to display a menu of zoom factors. Click the right mouse button to exit the procedure.

Using ZOOM with Draw Widgets

Note that the ZOOM procedure is only for use with IDL graphics windows. It should not be used with draw widgets. To obtain a zooming effect in a draw widget, use the CW_ZOOM function.

Syntax

ZOOM [, /CONTINUOUS] [, FACT=*integer*] [, /INTERP] [, /KEEP]
   [, /NEW_WINDOW] [, XSIZE=*value*] [, YSIZE=*value*]
   [, ZOOM_WINDOW=*variable*]

Arguments

None

Keywords

CONTINUOUS

Set this keyword to make the zoom window track the mouse without requiring the user to press the left mouse button. This feature only works well on fast computers.

FACT

Use this keyword to specify the zoom factor, which must be an integer. The default zoom factor is 4.

INTERP

Set this keyword to use bilinear interpolation. The default is to use pixel replication.

KEEP

Set this keyword to keep the zoom window after exiting the procedure.

NEW_WINDOW

Normally, if ZOOM is called with KEEP and then called again, it will use the same window to display the new zoomed image. Set the NEW_WINDOW keyword to force ZOOM to create a new window for this purpose.

XSIZE

Use this keyword to specify the X size of the zoom window. The default is 512.

YSIZE

Use this keyword to specify the Y size of the zoom window. The default is 512.

ZOOM_WINDOW

Set this keyword to a named variable that will contain the index of the zoom window. KEEP must also be set. If KEEP is not set, ZOOM_WINDOW will contain the integer -1.

Examples

Zooming in on a Direct Graphics Image Display

The following example imports a grayscale image from the convec.dat binary file. This grayscale image shows the convection of the Earth's mantle. The image contains byte data values and is 248 pixels by 248 pixels. The ZOOM procedure, which is a Direct Graphics routine, is used to zoom in on the lower left corner of the image.

Example Code

See zooming_direct.pro in the examples/doc/image subdirectory of the IDL installation directory for code that duplicates this example. Run the example

procedure by entering `zooming_direct` at the IDL command prompt or view the
file in an IDL Editor window by entering `.EDIT zooming_direct.pro`.

1. Determine the path to the `convec.dat` file:

    ```
    file = FILEPATH('convec.dat', $
        SUBDIRECTORY = ['examples', 'data'])
    ```

2. Initialize the image size parameter:

    ```
    imageSize = [248, 248]
    ```

3. Import the image from the file:

    ```
    image = READ_BINARY(file, DATA_DIMS = imageSize)
    ```

4. If you are running IDL on a TrueColor display, set the DECOMPOSED
   keyword to the DEVICE command to zero before your first color table related
   routine is used within an IDL session or program.

    ```
    DEVICE, DECOMPOSED = 0
    ```

5. Load a grayscale color table:

    ```
    LOADCT, 0
    ```

6. Create a window and display the original image with the TV procedure:

    ```
    WINDOW, 1, XSIZE = imageSize[0], YSIZE = imageSize[1], $
        TITLE = 'A Grayscale Image'
    TV, image
    ```

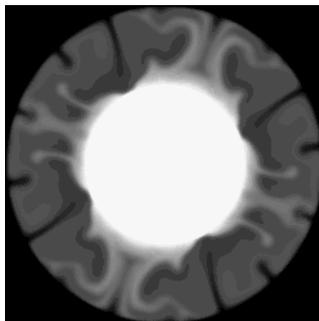
   The following figure shows the resulting grayscale image display.


Figure 27-1: A Grayscale Image in Direct Graphics

7. Use the ZOOM to enlarge the lower left quarter of the image:

```
ZOOM, /NEW_WINDOW, FACT = 2, $
   XSIZE = imageSize[0], YSIZE = imageSize[1]
```

Click in the lower left corner of the original image window.

The following figure shows the resulting zoomed image.

Figure 27-2: Enlarged Image Area in Direct Graphics

8. Right-click in the original image window to quit out of the ZOOM procedure.

CW_ZOOM, ZOOM_24

ZOOM_24

The ZOOM_24 procedure displays part of a 24-bit color image from the current window expanded in a new ("zoom") window, and provides information about cursor location and color values in an auxiliary ("data") window. The cursor is used to mark the center of the zoom area, and different zoom factors can be specified interactively.

Note ──
ZOOM only works on 24-bit color systems.
──

This routine is written in the IDL language. Its source code can be found in the file zoom_24.pro in the lib subdirectory of the IDL distribution.

Using ZOOM_24

After calling ZOOM_24, windows titled "Zoomed Image" (the zoom window) and "Pixel Values" (the data window) appear on the screen. Place the mouse cursor over a 24-bit color image in an IDL graphics window and click the left mouse button to display a magnified version of the image in the zoom window. The zoomed image is centered around the pixel selected in the original window. Move the mouse cursor in the zoom window to determine the coordinates (in the original image) and color values of individual pixels.

With the cursor located in the zoom window, click the right mouse button to return to selection mode, which allows you to either choose a new zoom center, change the zoom factor, or exit the procedure. Move the cursor to the original image and click the middle mouse button to display a menu of zoom factors, or click the right mouse button to exit the procedure.

Using ZOOM_24 with Draw Widgets

Note that the ZOOM_24 procedure is only for use with IDL graphics windows. It should not be used with draw widgets. To obtain a zooming effect in a draw widget, use the CW_ZOOM function.

Syntax

ZOOM_24 [, FACT=*integer*] [, /RIGHT] [, XSIZE=*value*] [, YSIZE=*value*]

Arguments

None.

Keywords

FACT

Use this keyword to specify the zoom factor, which must be an integer. The default zoom factor is 4.

RIGHT

Set this keyword to position the zoom and data windows to the right of the original window.

XSIZE

Use this keyword to specify the X size of the zoom window. The default is 512.

YSIZE

Use this keyword to specify the Y size of the zoom window. The default is 512.

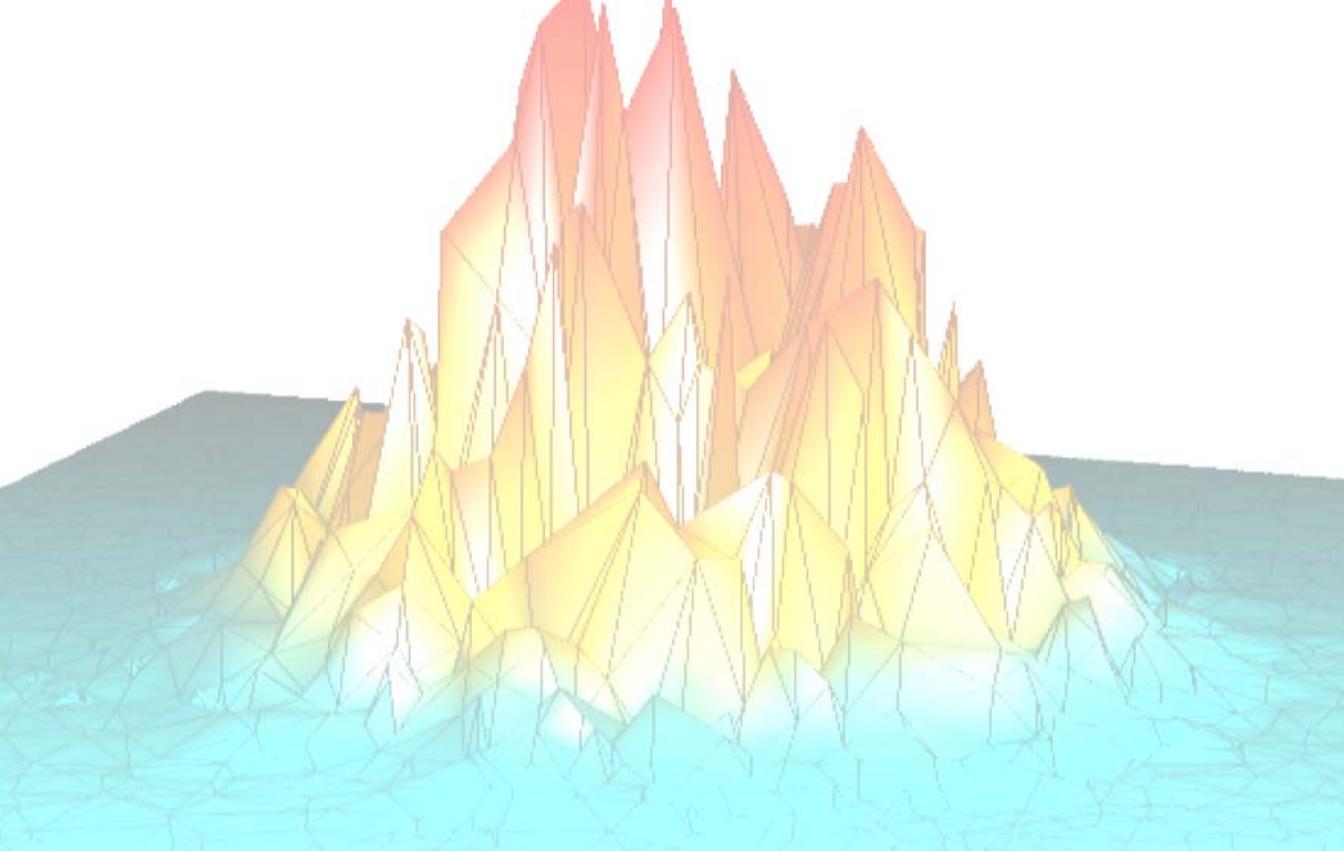
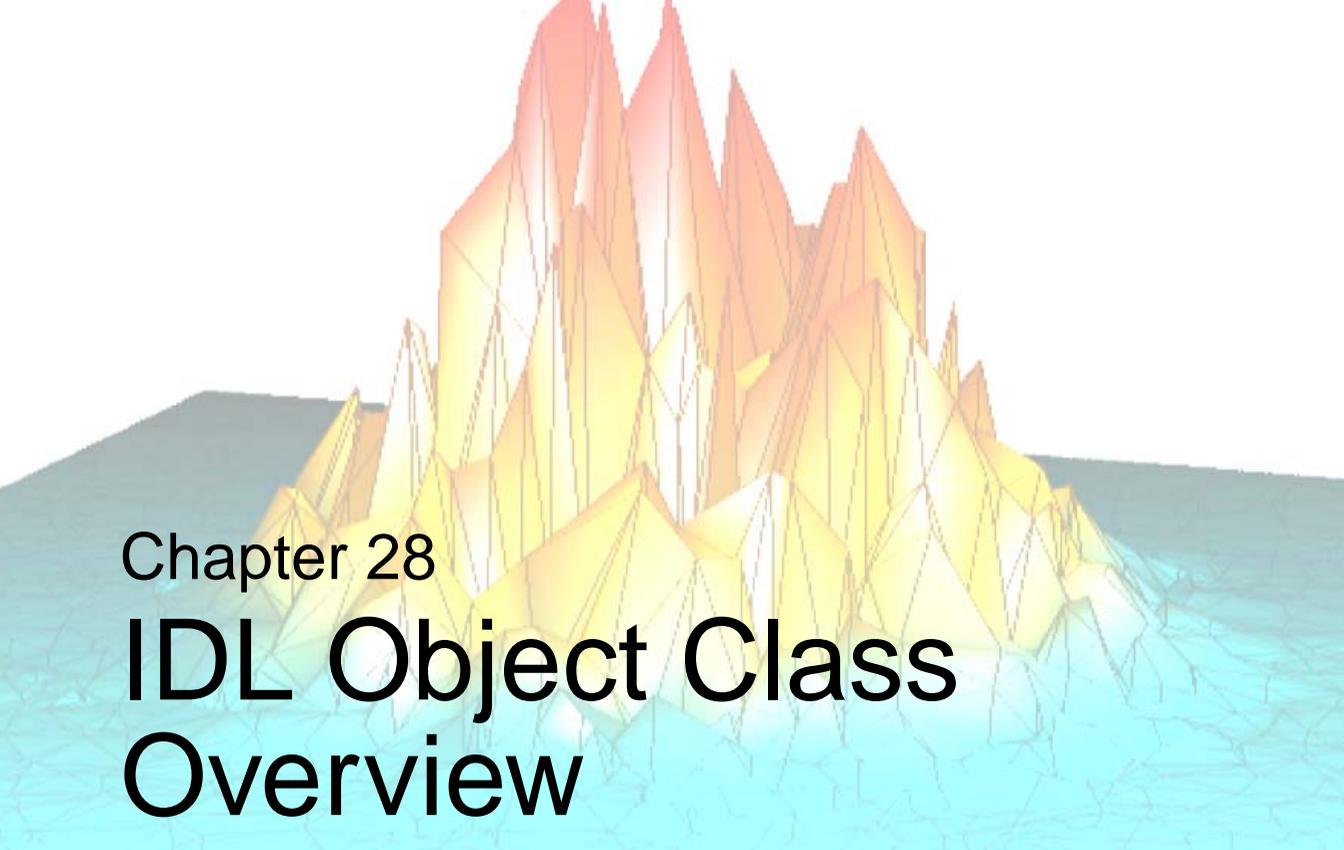
CW_ZOOM, ZOOM


Part II: Object Class and Method Reference


Chapter 28
IDL Object Class Overview

This section describes IDL's object class library.

Using the Class Reference

IDL's object class library is documented in this section. The page or pages describing each class include references to any superclasses of the class, to the properties of the class, and to the methods associated with the class. Class methods are documented alphabetically following the description of the class itself.

A description of each method follows its name. Beneath the general description of the method are a number of sections that describe the Syntax for the method, its arguments (if any), its keywords (if any). These sections are described below.

Object Method Syntax

In the *IDL Reference Guide*, the Syntax section of each object method shows the proper syntax for calling the method.

Procedure Methods

IDL procedure methods have the syntax:

Obj->Procedure_Name, *Argument* [, *Optional_Arguments*]

where *Obj* is a valid object reference, *Procedure_Name* is the name of the procedure method, *Argument* is a required parameter, and *Optional_Argument* is an optional parameter to the procedure method. The square brackets around optional arguments are not used in the actual call to the procedure, they are simply used to denote the optional nature of the arguments within this document.

Function Methods

IDL function methods have the syntax:

Result = Obj->Function_Name(*Argument* [, *Optional_Arguments*])

where *Obj* is a valid object reference, *Result* is the returned value of the function method, *Function_Name* is the name of the function method, *Argument* is a required parameter, and *Optional_Argument* is an optional parameter. The square brackets around optional arguments are not used in the actual call to the function, they are simply used to denote the optional nature of the arguments within this document.

Note ──

All arguments and keywords to functions should be supplied *within* the parentheses that follow the function's name.

───

Arguments

The *Arguments* section describes each valid argument to the method.

Note ───
These arguments are positional parameters that must be supplied in the order
indicated by the method's syntax.
───

Named Variables

Often, arguments that contain values upon return from the function or procedure
method ("output arguments") are described as accepting "named variables." A named
variable is simply a valid IDL variable name. This variable *does not* need to be
defined before being used as an output argument. Note, however that when an
argument calls for a named variable, only a named variable can be used—sending an
expression causes an error.

Keywords

The *Keywords* section describes each valid keyword argument to the method.

Note ───
Keyword arguments are formal parameters that can be supplied in any order.
───

Keyword arguments are supplied to IDL methods by including the keyword name
followed by an equal sign ("=") and the value to which the keyword should be set.
Note that keywords can be abbreviated to their shortest unique length. For example,
the XSTYLE keyword can be abbreviated to XST.

Note ───
In the case of Init, GetProperty and SetProperty methods, keywords often
correspond to object *properties*. See "Object Properties" on page 3133 for
additional discussion.
───

Setting Keywords

When the documentation for a keyword says something similar to, "Set this keyword
to enable logarithmic plotting," the keyword is simply a switch that turns an option
on and off. In general, setting such keywords equal to 1 (or using the /KEYWORD
syntax) causes the option to be turned on. Explicitly setting the keyword to zero (or
not including the keyword) turns the option off.

Creating Objects from the Class Library

To create an object from the IDL object class library, use the OBJ_NEW function. See "OBJ_NEW" on page 1734. The Init method for each class describes the arguments and keywords available when you are creating a new object.

For example, to create a new object from the IDLgrAxis class, use the following call to OBJ_NEW along with the arguments and keywords accepted by the IDLgrAxis::Init method:

```
myAxis = OBJ_NEW(IDLgrAxis, DIRECTION = 1, RANGE = [0.0, 40.0])
```

Object Properties

Some IDL objects have *properties* associated with them — things like color, line style, size, and so on. Properties are set or changed by supplying property-value pairs in a call to the object class' Init or SetProperty method:

```
Obj->OBJ_NEW('ObjectClass', PROPERTY = value, ... )
```

or

```
Obj->SetProperty, PROPERTY = value, ...
```

where *PROPERTY* is the name of a property and *value* is the associated property value.

Property values are retrieved by supplying property-value pairs in a call to the object class' GetProperty method:

```
Obj->GetProperty, PROPERTY = variable, ...
```

where *PROPERTY* is the name of a property and *variable* is the name of an IDL variable that will hold the associated property value.

Note

Property-value pairs behave in exactly the same way as Keyword-value pairs. This means that you can set the value of a boolean property to 1 by preceding the name of the property with a "/" character. The following are equivalent:

```
Obj->SetProperty, PROPERTY = 1

Obj->SetProperty, /PROPERTY
```

If you are familiar with IDL Direct Graphics, you will note that many of the properties of IDL objects correspond to keywords to the Direct Graphics routines. Unlike IDL Direct Graphics, the IDL Object Graphics system allows you to change the value of an object's properties without re-creating the entire object. Objects must be redrawn, however, with a call to the destination object's Draw method, for the changes to become visible.

Properties and the Property Sheet Interface

In addition to being able to set and change object property values programmatically, IDL provides a way for users to change property values via a graphical user interface. The WIDGET_PROPERTYSHEET function creates a user interface that allows users to select and change property values using the mouse and keyboard.

For an object property to be displayed in a property sheet, the property must be registered.

See "Registered Properties" on page 3137 for additional discussion.

Setting Properties at Initialization

Often, you will set an object's properties when creating the object for the first time, which is done by specifying any keywords to the object's Init method directly in the call of OBJ_NEW that creates the object. For example, suppose you are creating a plot and wish to use a red line to draw the plot line. You could specify the COLOR keyword to the IDLgrPlot::Init method directly in the call to OBJ_NEW:

```
myPlot = OBJ_NEW('IDLgrPlot', xdata, ydata, COLOR = [255, 0, 0])
```

In most cases, an object's Init method cannot be called directly. Arguments to OBJ_NEW are passed directly to the Init method when the object is created.

For some graphics objects, you can specify a keyword that has the same meaning as an argument. In Object Graphics, the value of the keyword overrides the value set by the argument. For example,

```
myPlot = OBJ_NEW('IDLgrPlot', xdata, ydata, DATAX = newXData)
```

The Plot object uses the data in `newXData` for the plot's X data.

Setting Properties of Existing Objects

After you have created an object, you can also set its properties using the object's SetProperty method. For example, the following two statements duplicate the single call to OBJ_NEW shown above:

```
myPlot = OBJ_NEW('IDLgrPlot', xdata, ydata)
myPlot->SetProperty, COLOR = [255, 0, 0]
```

Note ──

Not all keywords available when the object is being initialized are necessarily available via the SetProperty method. Keywords available when using an object's SetProperty method are noted with the word "Set" in the table included after the text description of the property.

──

Retrieving Property Settings

You can retrieve the value of a particular property using an object's GetProperty method. The GetProperty method accepts a list of keyword-variable pairs and returns

the value of the specified properties in the variables specified. For example, to return the value of the COLOR property of the plot object in our example, use the statement:

```
myPlot->GetProperty, COLOR = plotcolor
```

The value of the COLOR property is returned in the IDL variable `plotcolor`.

You can retrieve the values of all of the properties associated with a graphics object by using the ALL keyword to the object's GetProperty method. The following statement:

```
myPlot->GetProperty, ALL = allprops
```

returns an anonymous structure in the variable `allprops`; the structure contains the values of all of the retrievable properties of the object.

Note

Not all keywords available when the object is being initialized are necessarily available via the GetProperty method. Keywords available when using an object's GetProperty method are noted with the word "Get" in the table included after the text description of the property.

About Object Property Descriptions

In the documentation for the IDL object class library, the description of each class is followed by a section describing the properties of the class. Each property description is followed by a table that looks like this:

Property Type	Boolean		
Name String	Hide		
Get: Yes	**Set:** No	**Init:** Yes	**Registered:** Yes

where

- **Property Type** describes the property type associated with the property. If the property is *registered*, the property type will be one of a number of registered property data types. If the property is not registered, this field will describe the generic IDL data type of the property value.

- **Name String** is the default value of the Name property attribute. If the property is registered, this is the value that appears in the left-hand column when the property is displayed in a property sheet widget. If the property is not registered, this field will contain the words *not displayed*.

- **Get**, **Set**, and **Init** describe whether the property can be specified as a keyword to the GetProperty, SetProperty, and Init methods, respectively.

- **Registered** describes whether the property is registered for display in a property sheet widget.

See "Registered Property Data Types" on page 3138 and "Registered Properties" on page 3137 for additional information.

Registered Properties

In order for an object property to be displayed in the WIDGET_PROPERTYSHEET interface, which makes it possible for a user to interactively change the value of the property using the mouse and keyboard, the following two conditions must be met:

- The property must belong to an object that subclasses from the IDLitComponent class. IDLitComponent provides the infrastructure necessary to display property sheets.

- The property must be *registered*. Properties that are not registered will never be displayed in a property sheet. (Note that registered properties can also be *hidden*, which prevents them from being displayed in a property sheet.)

Note ──
This section provides a brief overview of property registration. See Chapter 4, "Property Management" (*iTool Developer's Guide*) for a more in-depth discussion.
──

Registering a Property

To register a property, use the RegisterProperty method of the IDLitComponent class:

```
Obj->IDLitComponent::RegisterProperty, PropertyIdentifier, $
   [, TypeCode] [, ATTRIBUTE = value]
```

where *PropertyIdentifier* is a string that uniquely identifies the property, *TypeCode* is an integer between 0 and 9 specifying the property data type, and *ATTRIBUTE* is a property attribute.

Property identifier strings must obey certain rules; see "Property Identifiers" (Chapter 4, *iTool Developer's Guide*) for details. Property type codes are discussed in "Registered Property Data Types" on page 3138. Property attributes are discussed in "Property Attributes" (Chapter 4, *iTool Developer's Guide*).

Registering All Available Properties

Some of the classes in the IDL object class library include a mechanism to register all available properties in a single operation. If an object class has a REGISTER_PROPERTIES property, then setting that property to 1 when creating the object automatically registers all properties that can be registered. If a property contains a "Yes" in the Registered box of the property description table, it will be

registered automatically if the REGISTER_PROPERTIES property is set when the object is created. (See "About Object Property Descriptions" on page 3135 for a description of the property description table.)

Registered Property Data Types

Registered properties must be of one of the data types listed in the following table.

Note ————————————————————————————————
Properties of objects that are *not* registered (that is, properties that cannot appear in a property sheet) can be of any IDL data type.
————————————————————————————————

Type Code	Type	Description
0	USERDEF	User Defined properties can contain values of any IDL type, but must also include a string value that will be displayed in the property sheet. See the following discussion for additional information.
1	BOOLEAN	Boolean properties contain either the integer 0 or the integer 1.
2	INTEGER	Integer properties contain an integer value. If a property of integer data type has a VALID_RANGE attribute that includes an increment value, the property is displayed in a property sheet using a slider. If no increment value is supplied, the property sheet allows the user to edit values manually.
3	FLOAT	Float properties contain a double-precision floating-point value. If a property of float data type has a VALID_RANGE attribute that includes an increment value, the property is displayed in a property sheet using a slider. If no increment value is supplied, the property sheet allows the user to edit values manually.
4	STRING	String properties contain a scalar string value
5	COLOR	Color properties contain an RGB color triplet

Table 28-1: iTools Property Data Types

Type Code	Type	Description
6	LINESTYLE	Linestyle properties contain an integer value between 0 and 6, corresponding to the following IDL line styles: • 0 = Solid • 1 = Dotted • 2 = Dashed • 3 = Dash Dot • 4 = Dash Dot Dot • 5 = Long Dashes • 6 = No Line See Appendix B, "Property Controls" (*iTool User's Guide*) for a visual example of the available line styles.
7	SYMBOL	Symbol properties contain an integer value between 0 and 8, corresponding to the following IDL symbol types: • 0 = No symbol • 1 = Plus sign • 2 = Asterisk • 3 = Period (Dot) • 4 = Diamond • 5 = Triangle • 6 = Square • 7 = X • 8 = "Greater-than" Arrow Head (>) • 9 = "Less-than" Arrow Head (<) See Appendix B, "Property Controls" (*iTool User's Guide*) for a visual example of the available symbols.

Table 28-1: iTools Property Data Types (Continued)

Type Code	Type	Description
8	THICKNESS	Thickness properties contain an integer value between 1 and 10, corresponding to the thickness (in points) of the line.
9	ENUMLIST	Enumerated List properties contain an array of string values defined when the property is registered. The GetProperty method returns the zero-based index of the selected item.

Table 28-1: iTools Property Data Types (Continued)

User Defined Property Types

The User Defined property type lets you create a custom interface that allow users of your iTool to select data of types other than the predefined iTool property types. Creating a user defined property type entails the following:

- Creating an EditUserDefProperty method for the iTool component (usually a visualization or operation) that uses the user defined property. See "IDLitComponent::EditUserDefProperty" (*IDL Reference Guide*) for details.

- Creating user interface code to allow users to select a value. In the initial release of the iTool system, this means writing an IDL widget interface, but in future releases other users interfaces may be available.

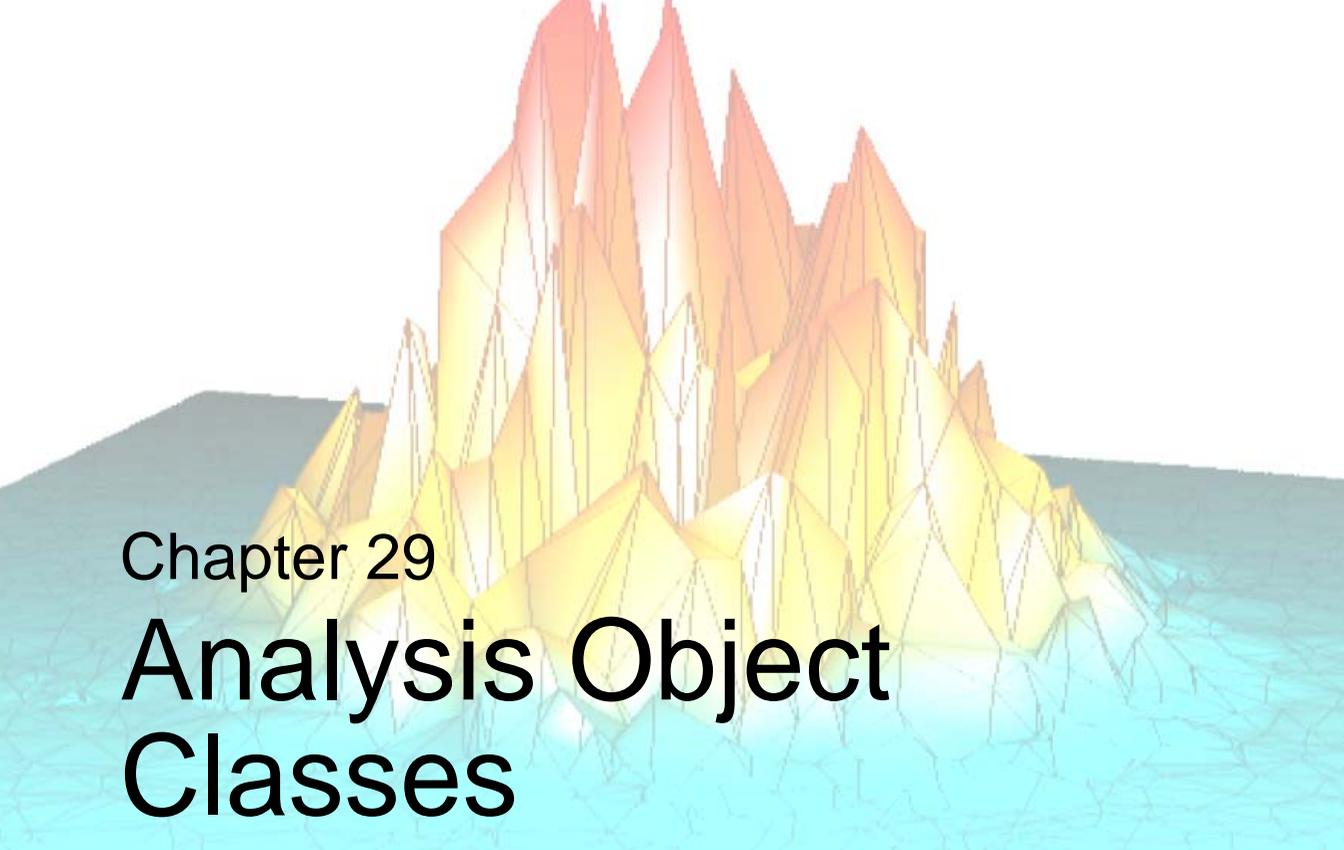
- Creating a *user interface service* to display the interface. See Chapter 13, "Creating a User Interface Service" (*iTool Developer's Guide*) for details.

Undocumented Object Classes

Some of IDL's object classes are subclassed from more generic IDL objects. You may see references to the generic IDL objects when using IDL's HELP procedure to get information on an object, or when you use the OBJ_ISA or OBJ_CLASS functions. You may also notice that the generic objects are not documented in this section. This is not an oversight.

We have chosen not to document the workings of the more generic objects from which the IDL graphics objects are subclassed because we reserve the right to make changes to their operation. We strongly recommend that you do not use the undocumented object classes directly, or subclass your own object classes from them. ITT Visual Information Solutions does not guarantee that user-written code that uses undocumented features will continue to function in future releases of IDL.

Note ———————————————————————————————

In addition to undocumented object classes, some documented object classes have undocumented properties and methods. Again, we do not guarantee that code using these features will continue to function in future releases of IDL.


Chapter 29
Analysis Object Classes

This chapter describes IDL's built-in analysis class library.

IDLanROI

The IDLanROI object class represents a region of interest.

Note ──

The IDLan* naming convention is used for objects in the analysis domain.

──

Regions of interest are described as a set of vertices that may be connected to generate a path or a polygon, or may be treated as separate points. This object may be used as a source for analytical computations on regions. (For additional information about display of ROIs in Object Graphics, refer to the IDLgrROI object class.)

Superclasses

None

Creation

See IDLanROI::Init.

Properties

Objects of this class have the following properties. See "IDLanROI Properties" on page 3146 for details on individual properties.

- ALL
- BLOCK_SIZE
- DATA
- DOUBLE
- INTERIOR
- N_VERTS
- ROI_XRANGE
- ROI_YRANGE
- ROI_ZRANGE
- TYPE

In addition, objects of this class inherit the properties of all superclasses of this class.

Methods

The IDLanROI class has the following methods.

- IDLanROI::AppendData
- IDLanROI::Cleanup
- IDLanROI::ComputeGeometry
- IDLanROI::ComputeMask
- IDLanROI::ContainsPoints
- IDLanROI::GetProperty
- IDLanROI::Init
- IDLanROI::RemoveData
- IDLanROI::ReplaceData
- IDLanROI::Rotate
- IDLanROI::Scale
- IDLanROI::SetProperty
- IDLanROI::Translate

In addition, this class inherits the methods of its superclasses (if any).

Examples

See "Programmatically Defining ROIs" (Chapter 6, *Image Processing in IDL*).

Version History

5.3	Introduced

IDLanROI Properties

IDLanROI objects have the following properties in addition to properties inherited from any superclasses. Properties with the word "Yes" in the "Get" column of the property table can be retrieved via IDLanROI::GetProperty. Properties with the word "Yes" in the "Init" column of the property table can be set via IDLanROI::Init. Properties with the word "Yes" in the "Set" column in the property table can be set via IDLanROI::SetProperty.

Note ───

For a discussion of the property description tables shown below, see "About Object Property Descriptions" on page 3135.

───

Objects of this class have the following properties.

- ALL
- BLOCK_SIZE
- DATA
- DOUBLE
- INTERIOR
- N_VERTS
- ROI_XRANGE
- ROI_YRANGE
- ROI_ZRANGE
- TYPE

In addition, objects of this class inherit the properties of all superclasses of this class.

ALL

An anonymous structure containing the values of all of the properties associated with the state of this object. State information about the object includes things like block size, type, etc., but not vertex data.

Note ───

The fields in this structure may change in subsequent releases of IDL.

───

Property Type	Structure		
Name String	*not displayed*		
Get: Yes	**Set:** No	**Init:** No	**Registered:** No

BLOCK_SIZE

The number of vertices to allocate per block as needed for the region. When additional vertices are required, an additional block is allocated. The default is 100.

Property Type	Integer		
Name String	*not displayed*		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** No

DATA

A *2 x n* or a *3 x n* array that defines the 2-D or 3-D vertex data, respectively. DATA is equivalent to the optional arguments, X, Y, and Z. This property is stored as double precision floating point values if the argument variable is of type DOUBLE or if the DOUBLE property is non-zero. Otherwise it is stored as single precision floating point.

Property Type	Array		
Name String	*not displayed*		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** No

Note ───

Setting the DATA property is equivalent to calling IDLanROI::ReplaceData when START=0 and FINISH=*nVerts*-1 (where *nVerts* is the number of vertices in the original ROI).

───

DOUBLE

A non-zero value that indicates whether or not data should be stored in this object in double precision floating point. Set this keyword to zero to indicate that the data should be stored in single precision floating point, which is the default. The

DOUBLE property controls the precision used for storing the data in the AppendData, Init, and ReplaceData methods via the X, Y, and Z arguments and in SetProperty method via the DATA keyword. IDL converts any data already stored in the object to the requested precision, if necessary. Note that this keyword does not need to be set if any of the X, Y, or Z arguments or the DATA parameters are of type DOUBLE. However, setting this keyword may be desirable if the data consists of large integers that cannot be accurately represented in single precision floating point. This property is also automatically set to one if any of the X, Y or Z arguments or the DATA parameter is stored using a variable of type DOUBLE.

Property Type	Boolean		
Name String	*not displayed*		
Get: Yes	Set: Yes	Init: Yes	Registered: No

INTERIOR

A Boolean variable that marks this region as an interior region (i.e., a region treated as a hole). By default, the region is treated as an exterior region.

Property Type	Boolean		
Name String	*not displayed*		
Get: Yes	Set: Yes	Init: Yes	Registered: No

N_VERTS

An integer that contains the number of vertices currently being used by the region.

Property Type	String		
Name String	*not displayed*		
Get: Yes	Set: No	Init: No	Registered: No

ROI_XRANGE

A two-element double-precision floating-point vector of the form [*xmin, xmax*] that specifies the range of X data coordinates covered by the region.

Property Type	Vector		
Name String	*not displayed*		
Get: Yes	**Set:** No	**Init:** No	**Registered:** No

ROI_YRANGE

A two-element double-precision floating-point vector of the form [*ymin, ymax*] specifying the range of Y data coordinates covered by the region.

Property Type	Vector		
Name String	*not displayed*		
Get: Yes	**Set:** No	**Init:** No	**Registered:** No

ROI_ZRANGE

A two-element double-precision floating-point vector of the form [*zmin, zmax*] specifying the range of Z data coordinates covered by the region.

Property Type	Vector		
Name String	*not displayed*		
Get: Yes	**Set:** No	**Init:** No	**Registered:** No

TYPE

An integer that indicates the type of the region. The TYPE keyword determines how computational operations, such as mask generation, are performed. Valid values include:

- 0 = points
- 1 = path
- 2 = closed polygon (the default)

Property Type	Integer		
Name String	*not displayed*		
Get: Yes	**Set:** No	**Init:** Yes	**Registered:** No

IDLanROI::AppendData

The IDLanROI::AppendData procedure method appends vertices to the region.

Syntax

Obj->[IDLanROI::]AppendData, *X* [, *Y*] [, *Z*] [, XRANGE=*variable*]
  [, YRANGE=*variable*] [, ZRANGE=*variable*]

Arguments

X

A vector providing the X components of the vertices to be appended. If the Y and Z arguments are not specified, X must be a two-dimensional array with the leading dimensions either 2 or 3 ([2,*] or [3,*]), in which case, X[0,*] represents the X values, X[1,*] represents the Y values, and X[2,*] represents the Z values. If the DOUBLE property is non-zero, the data is converted to double precision and is appended to the existing double precision data. Otherwise it is converted to single precision floating point and appended to the existing single precision data.

Y

A vector providing the Y components of the vertices to be appended. If the DOUBLE property is non-zero, the data is converted to double precision and is appended to the existing double precision data. Otherwise it is converted to single precision floating point and appended to the existing single precision data.

Z

A vector providing the Z components of the vertices to be appended. If the DOUBLE property is non-zero, the data is converted to double precision and is appended to the existing double precision data. Otherwise it is converted to single precision floating point and appended to the existing single precision data.

Keywords

XRANGE

Set this keyword to a named variable that upon return contains a two-element vector, [*xmin, xmax*], representing the *X* range of the modification to the region. The reported

range accounts for the last vertex in the region before the append occurred, as well as all vertices appended. This data is returned in double-precision floating-point.

YRANGE

Set this keyword to a named variable that upon return contains a two-element vector, [*ymin, ymax*], representing the *Y* range of the modification to the region. The reported range accounts for the last vertex in the region before the append occurred, as well as all vertices appended. This data is returned in double-precision floating-point.

ZRANGE

Set this keyword to a named variable that upon return contains a two-element vector, [*zmin, zmax*], representing the *Z* range of the modification to the region. The reported range accounts for the last vertex in the region before the append occurred, as well as all vertices appended. This data is returned in double-precision floating-point.

Version History

5.3	Introduced

IDLanROI::Cleanup

The IDLanROI::Cleanup procedure method performs all cleanup for a region of interest object.

Note

Cleanup methods are special life cycle methods, and as such cannot be called outside the context of object creation and destruction. This means that in most cases, you cannot call the Cleanup method directly. There is one exception to this rule: If you write your own subclass of this class, you can call the Cleanup method from within the Init or Cleanup method of the subclass.

Syntax

OBJ_DESTROY, *Obj*

or

Obj->[IDLanROI::]Cleanup　　*(In a lifecycle method only.)*

Arguments

None.

Keywords

None.

Version History

5.3	Introduced

IDLanROI::ComputeGeometry

The IDLanROI::ComputeGeometry function method computes the geometrical values for area, perimeter, and/or centroid of the region.

Syntax

Result = Obj->[IDLanROI::]ComputeGeometry([, AREA=*variable*]
   [, CENTROID=*variable*] [, PERIMETER=*variable*]
   [, SPATIAL_OFFSET=*vector*] [, SPATIAL_SCALE=*vector*])

Return Value

Result

This function method returns a 1 for success, or a 0 for failure. Each computed value is returned in the *variable* name assigned to each keyword.

Arguments

None.

Keywords

AREA

Set this keyword to a named variable that upon return contains a double-precision floating-point value representing the area of the region. Interior regions (holes) return a negative area.

Note that the computed area represents the geometric area described by the region's vertex data. A pixel-based area can be computed as follows:

1. Compute a mask for the region.

        mask = oROI->ComputeMask()

2. Call IMAGE_STATISTICS to count number of samples within the mask.

        IMAGE_STATISTICS, myImage, MASK = mask, COUNT = nSamples

3. Compute pixel area.

        pixelArea = nSamples * pixelXSize * pixelYSize

CENTROID

Set this keyword to a named variable that upon return contains a double-precision floating-point vector [*x*,*y*,*z*] representing the centroid for the region. If the TYPE of the region is 0 (points), the centroid is computed as the average of each of the vertices in the region. If the TYPE of the region is 1 (path), the centroid is computed as the weighted average of each of the midpoints of the lines in the region. Weights are proportional to the length of the lines. If the TYPE of the region is 2 (polygon), the centroid is computed as a weighted average of the centroids of the polygons making up the ROI (interior centroids use negative weights). Weights are proportional to the polygon area.

PERIMETER

Set this keyword to a named variable that upon return contains a double-precision floating-point value representing the perimeter of the region.

SPATIAL_OFFSET

Set this keyword to a two or three-element vector, [*tx*, *ty*] or [*tx*, *ty*, *tz*], representing the spatial calibration offset factors to be applied for the geometry calculations. The value of SPATIAL_SCALE is applied before the spatial offset values are applied. The default is [0.0, 0.0, 0.0]. IDL converts and maintains this value in double-precision floating-point.

SPATIAL_SCALE

Set this keyword to a two or three-element vector, [*sx*, *sy*] or [*sx*, *sy*, *sz*], representing the spatial calibration scaling factors to be applied for the geometry calculations. The spatial calibration scale is applied first, then the value of SPATIAL_OFFSET is applied. The default is [1.0, 1.0, 1.0]. IDL converts and maintains this value in double-precision floating-point.

Version History

5.3	Introduced

IDLanROI::ComputeMask

The IDLanROI::ComputeMask function method prepares a two-dimensional mask for the region.

Syntax

Result = Obj->[IDLanROI::]ComputeMask([, INITIALIZE={ –1 | 0 | 1 }]
   [, DIMENSIONS=*[xdim*, *ydim]*] | [, MASK_IN=*array*] [, LOCATION=*[x*, *y*
   [, *z]*/]] [, MASK_RULE={ 0 | 1 | 2 }] [, PIXEL_CENTER=*[x, y]*]
   [, PLANE_NORMAL=*[x, y, z]*] [, PLANE_XAXIS=*[x,y,z]*] [, /RUN_LENGTH])

Return Value

Result

The return value is a two-dimensional array of bytes whose values range from 0 to 255. The mask is computed by applying the following formula to the current mask for each mask point contained within the ROI:

$$M_{out} = \text{MAX}(\text{MIN}(255, (M_{roi}*Ext) + M_{in}), 0)$$

where M_{roi} is 255 and *Ext* is 1 for points within an exterior region and –1 for points within an interior region.

If the TYPE of the region is 0 (points), a single mask pixel is set for each region vertex that falls within the bounds of the mask.

If the TYPE of the region is 1 (path), one-pixel-wide line segments are set within the mask.

If the TYPE of the region is 2 (closed polygon), a mask pixel is set if that pixel is on the plane of a region, and the pixel falls within the region (according to the MASK_RULE).

Arguments

None.

Keywords

DIMENSIONS

Set this keyword to a two-element vector, [*xdim*, *ydim*], specifying the requested dimensions of the returned mask. If MASK_IN is provided, the value of this keyword is ignored and the dimensions of that mask are used. Otherwise, the default dimensions are [100, 100].

INITIALIZE

Set this keyword to indicate how the mask should be initialized. Valid values include:

- –1 = The mask is not initialized. This option is useful when updating an already existing mask. This is the default if the MASK_IN keyword is set.

- 0 = The mask is initialized so that each pixel is set to 0. This is the default if the MASK_IN keyword is not set.

- 1 = The mask is initialized so that each pixel is set to 255.

LOCATION

Set this keyword to a vector of the form [*X*, *Y*[, *Z*]] specifying the location of the origin of the mask. The default is [0, 0, 0]. IDL converts and maintains this value in double-precision floating-point.

MASK_IN

Set this keyword to a two-dimensional array representing a mask that is already allocated and to be updated for this region. If the variable specified by this keyword is of type BYTE and is also specified as the function result, then this method updates the mask data in-place without copying. If this keyword is not provided, a mask is allocated by default to match the dimensions specified via the DIMENSIONS keyword.

MASK_RULE

Set this keyword to an integer specifying the rule used to determine whether a given pixel should be set within the mask. Valid values include:

- 0 = Boundary only. All pixels falling on a region's boundary are set.

- 1 = Interior only. All pixels falling within the region's boundary, but not on the boundary, are set.

- 2 = Boundary + Interior. All pixels falling on or within a region's boundary are set. This is the default.

PIXEL_CENTER

Set this keyword to a 2-element vector, [*x*, *y*], to indicate where the lower-left mask pixel is centered relative to a Cartesian grid. The default value is [0.0, 0.0], indicating that the lower-left pixel is centered at [0.0, 0.0].

PLANE_NORMAL

Set this keyword to a three-element vector, [*x*, *y*, *z*], specifying the normal vector for the plane on which the mask is to be computed. The default is [0, 0, 1].

PLANE_XAXIS

Set this keyword to a three-element vector, [*x*, *y*, *z*], specifying the direction vector along which each row of mask pixels is to be computed (starting at LOCATION). The default is [1, 0, 0].

RUN_LENGTH

Set this keyword to a non-zero value to return a run-length encoded representation of the mask, stored in a one-dimensional unsigned long array. When run-length encoded, each element with an even subscript contains the length of the run, and the following element contains the starting index of the run.

Examples

See "Creating and Displaying an ROI Mask" (Chapter 6, *Image Processing in IDL*).

Version History

5.3	Introduced
5.6	Added RUN_LENGTH keyword

IDLanROI::ContainsPoints

The IDLanROI::ContainsPoints function method determines whether the given data coordinates are contained within the closed polygon region.

Syntax

Result = Obj->[IDLanROI::]ContainsPoints(*X* [, *Y* [, *Z*]])

Return Value

The return value is a vector of values, one per provided point, indicating whether that point is contained. Valid values within this return vector include:

- 0 = Exterior. The point lies strictly out of bounds of the ROI
- 1 = Interior. The point lies strictly inside the bounds of the ROI
- 2 = On edge. The point lies on an edge of the ROI boundary
- 3 = On vertex. The point matches a vertex of the ROI

A point is considered to be exterior if:

- The point falls within the boundary of an interior region (hole)
- The point does not lie in the plane of the region
- The region TYPE property is set to 0 (points) or 1 (path)

Arguments

X

A vector providing the *X* components of the points to be tested. If the *Y* and *Z* arguments are not specified, *X* must be a two-dimensional array with the leading dimension either 2 or 3 ([2,*] or [3,*]), in which case, *X*[0,*] represents the *X* values, *X*[1,*] represents the *Y* values, and *X*[2,*] represents the *Z* values.

Y

A vector providing the *Y* components of the points to be tested.

Z

A scalar or vector providing the *Z* component(s) of the points to be tested. If not provided, the *Z* components default to 0.0.

Keywords

None.

Examples

See "Testing an ROI for Point Containment" (Chapter 6, *Image Processing in IDL*).

Version History

5.3	Introduced

IDLanROI::GetProperty

The IDLanROI::GetProperty procedure method retrieves the value of a property or group of properties for the region.

Syntax

Obj->[IDLanROI::]GetProperty [, *PROPERTY=variable*]

Arguments

None.

Keywords

Any property listed under "IDLanROI Properties" on page 3146 that contains the word "Yes" in the "Get" column of the properties table can be retrieved using this method. To retrieve the value of a property, specify the property name as a keyword set equal to a named variable that will contain the value of the property.

Version History

5.3	Introduced

IDLanROI::Init

The IDLanROI::Init function method initializes a region of interest object.

Note ──
Init methods are special life cycle methods, and as such cannot be called outside the context of object creation. This means that in most cases, you cannot call the Init method directly. There is one exception to this rule: If you write your own subclass of this class, you can call the Init method from within the Init method of the subclass.
──

Syntax

Obj = OBJ_NEW('IDLanROI' [, *X* [, *Y* [, *Z*]]] [, *PROPERTY=value*])

or

Result = Obj->[IDLanROI::]Init([*X* [, *Y* [, *Z*]]] [, *PROPERTY=value*])   *(In a lifecycle method only.)*

Note ──
Keywords can be used in either form. They are omitted in the second form for brevity.
──

Arguments

Note ──
The values specified by the *X*, *Y*, and *Z* arguments are used to initialize the value of the DATA property of the IDLanROI object.
──

X

A vector providing the *X* components of the vertices for the region. If the *Y* and *Z* arguments are not specified, *X* must be a two-dimensional array with the leading dimension either 2 or 3 ([2,*] or [3,*]), in which case, *X*[0,*] represents the *X* values, *X*[1,*] represents the *Y* values, and *X*[2,*] represents the *Z* values. The value for this argument is double-precision floating-point if the DOUBLE keyword is set or the inputted value is of type DOUBLE. Otherwise, it is converted to single-precision floating-point.

Y

A vector providing the *Y* components of the vertices. The value for this argument is double-precision floating-point if the DOUBLE keyword is set or the inputted value is of type DOUBLE. Otherwise, it is converted to single-precision floating-point.

Z

A scalar or vector providing the *Z* component(s) of the vertices. If not provided, *Z* values default to 0.0. The value for this argument is double-precision floating-point if the DOUBLE keyword is set or the inputted value is of type DOUBLE. Otherwise, it is converted to single-precision floating-point.

Keywords

Any property listed under "IDLanROI Properties" on page 3146 that contains the word "Yes" in the "Init" column of the properties table can be initialized during object creation using this method. To initialize the value of a property, specify the property name as a keyword set equal to the appropriate property value.

Version History

5.3	Introduced

IDLanROI::RemoveData

The IDLanROI::RemoveData procedure method removes vertices from the region.

Syntax

Obj->[IDLanROI::]RemoveData[, COUNT=*vertices*] [, START=*index*]
    [, XRANGE=*variable*] [, YRANGE=*variable*] [, ZRANGE=*variable*]

Arguments

None.

Keywords

COUNT

Set this keyword to the number of vertices to remove. The default is one vertex.

START

Set this keyword to an index (into the region's current vertex list) where the removal is to begin. By default, the final vertex is removed.

XRANGE

Set this keyword to a named variable that upon return contains a two-element vector, [*xmin, xmax*], that represents the *X* range of the modification to the region. The reported range accounts for the vertex just before the removal (if any), the vertex just after the removal (if any), and the removed vertices. This data is returned in double-precision floating-point.

YRANGE

Set this keyword to a named variable that upon return contains a two-element vector, [*ymin, ymax*], that represents the *Y* range of the modification to the region. The reported range accounts for the vertex just before the removal (if any), the vertex just after the removal (if any), and the removed vertices. This data is returned in double-precision floating-point.

ZRANGE

Set this keyword to a named variable that upon return contains a two-element vector, [*zmin, zmax*], that represents the *Z* range of the modification to the region. The reported range accounts for the vertex just before the removal (if any), the vertex just after the removal (if any), and the removed vertices. This data is returned in double-precision floating-point.

Version History

5.3	Introduced

IDLanROI::ReplaceData

The IDLanROI::ReplaceData procedure method replaces vertices in the region with alternate values. The number of replacement values need not match the number of values being replaced.

Note ────────────────────────────────────

Setting the DATA property is equivalent to calling ReplaceData when START=0 and FINISH=*nVerts*-1 (where *nVerts* is the number of vertices in the original ROI).

──

Syntax

Obj->[IDLanROI::]ReplaceData, *X*[, *Y*[, *Z*]] [, START=*index*] [, FINISH=*index*]
    [, XRANGE=*variable*] [, YRANGE=*variable*] [, ZRANGE=*variable*]

Arguments

X

A vector providing the X components of the new replacement vertices. If the Y and Z arguments are not specified, X must be a two-dimensional array with the leading dimensions either 2 or 3 ([2, *] or [3, *]), in which case, X[0, *] represents the X values, X[1, *] represents the Y values, and X[2, *] represents the Z values. If the DOUBLE property is non-zero, the data is converted to double precision and is appended to the existing double precision data. Otherwise it is converted to single precision floating point and appended to the existing single precision data.

Y

A vector providing the Y components of the new replacement vertices. If the DOUBLE property is non-zero, the data is converted to double precision and is appended to the existing double precision data. Otherwise it is converted to single precision floating point and appended to the existing single precision data.

Z

A vector providing the Z components of the new replacement vertices. If the DOUBLE property is non-zero, the data is converted to double precision and is appended to the existing double precision data. Otherwise it is converted to single precision floating point and appended to the existing single precision data.

Keywords

FINISH

Set this keyword to the index of the region's current subregion vertex list where the replacement ends. If the START keyword value is ≥ 0, the default FINISH is given by

$$FINISH = ((START + N\_NEW - 1) \bmod N\_OLD)$$

where N_NEW is the number of replacement vertices provided via the [*X*, *Y*, *Z*] arguments and N_OLD is the number of vertices (prior to replacement) in the current subregion.

If the START keyword is not set or is negative, the default FINISH is given by

$$FINISH = N\_OLD - 1$$

FINISH may be less than START in which case the vertices, including and following START and the vertices preceding and including FINISH, are replaced with the new values.

START

Set this keyword to an index of the region's current subregion vertex list where the replacement begins. If the FINISH keyword value is ≥ 0, the default START is given by

$$START = ((FINISH - N\_NEW + 1) \bmod N\_OLD)$$

where N_NEW is the number of replacement vertices provided via the [*X*, *Y*, *Z*] arguments and N_OLD is the number of vertices (prior to replacement) in the current subregion.

If the FINISH keyword is not set (or negative), the default START is clamped to 0 and is given by

$$N\_OLD - N\_NEW$$

XRANGE

Set this keyword to a named variable that upon return contains a two-element vector, [*xmin, xmax*], representing the *X* range of the modification to the region. The reported range accounts for the replaced vertices, the vertex just before the replacement (if any), the vertex just after the replacement (if any), and the new replacement vertices. This data is returned in double-precision floating-point.

YRANGE

Set this keyword to a named variable that upon return contains a two-element vector, [*ymin, ymax*], representing the *Y* range of the modification to the region. The reported range accounts for the replaced vertices, the vertex just before the replacement (if any), the vertex just after the replacement (if any), and the new replacement vertices. This data is returned in double-precision floating-point.

ZRANGE

Set this keyword to a named variable that upon return contains a two-element vector, [*zmin, zmax*], representing the *Z* range of the modification to the region. The reported range accounts for the replaced vertices, the vertex just before the replacement (if any), the vertex just after the replacement (if any), and the new replacement vertices. This data is returned in double-precision floating-point.

Version History

5.3	Introduced

IDLanROI::Rotate

The IDLanROI::Rotate procedure method modifies the vertices for the region by applying a rotation.

Syntax

Obj->[IDLanROI::]Rotate, *Axis*, *Angle* [, CENTER=*[x, y[, z]]*]

Arguments

Axis

A three-element vector of the form [*x*, *y*, *z*] describing the axis about which the region is to be rotated.

Angle

The angle, measured in degrees, by which the rotation is to occur.

Keywords

CENTER

Set this keyword to a two or three-element vector of the form [*x, y*], or [*x, y, z*] specifying the center of rotation. The default is [0, 0, 0]. IDL converts and applies this data in double-precision floating-point.

Version History

5.3	Introduced

IDLanROI::Scale

The IDLanROI::Scale procedure method modifies the vertices for the region by applying a scale.

Syntax

Obj->[IDLanROI::]Scale, *Sx*[, *Sy*[, *Sz*]]

Arguments

Sx

The *X* scale factor. If the *Sy* and *Sz* arguments are not specified, *Sx* must be a two or three-element vector, in which case *Sx*[0] represents the scale in *X*, *Sx*[1] represents the scale in *Y*, *Sx*[2] represents the scale in *Z*. IDL converts and applies this data in double-precision floating-point.

Sy

The *Y* scale factor. IDL converts and applies this data in double-precision floating-point.

Sz

The *Z* scale factor. IDL converts and applies this data in double-precision floating-point.

Keywords

None.

Version History

5.3	Introduced

IDLanROI::SetProperty

The IDLanROI::SetProperty procedure method sets the value of a property or group of properties for the region.

Syntax

Obj->[IDLanROI::]SetProperty

Arguments

None.

Keywords

Any property listed under "IDLanROI Properties" on page 3146 that contains the word "Yes" in the "Set" column of the properties table can be set using this method. To set the value of a property, specify the property name as a keyword set equal to the appropriate property value.

Version History

5.3	Introduced

IDLanROI::Translate

The IDLanROI::Translate procedure method modifies the vertices for the region by applying a translation.

Syntax

Obj->[IDLanROI::]Translate, *Tx*[, *Ty*[, *Tz*]]

Arguments

Tx

The X translation factor. If the *Ty* and *Tz* arguments are not specified, *Tx* must be a two or three-element vector, in which case *Tx*[0] represents translation in *X*, *Tx*[1] represents translation in *Y*, *Tx*[2] represents translation in *Z*. IDL converts and applies this data in double-precision floating-point.

Ty

The *Y* translation factor. IDL converts and applies this data in double-precision floating-point.

Tz

The *Z* translation factor. IDL converts and applies this data in double-precision floating-point.

Keywords

None.

Version History

5.3	Introduced

IDLanROIGroup

The IDLanROIGroup object class is an analytical representation of a group of regions of interest.

Superclasses

IDL_Container

Creation

See IDLanROIGroup::Init.

Properties

Objects of this class have the following properties. See "IDLanROIGroup Properties" on page 3175 for details on individual properties.

- ALL
- ROIGROUP_XRANGE
- ROIGROUP_YRANGE
- ROIGROUP_ZRANGE

In addition, objects of this class inherit the properties of all superclasses of this class.

Methods

The IDLanROIGroup class has the following methods:

- IDLanROIGroup::Add
- IDLanROIGroup::Cleanup
- IDLanROIGroup::ComputeMask
- IDLanROIGroup::ComputeMesh
- IDLanROIGroup::ContainsPoints
- IDLanROIGroup::GetProperty
- IDLanROIGroup::Init
- IDLanROIGroup::Rotate

- IDLanROIGroup::Scale
- IDLanROIGroup::Translate

In addition, this class inherits the methods of its superclasses (if any).

Examples

See "Creating a Surface Mesh of an ROI Group" (Chapter 6, *Image Processing in IDL*).

Version History

5.3	Introduced

IDLanROIGroup Properties

IDLanROIGroup objects have the following properties in addition to properties inherited from any superclasses. Properties with the word "Yes" in the "Get" column of the property table can be retrieved via "IDLanROIGroup::GetProperty" on page 3186. Properties with the word "Yes" in the "Init" column of the property table can be set via "IDLanROIGroup::Init" on page 3187.

Note

For a discussion of the property description tables shown below, see "About Object Property Descriptions" on page 3135.

Objects of this class have the following properties.

- ALL
- ROIGROUP_XRANGE
- ROIGROUP_YRANGE
- ROIGROUP_ZRANGE

In addition, objects of this class inherit:

- IDL_Container

ALL

An anonymous structure with the values of all of the properties associated with the state of this object.

Note

The fields in this structure may change in subsequent releases of IDL.

Property Type	Structure		
Name String	*not displayed*		
Get: Yes	**Set:** No	**Init:** No	**Registered:** No

ROIGROUP_XRANGE

A two-element double-precision floating-point vector of the form [*xmin, xmax*] specifying the range of X data coordinates covered by the region.

Property Type	Vector		
Name String	*not displayed*		
Get: Yes	**Set:** No	**Init:** No	**Registered:** No

ROIGROUP_YRANGE

A two-element double-precision floating-point vector of the form [*ymin, ymax*] specifying the range of Y data coordinates covered by the region.

Property Type	Vector		
Name String	*not displayed*		
Get: Yes	**Set:** No	**Init:** No	**Registered:** No

ROIGROUP_ZRANGE

A two-element double-precision floating-point vector of the form [*zmin, zmax*] specifying the range of Z data coordinates covered by the region.

Property Type	Vector		
Name String	*not displayed*		
Get: Yes	**Set:** No	**Init:** No	**Registered:** No

IDLanROIGroup::Add

The IDLanROIGroup::Add procedure method adds a region to the region group. Only objects of the IDLanROI class may be added to the group. The regions in the group must all be of the same type: all points, all paths, or all polygons.

Syntax

Obj->[IDLanROIGroup::]Add, *ROI*

Arguments

ROI

A reference to an instance of the IDLanROI object class representing the region of interest to be added to the group.

Keywords

Accepts all keywords accepted by the IDL_Container::Add method.

Version History

5.3	Introduced

IDLanROIGroup::Cleanup

The IDLanROIGroup::Cleanup procedure method performs all cleanup for a region of interest group object.

Note

Cleanup methods are special life cycle methods, and as such cannot be called outside the context of object creation and destruction. This means that in most cases, you cannot call the Cleanup method directly. There is one exception to this rule: If you write your own subclass of this class, you can call the Cleanup method from within the Init or Cleanup method of the subclass.

Syntax

OBJ_DESTROY, *Obj*

or

Obj->[IDLanROIGroup::]Cleanup   *(In a lifecycle method only.)*

Arguments

None.

Keywords

None.

Version History

5.3	Introduced

IDLanROIGroup::ComputeMask

The IDLanROIGroup::ComputeMask function method prepares a two-dimensional mask for this group of regions.

Syntax

Result = Obj->[IDLanROIGroup::]ComputeMask([, INITIALIZE={ -1 | 0 | 1 }]
   [, DIMENSIONS=*[xdim, ydim]*] | [, MASK_IN=*array*] [, LOCATION=*[x, y*
   [, *z]]*] [, MASK_RULE={ 0 | 1 | 2 }] [, PLANE_NORMAL=*[x, y, z]*]
   [, PLANE_XAXIS=*[x, y, z]*] [, /RUN_LENGTH])

Return Value

Result

The return value is a two-dimensional array of bytes whose values range from 0 to 255. The mask is computed by applying the following formula to the current mask for each mask point contained within the ROI:

$$M_{out} = \text{MAX}(\text{MIN}(0, (M_{roi}*Ext) + M_{in}), 255)$$

where M_{roi} is 255 and *Ext* is 1 for points within an exterior region and –1 for points within an interior region.

If the TYPE of the contained regions is 0 (points), a single mask pixel is set for each region vertex that falls within the bounds of the mask.

If the TYPE of the contained regions is 1 (path), each pixel along the paths of the regions is set if it falls within the mask.

If the TYPE of the region is 2 (closed polygon), a mask pixel is set if that pixel is on the plane of a contained region, and the pixel falls within that region (according to the MASK_RULE).

Arguments

None.

Keywords

DIMENSIONS

Set this keyword to a two-element vector, [*xdim*, *ydim*], specifying the requested dimensions of the returned mask. If MASK_IN is provided, the value of this keyword is ignored, and the dimensions of that mask are used. Otherwise, the default dimensions are [100, 100].

INITIALIZE

Set this keyword to indicate how the mask should be initialized. Valid values include:

- −1 = The mask is not initialized; the default if the MASK_IN keyword is set. This option is useful when updating an already existing mask.

- 0 = The mask is initialized with each pixel set to 0; the default if the MASK_IN keyword is not set.

- 1 = The mask is initialized with each pixel set to 255.

LOCATION

Set this keyword to a vector of the form [*X*, *Y*[, *Z*]] specifying the location of the origin of the mask. The default is [0, 0, 0].

MASK_IN

Set this keyword to a two-dimensional array representing a mask that is already allocated and to be updated for this region. If the variable specified by this keyword is of type BYTE and is also specified as the function result, then this method updates the mask data in-place without copying. If this keyword is not provided, a mask is allocated by default to match the dimensions specified via the DIMENSIONS keyword.

MASK_RULE

Set this keyword to an integer specifying the rule used to determine whether a given pixel should be set within the mask. Valid values include:

- 0 = Boundary Only. All pixels falling on a region's boundary are set.

- 1 = Interior Only. All pixels falling within the region's boundary, but not on the boundary, are set.

- 2 = Boundary + Interior. All pixels falling on or within a region's boundary are set. This is the default.

PLANE_NORMAL

Set this keyword to a three-element vector, [*x*, *y*, *z*], specifying the normal vector for the plane on which the mask is to be computed. The default is [0, 0, 1].

PLANE_XAXIS

Set this keyword to a three-element vector, [*x*, *y*, *z*], specifying the direction vector along which each row of mask pixels is to be computed (starting at LOCATION). The default is [1, 0, 0].

RUN_LENGTH

Set this keyword to a non-zero value to return a run-length encoded representation of the mask, stored in a one-dimensional unsigned long array. When run-length encoded, each element with an even subscript contains the length of the run, and the following element contains the starting index of the run.

Version History

5.3	Introduced
5.6	Added RUN_LENGTH keyword

IDLanROIGroup::ComputeMesh

The IDLanROIGroup::ComputeMesh function method triangulates a surface mesh with optional capping from the stack of regions contained within this group.

Note ───

The contained regions may be concave. However, this method will fail under the following conditions:

- The region group contains fewer than two regions.
- The TYPE property of the contained regions is 0 (points) or 1 (path).
- Any of the contained regions are not simple
  (i.e., a region is self-intersecting).
- The region group contains interior regions (holes).
- More than one region lies on the same plane
  (i.e., the region group contains branches).

───

Each region pair is normalized by perimeter and the triangulation is computed by walking the contours in parallel, keeping the normalized progress along each contour in sync. The returned triangulation minimizes the mesh surface area. Each vertex may appear only once in the output, and the resulting polygon mesh is solid with outward facing normals computed via the right-hand rule. If capping is requested, it is computed using the IDLgrTessellator on the top and bottom regions, and/or the regions on either side of an inter-slice gap.

Syntax

Result = Obj->[IDLanROIGroup::]ComputeMesh(*Vertices*, *Conn*
    [, CAPPED={ 0 | 1 | 2}] [, SURFACE_AREA=*variable*])

Return Value

Result

The return value of this function method is the number of triangles generated if the surface mesh triangulation is successful, or zero if unsuccessful.

Arguments

Vertices

An output [3, n] array of vertices. If all regions in the group are defined with single precision vertices (DOUBLE property is zero), then IDL returns a single precision floating point array. Otherwise, if any of the regions in the group are defined with double precision vertices (DOUBLE property is non-zero), then IDL returns a double precision floating point array.

Conn

An output polygon mesh connectivity array.

Keywords

CAPPED

Set this keyword to a value to indicate whether flat caps are to be computed at the top-most or bottom-most regions (as selected by a counter-clockwise rule), or at the regions on either side of an inter-slice gap. The value of this keyword is a bit-wise OR of the values shown below. For example, to cap the top-most and bottom-most regions only, set the CAPPED keyword to 3. The default is 0 (no caps).

- 0 = no caps
- 1 = cap the top-most region
- 2 = cap the bottom-most region

SURFACE_AREA

Set this keyword to a named variable that upon return contains the overall surface area of the computed triangulation. This value was minimized in the computation of the triangulation. IDL returns this value in a double-precision floating-point variable.

Version History

5.3	Introduced

IDLanROIGroup::ContainsPoints

The IDLanROIGroup::ContainsPoints function method determines whether the given points (in data coordinates) are contained within this region group.

The regions within this group must have a TYPE of 2 (closed polygon) and must fall on parallel planes for successful containment testing to occur.

For each point to be tested:

- If the point lies directly on one of the region planes, it is tested for containment within each of the regions that fall on that plane.

- If the point lies between two of the region planes, it is projected onto the nearest region plane, and tested for containment within each of the regions on that plane.

- If the point lies above or below the stack of parallel region planes, the point will be considered to be exterior to the region group.

On a given plane, a point will be considered to be exterior if either of the following conditions are true:

- The point does not fall within any of the regions on that plane.

- The point falls within as many or more holes than non-hole regions on that plane.

Syntax

Result = Obj->[IDLanROIGroup::]ContainsPoints(*X*[, *Y*[, *Z*]])

Return Value

The return value is a vector of values, one per provided point, indicating whether that point is contained. Valid values within this return vector include:

- 0 = Exterior. The point lies strictly outside the bounds of the ROI.

- 1 = Interior. The point lies strictly inside the bounds of the ROI.

- 2 = On Edge. The point lies on an edge of the ROI boundary.

- 3 = On Vertex. The point matches a vertex of the ROI.

Arguments

X

A vector providing the *X* components of the points to be tested. If the *Y* and *Z* arguments are not specified, *X* must be a two-dimensional array with the leading dimension either 2 or 3 ([2,*] or [3,*]), in which case, *X*[0,*] represents the *X* values, *X*[1,*] represents the *Y* values, and *X*[2,*] represents the *Z* values.

Y

A vector providing the *Y* components of the points to be tested.

Z

A scalar or vector providing the *Z* components of the points to be tested. If not provided, the *Z* components default to 0.0.

Keywords

None.

Version History

5.3	Introduced

IDLanROIGroup::GetProperty

The IDLanROIGroup::Get Property procedure method retrieves the value of a property or group of properties for the region group.

Syntax

Obj->[IDLanROIGroup::]GetProperty [, *PROPERTY=value*]

Arguments

None.

Keywords

Any property listed under "IDLanROIGroup Properties" on page 3175 that contains the word "Yes" in the "Get" column of the properties table can be retrieved using this method. To retrieve the value of a property, specify the property name as a keyword set equal to a named variable that will contain the value of the property.

Version History

5.3	Introduced

IDLanROIGroup::Init

The IDLanROIGroup::Init function method initializes a region of interest group object.

Note ——

Init methods are special life cycle methods, and as such cannot be called outside the context of object creation. This means that in most cases, you cannot call the Init method directly. There is one exception to this rule: If you write your own subclass of this class, you can call the Init method from within the Init method of the subclass.

Syntax

Obj = OBJ_NEW('IDLanROIGroup')

or

Result = Obj->[IDLanROIGroup::]Init( )   *(In a lifecycle method only.)*

Arguments

None.

Keywords

Any property listed under "IDLanROIGroup Properties" on page 3175 that contains the word "Yes" in the "Init" column of the properties table can be initialized during object creation using this method. To initialize the value of a property, specify the property name as a keyword set equal to the appropriate property value.

Version History

5.3	Introduced

IDLanROIGroup::Rotate

The IDLanROIGroup::Rotate procedure method modifies the vertices for all regions within the group by applying a rotation.

Syntax

Obj->[IDLanROIGroup::]Rotate, *Axis*, *Angle*[, CENTER=*[x*, *y*[, *z*]*]*]

Arguments

Axis

A three-element vector of the form [*x*, *y*, *z*] describing the axis about which the region group is to be rotated.

Angle

The angle, measured in degrees, by which to rotate the ROI group.

Keywords

CENTER

Set this keyword to a two or three-element vector of the form [*x, y*], or [*x, y, z*] specifying the center of rotation. The default is [0, 0, 0]. IDL converts and applies this data in double-precision floating-point.

Version History

5.3	Introduced

IDLanROIGroup::Scale

The IDLanROIGroup::Scale procedure method modifies the vertices for the region by applying a scale.

Syntax

Obj->[IDLanROIGroup::]Scale, *Sx*[, *Sy*[, *Sz*]]

Arguments

Sx

The *X* scale factor. If the *Sy* and *Sz* arguments are not specified, *Sx* must be a two or three-element vector, in which case *Sx*[0] represents the scale in *X*, *Sx*[1] represents the scale in *Y*, *Sx*[2] represents the scale in *Z*. IDL converts and applies this data in double-precision floating-point.

Sy

The *Y* scale factor. IDL converts and applies this data in double-precision floating-point.

Sz

The *Z* scale factor. IDL converts and applies this data in double-precision floating-point.

Keywords

None.

Version History

5.3	Introduced

IDLanROIGroup::Translate

The IDLanROIGroup::Translate procedure method modifies the vertices of all regions within the group by applying a translation.

Syntax

Obj->[IDLanROIGroup::]Translate, *Tx*[, *Ty*[, *Tz*]]

Arguments

Tx

The *X* translation factor. If the *Ty* and *Tz* arguments are not specified, *Tx* must be a two or three-element vector, in which case *Tx*[0] represents translation in *X*, *Tx*[1] represents translation in *Y*, *Tx*[2] represents translation in *Z*. IDL converts and applies this data in double-precision floating-point.

Ty

The *Y* translation factor. IDL converts and applies this data in double-precision floating-point.

Tz

The *Z* translation factor. IDL converts and applies this data in double-precision floating-point.

Keywords

None.

Version History

5.3	Introduced

Chapter 30
File Format Object Classes

This chapter describes IDL's built-in file format class library.

IDLffDICOM

An IDLffDICOM object contains the data for one or more images embedded in a DICOM Part 10 file. The API to the IDLffDICOM object provides accessor methods to the basic data elements of a DICOM file, namely the group/element tag, value representation, length, and data values. Additional methods deal with the file header preamble, data dictionary description for individual elements, and embedded sequences of elements. Most methods take a DICOM group/element tag as a parameter. An alternative parameter to the DICOM tag in some methods is the reference. A reference value is a LONG integer that is unique to each element in the DICOM object. This value can be used to directly access a specific element and to differentiate between elements in the DICOM file that have the same group/element tag. Valid reference values are always positive.

See "IDLffDICOM Object DICOM Conformance Summary" on page 3194 for information regarding IDL DICOM file reading support.

Note ───

The IDLffDicomEx object greatly expands on the capabilities of the IDLffDICOM object and requires an additional license key to access the functionality. The IDLffDicomEx object includes methods for reading and writing pixel data to a DICOM file, and specifying the data compression. You can also add, modify, or remove public and private DICOM attribute tags, public and private sequences, and sets of repeating tags within sequences. See *Medical Imaging in IDL* for details.

IDLffDICOM Object DICOM Conformance Summary

Note —————————————————————————————

This Conformance Summary is for the IDLffDICOM object only and has no
relevance to IDL's DICOM Network Services or DICOM Read/Write support
(provided by the IDLffDicomEx object). See www.ittvis.com/idl/dicom for the
current DICOM Conformance Statement. See the following information for the
IDLffDICOM object's conformance information.

———

Introduction

This section is an abbreviated DICOM conformance statement for the IDLffDICOM
object, and specifies the compliance of this object's file reading support to the
DICOM v3.0 standard. As described in the DICOM Standard PS 3.2 (Conformance),
the purpose of this document is to outline the level of conformance to the DICOM
standard and to enumerate the supported DICOM Service Classes, Information
Objects, and Communications Protocols supported by the implementation of the
IDLffDICOM object.

The IDLffDICOM object does not contain or support any of the DICOM services
such as Storage, Query/Retrieve, Print, Verification, etc., so there will be no
conformance claims relating to these services and no mention of any Application
Entities for these services. Communications Protocol profiles will also be absent
from this document for the same reasons. The remainder of this document will
describe how the IDLffDICOM object handles the various Information Objects it is
capable of reading.

Reading of DICOM Part 10 files

IDL supports reading files that conform to the DICOM Standard PS 3.10 DICOM
File Format. This format provides a means to encapsulate in a file the Data Set
representing a SOP (Service Object Pair) Instance related to a DICOM IOD
(Information Object Definition). Files written to disk in this DICOM File Format will
be referred to as DICOM Part 10 files for the remainder of this document. Note that
the IDLffDICOM object does NOT support the writing of files in this DICOM File
Format, only reading.

Encapsulated Transfer Syntaxes Supported

IDL supports reading DICOM Part 10 files whose contents have been written using the following Transfer Syntaxes. The Transfer Syntax UID is in the file's DICOM Tag field (0002,0010).

UID Value	UID Name
1.2.840.10008.1.2	Implicit VR Little Endian: Default Transfer Syntax for DICOM
1.2.840.10008.1.2.1	Explicit VR Little Endian
1.2.840.10008.1.2.2	Explicit VR Big Endian

Table 30-1: Encapsulated Transfer Syntaxes Supported

Encapsulated Transfer Syntaxes NOT Supported

The IDLffDICOM object does NOT support reading DICOM Part 10 files whose contents have compressed data that has been written using the following Transfer Syntaxes. This object will NOT be able to access the data element (DICOM Tag field (7FE0,0010)) of files with these types of compressed data. The Transfer Syntax UID is in the file's DICOM Tag field (0002,0010).

UID Value	UID Name
1.2.840.10008.1.2.4.50	JPEG Baseline (Process 1): Default Transfer Syntax for Lossy JPEG 8 Bit Image Compression
1.2.840.10008.1.2.4.51	JPEG Extended (Process 2 & 4): Default Transfer Syntax for Lossy JPEG 12 Bit Image Compression (Process 4 only)
1.2.840.10008.1.2.4.52	JPEG Extended (Process 3 & 5)
1.2.840.10008.1.2.4.53	JPEG Spectral Selection, Non-Hierarchical (Process 6 & 8)
1.2.840.10008.1.2.4.54	JPEG Spectral Selection, Non-Hierarchical (Process 7 & 9)
1.2.840.10008.1.2.4.55	JPEG Full Progression, Non-Hierarchical (Process 10 & 12)

Table 30-2: Encapsulated Transfer Syntaxes NOT Supported

UID Value	UID Name
1.2.840.10008.1.2.4.56	JPEG Full Progression, Non-Hierarchical (Process 11 & 13)
1.2.840.10008.1.2.4.57	JPEG Lossless, Non-Hierarchical (Process 14)
1.2.840.10008.1.2.4.58	JPEG Lossless, Non-Hierarchical (Process 15)
1.2.840.10008.1.2.4.59	JPEG Extended, Hierarchical (Process 16 & 18)
1.2.840.10008.1.2.4.60	JPEG Extended, Hierarchical (Process 17 & 19)
1.2.840.10008.1.2.4.61	JPEG Spectral Selection, Hierarchical (Process 20 & 22)
1.2.840.10008.1.2.4.62	JPEG Spectral Selection, Hierarchical (Process 21 & 23)
1.2.840.10008.1.2.4.63	JPEG Full Progression, Hierarchical (Process 24 & 26)
1.2.840.10008.1.2.4.64	JPEG Full Progression, Hierarchical (Process 25 & 27)
1.2.840.10008.1.2.4.65	JPEG Lossless, Hierarchical (Process 28)
1.2.840.10008.1.2.4.66	JPEG Lossless, Hierarchical (Process 29)
1.2.840.10008.1.2.4.70	JPEG Lossless, Non-Hierarchical, First-Order Prediction (Process 14 [Selection Value 1]): Default Transfer Syntax for Lossless JPEG Image Compression
1.2.840.10008.1.2.5	RLE Lossless

Table 30-2: Encapsulated Transfer Syntaxes NOT Supported (Continued)

Encapsulated SOP Classes Supported

The IDLffDICOM object supports reading DICOM Part 10 files whose contents encapsulate the data of the following SOP Classes. The SOP Class UID is in the file's DICOM Tag field (0008,0016).

UID Value	UID Name
1.2.840.10008.5.1.4.1.1.1	CR Image Storage
1.2.840.10008.5.1.4.1.1.2	CT Image Storage
1.2.840.10008.5.1.4.1.1.4	MR Image Storage

Table 30-3: Encapsulated SOP Classes Supported

UID Value	UID Name
1.2.840.10008.5.1.4.1.1.6.1	Ultrasound Image Storage
1.2.840.10008.5.1.4.1.1.7	Secondary Capture Image Storage
1.2.840.10008.5.1.4.1.1.12.1	X-Ray Angiographic Image Storage
1.2.840.10008.5.1.4.1.1.12.2	X-Ray Radiofluoroscopic Image Storage
1.2.840.10008.5.1.4.1.1.20	Nuclear Medicine Image Storage
1.2.840.10008.5.1.4.1.1.128	Positron Emission Tomography Image Storage

Table 30-3: Encapsulated SOP Classes Supported (Continued)

Handling of odd length data elements

The DICOM Standard PS 3.5 (Data Structures and Encoding) specifies that the data element values which make up a DICOM data stream must be padded to an even length. The toolkit upon which IDL's DICOM reading functionality is built strictly enforces this specification. If IDL encounters an incorrectly formed odd length data field while reading a DICOM Part 10 file it will report an error and stop the reading process.

Handling of undefined VRs

The VR (Value Representation) of a data element describes the data type and format of that data element's values. If IDL encounters an undefined VR while reading a DICOM Part 10 file, it will set that data element's VR to be UN (unknown).

Handling of retired and private data elements

Certain data elements are no longer supported under the v3.0 of the DICOM standard and are denoted as retired. Also, some DICOM implementations may require the communication of information that cannot be contained in standard data elements, and thus create private data elements to contain such information. Retired and private data elements should pose no problem to IDL's DICOM Part 10 file reading capability. When the IDLffDICOM object encounters a retired or private data element tag during reading a DICOM Part 10 file, it will treat it just like any standard data element: read the data value and allow it to be accessed via the IDLffDICOM::GetValue method.

IDLffDICOM Properties

IDLffDICOM objects have the following properties. Properties with the word "Yes" in the "Init" column of the property table can be set via IDLffDICOM::Init.

Note ──

For a discussion of the property description tables shown below, see "About Object Property Descriptions" on page 3135.

──

Objects of this class have the following properties.

- VERBOSE

VERBOSE

A Boolean value that indicates whether informational messages are printed to the Output Log during the operational life of the object. If this value is true, the informational messages are printed to the Output Log. Otherwise, the messages are not printed.

Property Type	Boolean		
Name String	*not displayed*		
Get: No	**Set:** No	**Init:** Yes	**Registered:** No

IDLffDICOM::Cleanup

The IDLffDICOM::Cleanup procedure method destroys the IDLffDICOM object.

Note ───

Cleanup methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation and destruction. This means that in most cases, you cannot call the Cleanup method directly. There is one exception to this rule: if you write your own subclass of this class, you can call the Cleanup method from within the Init or Cleanup method of the subclass.

───

Syntax

OBJ_DESTROY, *Obj*

or

Obj->[IDLffDICOM::]Cleanup   *(In a lifecycle method only.)*

Arguments

None

Keywords

None

Examples

```
; Create a DICOM object, read a DICOM file and dump its contents:
obj = OBJ_NEW( 'IDLffDICOM' )
var = obj->Read(DIALOG_PICKFILE(FILTER="*"))
obj->DumpElements
OBJ_DESTROY, obj

; Executing this statement should produce an invalid object
; reference error since obj no longer exists:
obj->DumpElements
```

Version History

5.2	Introduced

IDLffDICOM::DumpElements

The IDLffDICOM::DumpElements procedure method dumps a description of the DICOM data elements of the IDLffDICOM object to the screen or to a file.

Syntax

Obj->[IDLffDICOM::]DumpElements [, *Filename*]

Arguments

Filename

A scalar string containing the full path and filename of the file to which to dump the elements. The file is written as ASCII text.

Keywords

None

Examples

The columns output by DumpElements are the element reference, the (group, element) tuple, the value representation, the description, the value length, and some of the data values.

```
; Create a DICOM object, read a DICOM file and dump its contents:
obj = OBJ_NEW( 'IDLffDICOM' )
var = obj->Read(DIALOG_PICKFILE(FILTER='*'))
obj->DumpElements

; Dump the contents of the current DICOM object to a file under
; Windows:
obj->DumpElements, 'c:\itt\elements.dmp'

; Dump the contents of the current DICOM object to a file under
; UNIX:
obj->DumpElements, '/itt/elements.dmp'

OBJ_DESTROY, obj
```

Version History

5.2	Introduced

IDLffDICOM::GetChildren

The IDLffDICOM::GetChildren function method is used to find the member element references of a DICOM sequence. It takes as an argument a scalar reference to a DICOM element representing the parent of the sequence.

Syntax

Result = Obj->[IDLffDICOM::]GetChildren(*Reference*)

Return Value

Returns an array of references to the elements of the object that are members of that sequence. The scalar parent reference is possibly obtained by a previous call to GetReference or any method that generates a reference list. Any member of a sequence may also itself be the parent of another sequence. If the scalar reference argument is not the parent of a sequence, the method returns -1.

Arguments

Reference

A scalar reference to a DICOM element that is known to be the parent of a DICOM sequence.

Keywords

None

Examples

```
obj = OBJ_NEW('IDLffDICOM')
read = obj->Read(DIALOG_PICKFILE(FILTER='*'))

; Get a list of references to all elements that are sequences:
refs = obj->GetReference(VR='SQ')

; Cycle through the returned list and print out the immediate
; children references and descriptions of each sequence:
FOR i = 0, N_ELEMENTS(refs)-1 DO BEGIN
   IF (refs[i] NE -1) THEN $
      BEGIN
         children = obj->GetChildren(refs[i])
```

```
                FOR j = 0, N_ELEMENTS(children)-1 DO $
                   BEGIN
                       PRINT,children[j]
                          PRINT,obj->GetDescription(REFERENCE=children[j])
                   ENDFOR
          ENDIF
      ENDFOR
      OBJ_DESTROY,obj
```

Version History

5.2	Introduced

IDLffDICOM::GetDescription

The IDLffDICOM::GetDescription function method takes optional DICOM group and element arguments and returns an array of STRING descriptions.

Syntax

Result = Obj->[IDLffDICOM::]GetDescription([*Group* [, *Element*]]
   [, REFERENCE=*list of element references*])

Return Value

Returns an array of strings describing the field's contents as per the data dictionary in the DICOM specification PS 3.6. If no arguments or keywords are specified, the returned array contains the descriptions for all elements in the object. The effect of multiple keywords and parameters is to AND their results. If no DICOM elements can be found matching the search criteria, -1 will be returned.

Arguments

Group

An optional argument representing the value for the DICOM group to search for, i.e. '0018'x. If this argument is omitted, then all of the DICOM array elements are returned.

Element

An optional argument specified only if the *Group* argument has also been specified. Set this argument to the value for the DICOM element for which to search, such as '0010'x. If this argument is omitted and the *Group* argument was specified, then all elements of the specified *Group* are returned.

Keywords

REFERENCE

Set this keyword to a list of element reference values from which to return description values.

Examples

```
obj = OBJ_NEW('IDLffDICOM')
read = obj->Read(DIALOG_PICKFILE(FILTER='*'))

; Get the description of the patient name element:
arr = obj->GetDescription('0010'x,'0010'x)
PRINT, arr

; Get array of all of the descriptions from the patient info group:
arr = obj->GetDescription('0010'x)
FOR i = 0, N_ELEMENTS(arr)-1 DO BEGIN
   PRINT, arr[i]
ENDFOR

OBJ_DESTROY, obj
```

Version History

5.2	Introduced

IDLffDICOM::GetElement

The IDLffDICOM::GetElement function method takes optional DICOM group and/or element arguments and returns an array of DICOM Element numbers for those parameters.

Syntax

Result = Obj->[IDLffDICOM::]GetElement([*Group* [, *Element*]]
   [, REFERENCE=*list of element references*])

Return Value

Returns an array of integers representing the DICOM Element numbers for the parameters of the *Group* and *Element* arguments. If no arguments or keywords are specified, the returned array contains Element numbers for all elements in the object. The effect of multiple keywords and parameters is to AND their results. If no matching elements can be found, the function returns -1.

Arguments

Group

An optional argument representing the value for the DICOM group to search for, i.e. '0018'x. If this argument is omitted, then all of the DICOM array elements are returned.

Element

An optional argument specified only if the Group argument has also been specified. Set this argument to the value for the DICOM element to search for, such as '0010'x. If this argument is omitted and the Group argument was specified, then all elements of the specified Group are returned.

Keywords

REFERENCE

Set this keyword to a list of element reference values from which to return element number values.

Examples

```
obj = OBJ_NEW('IDLffDICOM')
read = obj->Read(DIALOG_PICKFILE(FILTER='*'))

; Get references to all elements with "patient" in the description:
refs = obj->GetReference(DESCRIPTION='patient')

; Get the element numbers of the elements containing "patient":
FOR i = 0, N_ELEMENTS(refs)-1 DO BEGIN
   num = obj->GetElement(REFERENCE=refs[i])
   PRINT,num
ENDFOR

; Get the element numbers from the Patient Info group, 0010:
elements = obj->GetElement('0010'x)
PRINT, elements

OBJ_DESTROY,obj
```

Version History

5.2	Introduced

IDLffDICOM::GetGroup

The IDLffDICOM::GetGroup function method takes optional DICOM group and/or element arguments and returns an array of DICOM Group numbers for those parameters.

Syntax

Result = Obj->[IDLffDICOM::]GetGroup([*Group*[, *Element*]]
    [, REFERENCE=*list of element references*])

Return Value

Returns an array of integers representing the DICOM Group numbers for *Group* parameters. If no arguments or keywords are specified, the returned array contains Group numbers for all groups in the object. The effect of multiple keywords and parameters is to AND their results. If no matching elements can be found, the function returns -1.

Arguments

Group

An optional argument representing the value for the DICOM group for which to search, such as '0018'x. If this argument is omitted, then all of the DICOM array elements are returned.

Element

An optional argument specified only if the *Group* argument has also been specified. Set this to the value for the DICOM element for which to search, such as '0010'x. If this argument is omitted and the *Group* argument was specified, then all elements of the specified *Group* are returned.

Keywords

REFERENCE

Set this keyword to a list of element references from which to return group number values.

Examples

```
obj = OBJ_NEW('IDLffDICOM')
read = obj->Read(DIALOG_PICKFILE(FILTER='*'))

; Get references to all elements with "patient" in the description:
refs = obj->GetReference(DESCRIPTION='patient')

; Get the group numbers of the elements containing "patient":
FOR i = 0, N_ELEMENTS(refs)-1 DO BEGIN
   num = obj->GetGroup(REFERENCE=refs[i])
   PRINT, num
ENDFOR

; Get the group numbers from the Patient Info group, 0010:
grp = obj->GetGroup('0010'x)
PRINT, grp

OBJ_DESTROY,obj
```

Version History

5.2	Introduced

IDLffDICOM::GetLength

The IDLffDICOM::GetLength function method takes optional DICOM group and/or element arguments and returns an array of LONGs.

Syntax

Result = Obj->[IDLffDICOM::]GetLength([*Group* [, *Element*]] [, REFERENCE=*list of element references*])

Return Value

Returns an array of longword integers. The length is the field length that explicitly exists in the DICOM file, and represents the length of the element value in bytes. If no arguments or keywords are specified, the returned array contains the lengths for all elements in the object. The effect of multiple keywords and parameters is to AND their results. If no matching elements can be found, the function returns -1.

Arguments

Group

An optional argument representing the value for the DICOM group for which to search, such as '0018'x. If this argument is omitted, all DICOM array elements are returned.

Element

An optional argument specified only if the *Group* argument has also been specified. Set this to the value for the DICOM element for which to search, such as '0010'x. If this argument is omitted and the *Group* argument was specified, then all elements of the specified *Group* are returned.

Keywords

REFERENCE

Set this keyword to a list of element references from which to return length values.

Examples

```
obj = OBJ_NEW('IDLffDICOM')
read = obj->Read(DIALOG_PICKFILE(FILTER='*'))

; Get the length of the patient name element:
arr = obj->GetLength('0010'x,'0010'x)
PRINT, arr

; Get an array of all of the lengths from the patient info group:
arr = obj->GetLength('0010'x)
PRINT, arr
OBJ_DESTROY, obj
```

Version History

5.2	Introduced

IDLffDICOM::GetParent

The IDLffDICOM::GetParent function method is used to find the parent references of a set of elements in a DICOM sequence.

Syntax

Result = Obj->[IDLffDICOM::]GetParent(*ReferenceList*)

Return Value

Returns the parent references of a set of elements in a DICOM sequence. It takes as an argument an array of references that represent DICOM elements. If no members of the *ReferenceList* are members of a sequence, a -1 is returned, and for each member of the *ReferenceList* which is not a member of a sequence, a -1 is returned.

Arguments

ReferenceList

An array of references to DICOM elements that are known to be members of a DICOM sequence.

Keywords

None

Examples

```
obj = OBJ_NEW('IDLffDICOM')
read = obj->Read(DIALOG_PICKFILE(FILTER = '*'))

; Get the reference to the Referenced Study Sequence
; element, if it exists:
ref = obj->GetReference('0008'x, '1110'x)
PRINT, ref
PRINT, obj->GetDescription(REFERENCE = ref)

; Get and print the parent sequence, if it exists.
; This should result in a -1 since this element is not
; a member of a sequence:
parent = obj->GetParent(ref)
PRINT, parent
```

```
PRINT, obj->GetDescription(REFERENCE=parent)

; Get the children of the Referenced Study Sequence
; element, if it exists:
refs = obj->GetChildren(ref[0])
PRINT, refs
PRINT, obj->GetDescription(REFERENCE = refs)
OBJ_DESTROY, obj
```

Version History

5.2	Introduced

IDLffDICOM::GetPreamble

The IDLffDICOM::GetPreamble function method returns the preamble of a DICOM v3.0 Part 10 file.

Syntax

Result = Obj->[IDLffDICOM::]GetPreamble()

Return Value

Returns a 128-element byte array containing the preamble, which is a fixed 128 byte field available for implementation specified usage. If it is not used by the implementor of the file, it will be set to all zeroes.

Arguments

None

Keywords

None

Examples

```
; Create a DICOM object, read a DICOM file:
obj = OBJ_NEW('IDLffDICOM')
var = obj->Read(DIALOG_PICKFILE(FILTER = '*'))

; Get an array of the byte contents of the DICOM file preamble:
arr = obj->GetPreamble()
PRINT, arr

OBJ_DESTROY, obj
```

Version History

5.2	Introduced

IDLffDICOM::GetReference

The IDLffDICOM::GetReference function method takes optional DICOM group and/or element arguments and returns an array of references to matching elements in the object.

Syntax

Result = Obj->[IDLffDICOM::]GetReference([*Group* [, *Element*]]
 [, DESCRIPTION=*string*] [, VR=*DICOM VR string*])

Return Value

Returns an array referencing the matching elements in the object. References are opaque, meaning that they have no specific significance other than a correspondence to the element they refer to. If no arguments or keywords are specified, the returned array contains references to all elements in the object. The effect of multiple keywords and parameters is to AND their results. If no matching elements can be found, the function returns -1.

Arguments

Group

An optional argument representing the value for the DICOM group for which to search, such as '0018'x. If this argument is omitted, then all of the DICOM array elements are returned.

Element

An optional argument specified only if the *Group* argument has also been specified. Set this to the value for the DICOM element to search for, such as '0010'x. If this argument is omitted and the *Group* argument was specified, then all elements of the specified *Group* are returned.

Keywords

DESCRIPTION

Set this keyword to a string containing text to be searched for in each element's DICOM description. An element will be returned only if the text in this string can be found in the description. The text comparison is case-insensitive.

VR

Set this keyword to a DICOM VR string. An element will be returned only if its value representation matches this string.

Examples

```
obj = OBJ_NEW('IDLffDICOM')
read = obj->Read(DIALOG_PICKFILE(FILTER = '*'))

; Get the reference to the patient name element:
ref = obj->GetReference('0010'x,'0010'x)
PRINT, ref

; Get references to all elements with "patient" in the description:
refs = obj->GetReference(DESCRIPTION = 'patient')
FOR i = 0, (N_ELEMENTS(refs) - 1) DO BEGIN
   PRINT, refs[i]
   PRINT, obj->GetDescription(REFERENCE = refs[i])
ENDFOR

; Get references to all elements with a VR of DA (date):
refs = obj->GetReference(vr = 'DA')
FOR i = 0, (N_ELEMENTS(refs) - 1) DO BEGIN
   PRINT, refs[i]
   PRINT, obj->GetDescription(REFERENCE = refs[i])
ENDFOR

OBJ_DESTROY, obj
```

Version History

5.2	Introduced

IDLffDICOM::GetValue

This method takes optional DICOM group and/or element arguments and returns an array of POINTERs to the values of the elements matching those parameters.

Syntax

Result = Obj->[IDLffDICOM::]GetValue([*Group* [, *Element*]]
   [, REFERENCE=*list of element references*] [, /NO_COPY])

Return Value

Returns an array of pointers to the values of the elements matching the *Group* and *Element* parameters. If no arguments or keywords are specified, the returned array contains pointers to all elements in the object. The effect of multiple keywords and parameters is to AND their results. If no matching elements can be found, the function returns -1.

Arguments

Group

Set this optional argument to the value for the DICOM group for which to search, such as '0018'x. If this argument is omitted, then all of the DICOM array elements are returned.

Element

This optional argument can be specified only if the Group argument has also been specified. Set this to the value for the DICOM element for which to search, such as '0010'x. If this argument is omitted and the Group argument was specified, then all elements of the specified Group are returned.

Keywords

REFERENCE

Set this keyword to a list of element references from which to return pointer values.

NO_COPY

If this keyword is set, the pointers returned point to the actual data in the object for the specified DICOM fields. If not set (the default), the pointers point to copies of the data instead, and need to be freed by using PTR_FREE.

Examples

Example 1

```
obj = OBJ_NEW('IDLffDICOM')
read = obj->Read(DIALOG_PICKFILE(FILTER='*'))

; Get the image data
array = obj->GetValue('7fe0'x, '0010'x)
OBJ_DESTROY, obj

TVScl, *array[0]
PTR_FREE, array
```

Example 2

```
obj = OBJ_NEW('IDLffDICOM')
read = obj->Read(DIALOG_PICKFILE(FILTER='*'))

; Get all of the image data element(s), 7fe0,0010, from the file:
array = obj->GetValue('7fe0'x,'0010'x,/NO_COPY)

; Get the row & column size of the image(s):
rows = obj->GetValue('0028'x,'0010'x,/NO_COPY)
cols = obj->GetValue('0028'x,'0011'x,/NO_COPY)

; If the image has a samples per pixel value greater than 1
; it is most likely a color image, get the samples per pixel:
isColor = 0
samples = obj->GetValue('0028'x,'0002'x,/NO_COPY)
IF (SIZE(samples,/N_DIMENSIONS) NE 0) THEN BEGIN
   IF (*samples[0] GT 1) THEN isColor = 1
ENDIF

; Next, we need to differentiate between files with color data
; that is either color-by-plane or color-by-pixel, get the planar
; configuration:
IF (isColor EQ 1) THEN BEGIN
   isPlanar = 0
   planar = obj->GetValue('0028'x,'0006'x, /NO_COPY)
   IF (SIZE(planar, /N_DIMENSIONS) NE 0) THEN BEGIN
```

```

IDLffDICOM::GetVR

The IDLffDICOM::GetVR function method takes optional DICOM group and/or element arguments and returns an array of VR (Value Representation) STRINGs for those parameters.

Syntax

array = Obj->[IDLffDICOM::]GetVR([*Group* [, *Element*]]
   [, REFERENCE=*list of references*])

Return Value

Returns an array of strings containing VRs (Value Representations) for the *Group* and *Element* parameters. A VR is a DICOM value representation as described in the DICOM specification PS 3.5. If no arguments or keywords are specified, the returned array contains VRs for all elements in the object. The effect of multiple keywords and parameters is to AND their results. If no matching elements can be found, the function returns -1.

Arguments

Group

An optional argument representing the value for the DICOM group for which to search, such as '0018'x. If this argument is omitted, then all of the DICOM array elements are returned.

Element

An optional argument specified only if the *Group* argument has also been specified. Set this to the value for the DICOM element for which to search, such as '0010'x. If this argument is omitted and the *Group* argument was specified, then all elements of the specified *Group* are returned.

Keywords

REFERENCE

Use the specified list of references from which to return VR STRING values.

Examples

```
obj = OBJ_NEW('IDLffDICOM')
read = obj->Read(DIALOG_PICKFILE(FILTER='*'))

; Get the VR of the patient name element:
arr = obj->GetVR('0010'x,'0010'x)
PRINT, arr

; Get an array of all of the VRs from the patient info group:
arr = obj->GetVR('0010'x)
PRINT, arr

OBJ_DESTROY,obj
```

Version History

5.2	Introduced

IDLffDICOM::Init

The IDLffDICOM::Init function method creates a new IDLffDICOM object and optionally reads the specified file as defined in the IDLffDICOM::Read method.

Note —————————————————————————————

Init methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation. This means that in most cases, you cannot call the Init method directly. There is one exception to this rule: If you write your own subclass of this class, you can call the Init method from within the Init method of the subclass.

———————————————————————————————————————

Syntax

Result = OBJ_NEW('IDLffDICOM' [, *Filename*] [, *PROPERTY=value*])

or

Result = *Obj*->[IDLffDICOM::]Init([*Filename*] [, *PROPERTY=value*])   *(In a lifecycle method only.)*

Return Value

When this method is called indirectly, as part of the call to the OBJ_NEW function, the return value is an object reference to the newly-created object.

When called directly within a subclass Init method, the return value is 1 if initialization was successful, or zero otherwise.

Arguments

Filename

An optional scalar string argument containing the full path and filename of a DICOM v3.0 Part 10 file to open, read into memory, then close, when the object is created. It is the same as calling: result->Read(Filename).

Keywords

Any property listed under "IDLffDICOM Properties" on page 3198 that contains the word "Yes" in the "Init" column of the properties table can be initialized during

object creation using this method. To initialize the value of a property, specify the property name as a keyword set equal to the appropriate property value.

Examples

```
; Create a DICOM object:
obj = OBJ_NEW( 'IDLffDICOM' )

; Create a DICOM object and read in a DICOM file named
; mr_brain.dcm:
obj = OBJ_NEW( 'IDLffDICOM', $
   FILEPATH('mr_brain.dcm', SUBDIRECTORY=['examples', 'data']))

; Create a DICOM object and allow the user to choose a DICOM file
; to be read:
obj = OBJ_NEW( 'IDLffDICOM', DIALOG_PICKFILE(FILTER='*'))
```

Version History

5.2	Introduced

IDLffDICOM::Read

The IDLffDICOM::Read function method opens and reads from the specified disk file, places the information into the DICOM object, then closes the file.

Syntax

Result = Obj->[IDLffDICOM::]Read(*Filename* [, ENDIAN={1 | 2 | 3 | 4}])

Return Value

Return a 1 if successful and 0 otherwise.

Arguments

Filename

A scalar string argument containing the full path and filename of a DICOM Part 10 file to open and read into memory.

Keywords

ENDIAN

Set this keyword to configure the endian format when reading a DICOM file.

- 1 = Implicit VR Little Endian

- 2 = Explicit VR Little Endian

- 3 = Implicit VR Big Endian

- 4 = Explicit VR Big Endian

Examples

```
; Create a DICOM object and read a DICOM file:
obj = OBJ_NEW('IDLffDICOM')
var = obj->Read(DIALOG_PICKFILE(FILTER = '*'))
OBJ_DESTROY, obj
```

Version History

5.2	Introduced

IDLffDICOM::Reset

The IDLffDICOM::Reset procedure method removes all of the elements from the IDLffDICOM object, leaving the object otherwise intact.

Syntax

Obj->[IDLffDICOM::]Reset

Arguments

None

Keywords

None

Examples

```
; Create a DICOM object, read a DICOM file and dump its contents:
obj = OBJ_NEW( 'IDLffDICOM' )
var = obj->Read(DIALOG_PICKFILE(FILTER='*'))
obj->DumpElements
obj->Reset

; DumpElements should produce no output here:
obj->DumpElements
OBJ_DESTROY, obj
```

Version History

5.2	Introduced

IDLffDXF

An IDLffDXF object contains geometry, connectivity and attributes for graphics primitives.

Note ───
IDL supports version 2.003 of the DXF Library.
───

Note ───
IDL does not provide DXF functionality under Macintosh OS X or on 64-bit platforms.
───

This object treats a DXF file as a list of entities. Note, these are not directly mapped to DXF entity types, rather they are an abstraction of the DXF types. The Read method is used to read the contents of a DXF file into the current entity list. The user may then query this list using the GetContents method to determine the types and number of entities in the file. The user may retrieve arrays of entities from the list using the GetEntity method and add additional entities using the PutEntity method. Entities can also be removed from the list (RemoveEntity) or the entire list destroyed (Reset). The current list of entities can also be written to disk as a DXF file. Note, this object converts DXF entities to IDL entities and back. This conversion is not reversible; thus, if a DXF file is read and then written, the data in the file is not changed, but the internal DXF entity types may be changed by IDL. As an example, DXF face3d entities may be written as DXF polyline entities.

The object has one attribute which can be modified using the Get/SetPalette methods. This palette is used to convert color index values. The palette is not actually written to the DXF file. So, if the user wanted to specify entity colors from a 256 entry table, that table would be set using SetPalette, but the actual colors written to the file are the closest colors matched to the fixed AutoCAD color palette. There are two special color values: (0) = color by block color, (256) = color by layer color.

In this object, blocks and layers are treated as named entities with attributes, but are special in that all other entities have a block and layer entity reference in them. This allows the user to use these entity names as filters for many operations. There is a default block and a default layer. The default block has the name "" (the null string), and the default layer is '0'. The user may change the (non-name) attributes for these implicit blocks using PutEntity.

Superclasses

None

Creation

See "IDLffDXF::Init" on page 3249

Properties

Objects of this class have no properties of their own.

Methods

This class has the following methods:

- IDLffDXF::Cleanup
- IDLffDXF::GetContents
- IDLffDXF::GetEntity
- IDLffDXF::GetPalette
- IDLffDXF::Init
- IDLffDXF::PutEntity
- IDLffDXF::Read
- IDLffDXF::RemoveEntity
- IDLffDXF::Reset
- IDLffDXF::SetPalette
- IDLffDXF::Write

Version History

5.2	Introduced

IDLffDXF Properties

Objects of this class have no properties of their own.

IDLffDXF::Cleanup

The IDLffDXF::Cleanup procedure method performs all cleanup on the object.

Note ————————————————————————————

Cleanup methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation and destruction. This means that in most cases, you cannot call the Cleanup method directly. There is one exception to this rule: If you write your own subclass of this class, you can call the Cleanup method from within the Init or Cleanup method of the subclass.

Syntax

OBJ_DESTROY, *Obj*

or

Obj->[IDLffDXF::]Cleanup   *(In a lifecycle method only.)*

Arguments

None

Keywords

None

Version History

5.2	Introduced

IDLffDXF::GetContents

The IDLffDXF::GetContents function method returns a description of the content of the DXF file.

See the Examples following the GetEntity method description for an illustration of the difference between the GetContents and the GetEntity methods.

Note

The Read or PutEntity methods must have been called previously for the results of this method to be valid.

Valid DXF ENTITY Types	DXF_TYPE (0=default)
ARC	1
CIRCLE	2
ELLIPSE	3
LINE	4
LINE3D	5
TRACE	6
POLYLINE	7
LWPOLYLINE	8
POLYGON	9
FACE3D	10
SOLID	11
RAY	12
XLINE	13
TEXT	14
MTEXT	15

Table 30-4: DXF Entity Types

Valid DXF ENTITY Types	DXF_TYPE (0=default)
POINT	16
SPLINE	17
BLOCK	18
INSERT	19
LAYER	20

Table 30-4: DXF Entity Types (Continued)

This object uses a small number of IDL named structures to return the data associated which each entity. This means that several of these DXF types are returned in the same structures, using different values of the DXF_TYPE field. The mapping of DXF entities to IDL named structures is as follows (each of these structures is documented in the GetEntity method):

IDL Structure	DXF Entity
IDL_DXF_ELLIPSE	arc, circle, ellipse
IDL_DXF_POLYLINE	line, line3d, trace, polyline, lwpolyline
IDL_DXF_POLYGON	face3d, solid, polyline (3-d mesh)
IDL_DXF_POINT	point
IDL_DXF_XLINE	ray, xline
IDL_DXF_SPLINE	spline
IDL_DXF_TEXT	text, multitext
IDL_DXF_BLOCK	block
IDL_DXF_INSERT	insert
IDL_DXF_LAYER	layer

Table 30-5: DXF mapping to IDL structures

Syntax

Result = Obj->[IDLffDXF::]GetContents([*Filter*] [, BLOCK=*string*]
   [, COUNT=*variable*] [, LAYER=*string*])

Return Value

Returns an integer array containing the DXF entity type codes and the number of
occurrences of each entity type contained in the object

Arguments

Filter

An integer array of the DXF entity types to which the return types are restricted. If
set, Result can contain only types given in this argument and count will also reflect
that restriction.

Keywords

BLOCK

Set this keyword to a string value containing the block name to obtain the entities
from. The default is all blocks.

COUNT

A long array containing the number of each entity type contained within the DXF
object. If the Filter argument was provided, the numbers reflect the reduced set of
entities caused by the Filter argument.

LAYER

Set this keyword to a string value containing the layer name to obtain the entities
from. The default is all layers.

Version History

5.2	Introduced

IDLffDXF::GetEntity

The IDLffDXF::GetEntity function method returns an array of data for the requested entity type.

Syntax

Result = Obj->[IDLffDXF::]GetEntity(*Type* [, BLOCK=*string*] [, INDEX=*value*]
  [, LAYER=*string*])

Return Value

Returns one of the named structure formats described in "Structure Formats" on page 3237.

Arguments

Type

The integer DXF entity type from which to obtain the geometry information.

Keywords

BLOCK

Set this keyword to a block name specifying the graphic block from which to obtain the entity geometry information. The default is all blocks. Setting this keyword to the null string " " will cause this method to only return entities from the default DXF entity block.

INDEX

Set this keyword to a scalar index or a long array of indices of entities of the given type to return. If not set, this method returns all entities for the given type.

LAYER

Set this keyword to a string value containing the layer name to obtain the entities from. The default is all layers.

Fields Common to All Structures

BLOCK

The name of the block this entity is in (these may be in the default block "").

COLOR

A color index value into the current object palette with 0=use block color and 256=use layer color.

EXTRUSION

The DXF extrusion vector (if any).

LAYER

The name of the layer this entity is in (the default layer is '0').

LINESTYLE

Defined the same as the user linestyle for IDLgrPolyline::Init.

Note
IDL will always return a solid line regardless of the linestyle in DXF

THICKNESS

In AutoCAD units.

DXF_TYPE

Set to one of the values listed in IDLffDXF::GetContents.

Note
It is the user's responsibility to free all the pointers returned in these structures when the entity is no longer needed.

Structure Formats

Structure IDL_DXF_ELLIPSE

Field	Data Type
PT0	Double [3]
PT1_OFFSET	Double [3]
MIN_TO_MAJ_RATIO	Double
START_ANGLE	Double
END_ANGLE	Double
EXTRUSION	Double [3]
LINESTYLE	Integer [2]
THICKNESS	Double
COLOR	Integer
DXF_TYPE	Integer
BLOCK	String
LAYER	String

Table 30-6: Fields of the IDL_DXF_ELLIPSE Structure

This object is centered at PT0 and has a radius defined by the vector PT1_OFFSET. This vector determines the length and orientation of the major axis of an ellipse as well.

The MIN_TO_MAJ_RATIO value specifies the length of the minor axis as a fraction of the major axis length. For a circle, this value is 1.0.

The START_ANGLE and END_ANGLE values select the portion of the curve to be drawn. If they are equal, the entire circle or ellipse is drawn.

Structure IDL_DXF_POLYGON

Field	Data Type
VERTICES	Pointer (to an array of 3-D points)
CONNECTIVITY	Pointer (to an array of integers)
VERTEX_COLORS	Pointer (to an array of integers)
MESH_DIMS	Integer [2]
CLOSED	Integer [2]
COLOR	Integer
EXTRUSION	Double [3]
FIT_TYPE	Integer
CURVE_FIT	Integer
SPLINE_FIT	Integer
DXF_TYPE	Integer
BLOCK	String
LAYER	String

Table 30-7: Fields of the IDL_DXF_POLYGON Structure

VERTICES is a pointer to an array of dimension [3, n] containing the points for this entity.

CONNECTIVITY is the array used to connect these points into polygons (see the POLYGONS keyword for IDLgrPolygon::Init). If this array is not present, the connectivity is implicit in (U, V) space defined by the values in MESH_DIMS; the vertices represent a quad mesh of dimensions (MESH_DIMS[0], MESH_DIMS[1]).

Note ───

If a connectivity array is not supplied and the MESH_DIMS are left at 0,0, then IDL will tessellate the vertex list and store the polygon with the resulting connectivity list. If tessellation fails, IDL will throw an error that should be detected and dealt with using the CATCH mechanism. An alternative to this is to pass the polygon to the IDLgrTessellator object, which returns a zero instead of throwing an error if tessellation fails. The results of a successful tessellation can be put into a DXF

entity and passed to the IDLffDXF object, which will not attempt to tessellate the polygon as it has already been tessellated.

VERTEX_COLORS points to an array of color index values for each of the vertices. If a quad mesh is being returned, it can be closed in either dimension according to the CLOSED array.

FIT_TYPE, CURVE_FIT, and SPLINE_FIT return the type of curve fit (if any) this polygon assumes.

Structure IDL_DXF_POLYLINE

Field	Data Type
VERTICES	Pointer (to an array of 3-D points)
CONNECTIVITY	Pointer (to an array of integers)
VERTEX_COLORS	Pointer (to an array of integers)
COLOR	Integer
MESH_DIMS	Integer [2]
CLOSED	Integer [2]
THICKNESS	Double
LINESTYLE	Integer [2]
EXTRUSION	Double [3]
FIT_TYPE	String
CURVE_FIT	Integer
SPLINE_FIT	Integer
DXF_TYPE	Integer
BLOCK	String
LAYER	String

Table 30-8: Fields of the IDL_DXF_POLYLINE Structure

VERTICES is a pointer to an array of dimension [3, n] containing the points for this entity.

CONNECTIVITY is the array used to connect these points into polylines (see the POLYLINES keyword for IDLgrPolyline::Init). If this array is not present, the connectivity is implicit in (U, V) space defined by the values in MESH_DIMS; the vertices represent a quad mesh of dimensions (MESH_DIMS[0], MESH_DIMS[1]).

VERTEX_COLORS points to an array of color index values for each of the vertices. If a quad mesh is being returned, it can be closed in either dimension according to the CLOSED array.

FIT_TYPE, CURVE_FIT, and SPLINE_FIT return the type of curve fit (if any) this polyline assumes.

Structure IDL_DXF_POINT

Field	Data Type
PT0	Double [3]
UCSX_ANGLE	Double
THICKNESS	Double
COLOR	Integer
DXF_TYPE	Integer
BLOCK	String
LAYER	String

Table 30-9: Fields of the IDL_DXF_POINT Structure

PT0 is the location of the point in space.

UCSX_ANGLE is an internal DXF orientation parameter used for symbol plotting.

Structure IDL_DXF_SPLINE

Field	Data Type
CTR_PTS	Pointer
FIT_PTS	Pointer
KNOTS	Pointer
WEIGHTS	Pointer
COLOR	Integer
DEGREE	Integer
PERIODIC	Integer
RATIONAL	Integer
PLANAR	Integer
LINEAR	Integer
KNOT_TOLERANCE	Double
CTL_TOLERANCE	Double
FIT_TOLERANCE	Double
START_TANGENT	Double [3]
END_TANGENT	Double [3]
THICKNESS	Double
LINESTYLE	Integer [2]
EXTRUSION	Double [3]
DXF_TYPE	Integer
BLOCK	String
LAYER	String

Table 30-10: Fields of the IDL_DXF_SPLINE Structure

This structure is returned verbatim from the DXF spline structure without interpretation. It is up to the user to interpret these values.

Structure IDL_DXF_TXT

Field	Data Type
PT0	Double [3]
TEXT_STR	String
COLOR	Integer
HEIGHT	Double
WIDTH_FACTOR	Double
BOX_WIDTH	Double
DIRECTION	Double [3]
ROT_ANGLE	Double
JUSTIFICATION	Integer (0=left, 1=center, 2=right, 3=aligned, 4=middle, 5=fit)
VERTICAL_ALIGN	Integer (0=baseline, 1=bottom, 2=middle, 3=top)
SHAPE_FILE	String
THICKNESS	Double
EXTRUSION	Double [3]
DXF_TYPE	Integer
BLOCK	String
LAYER	String

Table 30-11: Fields of the IDL_DXF_TXT Structure

PT0 is the location of the text string.

TEXT_STR is the actual string.

HEIGHT specifies the overall scaling of the glyphs while WIDTH_FACTOR is a correction in the baseline direction (anisotropic scaling). For multi-line text, BOX_WIDTH determines where the line breaks should be placed (0.0 for single line text).

The text baseline is specified by DIRECTION and its rotation about the *z*-axis is specified by ROT_ANGLE. Justification is specified by JUSTIFICATION and VERTICAL_ALIGN. SHAPE_FILE is the name of the glyph file used to image this string. The shape file is NOT read by IDL.

Structure IDL_DXF_XLINE

Field	Data Type
PT0	Double [3]
UNIT_VEC	Double [3]
COLOR	Integer
THICKNESS	Double
LINESTYLE	Integer [2]
EXTRUSION	Double [3]
DXF_TYPE	Integer
BLOCK	String
LAYER	String

Table 30-12: Fields of the IDL_DXF_XLINE Structure

PT0 is the start of a ray or a point on a infinite line in space in the case of an XLINE entity.

UNIT_VEC determines the direction of the line in space.

Structure IDL_DXF_INSERT

Field	Data Type
SCALE	Double [3]
PT0	Double [3]
ROTATION	Double
INSTANCE_BLOCK	String
NUM_ROW_COL	Integer [2]
DISTANCE_BETWEEN	Double [2]
DXF_TYPE	Integer
BLOCK	String
COLOR	Integer
LAYER	String

Table 30-13: Fields of the IDL_DXF_INSERT Structure

The insert entity allows for the "instancing" of a block in a grid fashion.

INSTANCE_BLOCK is the name of a block to repeat.

The block is scaled by SCALE and rotated about the Z axis by ROTATION. The grid begins at PT0 and contains the number of rows and columns specified by NUM_ROW_COL (Note: 0 rows or columns will always give a single instance of the block).

The spacing of the grid is specified by DISTANCE_BETWEEN.

Structure IDL_DXF_BLOCK

Field	Data Type
PT0	Double [3]
COLOR	Integer
NAME	String
DXF_TYPE	Integer

Table 30-14: Fields of the IDL_DXF_BLOCK Structure

This entity specifies a BLOCK. Blocks have a location in space (PT0) [objects in the block are interpreted relative to this point], a name, and a COLOR. They are not contained in layers or other blocks, so these fields are not present.

Structure IDL_DXF_LAYER

Field	Data Type
COLOR	Integer
NAME	String
DXF_TYPE	Integer

Table 30-15: Fields of the IDL_DXF_LAYER Structure

This entity specifies a LAYER. Layer is a NAME and a COLOR. They are not contained in layers or other blocks, so these fields are not present.

Examples

This example illustrates the difference between the GetEntity and GetContents methods within the IDLffDXF object method. The GetContents method gives a description of the content of the file read, listing the entity types and the number of occurrences. GetEntity accesses the values returned by GetContents and determines how the entities can be logically combined into common structures for drawing efficiency.

```
PRO view_heart
; Determine path to data file.
heartFile = FILEPATH('heart.dxf', $
   SUBDIRECTORY = ['examples', 'data'])
; Initialize DXF data access object.
oHeart = OBJ_NEW('IDLffDXF')
; Read data within DXF file into access object.
status = oHeart->Read(heartFile)
; Determine what type of entities (and how many of
; each entity) exist in the file.
heartTypes = oHeart->GetContents(COUNT = heartCounts)
PRINT, 'Entity Types:   ', heartTypes
PRINT, 'Count of Types: ', heartCounts
; Initialize a model for displaying polygon and polyline
; objects.
oModel = OBJ_NEW('IDLgrModel')
; Obtain the tissue data. The tissue is accessed into
; IDL as a single polygon.
tissue = oHeart->GetEntity(heartTypes[1])
HELP, tissue
HELP, tissue, /STRUCTURE
; Initialize color parameter.
tissueColor = [255, 0, 0]
; Initialize polygon data.
vertices = tissue.vertices
connectivity = tissue.connectivity
; Initialize the polygon object.
oTissue = OBJ_NEW('IDLgrPolygon', $
   *vertices, POLYGONS = *connectivity, $
   COLOR = tissueColor)
; Add the polygon to the model.
oModel->Add, oTissue
; Clean-up all the related pointers.
PTR_FREE, tissue.vertices, tissue.connectivity, $
   tissue.vertex_colors
PTR_FREE, vertices, connectivity
; Display the polylines and the polygon in the XOBJVIEW
; utility.
XOBJVIEW, oModel, /BLOCK, SCALE = 0.75
; Clean-up the object references.
OBJ_DESTROY, [oHeart, oModel]
END
```

An XOBJVIEW window with the mesh heart object appears when this program is
compiled and run. The following lines are found in the workbench Output Log
window.

```
IDL> view_heart
% Compiled module: VIEW_HEART.
```

```
% Compiled module: FILEPATH.
% Loaded DLM: DXF.
Entity Types:              7          10          18          20
Count of Types:           13        1624           1           2
```

The Entity Types (7, 10, 18, and 20) are the GetContents method return values corresponding to the occurrence of DXF ENTITY types found in the object: POLYLINES, FACE3D, BLOCK, and LAYER, respectively. Note there are a total of 1624 FACE3D entity types, but for efficiency and speed IDL logically combines all of the similar entities into a single structure that can be used in an IDLgrPolygon object. This is illustrated by the output resulting from the first Help command in the program as shown below.

```
TISSUE            STRUCT    =->IDL_DXF_POLYGON Array[1]
** Structure IDL_DXF_POLYGON, 13 tags, length=72:
   EXTRUSION         DOUBLE    Array[3]
   VERTICES          POINTER   <PtrHeapVar3>
   CONNECTIVITY      POINTER   <PtrHeapVar4>
   VERTEX_COLORS     POINTER   <PtrHeapVar5>
   MESH_DIMS         INT       Array[2]
   CLOSED            INT       Array[2]
   COLOR             INT            256
   FIT_TYPE          INT             -1
   CURVE_FIT         INT              0
   SPLINE_FIT        INT              0
   DXF_TYPE          INT             10
   BLOCK             STRING    ''
   LAYER             STRING    '0----'
% Compiled module: XOBJVIEW.
% Compiled module: UNIQ.
% Compiled module: IDENTITY.
% Compiled module: XMANAGER.
```

Note that the tissue is represented as an array of polygons having 1 element. This is evident by the mesh representation of the heart object showing the 1624 individual polygons as a single object.

Version History

5.2	Introduced

IDLffDXF::GetPalette

The IDLffDXF::GetPalette procedure method returns the current color table in the object.

Syntax

Obj->[IDLffDXF::]GetPalette, *Red*, *Green*, *Blue*

Arguments

Red

Returns an array of the red components to the current color table.

Green

Returns an array of the green components to the current color table.

Blue

Returns an array of the blue components to the current color table.

Keywords

None

Version History

5.2	Introduced

IDLffDXF::Init

The IDLffDXF::Init function method initializes the DXF object.

Note ————————————————————————————————————

Init methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation. This means that in most cases, you cannot call the Init method directly. There is one exception to this rule: If you write your own subclass of this class, you can call the Init method from within the Init method of the subclass.

Syntax

Result = OBJ_NEW('IDLffDXF' [, *Filename*])

or

Result = *Obj*->[IDLffDXF::]Init([*Filename*])   *(In a lifecycle method only.)*

Return Value

When this method is called indirectly, as part of the call to the OBJ_NEW function, the return value is an object reference to the newly-created object.

When called directly within a subclass Init method, the return value is 1 if initialization was successful, or zero otherwise.

Arguments

Filename

A scalar string optional argument containing the full path and filename of a DXF file to be read as the object is created.

Keywords

None

Version History

5.2	Introduced

IDLffDXF::PutEntity

The IDLffDXF::PutEntity procedure method inserts an entity into the DXF object. The type of the entity is determined from the DXF_TYPE field of the entity structure. If DXF_TYPE is set to 0, the type is implied by the entity structure.

Note ⎯⎯⎯⎯⎯⎯⎯⎯⎯⎯⎯⎯⎯⎯⎯⎯⎯⎯⎯⎯⎯⎯⎯⎯⎯⎯⎯⎯⎯⎯⎯

Line3D entity types will be written as Line entities due to the obsolete status of Line3D. Polyline entities will be automatically converted to Lightweight Polylines where applicable.

Syntax

Obj->[IDLffDXF::]PutEntity, *Data*

Arguments

Data

An array of Entity structures as defined by the GetEntity method.

Note ⎯⎯⎯⎯⎯⎯⎯⎯⎯⎯⎯⎯⎯⎯⎯⎯⎯⎯⎯⎯⎯⎯⎯⎯⎯⎯⎯⎯⎯⎯⎯

If the entity references a non-existent block or layer, one will automatically be created. Blocks and layers can also be created by passing IDL_DXF_BLOCK or IDL_DXF_LAYER structures to this routine.

Keywords

None

Version History

5.2	Introduced

IDLffDXF::Read

The IDLffDXF::Read function method reads a file, parsing the DXF object information contained in the file, and inserts it into itself.

Syntax

Result = Obj->[IDLffDXF::]Read(*Filename*)

Return Value

Returns a 1 indicating success in reading the file, otherwise 0.

Arguments

Filename

A scalar string containing the full path and filename of the DXF file to be read.

Keywords

None

Examples

```
; Read all the lines from the electrical layer:
oDXF = OBJ_NEW('IDLffDXF')
IF (oDXF->Read('myDXF.dxf')) THEN BEGIN
   contents = oDXF->GetContents(4,COUNT=numLines, $
      LAYER='Electrical')
   IF (numLines ne 0) THEN BEGIN
      lines = oDXF->GetEntity(4,LAYER='Electrical')
   ENDIF
ENDIF
```

Version History

5.2	Introduced

IDLffDXF::RemoveEntity

The IDLffDXF::RemoveEntity procedure method removes the specified entity or entities from the DXF object.

Syntax

Obj->[IDLffDXF::]RemoveEntity[, *Type*] [, INDEX=*value*]

Arguments

Type

An optional scalar string containing the DXF type to be removed from the DXF object.

Note ―――――――――――――――――――――――――――――――――
Specifying a block or layer entity will cause all the entities in that layer or block to be removed.
――

Keywords

INDEX

Set this keyword to a scalar long or a long array of indices to remove from the DXF object. If not set, or set negative, all entities of the given type are removed.

Version History

5.2	Introduced

IDLffDXF::Reset

The IDLffDXF::Reset procedure method removes all the entities from the DXF object.

Syntax

Obj->[IDLffDXF::]Reset

Arguments

None

Keywords

None

Version History

5.2	Introduced

IDLffDXF::SetPalette

The IDLffDXF::SetPalette procedure method sets the current color table in the object.

Syntax

Obj->[IDLffDXF::]SetPalette, *Red*, *Green*, *Blue*

Arguments

Red

Sets the red components of the current color table to this array.

Green

Sets the green components of the current color table to this array.

Blue

Sets the blue components of the current color table to this array.

Keywords

None

Version History

5.2	Introduced

IDLffDXF::Write

The IDLffDXF::Write function method writes a file for the DXF entity information this object contains.

Syntax

Result = Obj->[IDLffDXF::]Write(*Filename*)

Return Value

Returns a 1 if successful in writing the file, 0 otherwise.

Arguments

Filename

A scalar string containing the full path and filename of the DXF file to be written.

Keywords

None

Examples

```
; Write a square to a new DXF file using lines:
oDXF = OBJ_NEW('IDLffDXF')
lines = {IDL_DXF_POLYLINE}
lines.dxf_type = 4
lines.layer='myLayer'
lines.thickness = 1.0

; Create clockwise square:
lines = REPLICATE(lines, 4)
lines[0].vertices = PTR_NEW([[0.0,0.0,0.0], $
     [0.0,1.0,0.0]])
lines[0].connectivity = PTR_NEW([0,1])
lines[1].vertices = PTR_NEW([[0.0,1.0,0.0], $
    [1.0,1.0,0.0]])
lines[1].connectivity = PTR_NEW([0,1])
lines[2].vertices = PTR_NEW([[1.0,1.0,0.0], $
    [1.0,0.0,0.0]])
lines[2].connectivity = PTR_NEW([0,1])
lines[3].vertices = PTR_NEW([[1.0,0.0,0.0], $
```

```
      [0.0,0.0,0.0]])
lines[3].connectivity = PTR_NEW([0,1])
oDXF->PutEntity, lines
IF (not oDXF->Write('mySquare.dxf')) THEN $
   PRINT, 'Write Failed.'
   ; Clean up the memory in the structs:
   OBJ_DESTROY, oDXF
   FOR i=0,3 DO BEGIN
      PTR_FREE, lines[i].vertices, lines[i].connectivity
ENDFOR
```

IDLffJPEG2000

An IDLffJPEG2000 object contains the data for one or more images embedded in a JPEG2000 file as well as functionality for reading and writing JPEG2000 files. For additional information on the JPEG 2000 file format, see "Overview of IDL and JPEG2000" on page 3260.

Superclasses

None

Creation

See "IDLffJPEG2000::Init" on page 3288.

Properties

Objects of this class have the following properties. See "IDLffJPEG2000 Properties" on page 3265 for details on individual properties.

- BIT_DEPTH
- BIT_RATE
- COLOR_SPACE
- COMMENT
- DIMENSIONS
- DISPLAY_RESOLUTION
- FILENAME
- JP2
- N_LAYERS
- N_LEVELS
- N_COMPONENTS
- N_TILES
- OFFSET
- PALETTE
- PROGRESSION
- QUIET
- READ
- REVERSIBLE
- SIGNED
- SUBSAMPLING
- TILE_DIMENSIONS
- TILE_OFFSET
- TILE_RANGE
- UUIDS
- WRITE
- XML
- YCC

Methods

This class has the following methods:

- IDLffJPEG2000::Cleanup

- IDLffJPEG2000::GetData
- IDLffJPEG2000::GetProperty
- IDLffJPEG2000::GetTileProperty
- IDLffJPEG2000::GetUUID
- IDLffJPEG2000::Init
- IDLffJPEG2000::SetData
- IDLffJPEG2000::SetProperty
- IDLffJPEG2000::SetUUID

Version History

6.1	Introduced
6.2	Added BIT_RATE and UUIDS properties.
	Added GetUUID and SETUUID methods.

Overview of IDL and JPEG2000

JPEG2000 is an open, international standard for image compression based on wavelet technology. It offers multiple advantages over other image file standards and compression methods. Among these advantages are:

- Low-bit rate compression performance equal to and often above that of other standards.

- Progressive transmission by quality, resolution, component, or region.

- Both lossless *and* lossy compression. (Lossless decompression is achieved naturally via progressions of increasing resolutions and/or quality.)

- Decompression of images which have user-selectable regions, resolutions, and quality.

- Random spatial access to the encoded stream of bits (code stream).

- Support for metadata, in the form of XML boxes.

A JPEG2000 encoded image and its most basic metadata comprise a code stream. This raw code stream may be placed in a file, usually given an extension of .j2k.

The JPEG2000 standard also allows for additional application-specific metadata to be added to a JPEG2000 file. A file that encapsulates the raw code stream and contains this additional metadata is referred to as a JP2 format file. IDL's support of the JP2 standard provides access to the following additional metadata types: color system specifications, palettes, XML containers, and display resolution information. These metadata are exposed through the COLOR_SPACE, PALETTE, XML, and DISPLAY_RESOLUTION object properties. (See "Properties" on page 3258).

Note ———————————————————————————————————————
JP2 format files must always have the file-type extension of `.jp2` or `.jpx` (which are case insensitive).
———

The IDLffJPEG2000 object class in IDL provides access to the features of JPEG2000 and the JP2 file format for both input and output. This object class is detailed in the following section.

Note ———————————————————————————————————————
Portions of IDL's JPEG2000 functionality were developed using Unisearch's Kakadu software. Kakadu Software. Copyright © 2001. The University of New South Wales, UNSW, Sydney NSW 2052, Australia, and Unisearch Ltd, Australia.
———

Examples

The following examples showcase various functionality when working with the IDLffJPEG2000 object.

Example One

This example shows how to both use the bit rate keyword to create an image with four layers and how to get and display a specific layer:

```
PRO JP2_BIT_RATE_EXAMPLE

; create a new JPEG2000 file
; the file will have four layers with the given bits rates
oJP2 = OBJ_NEW('IDLffJPEG2000', 'jp2_bit_rate_example.jp2',$
   /WRITE, BIT_RATE=[.02,.022,.032,.1])

; set the image data [256x256]
oJP2->SetData, DIST(256)

; this will release the object
OBJ_DESTROY, oJP2

; open the file we just created
oJP2=OBJ_NEW('IDLffJPEG2000', 'jp2_bit_rate_example.jp2')

; create a window to display the four layers
WINDOW, xsize=512, ysize=512

; get and display each layer
TV, oJP2->GetData(MAX_LAYERS=1), 0
TV, oJP2->GetData(MAX_LAYERS=2), 1
TV, oJP2->GetData(MAX_LAYERS=3), 2
TV, oJP2->GetData(MAX_LAYERS=4), 3

; this will close the file
OBJ_DESTROY, oJP2

END
```

Example Two

This example shows how to add a UUID box to a new JPEG2000 file and how to read a UUID box from an existing JPEG2000 file:

```
PRO JP2_UUid_EXAMPLE

; create a new jp2 file that we can write to
oJP2 = OBJ_NEW('idLFFJPEG2000', 'jp2_uuid_example.jp2', /WRITE)
```

```
; create a bogus id for the uuid box
id = BINDGEN(16)
id[*] = id[*] + 1

; create some data for the uuid box
data = BINDGEN(37)
data[*] = data[*] + 100

; add a new uuid box to the new jp2 file
oJP2->SetUUid, id, data

; set some image data
oJP2->Setdata, BYTARR(10,10, /NOZERO)

; close the file
OBJ_DESTROY, oJP2

; open the file we just created in read only mode
oJP2 = OBJ_NEW('idLffJPEG2000', 'jp2_uuid_example.jp2')

; ask the jp2 object for a list of uuids in the file
; this will return an array of 16 uuids eg..[1,16], [2,16]....
oJP2->GetProperty, UUIDS=uuid_list
HELP, uuid_list

; we get the data for the first uuid found in the file
data1 = oJP2->GetUUid(uuid_list[0,*], LEN=len)
PRINT, 'data len = ', STRTRIM(len,2), '   data =  ', data1

; this will cause the object to go away
OBJ_DESTROY, oJP2

END
```

The JPEG2000 Canvas Coordinate System

JPEG2000 uses the concept of the canvas to align multiple image components and tiles in a single coordinate system. This section explains the layout of image components and tiles within the canvas coordinate system.

Image Offsets and Image Subsampling

By default, images are placed on the canvas so that the image and canvas origins align. If an image offset is specified, the origin of all image components will be located at the specified *X* and *Y* offsets from the canvas origin.

Each image component can also be subsampled. The subsampling factors for a component indicate the scaling factor between the component dimensions and the

image dimensions. If an image has dimensions X_I by Y_I, and a component has subsampling factors X_S by Y_S, the dimensions of the component will be the ceiling of X_I/X_S by the ceiling of Y_I/Y_S. For example, suppose an image has an overall size of 512 by 384 samples. An image component that has subsampling factors of 2 by 2 will have dimensions 256 by 192 samples. Calling the GetData method to retrieve just this component will return a 256 by 192 array.

In the canvas coordinate system, the subsampling factors have been applied to each component so that the dimensions of all components are always equal.

Note

When reading a region within the image with the GetData method, the values passed to the REGION keyword ([*StartX*, *StartY*, *Width*, *Height*]) are measured in the canvas coordinate system. The *StartX* and *StartY* values are measured from the canvas origin, and the *Width* and *Height* values are measured after any subsampling has been applied to the image components. This allows a single set of *Width* and *Height* values to be used for every component.

Note

If all components in an image have subsampling factors of 1 by 1, the dimensions of each component will be equal to the value contained in the DIMENSIONS property. To calculate the dimensions of individual components when some components have subsamplings other than 1 by 1, the following code can be used:

```
object->GetProperty, DIMENSIONS = dimensions, $
   SUBSAMPLING = subsampling, N_COMPONENTS = n_components
comp_sizes = ULONARR(2, n_components)
FOR i = 0, n_components - 1 do $
   comp_sizes[*,i] = CEIL(FLOAT(dimensions) /
subsampling[*,i])
```

Tile Dimensions and Tile Offsets

By default, images will have one tile that has the same dimensions and offset on the canvas as the image. If the tile dimensions are smaller than the image dimensions and the tile offsets are different than the images offsets, some tiles may extend beyond the borders of the image.

The values returned via the TILE_DIMENSIONS and TILE_OFFSET keywords in the GetTileProperty method are the dimensions and location of the tile on the image itself, and not necessarily the dimensions and location on the canvas. To determine

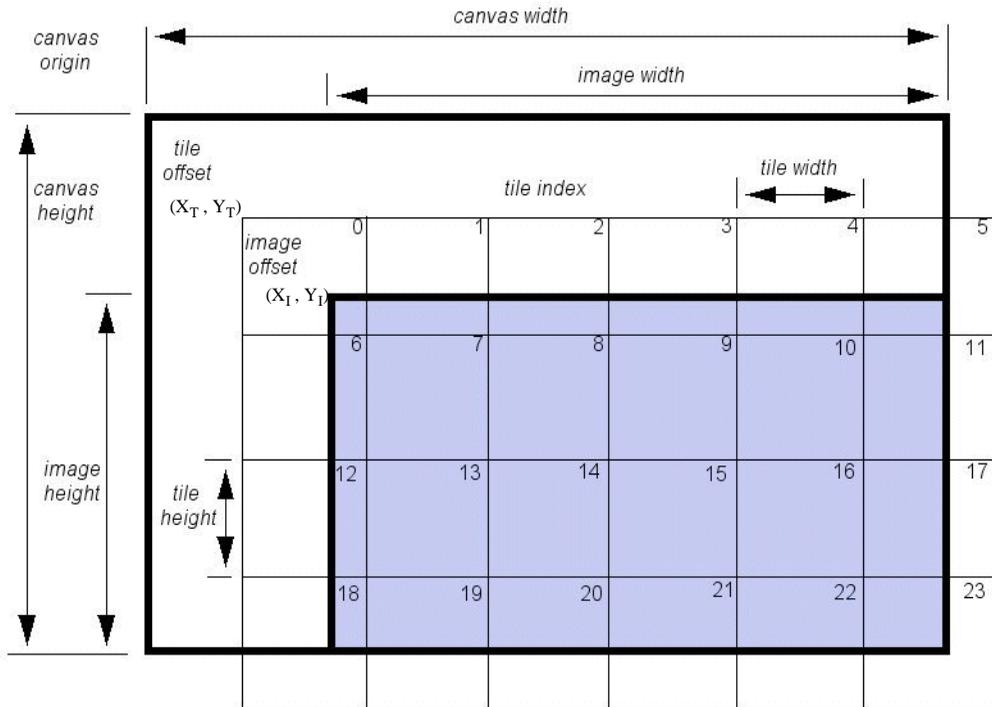
the overall dimensions of a tile, whether or not it falls outside the boundaries of the image, check the TILE_DIMENSIONS property with the GetProperty method.


Figure 30-1: Image Tile Dimensions and Offsets

Saving and Restoring IDLffJPEG2000 Objects

IDL does not save IDLffJPEG2000 objects in a SAVE file. If you restore a SAVE file that contains object references to IDLffJPEG2000 objects, the object references are restored, but are set to null object references. The IDLffJPEG2000 objects are not saved because they contain state information for the external JPEG2000 library. This state information is not available to IDL and cannot be restored.

It is recommended that applications complete any JPEG2000 operations before saving their data in a SAVE file.

IDLffJPEG2000 Properties

IDLffJPEG2000 objects have the following properties. Properties with the word "Yes" in the "Get" column of the property table can be retrieved via IDLffJPEG2000::GetProperty. Properties with the word "Yes" in the "Init" column of the property table can be set via IDLffJPEG2000::Init. Properties with the word "Yes" in the "Set" column in the property table can be set via IDLffJPEG2000::SetProperty.

Note
For more information about the "Property Type", "Name String", and "Registered" columns, see "About Object Property Descriptions" on page 3135.

Objects of this class have the following properties.

- BIT_DEPTH
- BIT_RATE
- COLOR_SPACE
- COMMENT
- DIMENSIONS
- DISPLAY_RESOLUTION
- FILENAME
- JP2
- N_LAYERS
- N_LEVELS

- N_COMPONENTS
- N_TILES
- OFFSET
- PALETTE
- PROGRESSION
- QUIET
- READ
- REVERSIBLE
- SIGNED
- SUBSAMPLING

- TILE_DIMENSIONS
- TILE_OFFSET
- TILE_RANGE
- UUIDS
- WRITE
- XML
- YCC

BIT_DEPTH

An integer vector containing the bit depth for each image component. Values must be in the range 1 ... 24.

Note
When writing out JPEG2000 files, the default BIT_DEPTH is 8 for all components, regardless of the data type supplied to SetData. If you are writing out short or long integer data, you may wish to set BIT_DEPTH to a larger value for those components.

Property Type	Integer Vector		
Name String	*not displayed*		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** No

BIT_RATE

A floating-point vector containing the bit rate for each layer, measured in bits per pixel per component (or band). The number of elements in BIT_RATE must be equal to the number of quality layers or, alternatively, may be two.

When writing files, the values in BIT_RATE may be given in any order, and will be automatically sorted into ascending order. A value of -1 anywhere within the BIT_RATE vector indicates that the highest quality layer should include all compressed bits. BIT_RATE may also be set to a two-element vector, in which case the rates will be approximately logarithmically spaced between the two values.

When the /REVERSIBLE switch is set the last rate will be automatically set to -1 to ensure that the last layer contains the bits needed to recreate the original image data.

When the number of rates being set exceeds the number of layers being set an error is thrown. The value in the N_LAYERS property must always be equal to or greater than the number of bit rates in the BIT_RATE property (unless the number of bit rates is two).

Property Type	Float Vector		
Name String	*not displayed*		
Get: No	**Set:** Yes	**Init:** Yes	**Registered:** No

COLOR_SPACE

A string containing one of the following values:

- sLUM - a luminance (monochrome) space.

- sRGB - the sRGB space is a reasonably good model for color imagery which has been corrected to look good on a monitor.

- sYCC - a three-component color space derived by applying the standard YCbCr color transform to sRGB data; the YCbCr transform is identical to

the irreversible color transform defined by JPEG2000 at the code stream level.

- iccLUM - a monochrome color space defined by an embedded ICC profile.

- iccRGB - an RGB color space defined by an embedded ICC profile.

- <Null string> - none of the above. A null string will result if the source is not a JP2 source.

Property Type	String		
Name String	*not displayed*		
Get: Yes	**Set:** No	**Init:** No	**Registered:** No

COMMENT

A string vector containing an element for each comment associated with the object. If the object has no associated comments, the result will be a scalar null string.

Property Type	String Vector		
Name String	*not displayed*		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** No

DIMENSIONS

A two-element 64-bit integer array giving the width and height of the image. Values for DIMENSIONS should be in the range $1 ... 2^{32}-1$.

Property Type	Integer Vector		
Name String	*not displayed*		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** No

DISPLAY_RESOLUTION

A two-element floating-point vector giving the default horizontal and vertical display resolution (in samples per meter). This property will return a value of [0.0, 0.0] if the file has no display resolution specified. This keyword is only valid for JP2 files.

Note ———

The JPEG2000 code stream stores the display resolution values using only 24 bits
of precision. When writing files, you may notice slight differences between your
input values and the values returned when reading the file.

———

Property Type	Float Vector		
Name String	*not displayed*		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** No

FILENAME

A string containing the name of the file associated with the object

Note ———

This property can only be set via the *Filename* argument to the
IDLffJPEG2000::Init method.

———

Property Type	String		
Name String	*not displayed*		
Get: Yes	**Set:** No	**Init:** No	**Registered:** No

JP2

A boolean value indicating whether the JPEG2000 file consists of only a codestream
(usually referred to as a .j2c file) or of a codestream and metadata information
(usually referred to as a .jp2 or .jpx file).

Note ———

This property can only be set when the IDLffJPEG2000 object is created.

———

When writing a JPEG2000 file (that is, when the WRITE property is set to 1):

- If the JP2 property is set to 1, the file created will contain a codestream and
  metadata (.jp2 file type), regardless of the file extension specified.

- If the JP2 property is set to 0, the file created will contain only a codestream
  (.j2c file type), regardless of the file extension specified.

- If the JP2 property is *not set* when the IDLffJPEG2000 object is created:

  - If the file extension specified is either `.jp2` or `.jpx`, the file created will contain both codestream an metadata (`.jp2` file type).

  - If the file extension is anything other than `.jp2` or `.jpx`, the file created will contain only the codestream (`.j2c` file type).

When reading a JPEG2000 file:

- The JP2 property will be set to 1 if the file contains both codestream and metadata.

- The JP2 property will be set to 0 if the file contains only the codestream.

Property Type	Boolean		
Name String	*not displayed*		
Get: Yes	**Set:** No	**Init:** Yes	**Registered:** No

N_COMPONENTS

An integer containing the number of image components (or channels) in the entire file or code stream. If N_COMPONENTS is not supplied in the first call to Init or SetProperty, it will be the same as the number of components contained in the image parameters in the first call to SetData.

Property Type	Integer		
Name String	*not displayed*		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** No

N_LAYERS

A positive integer specifying the number of quality layers. A quality layer is one quality increment for the entire image at full resolution. Each layer contains the information required to represent the image at a higher quality, given the information from all the previous layers. All image data bits may be encoded in one layer, or may be broken up into a larger number of layers each containing a further quality refinement.

When writing, the default is one. If N_LAYERS is greater than one, the layers will be assigned roughly logarithmically-spaced bit rates, with the last layer containing all of the compressed bits.

When setting N_LAYERS, the value is limited to 244

Property Type	Integer		
Name String	*not displayed*		
Get: Yes	Set: Yes	Init: Yes	Registered: No

N_LEVELS

An integer specifying the number of wavelet decomposition levels, or stages, in the range of 0...15.

When writing files, a value of zero indicates that no wavelet transform will be used. If this keyword is omitted, then the default value of 5 is used. When writing JP2 files, if the PALETTE property is set then the default is N_LEVELS=0.

Property Type	Integer		
Name String	*not displayed*		
Get: Yes	Set: Yes	Init: Yes	Registered: No

N_TILES

An integer specifying the number of tiles within the file.

Property Type	Integer		
Name String	*not displayed*		
Get: Yes	Set: No	Init: No	Registered: No

OFFSET

A two-element integer array giving the X and Y offsets of all image components. Values for OFFSET should be positive, in the range of a 32-bit integer $0 \ldots 2^{31}$-2 .

Property Type	Integer Vector		
Name String	*not displayed*		
Get: Yes	Set: Yes	Init: Yes	Registered: No

PALETTE

JP2 files may contain a "palette", or color table, which efficiently stores images with only a few distinct colors. The palette associates a color index with each distinct color present in the image. Images stored in JP2 files with a palette consist of only one component which contains the color indices.

When writing a JP2 file, set this property to a 3-by-*n* or an *n*-by-3 array of byte or integer values, where *n* is the number of intensity values, for the three color channels of red, green, and blue. In this case *n* must be a power of 2 and ≤ 256.

When reading JP2 files, this property will return an *n*-by-*m* array of byte or integer values, where *n* is the number of intensity values, and *m* is the number of lookup tables (*m* is usually 3, indicating red, green, and blue). If the associated object has no palette, this property will return a scalar zero.

Note ———

When writing JP2 files, if PALETTE is present, then the default values for other properties are N_LEVELS=0, REVERSIBLE=1, and YCC=0.

Property Type	Byte or Integer Array		
Name String	*not displayed*		
Get: Yes	Set: Yes	Init: Yes	Registered: No

PROGRESSION

A string defining the progression order of the output. Progression order may be one of the following: LRCP, RLCP, RPCL, PCRL, CPRL. The four character identifiers have the following interpretation: L = layer; R = resolution; C = component; P = position. Data is written to the output file iteratively over the four progression

identifiers in this string, that is, the output is written in four nested iteration levels. The first character in the identifier refers to the outermost level of the iteration, while the last refers to the innermost level. The default is LRCP. This property is ignored when used with files opened for reading.

For example, "LRCP" means that an image is encoded in the following order, with quality being the outermost loop:

- L - a series of one or more quality layers, each contributing a quality increment for the entire image at full resolution. The quality layers may be interpreted as sub-bitplanes containing the image data at a specified, possibly fractional, bit-rate.

- R - each resolution level of the image, which corresponds to the N_LEVELS keyword used in encoding, and can be considered to contain the image data at a given size or resolution. Each level adds another level of detail to the previous levels.

- C - each image component of the above.

- P - each position (tile) within the image component.

In this example, if an image consists of 2 quality layers, 5 resolution levels, 3 components, and 16 positions or tiles, the image would be encoded in a series of packets as follows:

```
P0C0R0L0, P1C0R0L0, P2C0R0L0, ..., P15C0R0L0
P0C1R0L0, P1C1R0L0, P2C1R0L0, ..., P15C1R0L0
P0C2R0L0, P1C2R0L0, P2C2R0L0, ..., P15C2R0L0
P0C0R1L0, P1C0R1L0, P2C0R1L0, ..., P15C0R1L0
P0C1R1L0, P1C1R1L0, P2C1R1L0, ..., P15C1R1L0
P0C2R1L0, P1C2R1L0, P2C2R1L0, ..., P15C2R1L0
... ... ...
... ... ...
... ... ...
P0C2R4L0, P1C2R4L0, P2C2R4L0, ..., P15C2R4L0

P0C0R0L1, P1C0R0L1, P2C0R0L1, ..., P15C0R0L1
P0C1R0L1, P1C1R0L1, P2C1R0L1, ..., P15C1R0L1
P0C2R0L1, P1C2R0L1, P2C2R0L1, ..., P15C2R0L1
```

This encodes all components over the entire image at a given quality level, before sending the next quality refinement.

When encoding a large image with a large number of components, memory requirements will be minimized by sending each component by means of a separate call to SetData, and by specifying a progression order of "CPRL".

Property Type	String		
Name String	*not displayed*		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** No

QUIET

A boolean that when set to a non-zero value suppresses the printing of warnings for this object. The default is not to suppress warnings.

Property Type	Boolean		
Name String	*not displayed*		
Get: No	**Set:** Yes	**Init:** Yes	**Registered:** No

READ

A boolean set to 1 if the file is to be accessed for reading. The default is to open the file for reading.

Property Type	Boolean		
Name String	*not displayed*		
Get: Yes	**Set:** No	**Init:** Yes	**Registered:** No

REVERSIBLE

A boolean that specifies the type of compression that should be used. A non-zero value indicates that reversible compression should be used. The default is to use irreversible compression. When writing JP2 files, if the PALETTE property is set then the default is REVERSIBLE=1.

Property Type	Boolean		
Name String	*not displayed*		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** No

SIGNED

An *n*-element boolean vector where *n* is the number of components. A value of one indicates pixels in that component are interpreted as signed numbers, otherwise the pixels are interpreted as unsigned numbers. The default is to interpret the numbers as unsigned.

Note ———

When writing out JPEG2000 files, the default is SIGNED=0 for all components, regardless of the data type supplied to SetData. If you are writing out signed integer data, you should set SIGNED to 1 for those components.

———

Property Type	Boolean Vector		
Name String	*not displayed*		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** No

SUBSAMPLING

A 2 by N_COMPONENTS integer array containing the subsampling factors in the horizontal and vertical dimensions for each image component. The dimensions of each component will be the ceiling of the image dimensions divided by the respective subsampling factor.

Property Type	Integer Array		
Name String	*not displayed*		
Get: Yes	**Set:** No	**Init:** No	**Registered:** No

TILE_DIMENSIONS

A 2-element integer vector defining the width and height of each tile. When writing files, the default is to write one tile with the same dimensions as the image parameter. Values for TILE_DIMENSIONS should be in the range $1 \ldots 2^{32}-1$.

Property Type	Integer Vector		
Name String	*not displayed*		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** No

TILE_OFFSET

A 2-element integer vector containing the X and Y offset of the first tile on the canvas.

When reading, the TILE_OFFSET will return the X and Y offset of the first tile. The GetTileProperty method may be used to retrieve the TILE_OFFSET for other tiles.

When writing, the default is TILE_OFFSET=[0,0]. The values of TILE_OFFSET must be less than or equal to the corresponding values of the OFFSET property. Values for TILE_OFFSET should be positive, in the range $0...2^3-2$.

Property Type	Integer Vector		
Name String	*not displayed*		
Get: Yes	Set: Yes	Init: Yes	Registered: No

TILE_RANGE

A two-element integer vector giving the number of tiles in the X and Y directions.

Property Type	Integer Vector		
Name String	*not displayed*		
Get: Yes	Set: No	Init: No	Registered: No

UUIDS

This property provides a mechanism to retrieve the Universally Unique Identifiers (UUIDs) for the UUID boxes in the JPEG2000 file.

A JPEG2000 file can contain 0-*n* number of UUID boxes. A UUID is a 16 byte value. Each UUID box is made up of a UUID field and a user data field. A UUID box allows the user to store application specific data inside a JPEG2000 file using a universally unique identifier.

The property returns one of the following:

- a scalar value of 0 when the file does not contain any UUID boxes

- a 16 x *n* byte array, where *n* is the number of UUIDs included. UUID boxes that exist in the file but do not contain any data are not included in the returned array.

For example, if the file contains 10 UUID boxes then this property returns a 16x10 byte array.

Property Type	Byte array		
Name String	*not displayed*		
Get: Yes	**Set:** No	**Init:** No	**Registered:** No

WRITE

A boolean that is 1 if the object is open for writing, 0 if not.

Property Type	Boolean		
Name String	*not displayed*		
Get: Yes	**Set:** No	**Init:** Yes	**Registered:** No

XML

A string vector, each element of which contains the contents for a corresponding XML box of the object. If the object has no XML boxes, the result will be a null string. This keyword is only valid for JP2 files.

Property Type	String Vector		
Name String	*not displayed*		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** No

YCC

When reading files, this property indicates whether the data was originally converted from the RGB color space to the YCC color space. If YCC is true, then when calling GetData, you may wish to return all three image components so that the YCC data can be correctly transformed back to RGB.

When writing files, set this property to a boolean which specifies whether RGB data should be converted to YCrCb before being written. If the image being written has three components, the default is to assume the image contains RGB components, which are automatically converted to YCrCb, and then written. The default action to convert RGB to YCC may be overridden by explicitly setting the YCC keyword to zero. When writing JP2 files, if the PALETTE property is set then the default is

YCC=0. If the image being written does not have three components, this property is ignored.

Transforming the color coordinates from RGB to YCC decorrelates the three color components and improves compression performance for RGB images. JPEG2000 readers will then convert back to RGB.

Note ───

For the RGB-to-YCC conversion to occur, all three components must be provided at the same time (either the entire image or as separate tiles). If the components are provided in separate calls to SetData, the YCC conversion is not performed.

───

Property Type	Boolean		
Name String	*not displayed*		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** No

IDLffJPEG2000::Cleanup

The IDLffJPEG2000::Cleanup procedure method performs all cleanup on the object.

Note ───

Cleanup methods are special life cycle methods, and as such cannot be called outside the context of object creation and destruction. This means that in most cases, you cannot call the Cleanup method directly. There is one exception to this rule: If you write your own subclass of this class, you can call the Cleanup method from within the Init or Cleanup method of the subclass.

───

Note ───

Calling OBJ_DESTROY will also close any files that have been opened for reading or writing.

───

Syntax

OBJ_DESTROY, *Obj*

or

Obj - > [IDLffJPEG2000::]Cleanup   *(In a lifecycle method only.)*

Arguments

None

Keywords

None

IDLffJPEG2000::GetData

The IDLffJPEG2000::GetData function method returns image data from the IDLffJPEG2000 object.

Syntax

Result = Obj->[IDLffJPEG2000::]GetData([, COMPONENT=*value*]
    [, DISCARD_LEVELS=*value*] [, MAX_LAYERS=*value*]
    [, N_COMPONENTS=*value*] [, ORDER=*value*] [, REGION=*value*] [, /RGB]
    [, TILE_INDEX=*value*])

Return Value

An array with two or three dimensions containing the image data from the object. Dimensions of the result are: [3, *Width*, *Height*] if the RGB keyword is set; or [*nComponents*, *Width*, *Height*] if the RGB keyword is not set. *nComponents* is the number of components present in the file. Images with only one component (which are read with RGB not set) return a two dimensional array [*Width*, *Height*].

The data type of the result is automatically determined using the bit-depth and signed properties of the returned components. For bit-depths ≤ 8 (or if RGB is set) the result will be of type byte. For bit-depths ≥ 9 and ≤ 16 the result will be of type integer or uint. For bit-depths > 16 the result will be long or ulong. Components with differing bit-depths will be returned using the largest bit-depth. Components which are a mix of signed and unsigned will be returned as signed.

Note

If the PERSISTENT keyword was set to zero when the object was created, the object may not be accessed after GetData is called, with the exception of the GetProperty and Cleanup methods.

Note

If the data in the file was transformed from RGB to YCC before saving, the library will only transform back from YCC to RGB if all three components are read in simultaneously. Reading in each component separately will return the data in the YCC space. The YCC property may be used to determine if the RGB-to-YCC conversion took place. If YCC is true, you may wish to avoid using the COMPONENT or N_COMPONENTS keywords.

Keywords

COMPONENT

Set this keyword to an integer giving the index of the component at which to start reading. The number of components to read may be specified using the N_COMPONENTS keyword. The default is COMPONENT=0.

DISCARD_LEVELS

Set this keyword to an integer that indicates the number of resolution levels to be discarded, starting with the highest resolution level (the full image).

For example, setting this keyword equal to 2 will discard the two highest resolution levels — that is, the full- and half-resolution images. The returned array will contain the quarter-resolution image.

The resulting image dimensions are given by:

```
CEIL((Dimensions + Offset)/(2^DL)) - CEIL(Offset/(2^DL))
```

where *Dimensions* and *Offset* are the image dimensions and offset, and *DL* is the value of DISCARD_LEVELS.

MAX_LAYERS

Set this keyword to the maximum number of quality layers which will appear to be present. A quality layer is one quality increment for the entire image at full resolution. Each layer contains the information required to represent the image at a higher quality, given the information from all the previous layers. All image data bits may be encoded in one layer, or may be broken up into a larger number of layers each containing a further quality refinement. A value of 0, the default, implies that all layers should be retained. For example, specifying MAX_LAYERS = 4 processes only the first four quality layers. The number of quality layers in a file may be determined by checking the value of the N_LAYERS property.

N_COMPONENTS

Set this keyword to an integer giving the number of components to read, starting at the component index given by the COMPONENT keyword. If neither COMPONENT nor N_COMPONENTS is specified then all components will be read. If COMPONENT is specified then the default is N_COMPONENTS=1.

ORDER

JPEG2000 images are assumed to be stored in top-to-bottom order, while IDL usually assumes images are in bottom-to-top order. By default (ORDER = 0), GetData will automatically flip the result to match IDL's bottom-to-top order. Setting ORDER to a nonzero value will return the JPEG2000 image without doing the vertical flip.

REGION

Set this keyword to a four-element vector containing the rectangular region of the image to read in the canvas coordinate system. The region is specified as [*StartX*, *StartY*, *Width*, *Height*]], where *StartX* and *StartY* must be in the range 0 ... 2^{32}-2, and *Width* and *Height* must be in the range 1 ... 2^{32}-1. The region must contain at least some portion of the image, or an error will occur. If the region is larger than the image, or extends outside of the image, then only that portion that lies within the image will be returned.

Note ———————————————————————————————————————

The region parameters should be specified in the canvas coordinate system, taking into account the canvas offset and canvas dimensions.

———

RGB

If this keyword is set, the data stream will be interpreted as RGB imagery and all details concerning color transformations (for example: sRGB, sLUM and sYCC), together with restricted ICC-profiles for specifying more general 3-color "RGB-like" spaces, plus indexed color with palettes, are handled automatically. If this keyword is set, the result of this function will always have three components, red, green, and blue; and the dimensions of the result will be [3, *Width*, *Height*].

The JPEG2000 standard allows a decorrelating color transformation to be applied to the first three image components. This transformation is identical or similar to the conventional YCbCr color transformation. To determine if this transform has been applied, examine the YCC keyword returned by the ::GetTileProperty method.

If RGB is set and the file contains more than three components, only the first three components are returned. If RGB is set and the file contains less than three components an error is issued.

If RGB is not set, and three components are transferred, and a color transformation has been applied to the input stream, the three components which are encoded in a form of YCC will automatically be converted to RGB. If it is desired to avoid this

conversion, then the user should transfer more or less than three components in the call or calls to GetData.

If RGB is not set and the number of components is not three, then each component in the data stream will be placed in the result without interpretation. Result will have dimensions: [N_COMPONENTS, *Width, Height*].

The RGB keyword may not be specified if the COMPONENT or N_COMPONENTS keywords are present.

TILE_INDEX

Set this keyword to an integer giving the tile index to read. If this keyword is specified then the REGION keyword is ignored.

Examples

This example illustrates the use of GetData to read an image a number of different ways:

```
;Create object, open file.
a = OBJ_NEW('IDLffJPEG2000', 'boat2.jp2')

;Read the entire image.
b = a->GetData()

;Read a 512x512 portion of the image, starting
;at column 100, row 200.
b = a->GetData(REGION = [100, 200, 512, 512])

;Read the portion of the above, but sub-sample it down by a
;factor of 2, returning an nComponents x 256 x 256 image.
b = a->GetData(REGION = [100, 200, 512, 512], DISCARD_LEVELS=1)

;Read only the 2nd component.
;The result will have two dimensions.
b = a->GetData(COMPONENT = 1)
```

Version History

6.1	Introduced

IDLffJPEG2000::GetProperty

The IDLffJPEG2000::GetProperty procedure method returns information describing the properties of an IDLffJPEG2000 object in the supplied variable - keyword pairs.

Syntax

Obj->[IDLffJPEG2000::]GetProperty [, *PROPERTY=variable*]

Arguments

None

Keywords

Any property listed under "IDLffJPEG2000 Properties" on page 3265 that contains the word "Yes" in the "Get" column of the properties table can be retrieved using this method. To retrieve the value of a property, specify the property name as a keyword set equal to a named variable that will contain the value of the property.

Version History

6.1	Introduced

IDLffJPEG2000::GetTileProperty

The IDLffJPEG2000::GetTileProperty procedure method returns information describing the properties of a tile in an IDLffJPEG2000 object in the supplied variable-keyword pairs. The object must be open for reading. An error is produced if the object is open for writing.

Syntax

Obj->[IDLffJPEG2000::]GetTileProperty [, TileIndex [, TileComponent]],
    [, N_LAYERS=*variable*] [, N_LEVELS=*variable*] [, PROGRESSION=*variable*]
    [, REVERSIBLE=*variable*] [, TILE_DIMENSIONS=*variable*]
    [, TILE_OFFSET=*variable*] [, YCC=*variable*]

Arguments

TileIndex

This argument specifies the index of the tile whose attributes are to be returned. JPEG2000 tiles are numbered in raster scan fashion, starting from 0 and going up to a maximum of 65535. The default value for this argument is 0.

TileComponent

This argument specifies the component index of the tile whose attributes are to be queried. Indices range from 0 to N_COMPONENTS-1. The default value for this argument is 0.

Keywords

N_LAYERS

Set this keyword to a named variable in which to return the number of quality layers available for the tile. If this keyword is set, the TileComponent argument is ignored.

N_LEVELS

Set this keyword to a named variable in which to return the total number of available resolution levels for this tile component.

PROGRESSION

Set this keyword to a named variable in which to return a string containing the progression order for that tile. The returned value will be one of: LRCP, RLCP, RPCL, PCRL, CPRL.

See "PROGRESSION" on page 3271 under Properties for the definition of these values.

REVERSIBLE

Set this keyword to a named variable in which to return 1 if the tile-component is compressed reversibly, 0 if irreversible.

TILE_DIMENSIONS

Set this keyword to a named variable in which to return a two-element vector containing the width and height of the tile, taking into account any clipping of the tile to the image.

TILE_OFFSET

Set this keyword to a named variable in which to return a two-element vector containing the horizontal and vertical offset of the tile, taking into account any clipping of the tile to the image.

YCC

Set this keyword to a named variable in which to return 1 if a component color transform was used for the first 3 components of the tile specified by the TileIndex argument, 0 otherwise.

Version History

6.1	Introduced

IDLffJPEG2000::GetUUID

The IDLffJPEG2000::GetUUID function method allows you to get the data field from the specified UUID box.

A JPEG2000 file can contain 0-*n* number of UUID boxes. Each UUID box in a JPEG2000 file is made up of a UUID field and a user data field. A UUID box allows the user to store application specific data inside a JPEG2000 file using a universally unique identifier.

Syntax

Data = *Obj*->[IDLffJPEG2000::]GetUUID(*UUID* [, LENGTH=*length*])

Return Value

Returns one of the following:

- • a scalar zero when the passed in UUID is not found in the file
- • a byte array containing the data found in the data field of the UUID box.
- • a scalar zero when the passed UUID is found in the file but does not contain any data (i.e. the data field is empty).

Arguments

UUID

The UUID argument is required. The UUID argument must be a 16 byte array.

Keywords

LENGTH

Length is an optional keyword. If present, the length variable will be set to the number of bytes in the returned data array. If present and the requested UUID is not found, length will be 0. If present and the requested UUID is found but does not contain any data (i.e. the data field is empty), the length will be -1.

Version History

6.2	Introduced

IDLffJPEG2000::Init

The IDLffJPEG2000::Init() function method initializes an IDLffJPEG2000 object that can be used to read (decode) image data from a JPEG2000 image file, or write (encode) image data to a JPEG2000 image file.

Note ───

Init methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation. This means that in most cases, you cannot call the Init method directly. There is one exception to this rule: If you write your own subclass of this class, you can call the Init method from within the Init method of the subclass.

──

Syntax

Obj = OBJ_NEW('IDLffJPEG2000' , *Filename* [, /PERSISTENT]
  [, PROPERTY = value])

or

Result = *Obj->*[IDLffJPEG2000::]Init(*Filename* [, /PERSISTENT]
  [, *PROPERTY = value*])   *(In a lifecycle method only.)*

Return Value

When this method is called indirectly, as part of the call to the OBJ_NEW function, the return value is an object reference to the newly-created object.

When called directly within a subclass Init method, the return value is 1 if initialization was successful, or zero otherwise.

Arguments

Filename

Set this argument to a scalar string containing the path and filename of a file containing JPEG 2000 compressed image data to be accessed through this object. If the file type suffix is .jp2 or .jpx, case insensitive, the file is a JP2 file. Otherwise the file contains a raw JPEG2000 code stream.

Note ────────

The value specified by the *Filename* argument is used to initialize the value of the FILENAME property of the IDLffJPEG2000 object.

Keywords

In addition to the following keyword, any property listed under "IDLffJPEG2000 Properties" on page 3265 that contains the word "Yes" in the "Init" column of the properties table can be initialized during object creation using this method. To initialize the value of a property, specify the property name as a keyword set equal to the appropriate property value.

PERSISTENT

A boolean value that indicates whether the image contained in the object may be accessed more than once. If set to zero, the image contained within the object may not be accessed more than once, and data are discarded whenever possible, minimizing memory usage. The default is PERSISTENT=1, which allows access to the image multiple times. This keyword is ignored if the file is opened for writing

Version History

6.1	Introduced

IDLffJPEG2000::SetData

The IDLffJPEG2000::SetData procedure method writes data to the IDLffJPEG2000 object.

Syntax

Obj->[IDLffJPEG2000::]SetData, *P_1, ..., P_n* [, COMPONENT=*value*] [, /ORDER] [, TILE_INDEX=*value*]

Arguments

P_1 ... P_n

Arguments may be one or more arrays containing the image components or tile components to be written to the JPEG2000 object. The arrays may have either two or three dimensions. Two-dimensional arrays contain one image or tile component with the dimensions of width and height. Three-dimensional arrays are dimensioned [*nComponents*, *width*, *height*]. All parameters must have the same width and height.

The array parameters are converted to byte data type if the bit-depth for the corresponding component is less than or equal to 8; to signed or unsigned integer, depending on the signed setting, for bit-depths from 9 - 16; and to signed or unsigned long integers, depending on the signed setting for bit-depths over 16.

Note ———

The bit depths used for output are determined from the BIT_DEPTH property, and not from the data type of the input arguments. If you are writing out short or long integer data, you should set the BIT_DEPTH property before calling SetData.

———

Note ———

The SIGNED property determines whether the data are written out using signed or unsigned integers, and is not affected by the data type of the input arguments. If you are writing out signed integer data, you may wish to set the SIGNED property before calling SetData.

———

Image Dimensions, Tile Dimensions, and Component Number

Images may be written using multiple calls to SetData with each call transferring one or more tile components. A tile component contains one image component for a given tile and is the smallest unit of data that can be supplied to SetData. The dimensions of the entire image and tiles, plus the number of components are

determined the first time they are specified to Init or SetProperty, and may not be changed once established. If the dimensions or number of components are not specified explicitly they are inferred from the image parameters supplied in the first call to SetData.

If transferring an image with multiple calls to SetData, try to supply the data to SetData in a manner consistent with the progression setting of PROGRESSION to ensure optimum performance and minimize memory requirements.

Note ───
If you do not complete writing all of the tiles or components, or your array dimensions are not the same as the overall image dimensions, then the library will be unable to complete the code stream. In this case, reading the data back in may result in unexpected or incorrect values.

───

Note ───
If the YCC property is set (indicating that you want the library to convert from RGB to YCC before compressing the data), then you must supply all three image components in the same call to SetData (either the entire image or one tile at a time). If the components are provided in separate calls to SetData, the YCC conversion is not performed.

───

Keywords

COMPONENT

Set this keyword to be the index of the first component to be written by this call to SetData. Default is 0.

ORDER

JPEG2000 images are assumed to be stored in top-to-bottom order, while IDL usually assumes images are in bottom-to-top order. By default (ORDER = 0), SetData will automatically flip the input arrays to match JPEG2000's top-to-bottom order. Setting ORDER to a nonzero value will save the image directly to the JPEG2000 file without doing the vertical flip.

TILE_INDEX

Set this keyword to specify the index of the first tile to be written. JPEG2000 tiles are numbered in raster scan fashion, starting from 0. The default value for this keyword is 0. The tile indices must range from 0 to one less than the number of tiles in the image file, which is determined by the tile dimensions and image dimensions.

Examples

Write a one-component image:

```
;Open file to write
jp2 = OBJ_NEW('IDLffJPEG2000', 'test.jp2', /WRITE)

;Write the image
jp2->SetData, BYTSCL(DIST(400,300))

OBJ_DESTROY, jp2
```

Read a one-component image:

```
;Open file to read
jp2_in = OBJ_NEW('IDLffJPEG2000', 'test.jp2')

img = jp2_in->GetData() ; Read the file.

OBJ_DESTROY, jp2_in
```

Write an indexed-color image with a palette:

```
;Load IDL color table #5, this example assumes we have 256 colors.
LOADCT, 5

;Read color tables
TVLCT, /GET, Red, Green, Blue

;Open file to write
jp2 = OBJ_NEW('IDLffJPEG2000', 'test.jp2', /WRITE, /JP2, $
   PALETTE=[[Red], [Green], [Blue]])

;Write the image with the palette
jp2->SetData, BYTSCL(DIST(400,300))
OBJ_DESTROY, jp2
```

Read the above image and palette:

```
;Open file to read
jp2_in = OBJ_NEW('IDLffJPEG2000', 'test.jp2')

jp2_in->GetProperty, PALETTE=palette

;Read without RGB keyword. img is a 400 by 300 byte image.
img = jp2_in->GetData()

;With the RGB keyword, the image is now [3, 400, 300]
img3d = jp2_in->GetData(/RGB)

OBJ_DESTROY, jp2_in
```

Show the images:

```
TVLCT, palette[*, 0], palette [*, 1], palette[*, 2]
DEVICE, DECOMPOSED = 0
TV, img
DEVICE, DECOMPOSED = 1
TV, img3d, TRUE=1
```

Write a 100 component file, one component at a time:

```
j2k = OBJ_NEW('IDLffJPEG2000', 'test.j2k', /WRITE, $
   N_COMPONENTS=100)
FOR i = 0, 99 DO j2k_in->SetData, $
   replicate(byte(i), 200, 300), COMPONENT = i
OBJ_DESTROY, j2k_in
```

Read the above file:

```
j2k_in = obj_new('IDLffJPEG2000', 'test.j2k')

;b is a [200, 300] array
b = j2k_in->GetData(COMPONENT=30)

;b is a [5, 200, 300] array
b = j2k_in->GetData(COMPONENT=50, N_COMPONENT = 5)

OBJ_DESTROY, j2k_in
```

Version History

6.1	Introduced

IDLffJPEG2000::SetProperty

This procedure sets the properties of an object that is open for writing. This method may not be called on files opened for reading.

Syntax

Obj->[IDLffJPEG2000::]SetProperty [, *PROPERTY=value*]

Arguments

None.

Keywords

Any property listed under "IDLffJPEG2000 Properties" on page 3265 that contains the word "Yes" in the "Set" column of the properties table can be set using this method. To set the value of a property, specify the property name as a keyword set equal to the appropriate property value.

Version History

6.1	Introduced

IDLffJPEG2000::SetUUID

The IDLffJPEG2000::SetUUID procedure method allows you to add UUID boxes when creating a new JPEG2000 file. This method can only be called when the JPEG2000 object was created with the WRITE property set. Each call to SetUUID will add a new *uuid box* to the JPEG2000 file.

A JPEG2000 file can contain zero or more uuid boxes. Each uuid box is made up of a uuid field and a user data field. A uuid box allows the user to store application specific data inside a JPEG2000 file using a universally unique identifier. User data is not compressed when the file is written.

Syntax

Obj->[IDLffJPEG2000::] SetUUID, *uuid*, *Data*

Arguments

uuid

The *uuid* argument must be a 16 byte array. If *uuid* passed in already has been used in a previous SetUUID call, an error is issued. The *uuid* is written into the uuid field of the new uuid box.

Data

The *Data* argument must be an array. The array can be of any type and any length. SetUUID treats the array as a stream of bytes. The stream of bytes are written into the data field of the new uuid box.

Keywords

None

Version History

6.2	Introduced

IDLffLangCat

The IDLffLangCat class is used to find and load an XML language catalog. A language catalog is composed of key names and key values. The key value of the specified key name can be retrieved to support internationalization. For example:

```
<KEY NAME='Menu:File:Open'>Open...</KEY>
```

in an English language catalog would appear as the following in a French language catalog:

```
<KEY NAME='Menu:File:Open'>Ouvrir...</KEY>
```

By handling files that contain keys and values like these, the IDLffLangCat class supports internationalization of user interfaces and other applications that need to display the same strings in more than one language.

The language catalogs included with IDL are in the `<IDL_DIR>/resource/langcat` directory and end in a `.cat` extension. You can use other catalogs, but all catalogs must end with the `.cat` extension.

Note ──
The IDLffLangCat class supports catalog files written in 8-bit strings (which can be encoded for languages using special marks; see below). Also, you must have the corresponding fonts installed on your machine before you can use a particular language.
──

A language-catalog file can support accent marks such as those in French (which stray from the first 128 character codes defined by ASCII into the ISO-8859 encodings) if you do one of the following actions:

- Add `encoding='ISO8859-1'` to the XML tag element at the beginning of the file (e.g., `<xml version='1.0' encoding='ISO8859-1'?>`)

- Save the XML file as Unicode

In general, you should use the encoding appropriate for your catalog's language. For the list of supported encodings and for more general information about XML, see "About XML" (Chapter 20, *Application Programming*).

Note ──
For more information on this class, including examples of how to use it, see "Using Language Catalogs" in the *Building IDL Applications* manual.

For a discussion of the property description tables shown below, see "About Object Property Descriptions" on page 3135.

───

Objects of this class have the following properties.

- APP_NAME
- APP_PATH
- AVAILABLE_LANGUAGES
- DEFAULT_KEYS
- DEFAULT_LANGUAGE
- DEFAULT_N_KEYS
- FILENAME
- KEYS
- LANGUAGE
- N_KEYS
- VERBOSE

APP_NAME

The name of one or more current applications, returned in alphabetical order.

Property Type	String or string array		
Name String	*not displayed*		
Get: Yes	**Set:** No	**Init:** Yes	**Registered:** No

APP_PATH

The directory or directories searched for each given application. Each directory path must be fully qualified and unambiguous (e.g., C:\ITT\IDL*xx*\lib\itools).

Property Type	String or string array		
Name String	*not displayed*		
Get: Yes	**Set:** No	**Init:** Yes	**Registered:** No

AVAILABLE_LANGUAGES

A list of all languages that exist in the input file or files. When APP_NAME is specified, this property returns all languages where the language-catalog files have the same internal application name. The languages return in alphabetical order.

Property Type	String or string array		
Name String	*not displayed*		
Get: Yes	**Set:** No	**Init:** No	**Registered:** No

DEFAULT_KEYS

A list of all the currently loaded keys in the default language.

Property Type	String or string array		
Name String	*not displayed*		
Get: Yes	**Set:** No	**Init:** No	**Registered:** No

DEFAULT_LANGUAGE

The current default language.

Property Type	String		
Name String	*not displayed*		
Get: Yes	**Set:** No	**Init:** Yes	**Registered:** No

DEFAULT_N_KEYS

The number of currently loaded keys in the default language.

Property Type	Long		
Name String	*not displayed*		
Get: Yes	**Set:** No	**Init:** No	**Registered:** No

FILENAME

The name of each currently loaded language catalog (`.cat`) file. In setting this property, each name is either a fully qualified path (e.g., `C:\ITT\IDLxx\resource\langcat`) to a location containing a file, or the name of a file in the current directory.In getting this property, it always returns the full path.

Property Type	String or string array		
Name String	*not displayed*		
Get: Yes	**Set:** No	**Init:** Yes	**Registered:** No

KEYS

A list of all the currently loaded keys, returned in upper-case.

Property Type	String or string array		
Name String	*not displayed*		
Get: Yes	**Set:** No	**Init:** No	**Registered:** No

LANGUAGE

The current language.

Property Type	String		
Name String	*not displayed*		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** No

N_KEYS

The number of currently loaded keys.

Property Type	Long		
Name String	*not displayed*		
Get: Yes	**Set:** No	**Init:** No	**Registered:** No

VERBOSE

The current setting of the verbose flag. If set, all catalog-loading messages will be sent to the output window. This list contains details resulting from an IDLffLangCat object initialization or modification, including the names and numbers of keys loaded, keys overwritten, and so on.

Property Type	Byte		
Name String	*not displayed*		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** No

IDLffLangCat::AppendCatalog

The IDLffLangCat::AppendCatalog function method adds keys from a file or files to those used to build the language catalog. All valid keys present in the current language will be inserted into the current key/value list. If any new languages are present in the new files, they will be added to the AVAILABLE_LANGUAGES property. If a duplicate key name is found, its value will replace the existing key name's value.

Note ⎯⎯

Whenever the object encounters a key (or language) that already exists, the key (or language) is overwritten with the new value.

⎯⎯⎯

Syntax

Result = Obj->[IDLffLangCat::]AppendCatalog([, APP_NAME=*applicationName*] [, FILENAME=*filename*] [, APP_PATH=*applicationPath*])

Return Value

Returns 1 if valid keys were found and loaded, or 0 otherwise.

Arguments

None

Keywords

APP_NAME

Set this keyword to a string or string array containing the name of each desired application for which to add keys. If APP_NAME is specified, it overrides any input to FILENAME. You can use the '*' wild card (e.g., 'MyApp*' instead of ['MyAppMenu', 'MyAppErrors', …]). You must provide either APP_NAME or FILENAME.

APP_PATH

Set this keyword to a string or string array containing the name of each directory in which to search for the given application's keys. Each path must be fully qualified

(e.g., C:\ITT\IDL*xx*\lib\itools). This keyword is ignored if APP_NAME is not specified.

FILENAME

Set this keyword to a string or string array containing the name of each language-catalog file to load. If APP_NAME is specified, it overrides any input to FILENAME. Each string is either a fully qualified path (e.g., C:\ITT\IDL*xx*\resource\langcat) to a location containing a file, or the name of a file in the current directory. You must provide either APP_NAME or FILENAME.

Version History

6.1	Introduced

IDLffLangCat::Cleanup

The IDLffLangCat::Cleanup procedure method performs all cleanup operations on the language catalog object, and should be called by the Cleanup method of a subclass.

Note

Cleanup methods are special life cycle methods, and as such cannot be called outside the context of object creation and destruction. This means that in most cases, you cannot call the Cleanup method directly. There is one exception to this rule: If you write your own subclass of this class, you can call the Cleanup method from within the Init or Cleanup method of the subclass.

Syntax

OBJ_DESTROY, *Obj*

or

Obj->[IDLffLangCat::]Cleanup   *(In a lifecycle method only.)*

Arguments

None

Keywords

None

Version History

6.1	Introduced

IDLffLangCat::GetProperty

The IDLffLangCat::GetProperty procedure method retrieves a property or group of properties for an IDLffLangCat object.

Comparisons such as those done with IDLffLangCat::Query are case insensitive, but the values returned by GetProperty are exactly as the last encountered value. For example, if File 1 has LANGUAGE='English' and File 2 has LANGUAGE='engLISh', then 'engLISh' will be returned, although only one ENGLISH language exists in the current catalog.

Syntax

Obj->[IDLffLangCat::]GetProperty [, *PROPERTY=variable*]

Arguments

None

Keywords

Any property listed under "IDLffLangCat Properties" on page 3299 that contains the word "Yes" in the "Get" column of the properties table can be retrieved using this method. To retrieve the value of a property, specify the property name as a keyword set equal to a named variable that will contain the value of the property.

Version History

6.1	Introduced

IDLffLangCat::Init

The IDLffLangCat::Init function method initializes an IDLffLangCat object.

Note

Init methods are special life cycle methods, and as such cannot be called outside the context of object creation. This means that in most cases, you cannot call the Init method directly. There is one exception to this rule: If you write your own subclass of this class, you can call the Init method from within the Init method of the subclass.

Any invalid input will result in a failure to create a valid object. Invalid input includes the following cases:

- The requested language is not found in any of the input files

- Any application in APP_NAME is not found

- Any file in FILENAME is not found

- Any directory in APP_PATH does not exist

- The requested default language is not found

You can set the VERBOSE keyword to view the output log for a detailed description of the creation (or failure) of the object. You can also set CONTINUE_ON_ERROR to override the failure behavior if you have the language specified, regardless of the language's existence.

Syntax

Obj = OBJ_NEW('IDLffLangCat', *Language* [, *PROPERTY=value*]
    [, /CONTINUE_ON_ERROR])

or

Result = *Obj*->[IDLffLangCat::]Init(*Language* [, *PROPERTY=value*]
    [, /CONTINUE_ON_ERROR])   *(In a lifecycle method only.)*

Return Value

Returns the new object if successful or a null object otherwise if initialized with OBJ_NEW, or returns 1 if successful or 0 otherwise if called from a subclass's Init method.

Arguments

Language

A string containing the name of the language to load from the catalog.

Keywords

Any property listed under "IDLffLangCat Properties" on page 3299 that contains the word "Yes" in the "Init" column of the properties table can be initialized during object creation using this method. To initialize the value of a property, specify the property name as a keyword set equal to the appropriate property value.

You must specify either APP_NAME or FILENAME for this method. If APP_NAME is specified, it overrides any input to FILENAME.

CONTINUE_ON_ERROR

If set, the object will be created as long as the language is specified, regardless of the validity of any of the input parameters. If not set, the object will not be created if any input is invalid. If a language is not specified or is specified incorrectly (e.g., as a multiple element array), the object will not be created, and an error will be thrown, regardless of the value of this keyword.

Version History

6.1	Introduced

IDLffLangCat::Query

The IDLffLangCat::Query function method returns the string or string array that corresponds to all supplied key values.

Syntax

Result = Obj->[IDLffLangCat::]Query(*Key* [, DEFAULT_STRING=*string*])

Return Value

Returns a string or string array that corresponds to all supplied key values. If no key can be found, then the default string or, if no default string is supplied, a null string is returned.

Arguments

Key

A string or string array used as the key or keys against which the query is performed. If a given key does not exist in the current language, the default language is queried (if one exists).

Keywords

DEFAULT_STRING

Set this keyword to a string or string array to be used if the key is not found in the catalog. If a scalar string is supplied, it will be returned for all keys not found. For example, if DEFAULT_STRING is "Key not found," this string is returned for each failed query on a key or keys. If a string array is supplied, only those values whose indices match the missing keys will be returned. That is, you can have different default strings for different cases of failed query matches (e.g., "No File key found" and "No Tools key found" returned, respectively, for failed queries on keys associated with a File menu and a Tools menu).

Version History

6.1	Introduced

IDLffLangCat::SetProperty

The IDLffLangCat::SetProperty procedure method sets the value of a property or group of properties for an IDLffLangCat object.

Syntax

Obj->[IDLffLangCat::]SetProperty [, *PROPERTY=variable*]

Arguments

None

Keywords

Any property listed under "IDLffLangCat Properties" on page 3299 that contains the word "Yes" in the "Set" column of the properties table can be set using this method. To set the value of a property, specify the property name as a keyword set equal to the appropriate property value.

Version History

6.1	Introduced

IDLffMJPEG2000

The IDLffMJPEG2000 object provides the ability to read and write Motion JPEG2000 (MJ2) files. Motion JPEG2000, like JPEG2000, uses the Discrete Wavelet Transform (DWT) to compress files. This lossless compression option permits retrieval of the original data. With lossy compression, original data is lost during compression and cannot be recovered. DWT is an excellent compression scheme for continuous tone images such as geospatial and medical imagery.

A Motion JPEG2000 (MJ2) file contains a series of frames, each of which is an independent JPEG2000 image. An MJ2 animation displays a timed sequence of frames and uses *intra-frame* coding, which means each frame is an independent entity. In contrast, MPEG files typically use *inter-frame* encoding (motion estimation)—each frame is dependent on the previous frames. Because of the intra-frame encoding, MJ2 files can support lossless compression and permit random access to individual frames. These features make the Motion JPEG2000 file format ideal for scientific applications.

Each frame of an MJ2 file (like a JPEG2000 image) may consist of one or more components (color or data bands), tiles, or regions. Using the IDLffMJPEG2000 object, you can play an animation consisting of frames, components, tiles or regions and can create a file containing frames, components, and tiles. Additionally, you can specify the number of levels (image resolutions) and quality layers when creating or playing back an MJ2 file

An IDLffMJPEG2000 object permits reading or writing an MJ2 file (based on the WRITE property value). However, the same IDLffMJPEG2000 object cannot be used to both write and read an MJ2 file. You can write a file with one object (where WRITE=1), but you must create a separate object (where WRITE=0, the default) in order to read or play the new MJ2 file.

Note ——
The rate at which the IDLffMJPEG2000 object can compress or decompress frames is affected by the contents of the individual frames being compressed or decompressed and by the processing speed of your system. The amount of compression is dependent on the contents of the frames being compressed.
——

About Processing Threads

Internally, several IDLffMJPEG2000 methods make use of background processing threads that allow the user interface to stay more responsive while MJ2 file data is being compressed (written) or decompressed (read). On a dual processor or

multiprocessor machine the UI thread (of the main IDL process) and the background thread will typically run on separate processors allowing higher compression and decompression throughput. These threads are described in each method where appropriate.

Reading MJ2 Files

You can read or play a sequence of frames, components, tiles or regions contained in an existing MJ2 file or you can randomly access individual elements. Additionally, any element may be returned at a specified resolution (level) or quality (layer). For details on how to use the IDLffMJPEG2000 object to read MJ2 files see "Playing a Motion JPEG2000 Animation" (Chapter 6, *Using IDL*).

Tip ——————————————————————————————————

You can view monochrome and RGB animations in the pre-built IDL Motion JPEG2000 Player. This example code, `mj2_player.pro`, and a sample image, `idl_mjpeg2000_example.mj2`, are located in the `IDL_DIR\examples\mjpeg2000` directory where `IDL_DIR` is the directory where you have installed IDL. If you have an MJPEG2000 codec installed, you can also play animations in other media players including the Windows Media Player.

——

Playback will occur as fast as the frames can be decompressed unless you implement some type of timer mechanism. See "Controlling the Playback Rate" (Chapter 6, *Using IDL*) for details.

Writing MJ2 Files

You can write (create) an MJ2 file that consists of frames, components and tiles, which contain the desired number of quality levels. An MJ2 file can store multiple related or non-related images (frames) as long as each frame has the same dimensions and same number of components. Files can be written in a lossless or lossy format depending on the value of the REVERSIBLE property.

The source of frame data for the animation can be existing images, generated images, or snapshots of an IDLgrWindow display. Regardless of the source, use the SetData method to write the data to the file, and the Commit method to close the processing thread once all of the frames have been added to the animation.

For an example that adds a series of IDLgrWindow screen captures to an MJ2 file, see the `mj2_writer_rgb.pro` example described below.

Depending on how you pass in data, you may need to set several properties prior to the first call to SetData in order to create the expected MJ2 file. For details on how to

use the IDLffMJPEG2000 object to write MJ2 files, see "Creating a Motion JPEG2000 Animation" (Chapter 6, *Using IDL*).

Tip ───

You can use the example IDL Motion JPEG2000 Writer, `mj2_writer_rgb.pro`, as a template for creating an MJ2 animation. This example is located in the `IDL_DIR\examples\mjpeg2000` directory where `IDL_DIR` is the directory where you have installed IDL. Running the example creates a new MJ2 file, which is written to your application user directory, a subdirectory of your home directory.

───

Note ──

The IDLffMJPEG2000 object supports reading and writing Motion JPEG2000 files stored in a progressive format. See the SCAN_MODE property for details.

───

Superclasses

None

Creation

See IDLffMJPEG2000::Init.

Properties

Objects of this class have the following properties. See "IDLffMJPEG2000 Properties" on page 3317 for details on individual properties.

- BIT_DEPTH
- BIT_RATE
- COLOR_SPACE
- COMMENT
- CURRENT_FRAME
- DIMENSIONS
- DURATION
- FILENAME
- FRAME_BUFFER_LENGTH
- N_LEVELS
- N_TILES
- PALETTE
- PROGRESSION
- REVERSIBLE
- SCAN_MODE
- SIGNED
- STATE
- TILE_DIMENSIONS

- FRAMES_IN_BUFFER
- FRAME_PERIOD
- N_COMPONENTS
- N_FRAMES
- N_LAYERS

- TIMESCALE
- WRITE
- XML
- YCC

Methods

This class has the following methods:

IDLffMJPEG2000::Cleanup

IDLffMJPEG2000::Commit

IDLffMJPEG2000::GetData

IDLffMJPEG2000::GetProperty

IDLffMJPEG2000::GetSequentialData

IDLffMJPEG2000::Init

IDLffMJPEG2000::ReleaseSequentialData

IDLffMJPEG2000::SetData

IDLffMJPEG2000::SetProperty

IDLffMJPEG2000::StartSequentialReading

IDLffMJPEG2000::StopSequentialReading

Examples

The following simple example adds slices of data from an MRI of a human head to an MJ2 file to create a short animation. Each SetData call adds a single slice of data, resulting in an animation consisting of 57 frames.

Note

For additional examples, see "Animations" (Chapter 6, *Using IDL*).

```
PRO mj2_simple_write_read

; Read image data, which contains 57 slices.
nFrames = 57
head = READ_BINARY( FILEPATH('head.dat', $
```

```
      SUBDIRECTORY=['examples','data']), $
      DATA_DIMS=[80,100, 57])

   ; Enter new name for MJ2 file or select existing file
   ; to be overwritten.
   file = DIALOG_PICKFILE(DEFAULT_EXTENSION="mj2", $
      TITLE="Enter Name for File")

   ; Create an IDLffMJPEG2000 object.
   oMJ2write=OBJ_NEW('IDLffMJPEG2000', file, /WRITE, /REVERSIBLE)

   ; Write the data of each frame into the MJ2 file.
   FOR i=0, nFrames-1 DO BEGIN
      data = head[*,*,i]
      result = oMJ2write->SetData(data)
   ENDFOR

   ; Commit and close the IDLffMJPEG2000 object.
   return = oMJ2write->Commit(10000)
   OBJ_DESTROY, oMJ2write

   ; Create a new IDLffMJPEG2000 object to read the MJ2 file.
   oMJ2read=OBJ_NEW("IDLffMJPEG2000", file)
   oMJ2read->GetProperty,N_FRAMES=nFrames, DIMENSIONS=dims

   ; Create a window and display simple animation.
   WINDOW, 0, XSIZE=2*dims[0], YSIZE=2*dims[1]

   FOR i=0, nFrames-1 DO BEGIN
      ; Return data and display magnified version. Use WAIT to
      ; pause between each frame for visibility. Unless a timer
      ; is used in conjunction with the FRAME_PERIOD and
      ; TIMESCALE properties, the default playback rate will be
      ; as fast as the frames can be decompressed.
      data = oMJ2read->GetData(i)
      TVSCL, CONGRID(data, 2*dims[0], 2*dims[1])
      WAIT, 0.1
   ENDFOR

   ; Cleanup.
   OBJ_DESTROY, oMJ2read

   End
```

IDLffMJPEG2000 Properties

IDLffMJPEG2000 objects have the following properties in addition to properties inherited from any superclasses. Properties with the word "Yes" in the "Get" column of the property table can be retrieved via IDLffMJPEG2000::GetProperty. Properties with the word "Yes" in the "Init" column of the property table can be set via IDLffMJPEG2000::Init. Properties with the word "Yes" in the "Set" column in the property table can be set via IDLffMJPEG2000::SetProperty.

Note
For a discussion of the property description tables shown below, see "About Object Property Descriptions" on page 3135.

Objects of this class have the following properties:

- BIT_DEPTH
- BIT_RATE
- COLOR_SPACE
- COMMENT
- CURRENT_FRAME
- DIMENSIONS
- DURATION
- FILENAME
- FRAME_BUFFER_LENGTH
- FRAMES_IN_BUFFER
- FRAME_PERIOD
- N_COMPONENTS
- N_FRAMES
- N_LAYERS
- N_LEVELS
- N_TILES
- PALETTE
- PROGRESSION
- REVERSIBLE
- SCAN_MODE
- SIGNED
- STATE
- TILE_DIMENSIONS
- TIMESCALE
- WRITE
- XML
- YCC

BIT_DEPTH

An integer value between 1 and 24 that indicates the bit depth of a file component. All components in the file must have the same bit depth. For example, RGB frames have a bit depth of 8 bits, so this property would be set to 8.

This property must be set prior to the first call to IDLffMJPEG2000::SetData. The
default value is 8 bits.

Note ───
When writing a MJPEG2000 file, the default BIT_DEPTH is 8 regardless of the
data type supplied to SetData. If you are writing out short or long integer data, you
must set BIT_DEPTH to the correct value for the data type.
───

Property Type	Integer		
Name String	*not displayed*		
Get: Yes	Set: Yes	Init: Yes	Registered: No

Note ───
You can set this property only for an MJ2 file that is open for writing (WRITE=1).
───

BIT_RATE

A floating-point vector specifying the bit rate for each layer. The BIT_RATE vector,
if set, is used by the compression engine when writing files to control the size of each
layer. The compression engine will compress each layer into the number of bytes
calculated from the bit rate for the layer. If the bit rate is not set, the compression
engine automatically calculates the number of bytes that will be used to store a layer.

The number of vector elements must be equal to one of the following:

- The number of quality layers (the N_LAYERS property value) — each vector
  element applies to one quality layer. The values may be given in any order and
  will be automatically sorted into ascending order.

- Two elements — the bit rates applied to each quality layer will be
  approximately logarithmically spaced between the two vector values.

A value of -1 anywhere within the BIT_RATE vector indicates that the highest
quality layer should include all compressed bits. When the REVERSIBLE property is
true, the last rate will be automatically set to -1 to ensure that the last layer contains
the bits needed to recreate the original frame data.

An error will be thrown if the number of vector elements exceeds the number of
layers. The value in the N_LAYERS property must always be equal to or greater than

the number of vector elements in the BIT_RATE property (unless there are two elements).

Property Type	Integer		
Name String	*not displayed*		
Get: No	**Set:** Yes	**Init:** Yes	**Registered:** No

COLOR_SPACE

A string identifying the color space of the MJ2 file. Allowable values are:

Value	Description
sLUM	The luminance (monochrome) space.
sRGB	The red, green, blue color space — a reasonably good model for color imagery which has been corrected for display on a monitor.
sYCC	A three-component color space derived by applying the standard YCbCr color transform to RGB data — the YCbCr transform is identical to the irreversible color transform defined by JPEG2000 at the code stream level.
	This property can be set to sYCC when you are writing RGB data and the YCC property is set to 1 (true).
	Note - Some players and codecs expect this COLOR_SPACE property to be set to sRGB even when the frames were compressed using YCC.

When writing a file, this property must be set prior to the first call to IDLffMJPEG2000::SetData in order to take effect. A value set to this property before calling SetData is always honored. If you do not set this property before calling SetData, the property value will be automatically set based on the dimensions of the data passed to SetData as follows:

SetData Data Characteristics	Resulting COLOR_SPACE
Number of frame components equals 3	sRGB
PALETTE property has been set	
Number of frame components not equal to 3	sLUM

Note

If you are writing 3-band monochrome data, you must set COLOR_SPACE to sLUM prior to the first call to SetData.

Property Type	String		
Name String	*not displayed*		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** No

COMMENT

A string providing a descriptive comment for the MJ2 file. When writing a file, this property must be set prior to the first call to IDLffMJPEG2000::SetData. The maximum length is 65,534 characters.

Property Type	String		
Name String	*not displayed*		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** No

CURRENT_FRAME

A long value that contains the frame number of the last frame compressed (in a file open for writing) or decompressed (in a file open for reading).

Property Type	Long		
Name String	*not displayed*		
Get: Yes	**Set:** No	**Init:** No	**Registered:** No

DIMENSIONS

A two element array giving the dimensions [*width*, *height*] of a frame.

In a file that is open for writing (WRITE=1), this property must be set prior to the first call to IDLffMJPEG2000::SetData in order to take effect. If you call SetData

before specifying this property, the DIMENSIONS property value will be automatically set based on the dimensions of the data passed to SetData.

Property Type	Long		
Name String	*not displayed*		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** No

Regardless of whether the DIMENSIONS property is set before the first call to SetData or is set by default based on data dimensions, each subsequent data array must have dimensions identical to that which has been set in order to avoid a SetData error.

DURATION

A floating-point value that returns the length of a movie in seconds. When reading an MJ2 file, this property comes from the file. When writing an MJ2 file, this property is automatically calculated and set in the MJ2 file based on the number of frames written and the TIMESCALE property value.

Property Type	Float		
Name String	*not displayed*		
Get: Yes	**Set:** No	**Init:** No	**Registered:** No

FILENAME

A string that specifies the full path and name of the file associated with the MJ2 file being read or written. The property can only be set as the *Filename* argument during IDLffMJPEG2000 object creation. See the IDLffMJPEG2000::Init method for details.

Property Type	String		
Name String	*not displayed*		
Get: Yes	**Set:** No	**Init:** No	**Registered:** No

FRAME_BUFFER_LENGTH

A long value that specifies the number of frames that can be held in the frame buffer when doing a sequential playback or when writing an MJ2 file. This property is used by the background read or write processing thread. You can change this property

value to enable high speed MJ2 file playback and creation as described in "High Speed MJ2 Reading and Writing" (Chapter 6, *Using IDL*).

This property must be set prior to calling IDLffMJPEG2000::StartSequentialReading when reading a file, or prior to the first call to IDLffMJPEG2000::SetData when writing a file. If this property is not set then the default value of 3 is used.

Property Type	Long		
Name String	*not displayed*		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** No

FRAMES_IN_BUFFER

A long value that returns the number of frames in the read or write frame buffer. When sequentially reading an MJ2 file, this property indicates the number of decompressed frames currently available in the frame buffer. When writing an MJ2 file, this property indicates the number of frames in the write frame buffer waiting to be compressed by the processing thread.

Property Type	Long		
Name String	*not displayed*		
Get: Yes	**Set:** No	**Init:** No	**Registered:** No

FRAME_PERIOD

A long value indicating the duration of a frame in ticks, which in conjunction with the TIMESCALE property, determines the playback rate. See "Computing Playback Rate" on page 3323 for details.

When this property is set, it is applied to the current frame and every subsequent frame in an MJ2 file unless it is overridden by the IDLffMJPEG2000::SetData FRAME_PERIOD keyword. When retrieving this property, it returns the frame period of the first frame in the file (when a file is first opened for reading) or the frame period of the current frame that is being read or written.

MJ2 players will typically attempt to playback the frames using the FRAME_PERIOD property. However, the actual playback rate may be slower than the desired rate if it exceeds the rate at which the MJ2 player can actually decompress and display frames.

The default FRAME_PERIOD value is 1000.

Property Type	Long		
Name String	*not displayed*		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** No

Note ────────────────────────────────

You should always append the value you set with "L" to ensure it is interpreted as a long value. For example, use FRAME_PERIOD=2000L.

──

Computing Playback Rate

To compute the playback rate, divide the FRAME_PERIOD value by the TIMESCALE property value. Take 1 (frame) over this value (seconds per frame) to get the number of frames per second. For example, the default FRAME_PERIOD (1000) and TIMESCALE (30,000) translate into a playback rate of approximately 30 frames per second:

$$\frac{1000\text{ticks}}{1\text{frame}} \times \frac{1\text{s}}{30000\text{ticks}} = 0.033\text{s/frame}$$

$$\frac{1\text{frame}}{0.033\text{s/frame}} \approx 30\text{frames/s}$$

Leaving the TIMESCALE property value unchanged, you can change the FRAME_PERIOD rate to control playback speed. A smaller FRAME_PERIOD rate speeds up playback; a larger FRAME_PERIOD rate slows playback.

Note ────────────────────────────────

See "Controlling the Playback Rate" (Chapter 6, *Using IDL*) for details and examples.

──

N_COMPONENTS

A long value that indicates the number of components (also known as bands or channels) in a frame.

When writing a file, this property must be set prior to the first call to IDLffMJPEG2000::SetData in order to take effect. If you call SetData before

specifying this property, the N_COMPONENTS property value will be automatically set based on the number of components in the first frame of data passed to SetData.

Property Type	Long		
Name String	*not displayed*		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** No

N_FRAMES

A long value that returns the number of frames in the file. This is either the total number of frames (in a file that is being read), or the number of frames added to the file prior to requesting this property (in a file that is being written).

Property Type	Long		
Name String	*not displayed*		
Get: Yes	**Set:** No	**Init:** No	**Registered:** No

N_LAYERS

A long value that indicates the number of quality layers used to build each frame. Possible values range from 1 to 244. Each layer contains the information required to represent the frame at a higher quality, given the information from all the previous layers. When a frame has more than one layer, the previous layers are used to build the frame at the requested layer value.

When writing an MJ2 file:

- If N_LAYERS is greater than one and the BIT_RATE property is not set, the layers will be assigned roughly logarithmically-spaced bit rates

- If N_LAYERS is greater than one and the BIT_RATE property has been set, the BIT_RATE property vector governs the number of bytes allocated to each layer

- If the REVERSIBLE property is true, then the last layer, in conjunction with the previous layers (if there are any), will produce a lossless frame

Suppose you have specified 3 layers. The first layer will undergo the greatest compression and be of the lowest quality. Successive layers will be less compressed and contain more clarity. If the REVERSIBLE property is set, the last layer will be equivalent to the original data.

This property must be set prior to the first call to IDLffMJPEG2000::SetData to take effect. If it is not set before calling SetData, the property will be set to the default value, 1. The largest possible value is 244.

Property Type	Long		
Name String	*not displayed*		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** No

Note

When you are playing an MJ2 animation, you can set the MAX_LAYERS keyword to IDLffMJPEG2000::StartSequentialReading or IDLffMJPEG2000::GetData to control what quality layers will be displayed.

N_LEVELS

An integer that specifies the number of wavelet decomposition (resolution) levels, or stages, in the range of 0...15 where a value of zero indicates no wavelet transform (the full resolution image). For instance, if you have a 1024 by 1024 pixel image, the resolution of each successive level is half of the width and height of the preceding one:

level 0	1024 by 1024
level 1	512 by 512
level 2	256 by 256

Tip

This level/resolution scheme is similar to image pyramids. See "Image Pyramids" (Chapter 4, *Object Programming*) for a visual representation.

If this property is not set prior to the first call to IDLffMJPEG2000::SetData then this property will be automatically set to the default value. If the PALETTE property has been set, the default value is 0. Otherwise, the default value is 5.

Property Type	Long		
Name String	*not displayed*		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** No

Note ──

When you are playing an MJ2 animation, you can set the DISCARD_LEVELS keyword to IDLffMJPEG2000::StartSequentialReading or IDLffMJPEG2000::GetData to control what level of data will be displayed.

──

N_TILES

A long value that returns the number of tiles in a component.

Property Type	Long		
Name String	*not displayed*		
Get: Yes	**Set:** No	**Init:** No	**Registered:** No

PALETTE

A byte or integer array that specifies the red, green, and blue values of the color lookup table to be associated with the color indices found in the frame. An MJ2 file that contains a palette (also known as a color table) stores frames that have only a single component consisting of the color indices.

If reading a file that contains a palette, this property will return an *n*-by-*m* array of byte or integer values, where *n* is the number of intensity values, and *m* is the number of lookup tables (*m* is usually 3, indicating red, green, and blue). If the file does not have a palette, this property will return a scalar zero.

When writing an MJ2 file, set this property to a 3-by-*n* or an *n*-by-3 array of byte or integer values, where *n* is the number of intensity values for the three color channels of red, green, and blue. The value *n* must be a power of 2 and ≤ 256.

This property must be set prior to the first call to IDLffMJPEG2000::SetData if it is to be used.

Note ──

The default values of several properties depend upon the presence of a palette. When a palette is specified, N_LEVELS=0, REVERSIBLE=1, and YCC=0 are set by default.

──

Property Type	Byte or integer array		
Name String	*not displayed*		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** No

PROGRESSION

A string defining the progression order. Progression order may be LRCP, RLCP, RPCL, PCRL, or CPRL where the progression identifiers are L = layer, R = resolution, C = component, and P = position. The four progression identifiers have the following interpretations:

Value	Meaning
L	Layer — a series of one or more quality layers, each contributing a quality increment for the entire frame at full resolution. The quality layers may be interpreted as sub-bitplanes containing the frame data at a specified, possibly fractional, bit-rate.
R	Resolution — each resolution level of a frame, which corresponds to the N_LEVELS keyword used in encoding, and can be considered to contain the frame data at a given size or resolution. Each level adds another level of detail to the previous levels.
C	Component — each frame component of the above.
P	Position — each position (tile) within the frame component.

Data is written to the output file iteratively over the four progression identifiers in this property string—that is, the output is written in four nested iteration levels. The first character refers to the outermost level of the iteration, while the last refers to the innermost level. For example, "LRCP" means that an image is encoded as shown in the preceding table, with quality being the outermost loop.

In the following PCRL example, if a frame consists of 2 quality layers, 5 resolution levels, 3 components, and 16 positions or tiles, the frame would be encoded in a series of packets as follows:

```
P0C0R0L0, P1C0R0L0, P2C0R0L0, ..., P15C0R0L0
P0C1R0L0, P1C1R0L0, P2C1R0L0, ..., P15C1R0L0
P0C2R0L0, P1C2R0L0, P2C2R0L0, ..., P15C2R0L0
P0C0R1L0, P1C0R1L0, P2C0R1L0, ..., P15C0R1L0
P0C1R1L0, P1C1R1L0, P2C1R1L0, ..., P15C1R1L0
```

```
P0C2R1L0, P1C2R1L0, P2C2R1L0, ..., P15C2R1L0
... ... ...
... ... ...
... ... ...
P0C2R4L0, P1C2R4L0, P2C2R4L0, ..., P15C2R4L0

P0C0R0L1, P1C0R0L1, P2C0R0L1, ..., P15C0R0L1
P0C1R0L1, P1C1R0L1, P2C1R0L1, ..., P15C1R0L1
P0C2R0L1, P1C2R0L1, P2C2R0L1, ..., P15C2R0L1
```

This encodes all components over the entire frame at a given quality level before sending the next quality refinement.

Note

When encoding a large frame with a large number of components, memory requirements will be minimized by sending each component by means of a separate call to SetData, and by using a progression order of CPRL.

Note

When writing frames with multiple components and the number of layers is greater than one, the progression order can be set to RPCL, PCRL, CPRL. The LRCP and RLCP progression orders are not usable in this case.

This property is ignored when MJ2 files are being read. The default value is LRCP.

Property Type	String		
Name String	*not displayed*		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** No

REVERSIBLE

A Boolean value that specifies whether or not you can get the original JP2 data from an MJ2 frame as follows:

0	Frames are irreversible (lossy). The default.
1	Frames are reversible (lossless).

Typically, it will be faster to compress and decompress lossy frames, but this is dependent upon image content.

To create reversible (lossless) frames, you must set this property to 1 prior to the first call to IDLffMJPEG2000::SetData. If the PALETTE property is set, this property is

automatically set to 1 (reversible, lossless frames). If you have not set the PALETTE property, and you call SetData before setting this property, it will be set to the default value, 0 (irreversible, lossy frames).

Property Type	Boolean		
Name String	*not displayed*		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** No

SCAN_MODE

A long value that returns whether a frame is stored in a progressive format or in an interlaced format.

Note

The IDLffMJPEG2000 object only supports the progressive format—this object can only read and write MJ2 files in the progressive format.

In the progressive format, all the rows are returned or set in one call. In the interlaced format (not supported), the even rows are returned in one call and the odd rows are returned in the next call. Possible values are:

0	Progressive (supported)
1	Interlaced with the top row first (not supported)
2	Interlaced with the bottom row first (not supported)

The default value is 0 and cannot be set.

Property Type	Long		
Name String	*not displayed*		
Get: Yes	**Set:** No	**Init:** No	**Registered:** No

SIGNED

A long value that indicates whether the frame data is signed or unsigned as follows:

0	Unsigned frame data (the default)
1	Signed frame data

If IDLffMJPEG2000::SetData is called before setting this property, it will be set to the default value, 0.

Property Type	Long		
Name String	*not displayed*		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** No

STATE

A long value that returns whether or not a background read or write processing thread is currently running. Possible values are:

0	Background thread is idle
Non-zero	Background thread is running

Property Type	Long		
Name String	*not displayed*		
Get: Yes	**Set:** No	**Init:** No	**Registered:** No

TILE_DIMENSIONS

A two-element vector indicating the [*width*, *height*] of each tile. If a frame component contains only one tile, this property will be automatically set to the DIMENSIONS of the frame.

When writing frame component(s) with more than one tile, this property must be set prior to the first call to IDLffMJPEG2000::SetData.

Property Type	Long vector		
Name String	*not displayed*		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** No

TIMESCALE

This property indicates the number of ticks in a second. This property, in conjunction with the FRAME_PERIOD period property, controls the playback rate. See "Computing Playback Rate" on page 3323 for details.

The default value is 30,000.

Property Type	Long		
Name String	*not displayed*		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** No

WRITE

A Boolean value that indicates whether a file is open for reading or writing as follows:

0	File is read-only (the default)
1	File is open for writing

This property can only be set during initialization (see IDLffMJPEG2000::Init) or retrieved.

Property Type	Boolean		
Name String	*not displayed*		
Get: Yes	**Set:** No	**Init:** Yes	**Registered:** No

XML

A string value containing XML data that is associated with an MJ2 file. When an MJ2 file is being created, call this property with a string value to add the corresponding XML to the MJ2 file. This property can be set multiple times. Each time it is set, the corresponding string will be added to a separate XML box.

When reading an MJ2 file, if the file does not contain any XML, the property will return an empty string. If the file contains a single XML box, the property will return a single string containing the entire contents of the XML box. If the file contains multiple XML boxes, the property will return an array of strings, each containing the contents of an entire XML box.

Property Type	String		
Name String	*not displayed*		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** No

YCC

A Boolean value indicating whether a frame (that consists of 3 components) has or
should undergo conversion from the RGB to the YCC Luminance-Chrominance
color space as follows:

- **When reading a file**:

0 (false)	Data was not originally converted from the RGB color space to the YCC color space.
1 (true)	Data was converted from the RGB color space to the YCC color space. Consider returning all three frame components when calling IDLffMJPEG2000::GetData or IDLffMJPEG2000::StartSequentialReading so that the YCC data can be correctly transformed back to the RGB color space.

- **When writing a file**:

0 (false)	Data should not be converted from the RGB color space to the YCC color space. When a PALETTE has been specified, YCC is automatically set to 0.
1 (true)	Convert RGB data to YCrCb. This is the default for a frame that has 3 components. The RGB components are automatically converted to YCrCb, and then written. **Note -** For the RGB-to-YCC conversion to occur, all three components must be provided at the same time. If the components are provided in separate calls to IDLffMJPEG2000::SetData, the YCC conversion is not performed.

Note

The default action that converts RGB to YCC when writing a file may be
overridden by explicitly setting YCC to zero.

If the frame being written does not have three components, this property is ignored.

Transforming the color coordinates from RGB to YCC decorrelates the three color components and improves both compression and decompression performance for RGB frames. MJPEG2000 readers will then convert frame data back to RGB. The default value is 1 except as noted above.

Property Type	Boolean		
Name String	*not displayed*		
Get: Yes	**Set:** Yes	**Init:** Yes	**Registered:** No

IDLffMJPEG2000::Cleanup

The IDLffMJPEG2000::Cleanup procedure method performs all cleanup operations on the Motion JPEG2000 object, and should be called by the Cleanup method of a subclass.

Note —————————————————————————————————————

Cleanup methods are special life cycle methods, and as such cannot be called outside the context of object destruction. This means that in most cases, you cannot call the Cleanup method directly. There is one exception to this rule: If you write your own subclass of this class, you can call the Cleanup method from within the Cleanup method of the subclass.

Syntax

OBJ_DESTROY, *Obj*

or

Obj->[IDLffMJPEG2000::]Cleanup   *(In a lifecycle method only.)*

Arguments

None

Keywords

None

Version History

6.3	Introduced

IDLffMJPEG2000::Commit

The IDLffMJPEG2000::Commit method shuts down the background processing thread and closes the MJ2 file that is being written. Although the MJ2 file does exist on disk, it cannot be accessed until this method successfully returns.

Note

The same IDLffMJPEG2000 object cannot be used to both write and read an MJ2 file. You can write a file with one object (where WRITE=1), but you must create a separate object (where WRITE=0, the default) in order to play the new MJ2 file.

The *Wait* argument provides time for the processing thread to finish compressing any images queued in the write frame buffer. The Commit call will return when the frame buffer is empty or when the wait period expires.

Tip

The FRAMES_IN_BUFFER property can be used to determine the current number of frames in the frame buffer.

When writing frames on a component-by-component basis or tile-by-tile basis, the frame must be completed prior to calling Commit. If the last frame being written is not complete (does not have all the needed components and or tiles to make a complete frame) when Commit is called, the method will throw an error and the file will not be closed. This method will throw an error if the commit fails. A CATCH statement can be used to trap these errors.

Syntax

Result = Obj->[IDLffMJPEG2000::]Commit(*Wait*)

Return Value

The return value indicates the state of the MJ2 file when it was committed to disk:

0	Failure. The file is not usable.
1	Success. The file has been created with all available frames in the frame buffer.
2	Wait period expired before the frame buffer was empty. The file has been created but may not contain all the frames passed in via the IDLffMJPEG2000::SetData method.

Arguments

Wait

A long, positive value specifying the number of milliseconds to wait for the frame buffer to become empty. For example, set the *Wait* argument to 10,000 in order to wait up to 10 seconds for the background processing thread to finish compressing all the remaining frames in the frame buffer before the Commit method is called. Regardless of the *Wait* argument, the Commit method will return as soon as the frame buffer is empty. If the wait period expires before all of the frames in the frame buffer can be compressed, the return value will be 2.

Keywords

None

Version History

6.3	Introduced

IDLffMJPEG2000::GetData

The IDLffMJPEG::GetData function method returns data for a specified frame (or component, tile or region of a frame) from an MJ2 file. This method does not return until the requested data has been decompressed. It will throw an error if the decompression fails. A CATCH statement can be used to trap such an error.

To playback a large number of frames in a sequential manner, consider using the StartSequentialReading method, which includes a built-in background processing thread for file decompression. See "Sequential Motion JPEG2000 Playback" (Chapter 6, *Using IDL*), which describes using the StartSequentialReading, GetSequentialData, ReleaseSequentialData and StopSequentialReading methods with a timer mechanism to create a sequential playback.

Note ──
You can use the WAIT procedure, a widget timer, or a IDLitWindow timer mechanism to control the rate at which random frames are retrieved if needed.
───

Note ──
If PERSISTENT = 0 (*the default*) when the IDLffMJPEG2000 object was created, only one GetData call can be made per frame when reading individual components, tiles or regions. PERSISTENT must be set on Init in order to access tiled data.
───

Syntax

Result = Obj->[IDLffMJPEG2000::]GetData(*FrameNumber*
   [, COMPONENT=*value*] [, DISCARD_LEVELS=*value*]
   [, MAX_LAYERS=*value*] [, N_COMPONENTS=*value*] [, /ORDER]
   [, REGION=*value*] [, /RGB] [, TILE_INDEX=*value*])

Return Value

Returns a two- or three-dimensional array containing the frame data that corresponds to the specified frame number. The exact dimensions are based on keyword values:

Keyword	Condition and Result
RGB	**Set**—array dimensions are [3, *width*, *height*].
	Not set—array dimensions are [*nComponents*, *width*, *height*] where *nComponents*, the number of bands or channels of data, depends on the COMPONENT and N_COMPONENTS keyword settings.
	If COMPONENT is not set, *nComponents* equals the number of components in the frame.
	If a starting COMPONENT is set, *nComponents* equals the number of components requested in N_COMPONENTS unless the frame has only one component. In this case the array dimensions are [*width*, *height*]. If a starting COMPONENT is set, but N_COMPONENTS is not set, *nComponents* equals all available components from the starting component.
REGION	If set, the array *width* and *height* are determined by the *width* and *height* values in the 4-element REGION vector [*startX*, *startY*, *width*, *height*].
TILE_INDEX	If set, the array *width* and *height* equal the dimensions of a single tile, defined in the TILE_DIMENSIONS property value.

The data type of the result is automatically determined using the BIT_DEPTH and SIGNED properties of the returned components as follows;

Data Properties	Result
BIT_DEPTH ≤ 8 or RGB is set	Byte
BIT_DEPTH ≥9 or ≤16	Integer or unsigned integer
BIT_DEPTH >16	Long or unsigned long

Note

All components in the MJ2 file must have the same bit depth and be either signed or unsigned. Components with different bit depths or a mixture of signed and unsigned data are not supported.

Arguments

FrameNumber

A long value specifying the number of the frame from which data is to be retrieved. Allowable values range from 0 to the total number of frames (the N_FRAMES property value) - 1.

Keywords

COMPONENT

An integer value indicating the zero-based index number of the first component to be returned. The total number of components returned depends upon this keyword and the value of N_COMPONENTS as follows:

- This keyword is set and N_COMPONENTS is not set — returns all the components from the starting COMPONENT

- This keyword is set and N_COMPONENTS is set — returns the number of components specified by N_COMPONENTS from the starting COMPONENT

If this keyword is not set, all the components are returned. The default is 0.

DISCARD_LEVELS

An integer value specifying the number of resolution levels to be excluded from the result starting with the highest resolution level. For example, given a full-resolution frame that is 1024 by 1024 pixels:

Value	Description
0	The default. No data is discarded.
1	Discard 1 level, the highest resolution data (e.g. discard the 1024 by 1024 level, leaving the 512 by 512 data).
2	Discard 2 levels of data (e.g. discard the 1024 by 1024 and 512 by 512 levels, leaving the 256 by 256 data).

Determine the number of resolution levels by checking the N_LEVELS property.

MAX_LAYERS

An integer value specifying the maximum number of quality layers to be read. Each layer contains the information required to represent the image at a higher quality, given the information from all the previous layers. A value of 0, the default, means all available layers should be returned. If MAX_LAYERS is 3, data from the first, second and third quality layers will be combined in the returned data. Determine the number of quality layers in a file by checking the value of the N_LAYERS property.

N_COMPONENTS

An integer value specifying the number of components to return from the starting component specified by the COMPONENT keyword. If this keyword is set, but COMPONENT is not set, the default COMPONENT value (0) will be used.

ORDER

An integer value specifying the order in which to return data. Motion JPEG2000 frames are assumed to be stored in top-to-bottom order, while IDL usually assumes frames are in bottom-to-top order. By default (ORDER= 0), this method will automatically flip the result to match IDL's bottom-to-top order. Setting ORDER to a nonzero value will return the Motion JPEG2000 frames without doing the vertical flip.

REGION

A four-element long vector containing the rectangular region of the frame to read. The region is specified as [*startX*, *startY*, *width*, *height*], where *startX* and *startY* must be in the range 0 ... 2^{32}-2, and *width* and *height* must be in the range 1 ... 2^{32}-1. The region must contain at least some portion of the frame, or an error will occur. If the region is larger than the frame, or extends beyond the frame, only the portion that lies within the frame will be returned.This keyword, in combination with the COMPONENT keyword, lets you access any region from a particular component.

RGB

If set, the resulting data stream will be interpreted as RGB frames. The returned array will always have three components (red, green, and blue) with the dimensions [3, *width*, *height*]. See the following table for information on what data will be read if fewer than or more than 3 components are specified, or if the keyword is not set.

Note

The Motion JPEG2000 standard allows a decorrelating color transformation to be applied to the first three image components. This transformation is identical or similar to the conventional YCbCr color transformation. To determine if this transform has been applied, examine the YCC property.

RGB Set?	Number of Components	Outcome
Yes	More than 3	Only the first three components are returned.
	Less than 3	An error is thrown.

RGB Set?	Number of Components	Outcome
No	3	If a color transformation has been applied to the input stream, the three components, which are encoded as YCC, will automatically be converted to RGB. To avoid this conversion you must transfer more than or fewer than three components when using GetData.
	Not equal to 3	Each component in the data stream will be placed in the result without interpretation. Result will have dimensions: [N_COMPONENTS, *width*, *height*].

You cannot specify RGB and COMPONENT or N_COMPONENTS at the same time. An error will be thrown in such cases.

TILE_INDEX

An integer value specifying the index of the tile to return. Tiles are numbered in raster scan fashion (from left to right starting at the top-left corner) starting with 0. This keyword, in combination with the COMPONENT keyword, lets you access any tile from a particular component. When this keyword is set, the REGION keyword is ignored.

Version History

6.3	Introduced

IDLffMJPEG2000::GetProperty

The IDLffMJPEG2000::GetProperty procedure method retrieves a property or group of properties for an IDLffMJPEG2000 object.

Syntax

Obj->[IDLffMJPEG2000::]GetProperty [, *PROPERTY=variable*]

Arguments

None

Keywords

Any property listed under "IDLffMJPEG2000 Properties" on page 3317 that contains the word "Yes" in the "Get" column of the properties table can be retrieved using this method. To retrieve the value of a property, specify the property name as a keyword set equal to a named variable that will contain the value of the property.

Version History

6.3	Introduced

IDLffMJPEG2000::GetSequentialData

The IDLffMPEG::GetSequentialData function method returns the frame index number and retrieves the associated frame data from the frame buffer. The StartSequentialReading method, which loads data into the frame buffer, must be called before calling this method.

The StartSequentialReading, GetSequentialData, ReleaseSequentialData and StopSequentialReading methods are used with a timer mechanism to create a sequential playback as described in "Sequential Motion JPEG2000 Playback" (Chapter 6, *Using IDL*).

Note
Always use a widget timer or IDLitWindow timer mechanism to control the playback rate. Avoid using the WAIT procedure with sequential playback methods as the interaction between the procedure and the background processing thread will cause adverse side effects on UNIX platforms.

This method will throw an error if retrieval fails. A CATCH statement can be used to trap these errors.

Syntax

Result = Obj->[IDLffMJPEG2000::]GetSequentialData(*Data*
   [, FRAME_NUMBER=*variable*] [, FRAME_PERIOD=value] [, STEP=*value*])

Return Value

If frame data is available in the frame buffer, the method returns a long value indicating the frame buffer index value. This index value is then used by the ReleaseSequentialData call to release the frame.

If no frame data is available, the return index value is -1. This indicates data is being read faster than it is being decompressed. See "High Speed Sequential Playback" (Chapter 6, *Using IDL*) for ways to avoid this problem.

Arguments

Data

If data is available, the *Data* variable will contain a two- or three-dimensional array associated with the returned frame index value. This data is essentially a pointer to a

slot in the frame buffer, and *not* a copy of the frame data. You should not attempt to modify this data as it is automatically freed when the ReleaseSequentialData method is called.

The array dimensions depend upon IDLffMJPEG2000::StartSequentialReading method keywords as follows:

Keyword	Result
RGB	**RGB is set**—array dimensions are [3, *width*, *height*].
	RGB is not set—array dimensions are [*nComponents*, *width*, *height*] where *nComponents*, the number of bands or channels of data, depends on the COMPONENT and N_COMPONENTS keyword settings.
	If a starting COMPONENT is set, *nComponents* equals the value specified in N_COMPONENTS unless N_COMPONENTS=1. In this case the array dimensions are [*Width*, *Height*].
	If a starting COMPONENT is set, but N_COMPONENTS is not set, *nComponents* equals all available components from the starting component.
	If a starting COMPONENT is not set, then *nComponents* equals all available components.
REGION	**REGION is set**—the array *width* and *height* are determined by the *width* and *height* values in the 4-element REGION vector [*startX*, *startY*, *width*, *height*].
TILE_INDEX	**TILE_INDEX is set**—the array *width* and *height* values equal the dimensions of a single tile, as defined in the TILE_DIMENSIONS property.

The data type of the result is automatically determined using the BIT_DEPTH and SIGNED properties of the returned components as follows:

Data Properties	Result
BIT_DEPTH ≤ 8 or RGB is set	Byte
BIT_DEPTH ≥9 or ≤16	Integer or unsigned integer
BIT_DEPTH >16	Long or unsigned long

Note ───

All components in the MJ2 file must have the same bit depth and be either signed or unsigned. Components with different bit depths or a mixture of signed and unsigned data are not supported.

───

Keywords

FRAME_NUMBER

A variable that will contain the long frame number of the frame that GetSequentialData is currently accessing.

FRAME_PERIOD

A long value specifying the duration of a frame in ticks. Each frame in an MJ2 file can have a unique frame period, which lets you display individual frames for different lengths of time. The FRAME_PERIOD acts in conjunction with the TIMESCALE property to determine the playback rate. See "Computing Playback Rate" on page 3323 for details.

STEP

A long value indicating the number of frames to skip when retrieving frames from the frame buffer as follows:

Value	Description
0	Reads the next sequential frame (the default)
Positive value	Indicates the number of frames to skip when reading frames in the forward direction
Negative value	Indicates the number of frames to skip when reading frames in the reverse direction

Note

This keyword is intended to be used for manually stepping through frames when sequential playback is paused. This keyword should not be used to skip frames during continuous playback.

If the STEP value results in a frame request that is beyond the range of values defined by IDLffMJPEG2000::StartSequentialReading START_FRAME and STOP_FRAME keywords, the request will wrap to return the appropriate frame.

Examples

The following simple program uses the four sequential playback methods: StartSequentialReading, GetSequentialData, ReleaseSequentialData and StopSequentialReading to display a sample MJ2 animation.

Note

In this example, the playback speed is equal to the frame rate calculated for the first frame. A more sophisticated example would handle varying frame rates. See "Controlling the Playback Rate" (Chapter 6, *Using IDL*) for more information and an additional example.

Example Code

This example mj2_simple_sequential_doc.pro, is located in the examples/doc/objects subdirectory of the IDL distribution. Run the example procedure by entering mj2_simple_sequential_doc at the IDL command prompt or view the file in an IDL Editor window by entering .EDIT mj2_simple_sequential_doc.pro.

Version History

6.3	Introduced

IDLffMJPEG2000::Init

The IDLffMJPEG::Init method initializes an IDLffMJPEG2000 object. When WRITE is not set or set equal to 0 (the default), the newly created Motion JPEG2000 object can be used to read (decode) frame data from a Motion JPEG2000 (MJ2) frame file. When WRITE is set or equal to one, the object can be used to create (encode) frame data to a Motion JPEG2000 file.

Note ──

When reading an MJ2 file that contains tiled data, you must set the PERSISTENT keyword to true in order to access tiles of data from an MJ2 file.

──

Syntax

Obj = OBJ_NEW('IDLffMJPEG2000', *Filename* [, /PERSISTENT]
   [, *PROPERTY=value*])

or

Result = Obj->[IDLffMJPEG2000::]Init(*Filename* [, /PERSISTENT]
   [, *PROPERTY=value*])   *(In a lifecycle method only.)*

Return Value

When this method is called indirectly, as part of the call to the OBJ_NEW function, the return value is an object reference to the newly-created object.

When called directly within a subclass Init method, the return value is 1 if initialization was successful, or zero otherwise.

Arguments

Filename

A string value that specifies the full path and name of the file associated with the MJ2 file being read or written, based on the WRITE property value as follows:

WRITE = 0	The file is opened for reading and cannot be modified.
WRITE = 1	The file is opened for writing. If an existing filename is given, the file contents will be overwritten without prompting.

Motion JPEG2000 files typically have a .mj2 extension, which is recognized by Motion JPEG2000 players. However, this object does not restrict or set the file extension, so it will reflect the value set in this *Filename* argument.

Keywords

In addition to the following keyword, any property listed under "IDLffMJPEG2000 Properties" on page 3317 that contains the word "Yes" in the "Init" column of the properties table can be initialized during object creation using this method. To initialize the value of a property, specify the property name as a keyword set equal to the appropriate property value.

PERSISTENT

A Boolean value that specifies whether or not data can be accessed more than a single time as follows:

0	Do not persist data. Minimize memory usage and limit certain types of data access to a single time. The default.
1	Persist data. Allow access to data multiple times and do not minimize memory usage. **Note -** You must set PERSISTENT to 1 if you want to access tiles from an MJ2 file.

The default value is 0.

Version History

6.3	Introduced

IDLffMJPEG2000::ReleaseSequentialData

The IDLffMJPEG2000::ReleaseSequentialData procedure method releases a frame from the frame buffer during animation playback. After calling GetSequentialData, which reads the frame from the frame buffer, call this method to release the frame and make the frame buffer slot available to the next frame being decompressed.

The StartSequentialReading, GetSequentialData, ReleaseSequentialData and StopSequentialReading methods are typically used with a timer mechanism to create a sequential playback as described in "Sequential Motion JPEG2000 Playback" (Chapter 6, *Using IDL*).

Note
Always use a widget timer or IDLitWindow timer mechanism to control the playback rate. Avoid using the WAIT procedure with sequential playback methods as the interaction between the procedure and the background processing thread will cause adverse side effects on UNIX platforms.

This method will throw an error if the release fails. A CATCH statement can be used to trap these errors.

Syntax

Obj->[IDLffMJPEG2000::]ReleaseSequentialData, *Frame_Index*

Arguments

Frame_Index

This long value is typically returned by the IDLffMJPEG2000::GetSequentialData method. If the *Frame_Index* is -1, it is ignored. If the *Frame_Index* is less than 0 or greater than the FRAME_BUFFER_LENGTH property, it is ignored.

Keywords

None

Examples

See the section of IDLffMJPEG2000::GetSequentialData for a simple example that uses the four sequential playback methods.

Version History

6.3	Introduced

IDLffMJPEG2000::SetData

The IDLffMJPEG::SetData function method starts a background processing thread and adds frame data to an MJ2 file that is being created. Each call to SetData call adds a frame to the frame buffer, which will be compressed by the processing thread. The length of the frame buffer is determined by the FRAME_BUFFER_LENGTH property.

If SetData is called faster than the background processing thread can compress the frame data, SetData will wait for an available frame buffer slot before returning. To avoid such delays, see "High Speed MJ2 Reading and Writing" (Chapter 6, *Using IDL*) for options.

The SetData and IDLffMJPEG2000::Commit methods are used together to create a new file. After adding all of the data to the MJ2 file using SetData, call Commit to close the file and shut down the processing thread. For a full description of creating a new file see "Creating a Motion JPEG2000 Animation" (Chapter 6, *Using IDL*). You can playback the new MJ2 file by creating a new Motion JPEG2000 object that opens the file for reading. See "Playing a Motion JPEG2000 Animation" in the same chapter for details.

This method will throw an error if the compression fails. A CATCH statement can be used to trap these errors.

Syntax

Result = Obj->[IDLffMJPEG2000::]SetData ($A_1 ...A_n$ [, COMPONENT=*value*]
   [, FRAME_PERIOD=*value*] [, /ORDER] [, TILE_INDEX=*value*])

Return Value

Returns a byte value indicating success (1) or failure (0).

Arguments

$A_1 ...A_n$

One or more arrays of data representing the component(s) or tile(s) of data associated with the single frame being written (see "Writing Frames, Components and Tiles" on page 3355). The arrays may be 2- or 3-dimensional. A 2-dimensional array contains one frame component or tile component, and has the dimensions [*width*, *height*]. A 3-dimensional array has the dimensions [*nComponents*, *width*, *height*]. All arrays must have the same *width*, *height* dimensions.

The data type of the array arguments are converted based the BIT_DEPTH and SIGNED property values as follows:

BIT_DEPTH	Converted to Data Type
≤8	Byte
≥9 or ≤16	Integer, signed or unsigned based on SIGNED property
>16	Long, signed or unsigned based on SIGNED property

Note

The data type of the input array has no effect on how the data is converted. If BIT_DEPTH and SIGNED are not set before the first call to SetData, data will be written as unsigned byte data. To write short or long integer data, or signed data, you must set the BIT_DEPTH and SIGNED properties before calling SetData.

Writing Frames, Components and Tiles

Frames may be written using multiple calls to SetData with each call transferring one or more components (channels or bands of data) or tile components. A tile component contains one frame component for a given tile and is the smallest unit of data that can be supplied to SetData.

The frame dimensions, tile dimensions and the number of components per frame are typically set prior to the first call to SetData. If they are not explicitly specified, they are inferred from the array parameters supplied in the first call to SetData. Once these properties (DIMENSIONS, TILE_DIMENSIONS, and N_COMPONENTS) are either explicitly set through Init or SetProperty, or set though the default action of SetData, they may not be changed. For example, if you pass in data arrays A_1, A_2, A_3, A_4 and A_5 in a single call to SetData, this will be interpreted as a single frame with 5 components. All subsequent frames will be expected to have the same number of components.

The frame will advance when all data for the current frame has been passed in. For example, if you pass in one frame of data at a time, each SetData call advances the frame (the N_FRAMES property value increases by 1). If you pass in individual components or tiles, multiple SetData calls may be needed to advance the frame. Suppose your frame consists of 4 components, which you are passing in one at a time. You will need to call SetData four times before the frame will advance. If you have a frame that consists of 2 components and 4 tiles, and you are passing in a single tile component in each SetData call, the frame will only advance after 8 calls.

Note ───

If you are writing individual components, you must set the N_COMPONENTS
property for the MJ2 file before the first call to SetData. If you are writing tiled
data, you must set the TILE_DIMENSIONS and DIMENSIONS properties for the
file before the first call to SetData.

───

If a file does not contain the expected number of tiles or components, an error will be
generated when you call IDLffMJPEG2000::Commit to store the data and close the
file. If you do not complete writing all of the tiles or components, or if your array
dimensions are not the same as the overall frame dimensions, the file storage process
will not be completed. In such a case, reading the data back may result in unexpected
or incorrect values.

Note ───

If transferring a frame with multiple calls to SetData, try to supply the data to
SetData in a manner consistent with the progression setting of PROGRESSION
property to ensure optimum performance and minimize memory requirements.

───

Color Space and Components

If not set prior to the first call to SetData, the COLOR_SPACE property will be
automatically set based on the number of components passed in during the first call to
SetData as follows:

Number of Components	**Color Space**
3	RGB
> 3 <	LUM

Note ───

If the YCC property is set (indicating that you want the library to convert from RGB
to YCC before compressing the data), then you must supply all three frame
components in the same call to SetData (either the entire frame or one tile at a time).
If the components are provided in separate calls to SetData, the YCC conversion is
not performed.

───

Keywords

COMPONENT

An integer value specifying the index of the component to be written in the current call to SetData. The default is 0. For example, suppose a frame consists of 4 components (N_COMPONENTS equals 4). If you pass in the first three components in one SetData call, you can pass in the fourth component in the next SetData call by setting COMPONENT equal to 3 (the zero-based index value of the fourth component). COMPONENT can only be used to write components sequentially.

You must set the N_COMPONENTS property before the first call to SetData if you are setting this keyword.

FRAME_PERIOD

A long value that indicates the duration of a frame in ticks. Each frame in an MJ2 file can be displayed a different period of time as defined by the FRAME_PERIOD. This value, in conjunction with the TIMESCALE property, determines the playback rate. See "Computing Playback Rate" on page 3323 for details.

The frame period of this frame and all subsequent frames will reflect the value set using the FRAME_PERIOD property, or set using this FRAME_PERIOD keyword.

ORDER

An integer value specifying the order in which to store data. Motion JPEG2000 frames are assumed to be stored in top-to-bottom order, while IDL usually assumes frames are in bottom-to-top order. By default (ORDER= 0), this method will automatically flip the result to match Motion JPEG2000's top-to-bottom order. Setting ORDER to a nonzero value will save the frame directly to the file without doing the vertical flip.

TILE_INDEX

An integer value that specifies the index of the tile to be written in the current SetData call. Frame tiles are numbered in raster scan fashion (from left to right starting at the upper left corner) beginning with an index value of 0. The default value for this keyword is 0. This keyword, like the COMPONENT keyword, lets you add data sequentially in separate SetData calls.

The tile indices must range from 0 to one less than the number of tiles in the frame, which is determined by the tile dimensions (TILE_DIMENSIONS property) and

frame dimensions (DIMENSIONS property). These properties must be set prior to
the first call to SetData if you are setting this keyword.

Examples

Write frame components in separate SetData calls using the COMPONENT
keyword. For a frame with 12 components, write the first five components in the first
SetData call. Set COMPONENT to 5 (the zero-based index value of the sixth
component) to add the remaining components in the next SetData call.

```
oMJ2write->SetProperty, N_COMPONENTS=12
result = oMJ2write->SetData(data0, data1, data2, data3, data4, $
   COMPONENT=0)
result = oMJ2write->SetData(data5, data6, data7, data8, data9, $
   data10, data11,COMPONENT=5)
```

Note ───

For additional examples using SetData, see "Adding Data to MJ2 Animations"
(Chapter 6, *Using IDL*).

───

Version History

6.3	Introduced

IDLffMJPEG2000::SetProperty

The IDLffMJPEG::SetProperty procedure method sets the value of properties of an IDLffMJPEG2000 object. You can only set object properties for an associated file that is open for writing (WRITE=1).

Syntax

Obj->[IDLffMJPEG2000::]SetProperty [, *PROPERTY=variable*]

Arguments

None

Keywords

Any property listed under "IDLffMJPEG2000 Properties" on page 3317 that contains the word "Yes" in the "Set" column of the properties table can be set using this method. To set the value of a property, specify the property name as a keyword set equal to the appropriate property value.

Version History

6.3	Introduced

IDLffMJPEG2000::StartSequentialReading

The IDLffMJPEG2000::StartSequentialReading function method initiates a sequential playback of a large number of frames. This method lets you configure what data is to be decompressed from each frame of the MJ2 file (the entire frame or a component, tile or region of the frame).

Internally, this method starts a background processing thread that decompresses frames into a frame buffer. This background thread allows the UI to remain active as described in "About Processing Threads" on page 3311).

The StartSequentialReading, GetSequentialData, ReleaseSequentialData and StopSequentialReading methods are used with a timer mechanism to create a sequential playback as described in "Sequential Motion JPEG2000 Playback" (Chapter 6, *Using IDL*).

Note ───

Always use a widget timer or IDLitWindow timer mechanism to control the playback rate. Avoid using the WAIT procedure with sequential playback methods as the interaction between the procedure and the background processing thread will cause adverse side effects on UNIX platforms.

───

This method will throw an error if the decompression fails. A CATCH statement can be used to trap these errors.

Syntax

Result = Obj->[IDLffMJPEG2000::]StartSequentialReading
   ([, COMPONENT=*value*] [, DISCARD_LEVELS=*value*]
   [, MAX_LAYERS=*value*] [, N_COMPONENTS=*value*] [, /ORDER]
   [, REGION=*vector*] [, /RGB] [, START_FRAME_NUMBER=*value*]
   [, STOP_FRAME_NUMBER=*value*] [, TILE_INDEX=*value*])

Return Value

Returns an integer value indicating success (1) or failure (0).

Arguments

None

Keywords

COMPONENT

An integer value indicating the zero-based index number of the first component to be returned as follows:

- This keyword is set and N_COMPONENTS is not set — returns all the components from the starting COMPONENT

- This keyword is set and N_COMPONENTS is set — returns the number of components specified by N_COMPONENTS from the starting compontent specified by COMPONENT

If this keyword is not set, all the components are returned. The default is 0.

DISCARD_LEVELS

An integer value specifying the number of resolution levels to be excluded from the result starting with the highest resolution level. For example, given a full-resolution frame that is 1024 by 1024 pixels:

Value	Description
0	The default. No data is discarded.
1	Discard 1 level, the highest resolution data (e.g. discard the 1024 by 1024 level, leaving the 512 by 512 data)
2	Discard 2 levels of data (e.g. discard the 1024 by 1024 and 512 by 512 levels, leaving the 256 by 256 data)

Determine the number of resolution levels by checking the N_LEVELS property.

MAX_LAYERS

An integer value specifying the maximum number of quality layers to be read. Each layer contains the information required to represent the image at a higher quality, given the information from all the previous layers. A value of 0, the default, means all available layers should be returned. If MAX_LAYERS is 3, data from the first, second and third quality layers will be combined in the returned data. Determine the number of quality layers in a file by checking the value of the N_LAYERS property.

N_COMPONENTS

An integer value specifying the number of components to return from the starting component specified by the COMPONENT keyword. If this keyword is set, but COMPONENT is not set, the default COMPONENT value (0) will be used.

ORDER

An integer value specifying the order in which to return data. Motion JPEG2000 frames are assumed to be stored in top-to-bottom order, while IDL usually assumes frames are in bottom-to-top order. By default (ORDER= 0), this method will automatically flip the result to match IDL's bottom-to-top order. Setting ORDER to a nonzero value will return the Motion JPEG2000 frames without doing the vertical flip.

REGION

A four-element long vector containing the rectangular region of the frame to read. The region is specified as [*startX*, *startY*, *width*, *height*], where *startX* and *startY* must be in the range 0 ... 2^{32}-2, and *width* and *height* must be in the range 1 ... 2^{32}-1. The region must contain at least some portion of the frame, or an error will occur. If the region is larger than the frame, or extends beyond the frame, only that portion that lies within the frame will be returned. This keyword, in combination with the COMPONENT keyword, lets you access any region from a particular component.

RGB

If set, the resulting data stream will be interpreted as RGB frames. The returned array will always have three components (red, green, and blue) with the dimensions [3, *width*, *height*]. See the following table for information on what data will be read if fewer than or more than 3 components are specified, or if the keyword is not set.

Note
The Motion JPEG2000 standard allows a decorrelating color transformation to be applied to the first three image components. This transformation is identical or similar to the conventional YCbCr color transformation. To determine if this transform has been applied, examine the YCC property.

RGB Set?	Number of Components	Outcome
Yes	More than 3	Only the first three components are returned.
	Less than 3	An error is thrown.
No	3	If a color transformation has been applied to the input stream, the three components which are encoded as YCC will automatically be converted to RGB. To avoid this conversion you must transfer more than or fewer than three components when using StartSequentialReading.
	Not equal to 3	Each component in the data stream will be placed in the result without interpretation. Result will have dimensions: [N_COMPONENTS, *width*, *height*].

You cannot specify RGB and COMPONENT or N_COMPONENTS at the same time. An error will be thrown in such cases.

START_FRAME_NUMBER

A long value specifying the frame index with which to start the sequential playback. If not set, the default value, 0, will be used.

STOP_FRAME_NUMBER

A long value specifying the frame index with which to stop the sequential playback. If not set, the stop frame will be the last frame in the file.

TILE_INDEX

An integer value specifying the index of the tile to return. Tiles are numbered in raster scan fashion (from left to right starting at the top-left corner) starting with an index value of 0. This keyword, in combination with the COMPONENT keyword, lets you access any tile from a particular component. When this keyword is set, the REGION keyword is ignored.

Examples

See the section of IDLffMJPEG2000::GetSequentialData for a simple example that uses the four sequential playback methods.

Version History

6.3	Introduced

IDLffMJPEG2000::StopSequentialReading

The IDLffMJPEG2000::StopSequentialReading function method releases the frame buffer memory and shuts down the background processing thread, if it is still running. Call this method when a sequential playback has been completed. Until StopSequentialReading is called, the decompressed frames will remain in the frame buffer.

The StartSequentialReading, GetSequentialData, ReleaseSequentialData and StopSequentialReading methods are used with a timer mechanism to create a sequential playback as described in "Sequential Motion JPEG2000 Playback" (Chapter 6, *Using IDL*).

Note

Always use a widget timer or IDLitWindow timer mechanism to control the playback rate. Avoid using the WAIT procedure with sequential playback as the interaction between the procedure and the background processing thread will cause adverse side effects on UNIX platforms.

This method will throw an error if the decompression fails. A CATCH statement can be used to trap these errors.

Syntax

Result = Obj->[IDLffMJPEG2000::]StopSequentialReading( )

Return Value

Returns an integer indicating success (1) or failure (0).

Arguments

None

Keywords

None

Examples

See the section of IDLffMJPEG2000::GetSequentialData for a simple example that uses the four sequential playback methods.

Version History

6.3	Introduced

IDLffMrSID

An IDLffMrSID object class is used to query information about and load image data from a MrSID (.sid) image file.

Note

The IDLffMrSID object is available only under Microsoft Windows. See "Feature Support by Operating System" (*What's New in IDL 6.4*) for details.

Superclasses

None

Creation

See IDLffMrSID::Init

Properties

Objects of this class have the following properties. See "IDLffMrSID Properties" on page 3368 for details on individual properties.

- QUIET

Methods

This class has the following methods:

- IDLffMrSID::Cleanup
- IDLffMrSID::GetDimsAtLevel
- IDLffMrSID::GetImageData
- IDLffMrSID::GetProperty
- IDLffMrSID::Init

Version History

5.5	Introduced

IDLffMrSID Properties

IDLffMrSID objects have the following properties. Properties with the word "Yes" in the "Init" column of the property table can be set via IDLffMrSID::Init.

Note
For a discussion of the property description tables shown below, see "About Object Property Descriptions" on page 3135.

Objects of this class have the following properties.

- QUIET

QUIET

A Boolean value to indicate whether error messages are suppressed while constructing the IDLffMrSID object. If this value is true, the errors messages are suppressed. Otherwise, the messages are printed to the Output Log.

Property Type	Boolean		
Name String	*not displayed*		
Get: No	**Set:** No	**Init:** Yes	**Registered:** No

IDLffMrSID::Cleanup

The IDLffMrSID::Cleanup procedure method deletes all MrSID objects, closing the MrSID file in the process. It also deletes the IDL objects used to communicate with the MrSID library.

Note ——————————————————————————————

Cleanup methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation and destruction. This means that in most cases, you cannot call the Cleanup method directly. There is one exception to this rule: If you write your own subclass of this class, you can call the Cleanup method from within the Init or Cleanup method of the subclass.

Syntax

OBJ_DESTROY, *Obj*

or

Obj->[IDLffMrSID::]Cleanup   *(In a lifecycle method only.)*

Arguments

None

Keywords

None

Version History

5.5	Introduced

IDLffMrSID::GetDimsAtLevel

The IDLffMrSID::GetDimsAtLevel function method is used to retrieve the dimensions of the image at a given level. This can be used, for example, to determine what level is required to fit the image into a certain area.

Syntax

Result = Obj->[IDLffMrSID::]GetDimsAtLevel (*Level*)

Return Value

Returns a floating-point two-element vector containing the dimensions of the image at a given level.

Arguments

Level

A scalar integer specifying the level at which the dimensions are to be determined. This level must be in the range returned by the LEVELS keyword of IDLffMrSID::GetProperty.

Keywords

None

Examples

Initialize the MrSID file object.

```
oFile = OBJ_NEW('IDLffMrSID', FILEPATH('test_gs.sid', $
    SUBDIRECTORY = ['examples', 'data']))
```

Get the range of levels of resolution contained within the file.

```
oFile->GetProperty, LEVELS = lvls
PRINT, lvls
```

IDL prints,

```
-9    4
```

Print the image dimensions at the lowest image resolution where image level = 4.

```
imgLevelA = MAX(lvls)
dimsAtA = oFile->GetDimsAtLevel(imgLevelA)
PRINT, 'Dimensions of lowest resolution image is', dimsAtA
```

IDL prints,

```
32    32
```

Print the image dimensions at full resolution where image level = 0

```
dimsAtFull = oFile->GetDimsAtLevel(0)
PRINT, 'Dimensions of full resolution image is', dimsAtFull
```

IDL prints,

```
512    512
```

Print the image dimensions at the highest resolution where image level = -9

```
highestLvl = MIN(lvls)
dimsAtHighest = oFile->GetDimsAtLevel(highestLvl)
PRINT, 'Dimensions of highest resolution image is', dimsAtHighest
```

IDL prints,

```
262144    262144
```

Clean up object references.

```
OBJ_DESTROY, [oFile]
```

Version History

5.5	Introduced

IDLffMrSID::GetImageData

The IDLffMrSID::GetImageData function method extracts and returns the image data from the MrSID file at the specified level and location.

Syntax

Result = Obj->[IDLffMrSID::]GetImageData ([, LEVEL = *lvl*]
   [, SUB_RECT = *rect*])

Return Value

Returns an *n*-by-*w*-by-*h* array containing the image data where *n* is 1 for grayscale or 3 for RGB images, *w* is the width and *h* is the height.

Note ──

The returned image is ordered bottom-up, the first pixel returned is located at the bottom-left corner of the image. This differs from how data is stored in the MrSID file where the image is top-down, meaning the pixel at the start of the file is located at the top-left corner of the image.

──

Arguments

None

Keywords

LEVEL

Set this keyword to an integer that specifies the level at which to read the image.

If this keyword is not set, the maximum level is used which returns the minimum resolution (see the LEVELS keyword to IDLffMrSID::GetProperty).

SUB_RECT

Set this keyword to a four-element vector [*x*, *y*, *xdim*, *ydim*] specifying the position of the lower left-hand corner and the dimensions of the sub-rectangle of the MrSID image to return. This is useful for displaying portions of a high-resolution image.

If this keyword is not set, the whole image will be returned. This may require significant memory if a high-resolution image level is selected.

If the sub-rectangle is greater than the bounds of the image at the selected level the area outside the image bounds will be set to black.

Note ───

The elements of SUB_RECT are measured in pixels at the current level. This means the point x = 10, y = 10 at level 1 will be located at x = 20, y = 20 at level 0 and x = 5, y = 5 at level 2.

───

Examples

```
PRO MrSID_GetImageData

; Initialize the MrSID file object.
oFile = OBJ_NEW('IDLffMrSID', FILEPATH('test_gs.sid', $
   SUBDIRECTORY = ['examples', 'data']))

; Get the range of levels of resolution contained within the file.
oFile->GetProperty, LEVELS = lvls
PRINT, lvls
; IDL prints, -9, 4

; Get the image data at level 0.
imgDataA = oFile->GetImageData(LEVEL = 0)
HELP, 'image array data at full resolution', imgDataA
;IDL prints, Array[1, 512, 512] indicating a grayscale 512 x 512
array.

; Display the full resolution image.
oImgA = OBJ_NEW('IDLgrImage', imgDataA)
oModelA = OBJ_NEW('IDLgrModel')
oModelA->Add, oImgA
XOBJVIEW, oModelA, BACKGROUND = [0,0,0], $
   TITLE = 'Full Resolution Image', /BLOCK

; Get the image data of a higher resolution image,
imgDataB = oFile->GetImageData(LEVEL = -2)
HELP, imgDataB
; IDL returns [1,2048,2048] indicating a grayscale 2048 x 2048
array.
```

```
; To save processing time, display only a 1024 x 1024 portion of
; the high resolution, using 512,512 as the origin.
imgDataSelect = oFile->GetImageData(LEVEL = -2,$
   SUB_RECT = [512, 512, 1024, 1024])
oImgSelect = OBJ_NEW('IDLgrImage', imgDataSelect)
oModel = OBJ_NEW('IDLgrModel')
oModel->Add, oImgSelect

XOBJVIEW, oModel, BACKGROUND = [0,0,0], $
   TITLE = 'Detail of High Resolution Image', /BLOCK

; Clean up object references.
OBJ_DESTROY, [oFile, oImgA, oModelA, oImgSelect, oModel]

IDLffMrSID::GetProperty

The IDLffMrSID::GetProperty function method is used to query properties associated with the MrSID image.

Syntax

Obj->[IDLffMrSID::]GetProperty [, CHANNELS=*nChannels*]
   [, DIMENSIONS=*Dims*] [, LEVELS=*Levels*] [, PIXEL_TYPE=*pixelType*]
   [, TYPE=*strType*] [, GEO_VALID=*geoValid*] [, GEO_PROJTYPE=*geoProjType*]
   [, GEO_ORIGIN=*geoOrigin*] [, GEO_RESOLUTION=*geoRes*]

Arguments

None

Keywords

CHANNELS

Set this keyword to a named variable that will contain the number of image bands. For RGB images this is 3, for grayscale it is 1.

DIMENSIONS

Set this keyword equal to a named variable that will contain a two-element long integer array of the form [*width*, *height*] that specifies the dimensions of the MrSID image at level 0 (full resolution).

GEO_ORIGIN

Set this keyword to a named variable that will contain a two-element double precision array of the form [*x*, *y*] that specifies the location of the center of the upper-left pixel.

GEO_PROJTYPE

Set this keyword to a named variable that will contain an unsigned integer that specifies the geoTIFF projected coordinate system type code. For example, type code 32613 corresponds to PCS_WGS84_UTM_zone_13N.

For more information on the geoTIFF file type and available type codes see:

   http://www.remotesensing.org/geotiff/geotiff.html

GEO_RESOLUTION

Set this keyword to a named variable that will contain a two-element double precision array of the form [*xres*, *yres*] that specifies the pixel resolution.

GEO_VALID

Set this keyword to a named variable that will contain a long integer that is set to:

- 1 - If the MrSID image contains valid georeferencing data.

- 0 - If the MrSID image does not contain georeferencing data or the data is in an unsupported format.

Note

Always verify that this keyword returns 1 before using the data returned by any other GEO_* keyword.

LEVELS

Set this keyword equal to a named variable that will contain a two-element long integer array of the form [*minlvl*, *maxlvl*] that specifies the range of levels within the current image. Higher levels are lower resolution. A level of 0 equals full resolution. Negative values specify higher levels of resolution.

PIXEL_TYPE

Set this keyword to a named variable that will contain the IDL basic type code for a pixel sample. For a list of the data types indicated by each type code, see the "IDL Type Codes" section of the SIZE function.

TYPE

Set this keyword to a named variable that will contain a string identifying the file format. This should always be MrSID.

Examples

```
PRO MrSID_GetProperty

; Initialize the MrSID object.
oFile = OBJ_NEW('IDLffMrSID', FILEPATH('test_gs.sid', $
   SUBDIRECTORY = ['examples', 'data']))
```

```
; Get the property information of the MrSID file.
oFile->GetProperty, CHANNELS = chan, LEVELS = $
   lvls, Pixel_Type = pType, TYPE = fileType, GEO_VALID = geoQuery

; Print MrSID file information.
PRINT, 'Number of image channels = ', chan
; IDL returns 1 indicating one image band.

PRINT, 'Range of image levels = ', lvls
; IDL returns -9, 4, the minimum and maximum level values.

PRINT, 'Type code of image pixels = ', pType
; IDL returns 1 indicating byte data type.

PRINT, 'Image file type = ', FileType
; IDL returns "MrSID"

PRINT, 'Result of georeferencing data query = ', geoQuery
; IDL returns 0 indicating that the image does not contain
; georeferencing data.

; Destroy object references.
OBJ_DESTROY, [oFile]

END
```

Version History

5.5	Introduced

IDLffMrSID::Init

The IDLffMrSID::Init function method initializes an IDLffMrSID object containing the image data from a MrSID image file.

Note ——————————————————————————————

Init methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation. This means that in most cases, you cannot call the Init method directly. There is one exception to this rule: If you write your own subclass of this class, you can call the Init method from within the Init method of the subclass.

Syntax

Result = OBJ_NEW('IDLffMrSID', *Filename* [, *PROPERTY=value*])

or

Result = *Obj*->[IDLffMrSID::]Init(*Filename* [, *PROPERTY=value*])   *(In a lifecycle method only.)*

Return Value

When this method is called indirectly, as part of the call to the OBJ_NEW function, the return value is an object reference to the newly-created object.

When called directly within a subclass Init method, the return value is 1 if initialization was successful, or zero otherwise.

Arguments

Filename

A scalar string argument containing the full path and filename of a MrSID file to be accessed through this IDLffMrSID object.

Note ——————————————————————————————

This is a required argument; it is not possible to create an IDLffMrSID object without specifying a valid MrSID file.

Keywords

Any property listed under "IDLffMrSID Properties" on page 3368 that contains the word "Yes" in the "Init" column of the properties table can be initialized during object creation using this method. To initialize the value of a property, specify the property name as a keyword set equal to the appropriate property value.

Examples

```
oMrSID = OBJ_NEW('IDLffMrSID', FILEPATH('test_gs.sid', $
   SUBDIRECTORY = ['examples', 'data']))
```

IDLffShape

An IDLffShape object contains geometry, connectivity and attributes for graphics primitives accessed from ESRI Shapefiles. See "Overview of ESRI Shapefiles" on page 3382 for more details on Shapefiles.

Superclasses

None

Creation

See IDLffShape::Init

Properties

Objects of this class have the following properties. See "IDLffShape Properties" on page 3394 for details on individual properties.

- ATTRIBUTE_INFO
- ATTRIBUTE_NAMES
- DBF_ONLY
- ENTITY_TYPE
- FILENAME
- IS_OPEN
- N_ATTRIBUTES
- N_ENTITIES
- N_RECORDS
- UPDATE

Methods

This class has the following methods:

- IDLffShape::AddAttribute
- IDLffShape::Cleanup

- IDLffShape::Close
- IDLffShape::DestroyEntity
- IDLffShape::GetAttributes
- IDLffShape::GetEntity
- IDLffShape::GetProperty
- IDLffShape::Init
- IDLffShape::Open
- IDLffShape::PutEntity
- IDLffShape::SetAttributes

Version History

5.4	Introduced
5.6	Added N_RECORDS, DBF_ONLY properties

Overview of ESRI Shapefiles

An ESRI Shapefile stores nontopological geometry and attribute information for the spatial features in a data set.

A Shapefile consists of a main file (.shp), an index file (.shx), and a dBASE table (.dbf). For example, the Shapefile "states" would have the following files:

- states.shp

- states.shx

- states.dbf

Naming Conventions for a Shapefile

All the files that comprise an ESRI Shapefile must adhere to the 8.3 filename convention and must be lower case. The main file, index file, and dBASE file must all have the same prefix. The prefix must start with an alphanumeric character and can contain any alphanumeric, underscore (_), or hyphen (-). The main file suffix must use the .shp extension, the index file the .shx extension, and the dBASE table the .dbf extension.

Major Elements of a Shapefile

A Shapefile consists of the following elements that you can access through the IDLffShape class:

- Entities

- Attributes

Entities

The geometry for a feature is stored as a shape comprising a set of vector coordinates (referred to as 'entities'). The (non-null) entities in a Shapefile must all be of the same type. The following are the possible types for entities in a Shapefile:

Shape Type	Type Code
Point	1
PolyLine	3
Polygon	5

Table 30-16: Entity Types

Shape Type	Type Code
MultiPoint	8
PointZ	11
PolyLineZ	13
PolygonZ	15
MultiPointZ	18
PointM	21
PolyLineM	23
PolygonM	25
MultiPointM	28
MultiPatch	31

Table 30-16: Entity Types (Continued)

When retrieving entities using the IDLffShape::GetEntity method, an IDL structure is returned. This structure has the following fields:

Field	Data Type
SHAPE_TYPE	IDL_LONG
ISHAPE	IDL_LONG
BOUNDS	Double[8]
N_VERTICES	IDL_LONG
VERTICES	Pointer (to Vertices array)
MEASURE	Pointer (to Measure array)
N_PARTS	IDL_LONG
PARTS	Pointer (to Parts array).
PART_TYPES	Pointer (to part types)
ATTRIBUTES	Pointer to attribute array.

Table 30-17: Entity Structure Field Data Types

The following table describes each field in the structure:

Field	Description
SHAPE_TYPE	The entity type.
ISHAPE	A read-only field containing the index of the specific entity within the shape object. This value is set automatically when the shape file is written.
BOUNDS	A bounding box that specifies the range limits of the entity. This eight element array contains the following information: • Index 0 — X minimum value • Index 1 — Y minimum value • Index 2 — Z minimum value (if Z is supported by type) • Index 3 — Measure minimum value (if measure is supported by entity type) • Index4 — X maximum value • Index5 — Y maximum value • Index6 — Z maximum value (if Z is supported by the entity type) • Index7 — Measure maximum value (if measure is supported by entity type) **Note -** If the entity is a point type, the values contained in the bounds array are also the values of the entity.
N_VERTICES	The number of vertices in the entity. If this value is one and the entity is a POINT type (POINT, POINTM, POINTZ), the vertices pointer will be set to NULL and the entity value will be maintained in the BOUNDS field.

Table 30-18: Entity Structure Field Descriptions

Field	Description
VERTICES	An IDL pointer that contains the vertices of the entity. This pointer contains a double array that has one of the following formats: • [2, *N*] - If Z data is not present • [3, *N*] - If Z data is present where *N* is the number of vertices. These array formats can be passed to the polygon and polyline objects of IDL Object Graphics. **Note -** This pointer will be null if the entity is a point type, with the values maintained in the BOUNDS array.
MEASURE	If the entity has a measure value (this is dependent on the entity type), this IDL pointer will contain a vector array of measure values. The length of this vector is N_VERTICES. **Note -** This pointer will be null if the entity is of type POINTM, with the values contained in the BOUNDS array.
N_PARTS	If the values of the entity are separated into parts, the break points are enumerated in the parts array. This field lists the number of parts in this entity. If this value is 0, the entity is one part and the PARTS pointer will be NULL.
PARTS	An IDL pointer that contains an array of indices into the vertex/measure arrays. These values represent the start of each part of the entity. The index range of each entity part is defined by the following: • Start = Parts[I] • End = Parts[I+1]-1 or the end of the array

Table 30-18: Entity Structure Field Descriptions (Continued)

Field	Description
PART_TYPES	This IDL pointer is only valid for entities of type MultiPatch and defines the type of the particular part. If the entity type is not MultiPatch, part types are assumed to be type RING (SHPP_RING). **Note -** This pointer is NULL if the entity is not type MultiPatch.
ATTRIBUTES	If the attributes for an entity were requested, this field contains an IDL pointer that contains a structure of attributes for the entity. For more information on this structure, see "Attributes" on page 3386.

Table 30-18: Entity Structure Field Descriptions (Continued)

Attributes

A Shapefile provides the ability to associate information describing each entity (a geometric element) contained in the file. This descriptive information, called attributes, consists of a set of named data elements for each geometric entity contained in the file. The set of available attributes is the same for every entity contained in a Shapefile, with each entity having its own set of attribute values.

An attribute consist of two components:

- A name
- A data value

The name consists of an 11 character string that is used to identify the data value. The data value is not limited to any specific format.

The two components that form an attribute are accessed differently using the shape object. To get the name of attributes for the specific file, the ATTRIBUTE_NAMES keyword to the IDLffShape::GetProperty method is used. This returns a string array that contains the names for the attributes defined for the file.

To get the attribute values for an entity, the IDLffShape::GetAttributes method is called or the ATTRIBUTES keyword of the IDLffShape::GetEntity method is set. In each case, the attribute values for the specified entity is returned as an anonymous IDL structure. The numeric order of the fields in the returned structure map to the numeric order of the attributes defined for the file. The actual format of the returned structure is:

> ATTRIBUTE_0 : VALUE,
>
> ATTRIBUTE_1 : VALUE,
>
> ATTRIBUTE_2 : VALUE,
>
> ...
>
> ATTRIBUTE_<N-1> : VALUE

To access the values in the returned structure, you can either hard code the structure field names or use the structure indexing feature of IDL.

Accessing Shapefiles

The following example shows how to access data in a Shapefile. This example sets up a map to display parts of a Shapefile, opens a Shapefile, reads the entities from the Shapefile, and then plots only the state of Colorado:

```
PRO ex_shapefile

DEVICE, RETAIN=2, DECOMPOSED=0

!P.BACKGROUND=255

;Define a color table
r=BYTARR(256) & g=BYTARR(256) & b=BYTARR(256)
r[0]=0 & g[0]=0 & b[0]=0              ;Definition of black
r[1]=100 & g[1]=100 & b[1]=255        ;Definition of blue
r[2]=0 & g[2]=255 & b[2]=0            ;Definition of green
r[3]=255 & g[3]=255 & b[3]=0          ;Definition of yellow
r[255]=255 & g[255]=255 & b[255]=255 ;Definition of white

TVLCT, r, g, b
black=0 & blue=1 & green=2 & yellow=3 & white=255

; Set up map to plot Shapefile on
MAP_SET, /ORTHO,45, -120,  /ISOTROPIC, $
/HORIZON, E_HORIZON={FILL:1, COLOR:blue}, $
/GRID, COLOR=black, /NOBORDER

; Fill the continent boundaries:
```

```
          MAP_CONTINENTS, /FILL_CONTINENTS, COLOR=green

          ; Overplot coastline data:
          MAP_CONTINENTS, /COASTS, COLOR=black

          ; Show national borders:
          MAP_CONTINENTS, /COUNTRIES, COLOR=black

          ;Open the states Shapefile in the examples directory
          myshape=OBJ_NEW('IDLffShape', FILEPATH('states.shp', $
             SUBDIR=['examples', 'data']))

          ;Get the number of entities so we can parse through them
          myshape->IDLffShape::GetProperty, N_ENTITIES=num_ent

          ;Parsing through the entities and only plotting the state of
          ;Colorado
          FOR x=1, (num_ent-1) DO BEGIN
             ;Get the Attributes for entity x
             attr = myshape->IDLffShape::GetAttributes(x)
             ;See if 'Colorado' is in ATTRIBUTE_1 of the attributes for
             ;entity x
             IF attr.ATTRIBUTE_1 EQ 'Colorado' THEN BEGIN
                ;Get entity
                ent=myshape->IDLffShape::GetEntity(x)
                ;Plot entity
                POLYFILL, (*ent.vertices)[0,*], (*ent.vertices)[1,*], $
                   COLOR=yellow
                ;Clean-up of pointers
                myshape->IDLffShape::DestroyEntity, ent
             ENDIF
          ENDFOR

          ;Close the Shapefile
          OBJ_DESTROY, myshape

          END
```

This results in the following:

Figure 30-2: Example Use of Shapefiles

Creating New Shapefiles

To create a Shapefile, you need to create a new Shapefile object, define the entity and attributes definitions, and then add your data to the file. For example, the following program creates a new Shapefile (cities.shp), defines the entity type to be "Point", defines 2 attributes (CITY_NAME and STATE_NAME), and then adds an entity to the new file:

```
PRO ex_shapefile_newfile

;Create the new shapefile and define the entity type to Point
mynewshape=OBJ_NEW('IDLffShape', FILEPATH('cities.shp', $
   SUBDIR=['examples', 'data']), /UPDATE, ENTITY_TYPE=1)

;Set the attribute definitions for the new Shapefile
mynewshape->AddAttribute, 'CITY_NAME', 7, 25, $
   PRECISION=0
mynewshape->AddAttribute, 'STAT_NAME', 7, 25, $
   PRECISION=0
```

```
;Create structure for new entity
entNew = {IDL_SHAPE_ENTITY}

; Define the values for the new entity
entNew.SHAPE_TYPE = 1
entNew.ISHAPE = 1458
entNew.BOUNDS[0] = -104.87270
entNew.BOUNDS[1] = 39.768040
entNew.BOUNDS[2] = 0.00000000
entNew.BOUNDS[3] = 0.00000000
entNew.BOUNDS[4] = -104.87270
entNew.BOUNDS[5] = 39.768040
entNew.BOUNDS[6] = 0.00000000
entNew.BOUNDS[7] = 0.00000000
entNew.N_VERTICES = 1 ; take out of example, need as workaround

;Create structure for new attributes
attrNew = mynewshape ->GetAttributes(/ATTRIBUTE_STRUCTURE)

;Define the values for the new attributes
attrNew.ATTRIBUTE_0 = 'Denver'
attrNew.ATTRIBUTE_1 = 'Colorado'

;Add the new entity to new shapefile
mynewshape -> PutEntity, entNew

;Add the Colorado attributes to new shapefile
mynewshape -> SetAttributes, 0, attrNew

;Close the shapefile
OBJ_DESTROY, mynewshape

END
```

Updating Existing Shapefiles

You can modify existing Shapefiles with the following:

- Adding new entities

- Adding new attributes (only to Shapefiles without any existing values in any attributes)

- Modifying existing attributes

Note ──

You cannot modify existing entities.

──

For example, the following program adds an entity and attributes for the city of
Boulder to the cities.shp file created in the previous example:

```
PRO ex_shapefile_modify

;Open the cities Shapefile
myshape=OBJ_NEW('IDLffShape', FILEPATH('cities.shp', $
    SUBDIR=['examples', 'data']), /UPDATE)

;Create structure for new entity
entNew = {IDL_SHAPE_ENTITY}

; Define the values for the new entity
entNew.SHAPE_TYPE = 1
entNew.ISHAPE = 200
entNew.BOUNDS[0] = -105.25100
entNew.BOUNDS[1] = 40.026878
entNew.BOUNDS[2] = 0.00000000
entNew.BOUNDS[3] = 0.00000000
entNew.BOUNDS[4] = -105.25100
entNew.BOUNDS[5] = 40.026878
entNew.BOUNDS[6] = 0.00000000
entNew.BOUNDS[7] = 0.00000000
entNew.N_VERTICES = 1 ; take out of example, need as workaround

;Create structure for new attributes
attrNew = myshape ->GetAttributes(/ATTRIBUTE_STRUCTURE)

;Define the values for the new attributes
attrNew.ATTRIBUTE_0 = 'Boulder'
attrNew.ATTRIBUTE_1 = 'Colorado'

;Add the new entity to new shapefile
myshape -> PutEntity, entNew

;Add the Colorado attributes to new shapefile
myshape -> SetAttributes, 0, attrNew

;Close the shapefile
OBJ_DESTROY, myshape

END
```

Graphing an Updated Shapefile

The following program graphs the `cities.shp` file that was created and updated in the previous examples:

```
pro plot_cities

DEVICE, RETAIN=2, DECOMPOSED=0

!P.BACKGROUND=255

;Define a color table
r=BYTARR(256) & g=BYTARR(256) & b=BYTARR(256)
r[0]=0 & g[0]=0 & b[0]=0                 ;Definition of black
r[1]=100 & g[1]=100 & b[1]=255           ;Definition of blue
r[2]=0 & g[2]=255 & b[2]=0               ;Definition of green
r[3]=255 & g[3]=255 & b[3]=0             ;Definition of yellow
r[255]=255 & g[255]=255 & b[255]=255 ;Definition of white

TVLCT, r, g, b
black=0 & blue=1 & green=2 & yellow=3 & white=255

; Set up map to plot Shapefile on
MAP_SET, /ORTHO,39, -104, SCALE=9e6, /ISOTROPIC, $
   /HORIZON, E_HORIZON={FILL:1, COLOR:green}, $
   COLOR=yellow

; Show state borders:
MAP_CONTINENTS, /USA, COLOR=black

;Open the states Shapefile in the examples directory
myshape=OBJ_NEW('IDLffShape', FILEPATH('states.shp', $
   SUBDIR=['examples', 'data']))

;Get the number of entities so we can parse through them
myshape->IDLffShape::GetProperty, N_ENTITIES=num_ent

;Parsing through the entities and only plotting the state of
;Colorado
FOR x=1, (num_ent-1) DO BEGIN
   ;Get the Attributes for entity x
   attr = myshape->IDLffShape::GetAttributes(x)
   ;See if 'Colorado' is in ATTRIBUTE_1 of the attributes for
   ;entity x
   IF attr.ATTRIBUTE_1 EQ 'Colorado' THEN BEGIN
      ;Get entity
      ent=myshape->IDLffShape::GetEntity(x)
      ;Plot entity
```

```
         POLYFILL, (*ent.vertices)[0,*], (*ent.vertices)[1,*], $
            COLOR=yellow
         ;Clean-up of pointers
         myshape->IDLffShape::DestroyEntity, ent
      ENDIF

ENDFOR

;Close the states Shapefile
OBJ_DESTROY, myshape

;Open the cities Shapefile
myshape=OBJ_NEW('IDLffShape', FILEPATH('cities.shp', $
   SUBDIR=['examples', 'data']))

;Get the number of entities so we can parse through them
myshape->IDLffShape::GetProperty, N_ENTITIES=num_ent

;Plot the cities on the map of Colorado

FOR x=0, (num_ent-1) DO BEGIN
   ;Get entity
   ent=myshape->IDLffShape::GetEntity(x)

   ;Get city attribute
   attr = myshape ->IDLffShape::GetAttributes(x)

   ;Plot the cities with a symbol, as well as the city name
   plots, ent.BOUNDS[0], ent.BOUNDS[1], psym=5, color=black
   xyouts, ent.BOUNDS[0] + 0.3, ent.BOUNDS[1], $
   attr.ATTRIBUTE_0, color=black

   ;Clean-up of pointers
   myshape->IDLffShape::DestroyEntity, ent

ENDFOR

;Close the Shapefile
OBJ_DESTROY, myshape

end
```

IDLffShape Properties

IDLffShape objects have the following properties in addition to properties inherited from any superclasses. Properties with the word "Yes" in the "Get" column of the property table can be retrieved via IDLffShape::GetProperty. Properties with the word "Yes" in the "Init" column of the property table can be set via IDLffShape::Init.

Note ──
For a discussion of the property description tables shown below, see "About Object Property Descriptions" on page 3135.
───

Objects of this class have the following properties.

- ATTRIBUTE_INFO
- ATTRIBUTE_NAMES
- DBF_ONLY
- ENTITY_TYPE
- FILENAME
- IS_OPEN
- N_ATTRIBUTES
- N_ENTITIES
- N_RECORDS
- UPDATE

ATTRIBUTE_INFO

A array of structures containing the attribute information for each attribute. The attribute information structures have the following fields:

Field	Description
NAME	A string that contains the name of the attribute
TYPE	The IDL type code of the attribute

Table 30-19: Attribute Information Fields

Field	Description
WIDTH	The width of the attribute
PRECISION	The precision of the attribute

Table 30-19: Attribute Information Fields (Continued)

The file must be open to obtain this information.

Property Type	Structure		
Name String	*not displayed*		
Get: Yes	**Set:** No	**Init:** No	**Registered:** No

ATTRIBUTE_NAMES

A string array containing the names of each attribute in the Shapefile object.

Property Type	String array		
Name String	*not displayed*		
Get: Yes	**Set:** No	**Init:** No	**Registered:** No

DBF_ONLY

A non-zero, positive integer value indicating whether the underlying dBASE table (.dbf) component of the shapefile is opened while all other entity related files are left closed. The following two values are accepted for this property:

- 1 - Open an existing .dbf file,

- Greater than 1 - Create a new .dbf file

Note ————

The UPDATE keyword is required to open the .dbf file for updating.

—————————————————————————————————————

Property Type	Integer		
Name String	*not displayed*		
Get: No	**Set:** No	**Init:** Yes	**Registered:** No

ENTITY_TYPE

If retrieving this property, its value is an integer representing the type code for the entities contained in the Shapefile object. If the value is unknown, this method returns -1. For more information on entity type codes, see "Entities" on page 3382.

If setting this property, its value is an integer representing the entity type of a new Shapefile. Use this setting only when creating a new Shapefile. For more information on entity types, see "Entities" on page 3382.

Property Type	Integer		
Name String	*not displayed*		
Get: Yes	**Set:** No	**Init:** Yes	**Registered:** No

FILENAME

A string representing the fully qualified path name of the Shapefile in the current Shapefile object.

Note ———

FILENAME can only be set via an argument to the IDLffShape::Init method.

Property Type	String		
Name String	*not displayed*		
Get: Yes	**Set:** No	**Init:** No	**Registered:** No

IS_OPEN

An integer value representing information about the status of a Shapefile. The following values can be returned:

0	File is not open
1	File is open in read-only mode
3	File is open in update mode

Property Type	Integer		
Name String	*not displayed*		
Get: Yes	**Set:** No	**Init:** No	**Registered:** No

N_ATTRIBUTES

A longword integer representing the number of attributes associated with a Shapefile object. If the number of attributes is unknown, this property returns 0.

Property Type	Long		
Name String	*not displayed*		
Get: Yes	**Set:** No	**Init:** No	**Registered:** No

N_ENTITIES

A longword integer representing the number of entities contained in Shapefile object. If the number of entities is unknown, this property returns 0.

Property Type	Long		
Name String	*not displayed*		
Get: Yes	**Set:** No	**Init:** No	**Registered:** No

N_RECORDS

A longword integer representing the number of records in the dBASE table (.dbf) component of the Shapefile. In a normal operating mode, this process is accomplished by getting the number of entities. However, in DBF_ONLY mode, no entity file exits.

Property Type	Long		
Name String	*not displayed*		
Get: Yes	**Set:** No	**Init:** No	**Registered:** No

UPDATE

A Boolean value indicating whether the file opened for writing. The file is opened for writing if this property is set to true. The default is read-only.

Property Type	Boolean		
Name String	*not displayed*		
Get: No	Set: No	Init: Yes	Registered: No

IDLffShape::AddAttribute

The IDLffShape::AddAttribute method adds an attribute definition to a Shapefile. Adding the attribute definition is required before adding the actual attribute data to a file. For more information on attributes, see "Attributes" on page 3386.

Note ──

You can only define new attributes to Shapefiles that do not have any existing values in any attributes.

──

Syntax

Obj->[IDLffShape::]AddAttribute, *Name*, *Type*, *Width* [, PRECISION=*integer*]

Arguments

Name

Set to a string that contains the attribute name. Name values are limited to 11 characters. Arguments longer than 11 characters will be truncated.

Type

Set to the IDL type code that corresponds to the data type that will be stored in the attribute. The valid types are:

3	Longword integer
5	Double-precision floating-point
7	String

Width

Set to the user-defined width of the field for the data value of the attribute. The
following table describes the possible values depending on the defined *Type*:

Longword Integer	Establishes the number of digits of the largest number that can be represented
Double-precision floating-point	Establishes the total number of digits, including the decimal point and the number of positions after the decimal point (see the PRECISION keyword)
String	Establishes the maximum length of the string that can be stored

Keywords

PRECISION

Set this keyword to the number of positions to be included after the decimal point.
The default is 8. This keyword is only valid for fields defined as double-precision
floating-point.

Examples

For an example of AddAttribute, see "Creating New Shapefiles" on page 3389.

Note
If cities.shp already contains data in an attribute for any of the entities defined
in the file, this operation will fail.

Version History

5.4	Introduced

IDLffShape::Cleanup

The IDLffShape::Cleanup procedure method performs all cleanup on a Shapefile object. If the Shapefile being accessed by the object is open and the file has been modified, the new information is written to the file if one of the following conditions is met:

- The file was opened with write permissions using the UPDATE keyword to the IDLffShape::Open method

- It is a newly created file that has not been written previously.

Note ———

Cleanup methods are special lifecycle methods, and as such cannot be called outside the context of object creation and destruction. This means that in most cases, you cannot call the Cleanup method directly. There is one exception to this rule: If you write your own subclass of this class, you can call the Cleanup method from within the Init or Cleanup method of the subclass.

Syntax

OBJ_DESTROY, *Obj*

or

Obj->[IDLffShape::]Cleanup   *(In a lifecycle method only.)*

Arguments

None

Keywords

None

Version History

5.4	Introduced

IDLffShape::Close

The IDLffShape::Close procedure method closes a Shapefile. If the file has been modified, it is also written to the disk if neither of the following conditions is met:

- The file was opened with write permissions using the UPDATE keyword to the IDLffShape::Open method

- It is a newly created file that has not been written previously.

If the file has been modified and one of the previous conditions is not met, the file is closed and the changes are not written to disk.

Syntax

Obj->[IDLffShape::]Close

Arguments

None

Keywords

None

Version History

5.4	Introduced

IDLffShape::DestroyEntity

The IDLffShape::DestroyEntity procedure method frees memory associated with the entity structure. For more information on the entity structure, see "Entities" on page 3382.

Syntax

Obj->[IDLffShape::]DestroyEntity, *Entity*

Arguments

Entity

A scalar or array of entities to be destroyed.

Keywords

None

Examples

In the following example, all of the entities from the states.shp Shapefile are read and then the DestroyEntity method is called to clean up all pointers:

```
PRO ex_shapefile

; Open the states Shapefile in the examples directory.
myshape=OBJ_NEW('IDLffShape', FILEPATH('states.shp', $
   SUBDIR=['examples', 'data']))

; Get the number of entities so we can parse through them.
myshape->GetProperty, N_ENTITIES=num_ent

; Read all the entities.
FOR x=1, (num_ent-1) DO BEGIN
   ;Read the entity x
   ent = myshape->GetEntity(x)
   ;Clean-up of pointers
   myshape->DestroyEntity, ent
ENDFOR

; Close the Shapefile.
OBJ_DESTROY, myshape
END
```

Version History

5.4	Introduced

IDLffShape::GetAttributes

The IDLffShape::GetAttributes function method retrieves the attributes for the entities you specify from a Shapefile.

Syntax

Result = Obj->[IDLffShape::]GetAttributes([*Index*] [, /ALL]
   [, /ATTRIBUTE_STUCTURE])

Return Value

Returns an anonymous structure array. For more information on the structure, see "Attributes" on page 3386.

Arguments

Index

A scalar or array of longs specifying the entities for which you want to retrieve the attributes, with 0 being the first entity in the Shapefile.

Note

If you do not specify *Index* and the ALL keyword is not set, the attributes for the first entity (0) are returned.

Keywords

ALL

Set this keyword to retrieve the attributes for all entities in a Shapefile. If you set this keyword, the *Index* argument is not required.

ATTRIBUTE_STUCTURE

Set this keyword to return an empty attribute structure that can then be used with the IDLffShape::SetAttributes method to add attributes to a Shapefile.

Examples

In the first example, we retrieve the attributes associated with entity at location 0 (the first entity in the file):

```
attr = myShape->getAttributes( 0)
```

In the next example, we retrieve the attributes associated with entities 10 through 20:

```
attr = myShape->getAttributes( 10+indgen(11) )
```

In the next example, we retrieve the attributes for entities 1,4, 9 and 70:

```
attr = myShape->getAttributes( [1, 4, 9, 70] )
```

In the next example, we retrieve all the attributes for a Shapefile:

```
attr = myShape->getAttributes( /ALL )
```

Version History

5.4	Introduced

IDLffShape::GetEntity

The IDLffShape::GetEntity function method returns the entities you specify from a Shapefile.

Syntax

Result = Obj->[IDLffShape::]GetEntity([*Index*] [, /ALL] [, /ATTRIBUTES])

Return Value

Returns a type {IDL_SHAPE_ENTITY} structure array. For more information on the structure, see "Entities" on page 3382.

Note ───

Since an entity structure contains IDL pointers, you must free all the pointers returned in these structures when the entity is no longer needed using the IDLffShape::DestroyEntity method.

───

Note ───

Since entities cannot be modified in a Shapefile, an entity is read directly from the Shapefile each time you use the IDLffShape::GetEntity method even if you have already read that entity. If you modify the structure array returned by this method for a given entity and then use IDLffShape::GetEntity on that same entity, the modified data will NOT be returned, the data that is actually written in the file is returned.

───

Arguments

Index

A scalar or array of longs specifying the entities for which you want to retrieve with 0 being the first entity in the Shapefile. If the ALL keyword is set, this argument is not required. If you do not specify any entities and the ALL keyword is not set, the first entity (0) is returned.

Keywords

ALL

Set this keyword to retrieve all entities from the Shapefile. If this keyword is set, the Index argument is not required.

ATTRIBUTES

Set this keyword to return the attributes in the entity structure. If not set, the ATTRIBUTES tag in the entity structure will be a null IDL pointer.

Examples

In the following example, all of the entities from the states.shp Shapefile are read:

```
PRO ex_shapefile

; Open the states Shapefile in the examples directory.
myshape=OBJ_NEW('IDLffShape', FILEPATH('states.shp', $
   SUBDIR=['examples', 'data']))

; Get the number of entities so we can parse through them.
myshape->GetProperty, N_ENTITIES=num_ent

; Read all the entities. The entity array in a Shapefile
; starts with index zero (0).
FOR x=0, (num_ent-1) DO BEGIN
   ;Read the entity x
   ent = myshape->GetEntity(x)
   ;Clean-up of pointers
   myshape->DestroyEntity, ent
ENDFOR

; Close the Shapefile.
OBJ_DESTROY, myshape

END
```

Version History

5.4	Introduced

IDLffShape::GetProperty

The IDLffShape::GetProperty procedure method returns the values of properties associated with a Shapefile object. These properties are:

- Number of entities

- The type of the entities

- The number of attributes associated with each entity

- The names of the attributes

- The name, type, width, and precision of the attributes

- The status of a Shapefile

- The filename of the Shapefile object

Syntax

Obj->[IDLffShape::]GetProperty [, *PROPERTY=variable*]

Arguments

None

Keywords

Any property listed under "IDLffShape Properties" on page 3394 that contains the word "Yes" in the "Get" column of the properties table can be retrieved using this method. To retrieve the value of a property, specify the property name as a keyword set equal to a named variable that will contain the value of the property.

Examples

In the following example, the number of entities and the entity type is returned:

```
PRO entity_info

; Open the states Shapefile in the examples directory.
myshape=OBJ_NEW('IDLffShape', FILEPATH('states.shp', $
   SUBDIR=['examples', 'data']))

; Get the number of entities and the entity type.
myshape->GetProperty, N_ENTITIES=num_ent, $
   ENTITY_TYPE=ent_type
```

```
; Print the number of entities and the type.
PRINT, 'Number of Entities: ', num_ent
PRINT, 'Entity Type: ', ent_type

; Close the Shapefile.
OBJ_DESTROY, myshape

END
```

This results in the following:

```
Number of Entities:        51
Entity Type:                5
```

In the next example, the definitions for attribute 1 are returned:

```
PRO attribute_info

; Open the states Shapefile in the examples directory.
myshape=OBJ_NEW('IDLffShape', FILEPATH('states.shp', $
   SUBDIR=['examples', 'data']))

; Get the info for all attribute.
myshape->GetProperty, ATTRIBUTE_INFO=attr_info

; Print Attribute Info.
PRINT, 'Attribute Number: ', '1'
PRINT, 'Attribute Name: ', attr_info[1].name
PRINT, 'Attribute Type: ', attr_info[1].type
PRINT, 'Attribute Width: ', attr_info[1].width
PRINT, 'Attribute Precision: ', attr_info[1].precision

; Close the Shapefile.
OBJ_DESTROY, myshape

END
```

This results in the following:

```
Attribute Number:          1
Attribute Name:    STATE_NAME
Attribute Type:            7
Attribute Width:          25
Attribute Precision:       0
```

Version History

5.4	Introduced

IDLffShape::Init

The IDLffShape::Init function method initializes or constructs a Shapefile object.

Note ────────────────────────────────────

Init methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation. This means that in most cases, you cannot call the Init method directly. There is one exception to this rule: If you write your own subclass of this class, you can call the Init method from within the Init method of the subclass.

──

Syntax

Result = OBJ_NEW('IDLffShape' [, *Filename*] [, *PROPERTY=value*])

or

Result = *Obj*->[IDLffShape::]Init([, *Filename*] [, *PROPERTY=value*])   *(In a lifecycle method only.)*

Return Value

When this method is called indirectly, as part of the call to the OBJ_NEW function, the return value is an object reference to the newly-created object.

When called directly within a subclass Init method, the return value is 1 if initialization was successful, or zero otherwise.

Arguments

Filename

A scalar string containing the full path and filename of a Shapefile (.shp) to open. If this file exists, it is opened. If the file does not exist, a new Shapefile object is constructed. You do not need to use IDLffShape::Open to open an existing file when specifying this argument.

Note ────────────────────────────────────

The .shp, .shx, and .dbx files must exist in the same directory for you to be able to open and access the file unless the UPDATE keyword is set.

──

Note ——

The value specified by the *Filename* argument is used to initialize the value of the FILENAME property of the IDLffShape object.

——

Keywords

Any property listed under "IDLffShape Properties" on page 3394 that contains the word "Yes" in the "Init" column of the properties table can be initialized during object creation using this method. To initialize the value of a property, specify the property name as a keyword set equal to the appropriate property value.

Examples

In the following example, we create a new Shapefile object and open the examples/data/states.shp file:

```
myshape=OBJ_NEW('IDLffShape', FILEPATH('states.shp', $
    SUBDIR=['examples', 'data']))
```

Version History

5.4	Introduced

IDLffShape::Open

The IDLffShape::Open function method opens a specified Shapefile.

Syntax

Result = Obj->[IDLffShape::]Open(*'Filename'* [, /DBF_ONLY]
   [, ENTITY_TYPE=*'value'*] [, /UPDATE])

Return Value

Returns 1 if the file can be read successfully. If not able to open the file, it returns 0.

Arguments

Filename

A scalar string containing the full path and filename of a Shapefile (.shp) to open.
Note that the .shp, .shx, and .dbx files must exist in the same directory for you to
be able to open and access the file unless the UPDATE keyword is set.

Keywords

DBF_ONLY

If this keyword is set to a positive value, only the underlying dBASE table (.dbf)
component of the shapefile is opened. All entity related files are left closed. Two
values to this keyword are accepted: 1 - Open an existing .dbf file, > 1 - Create a new
.dbf file

The UPDATE keyword is required to open the .dbf file for updating.

ENTITY_TYPE

Set this keyword to the entity type of a new Shapefile. Use this keyword only when
creating a new Shapefile. For more information on entity types, see "Entities" on
page 3382.

UPDATE

Set this keyword to have the file opened for writing. The default is read-only.

Examples

In the following example, the file `examples/data/states.shp` is opened for reading and writing:

```
status = myShape->Open(FILEPATH('states.shp', $
    SUBDIR=['examples', 'data']), /UPDATE)
```

Version History

5.4	Introduced

IDLffShape::PutEntity

The IDLffShape::PutEntity procedure method inserts an entity into the Shapefile object. The entity must be in the proper structure. For more information on the structure, see "Entities" on page 3382.

Note ──

The shape type of the new entity must be the same as the shape type defined for the Shapefile. If the shape type has not been defined for the Shapefile using the ENTITY_TYPE keyword for the IDLffShape::Open or IDLffShape::Init methods, the first entity that is inserted into the Shapefile defines the type.

──

Note ──

Only new entities can be inserted into a Shapefile. Existing entities cannot be updated.

──

Syntax

Obj->[IDLffShape::]PutEntity, *Data*

Arguments
