Rainfall Variability with Super-Parameterization

Charlotte A. DeMott Colorado State University

STC Planning Workshop, Fort Collins, CO, December 18, 2003

Introduction

- How does rainfall variability using SP compare to observations?
 - As a function of rainfall rate
 - As a function of precipitable water (PW)
- When the SP improves upon the CAM, does it do so for the right reasons?

"In modeling, there are a lot of wrong ways to get the right answer."--Bill Gray

• When the SP produces large errors, can variability analysis suggest why?

Outline

- Methodology
- Observational data
- Rainfall rate distributions
- Rainfall as a function of PW

Approach

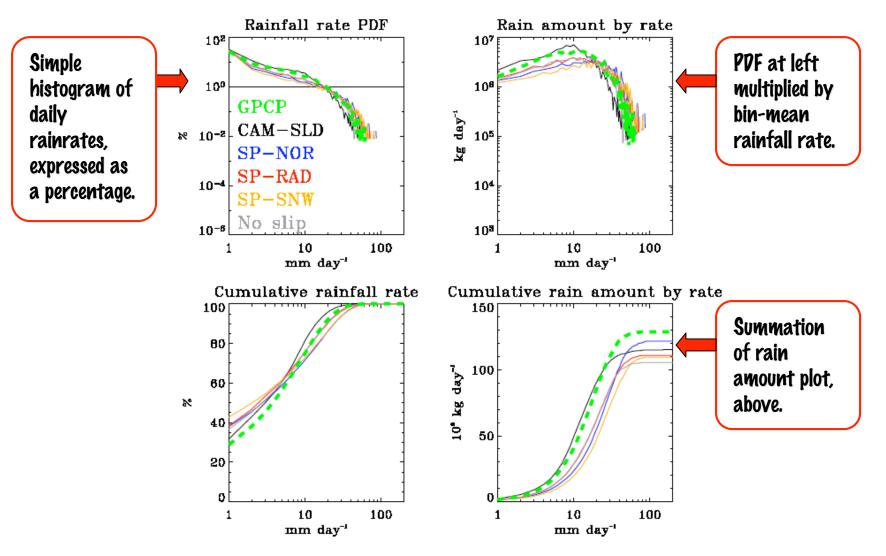

- Compare modeled and observed daily mean rainfall and PW over several locations and seasons.
- Regions and seasons:
 The Good News: Amazon Basin, DJF
 The Bad News: "Great Red Spot", JJA

Observational Data

- Precipitation
 - GPCP daily mean rainfall, 1°×1° resolution, 9/1998 - 12/1999.
 - Data regridded to 2.5°× 2.5° or 2.8°× 2.8° resolution for comparison with PW data or model output, respectively.
- Precipitable water
 - ECMWF ERA 40 Reanalysis dataset, 9/1998-12/1999, 2.5°× 2.5° resolution.

Rainfall vs. Precipitable Water

- Rainfall is influenced by PW and also influences PW by removing water vapor from the column.
- Comparing how rainfall relates to PW in models and observations may yield insight into how various parameterizations perform.

DFJ Amazon Basin

- CAM, SP-RAD produce too much rainfall at low PWs, not enough at high PWs.
- DRAG run produces too much rainfall at low RRs, but has smallest overall error.

- CAM places bulk of rainfall in a small RR-PW parameter space.
- SP runs have erroneously large PW values, which are associated with the highest rainfalls.

Summary

• SP runs tend to produce too much rainfall at the highest rainrates and too little at the lowest rainrates.

• CAM has the opposite problem.

- Rainfall-PW distribution errors are smallest in SP runs, especially DRAG.
- Unrealistically high PW, RR values in GRS may result in part from cyclic boundary condition on CRM.
