

# Subtropical Stratocumulus Processes and Feedbacks: The Role of Large-Scale Dynamics

Joel Norris

Eighth CMMAP Team Meeting

January 12, 2010

# Collaborators

Amy Clement and Robert Burgman

*Rosenstiel School of Marine and Atmospheric Science*

*University of Miami*

# Introduction and Motivation

# 4<sup>th</sup> IPCC: Key Uncertainties

- “Cloud feedbacks (particularly from low clouds) remain the largest source of uncertainty [to climate sensitivity].”
- “Surface and satellite observations disagree on total and low-level cloud changes over the ocean.”
- “Large uncertainties remain about how clouds might respond to global climate change.”
- “Cloud feedbacks are the primary source of intermodel differences in equilibrium climate sensitivity...”

# Low-Level Cloud and Net Radiation

Annual ISCCP C2 Inferred Stratus Cloud Amount

Hartmann et al. 1992

Cloud with tops below 680 mb  
(less than 3 km)

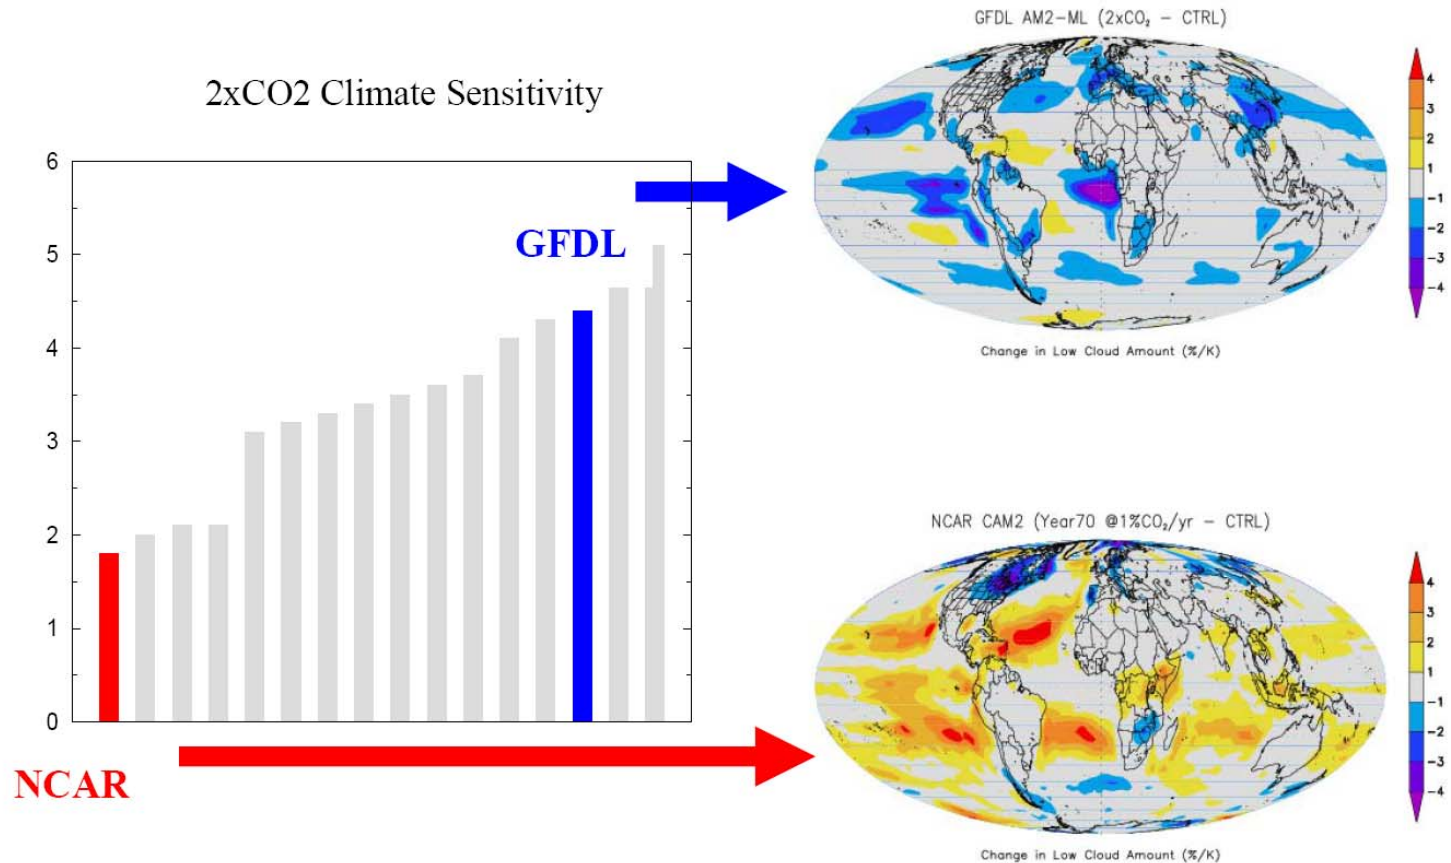

Annual ERBE Net Radiative Cloud Forcing

W/m<sup>2</sup>

Low-level clouds and especially marine stratocumulus cool the planet (solar reflection by clouds greater than greenhouse effect of clouds)

# Simulated Cloud Change for $2\times\text{CO}_2$

Courtesy of Brian Soden

Models predict different signs of cloud change

# Why is Cloud Simulation Difficult?

- Cloud distribution in boundary layer is controlled by small-scale processes
- Shallow convection, turbulence, entrainment, and radiative cooling are closely interacting
- Parameterizations in terms of resolved-scale processes are too crude and disconnected

# Boundary Layer Structure and Clouds

# What Promotes Decoupling?

- Entrainment of warm air stratifies boundary layer  
*except for condition of CTEI*
- Daytime solar heating of cloud layer  
*diurnal effect*
- Drizzle condensation in cloud layer and evaporation in subcloud layer  
*potentially influenced by anthropogenic aerosol*

# What Promotes Decoupling?

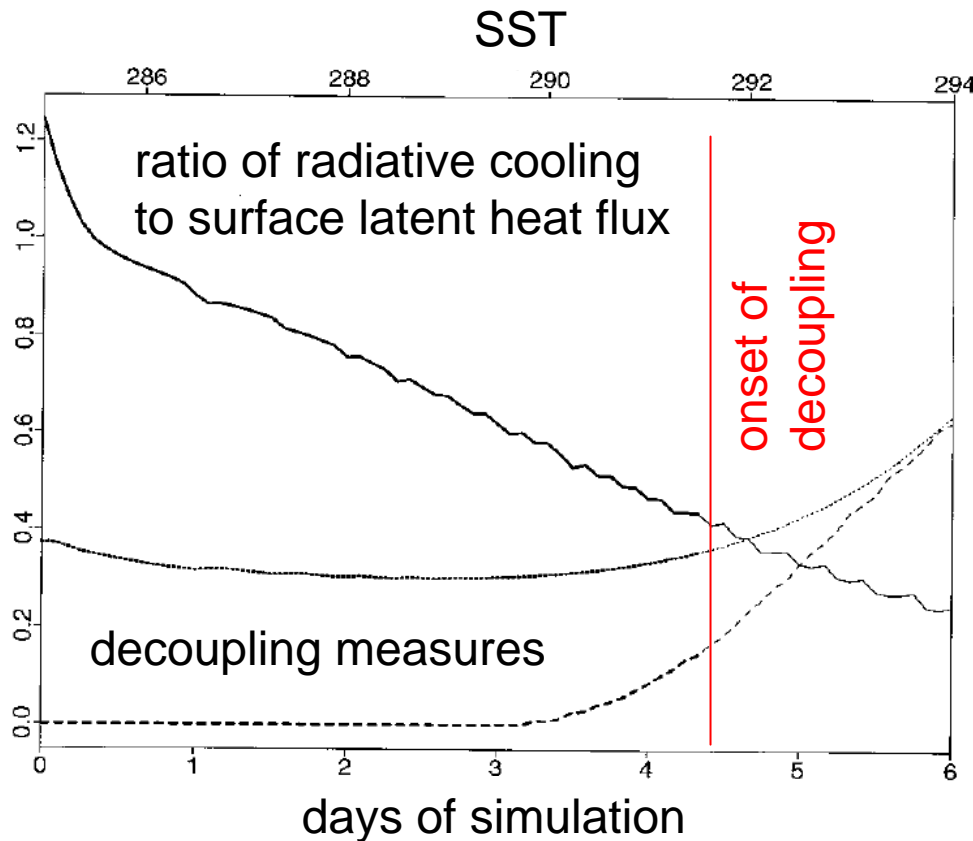

- Deeper boundary layer

from Wood and Bretherton (2004)

# What Promotes Decoupling?

- Surface heat flux stronger than radiative cooling

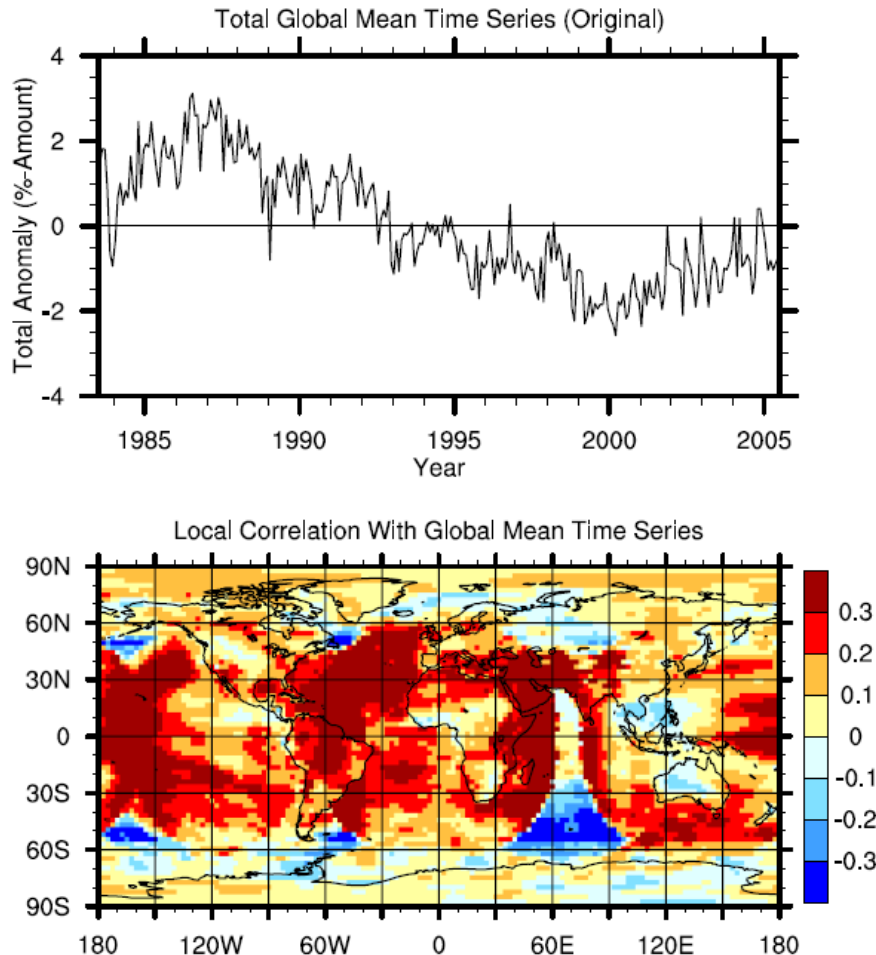

from Bretherton  
and Wyant (1997)

# Observed Multidecadal Relationships

# Artifacts Dominate Cloud Record

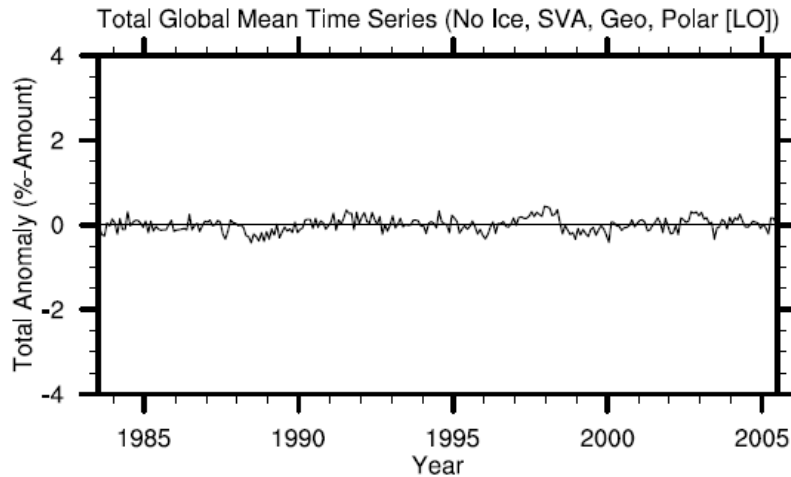

*ISCCP cloud amount is dominated by artifacts on multidecadal time scales caused by:*

changes in satellite view angle (Evan et al. 2007)

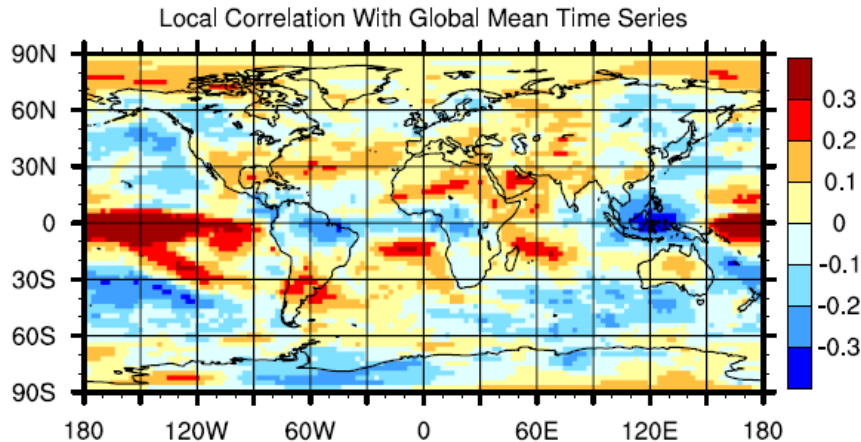

imperfect calibration of geostationary satellites

# But This Can Be Corrected

*ISCCP total cloud amount after statistical removal of artifacts via linear regression:*

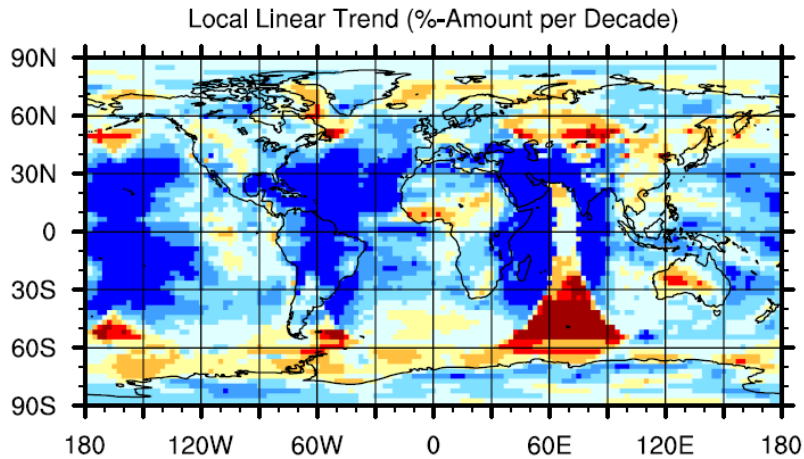

satellite view angle

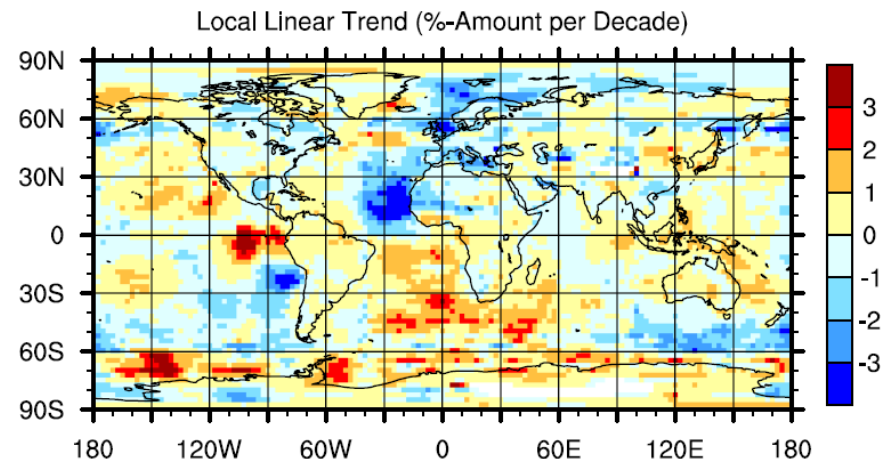

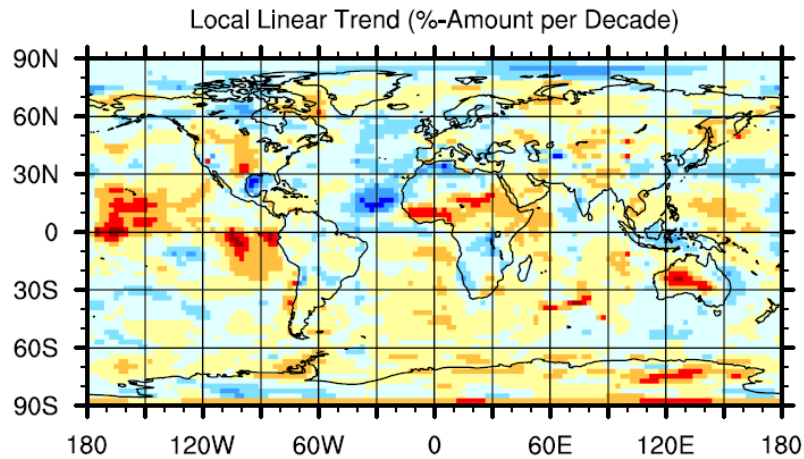

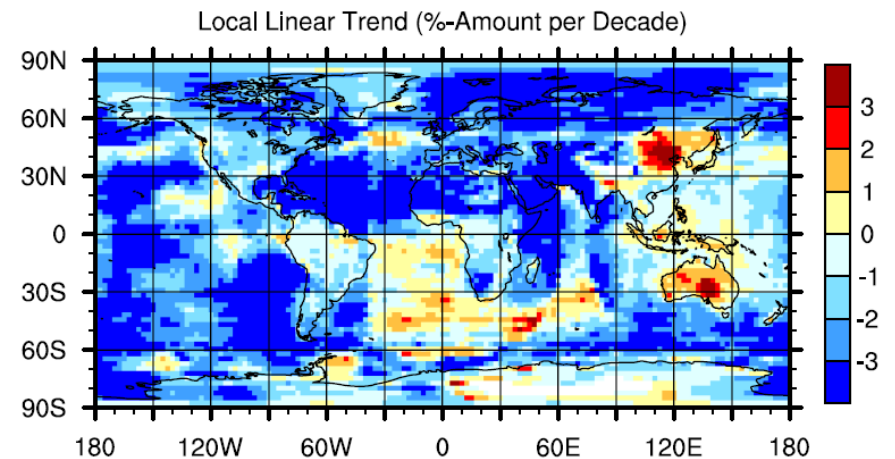

average normalized anomaly within view of a geostationary satellite

# Before and After Cloud Trends

total cloud

low-level cloud

# NE Pacific Decadal Variability

How is cloud variability related to SST and circulation?

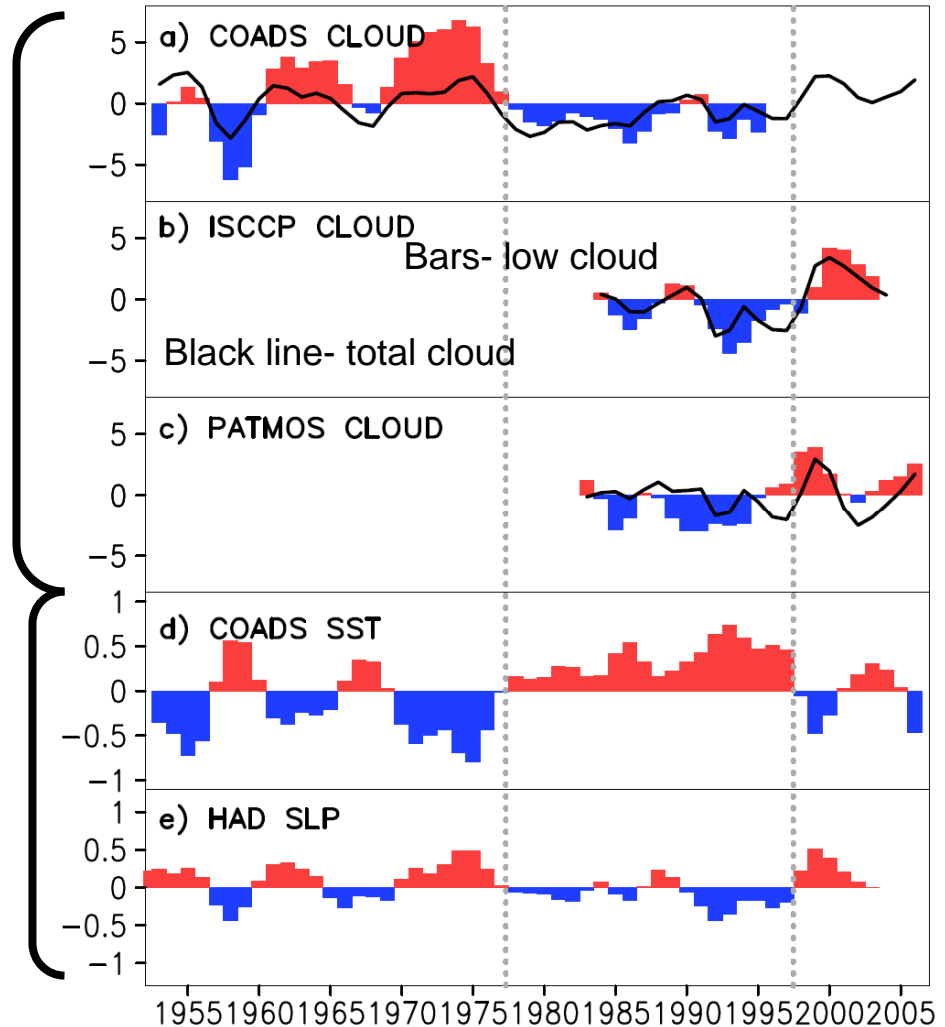

# NE Pacific Decadal Variability

Similar variations in three independent cloud datasets

Cloud fluctuations coincide with regional SST and SLP changes

- 1976 'shift'
- Late 1990's 'shift'

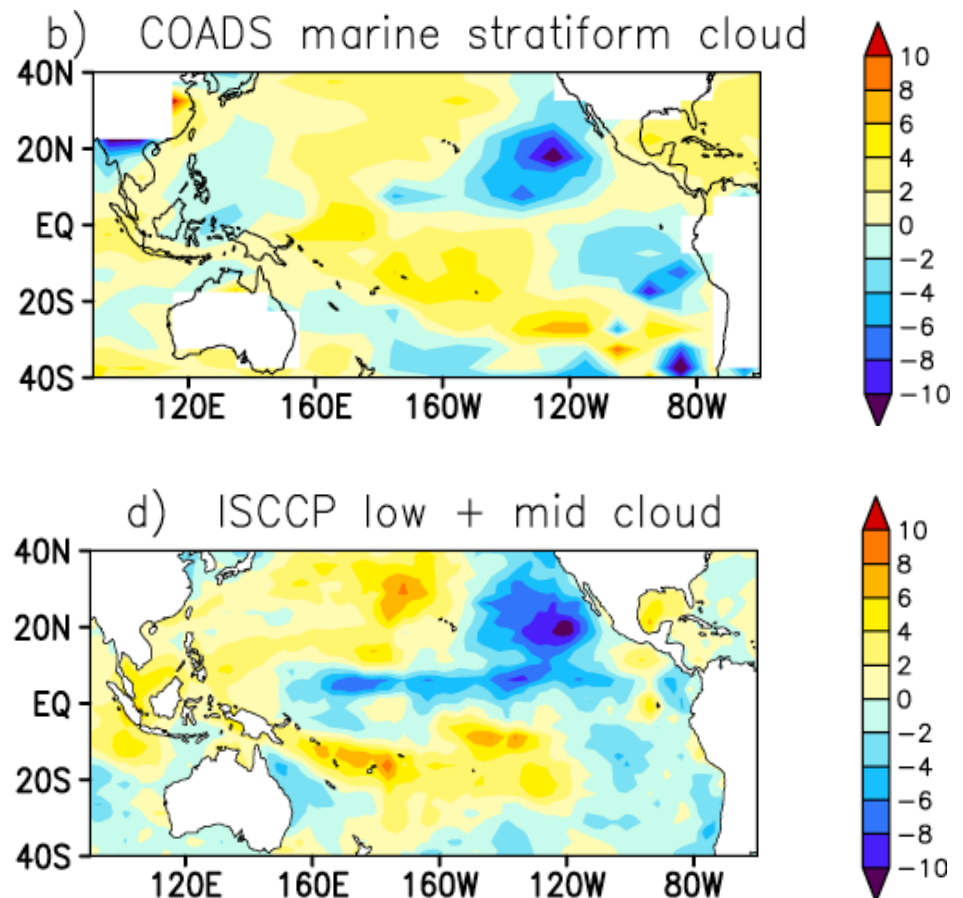

# Spatial Structure of Cloud Change

## Regression of low cloud on NE Pacific SST

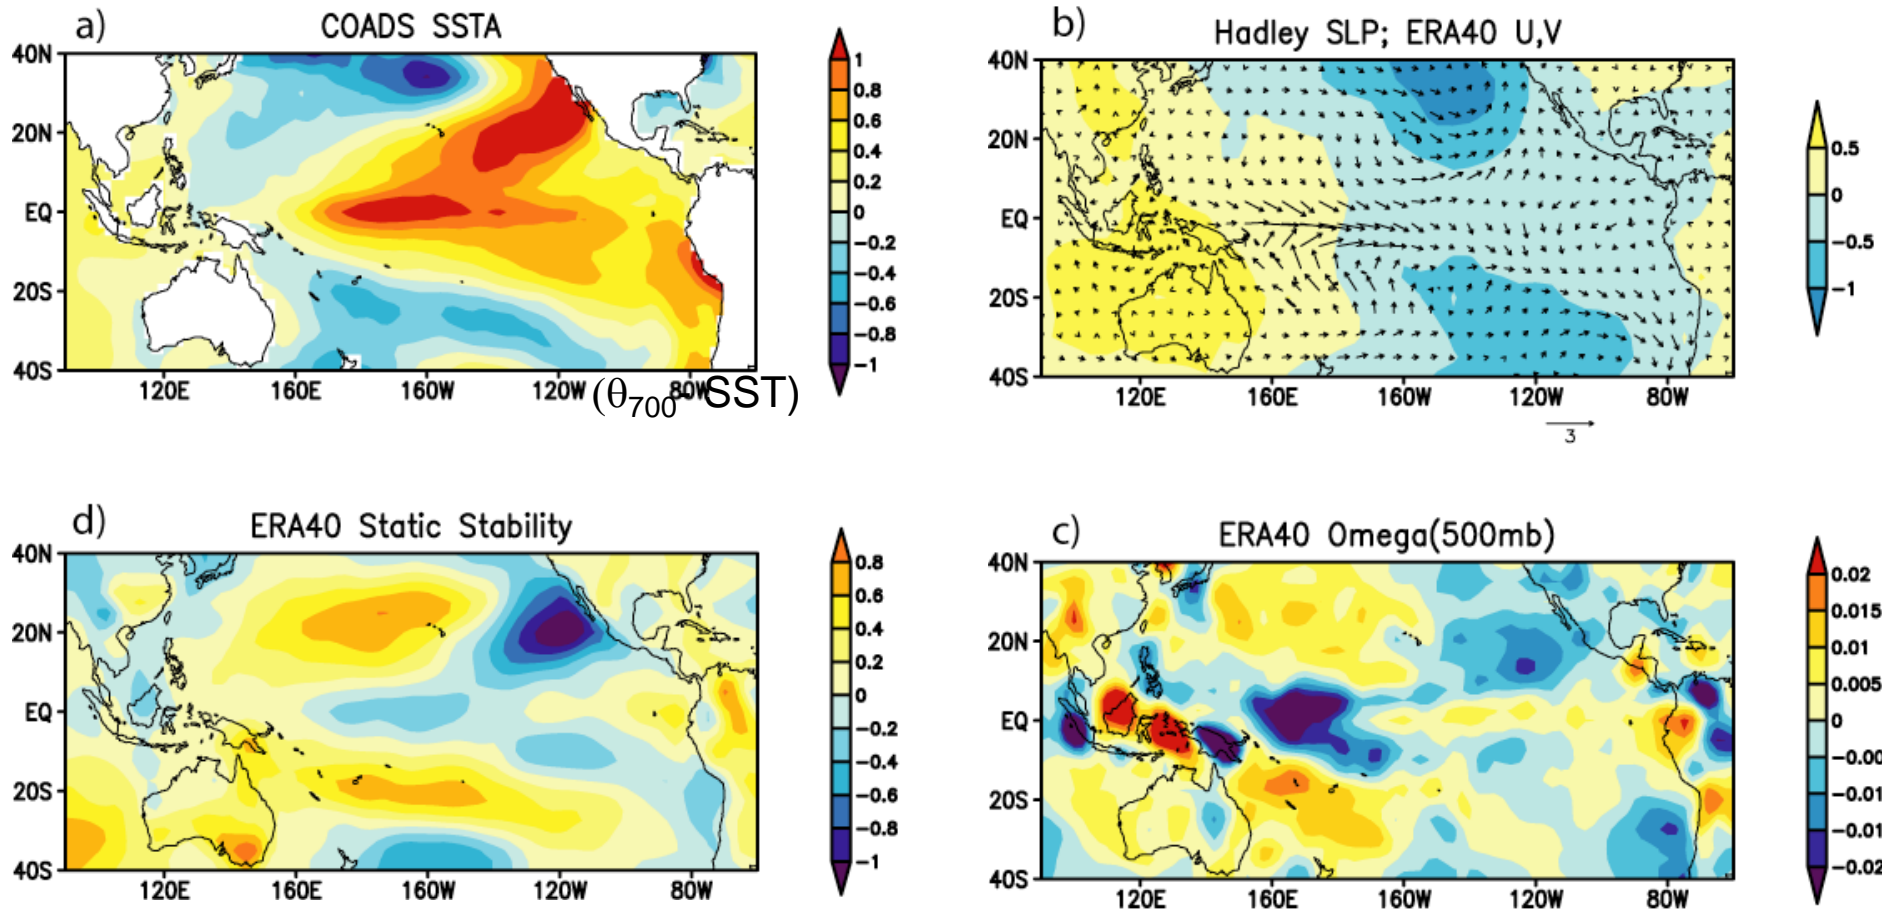

COADS and ISCCP show less low-level cloud cover over NE and SE subtropical Pacific when NE Pacific SST is warm

PATMOS pattern is similar (not shown)

# Structure of Meteorological Change

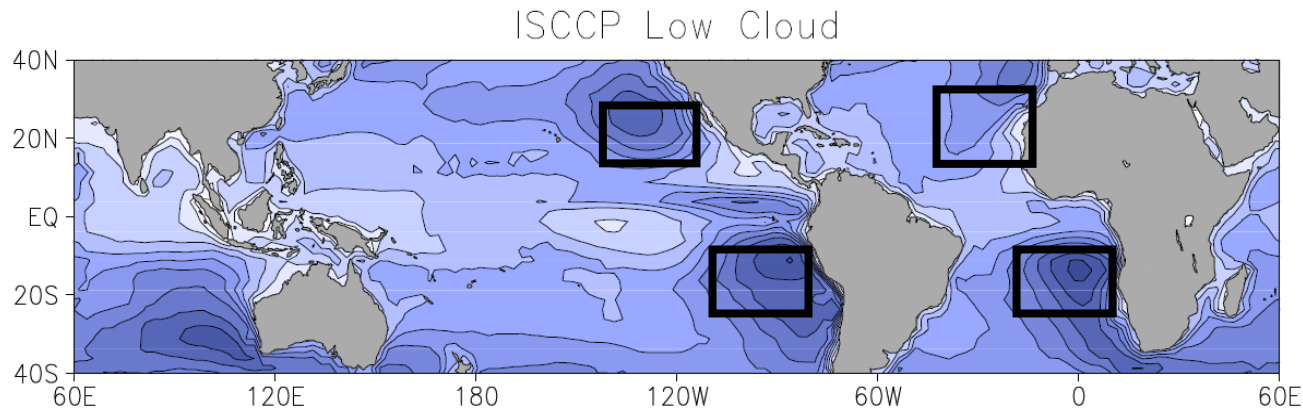

## Regression on NE Pacific SST

lower tropospheric static stability (LTS) =  $\theta_{700} - \theta_{SST}$

# Cloud-Meteorological Correlations

ISCCP low cloud amount	SST	LTS	SLP	$\omega_{500}$ (NCEP)
NE Pacific	<b>-0.85</b>	<b>0.65</b>	<b>0.71</b>	<b>0.42</b>
SE Pacific	<b>-0.53</b>	<b>0.65</b>	0.40	0.38
NE Atlantic	<b>-0.72</b>	<b>0.44</b>	<b>0.60</b>	<b>0.78</b>
SE Atlantic	<b>-0.52</b>	<b>0.51</b>	<b>0.58</b>	0.37

\*Significant correlations (based on t-statistic) at the 95% level are shown in **bold**.

# Co-Meteorological Correlations

<b>NE PACIFIC</b>	<b>SST</b>	<b>LTS</b>	<b>SLP</b>	$\omega_{500}$
<b>SST</b>	<b>1</b>	<b>-0.8</b>	<b>-0.7</b>	<b>-0.36</b>
<b>LTS</b>		<b>1</b>	<b>0.71</b>	<b>0.63</b>
<b>SLP</b>			<b>1</b>	<b>0.42</b>
$\omega_{500}$				<b>1</b>

Results are similar for other regions.

All values are significant at the 95% level based on t-statistic

# Mechanisms Driving Relationships

$$W_s < 0$$

*weaker subsidence*

*entrainment rate matches  
subsidence at higher elevation  
(Schubert et al., 1979)*

$$W_e$$

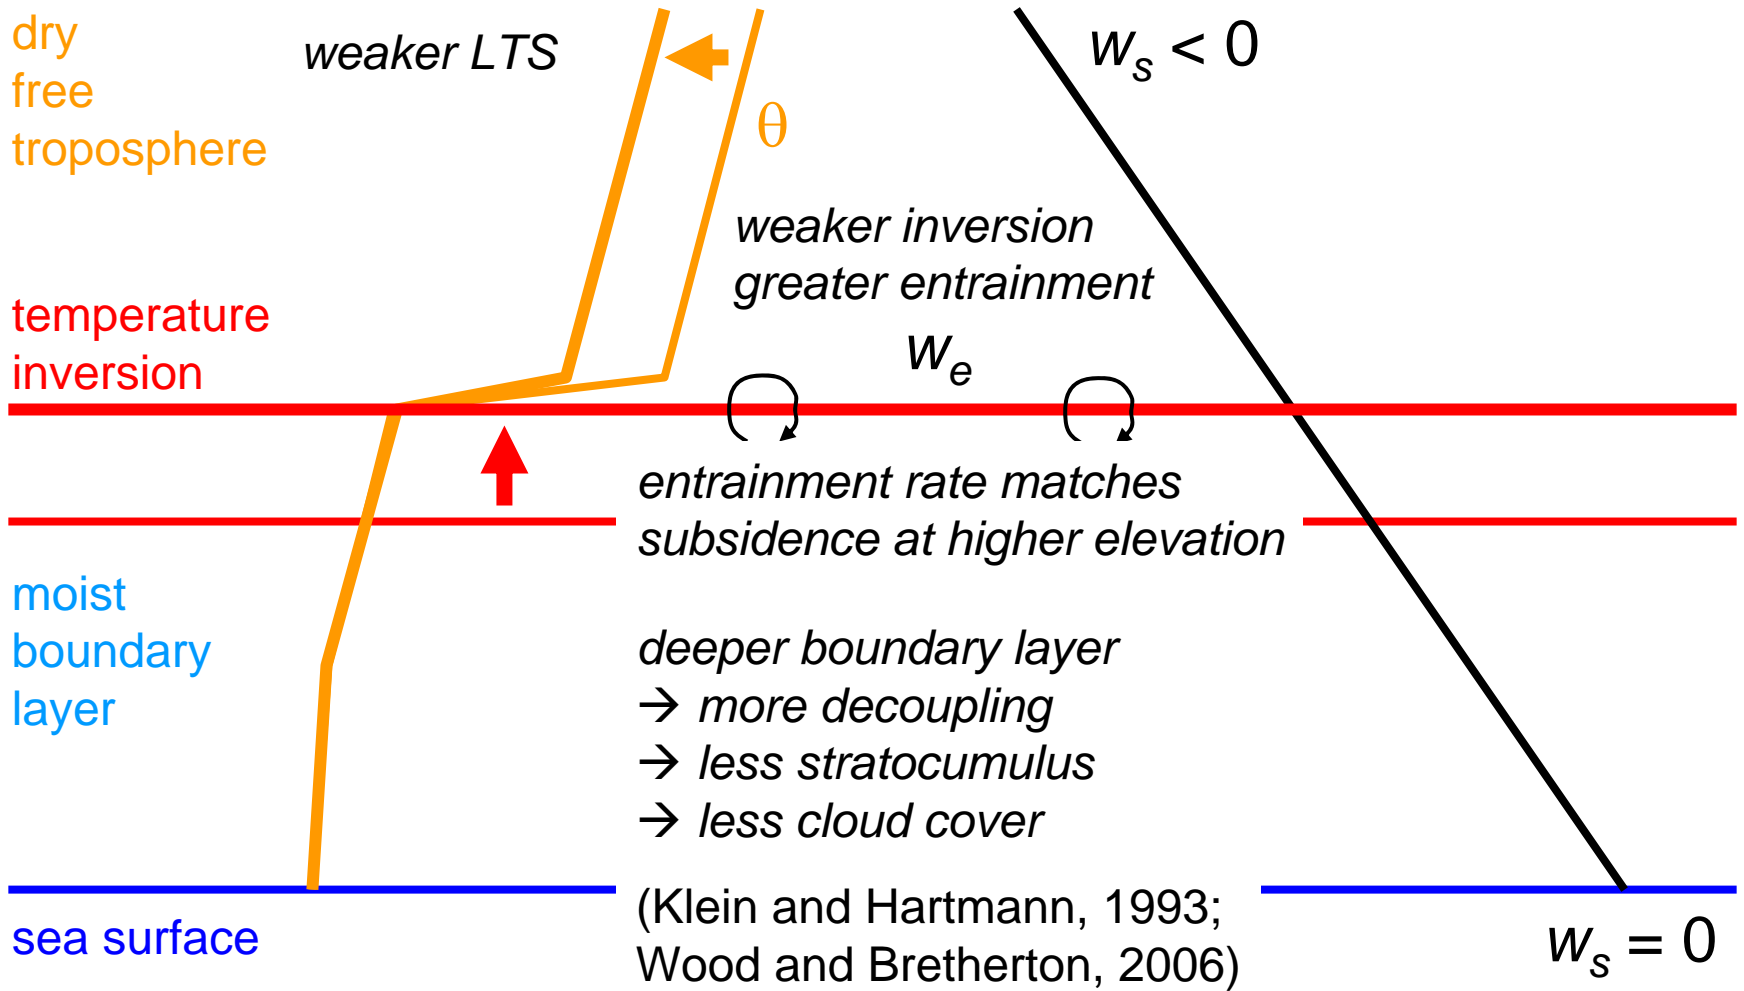

*deeper boundary layer  
→ more decoupling  
→ less stratocumulus  
→ less cloud cover*

$$W_s = 0$$

# LTS and Cloud

# SLP and Cloud

- SLP is positively correlated with LTS, divergence, and pressure vertical velocity
- Lower subtropical SLP is associated with weaker trade winds
- Weaker trade winds produce less advection from upwind stratocumulus regions
- Cloud cover locally decreases in downwind region

# SST and Cloud

- Warmer SST contributes to weaker LTS
- Warmer SST produces greater latent heat flux
- Greater latent heat flux favors more decoupling
- More decoupling promotes less stratocumulus and less cloud cover

# Cloud Feedbacks

- Less cloud cover warms the ocean and weakens LTS
- Less cloud cover reduces radiative cooling of the boundary layer
  - Weaker pressure gradient and trade winds (Ma et al. 1996, Nigam 1997)
  - Weaker subsidence warming

# Cloud Feedbacks and Climate

*In eastern subtropical oceans...*

- Surface cloud radiative warming anomalies are larger than latent heat cooling anomalies
- Ocean dynamical forcing is weak (Hazeleger et al., 2004)
- Cloud feedbacks may promote persistence of SST anomalies and enhance decadal variability
- What about global warming?

# Model Simulations

# Are CMIP3 Simulations Realistic?

- Do the models reproduce the correct sign of the observed correlation for all parameters?
- Examine total cloud correlation because low-level cloud usually not archived
- The preceding test is a necessary (but not sufficient) condition for a credible low-level cloud feedback
- Will examine CMIP5 archive when available

# Are CMIP3 Simulations Realistic?

Only two models (HadGEM1 and INMCM3) reproduced the correct sign of all observed correlations

INMCM3 had strongly empirical cloud schemes and produced a very unrealistic mean tropical climate

# HadGEM1 2×CO<sub>2</sub> Change

## Observed Decadal

## 2×CO<sub>2</sub> Simulation

2×CO<sub>2</sub> cloud and circulation changes resemble observed decadal cloud and circulation changes

# HadGEM1 2×CO<sub>2</sub> Change

- HadGEM1 SLP change resembles multimodel mean, suggesting it is robust
- HadGEM1 cloud and SLP changes resemble observed NE Pacific patterns, suggesting similar mechanisms apply
- This implies a regional positive subtropical stratocumulus feedback under global warming  
*but...*
- LTS change is different sign from observed

# Tropical LTS and Regional Dynamics

# Increased LTS for Global Warming

- Moist adiabatic lapse rate in deep convection regions decreases for warmer SST
- The decreased lapse rate is communicated throughout the tropical free troposphere
- LTS increases in subtropical regions
- Stronger LTS promotes more stratocumulus and more cloud cover (Miller 1997; Medeiros et al., 2008)

*Is the last step correct?*

# LTS and EIS

*Estimated inversion strength* (EIS) takes into account the temperature dependence of the moist adiabatic lapse rate (Wood and Bretherton 2006)

Climatological low-level cloud cover has higher correlation with EIS than LTS

# LTS and EIS

In a warmer climate, EIS does not change as much as LTS because  $d\theta/dz$  between inversion and 700 hPa is larger (WB 2006)

→ Much smaller impact on cloud!

# LTS and Subsidence

*What is the relationship between LTS and subsidence?*

- Dynamical control of LTS?
- Thermodynamical control of subsidence?

# Dynamical Control of LTS?

- Stronger subsidence produces warming through greater vertical temperature advection
- Because subsidence rate increases with height, warming increases with height (e.g, stronger LTS)
- Consistent with positive observed correlation between  $\omega_{500}$  and LTS

# Thermodynamic Control of Subsidence

- Stronger LTS associated with weaker lapse rate
- Less subsidence needed for vertical temperature advection to balance tropospheric radiative cooling

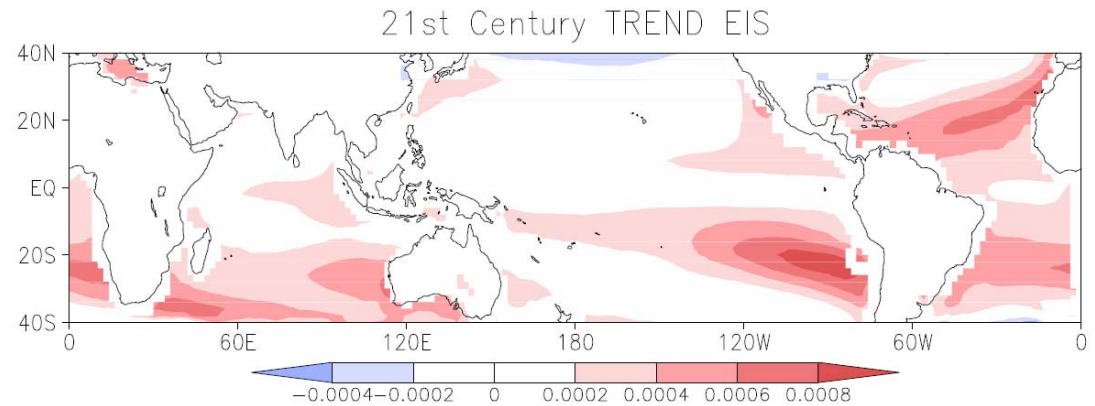

*But...*

- Negative correlation between  $\omega_{500}$  and LTS not regionally observed on multiyear time scales
- Regional dynamics may differ from tropical mean circulation change under global warming

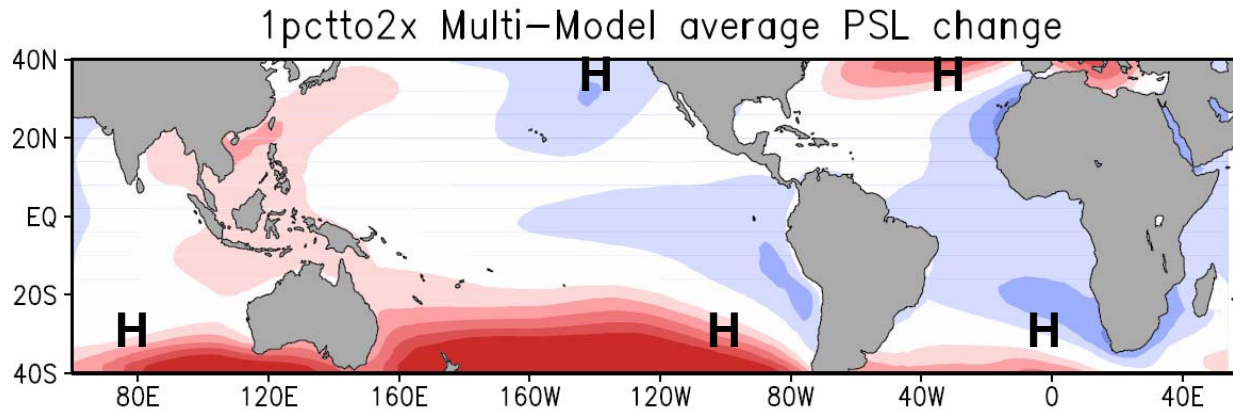

# Multimodel Trend in LTS and EIS

Much smaller trends in EIS than LTS

Positive EIS trends due to less SST warming than elsewhere

# Multimodel Trend in SLP

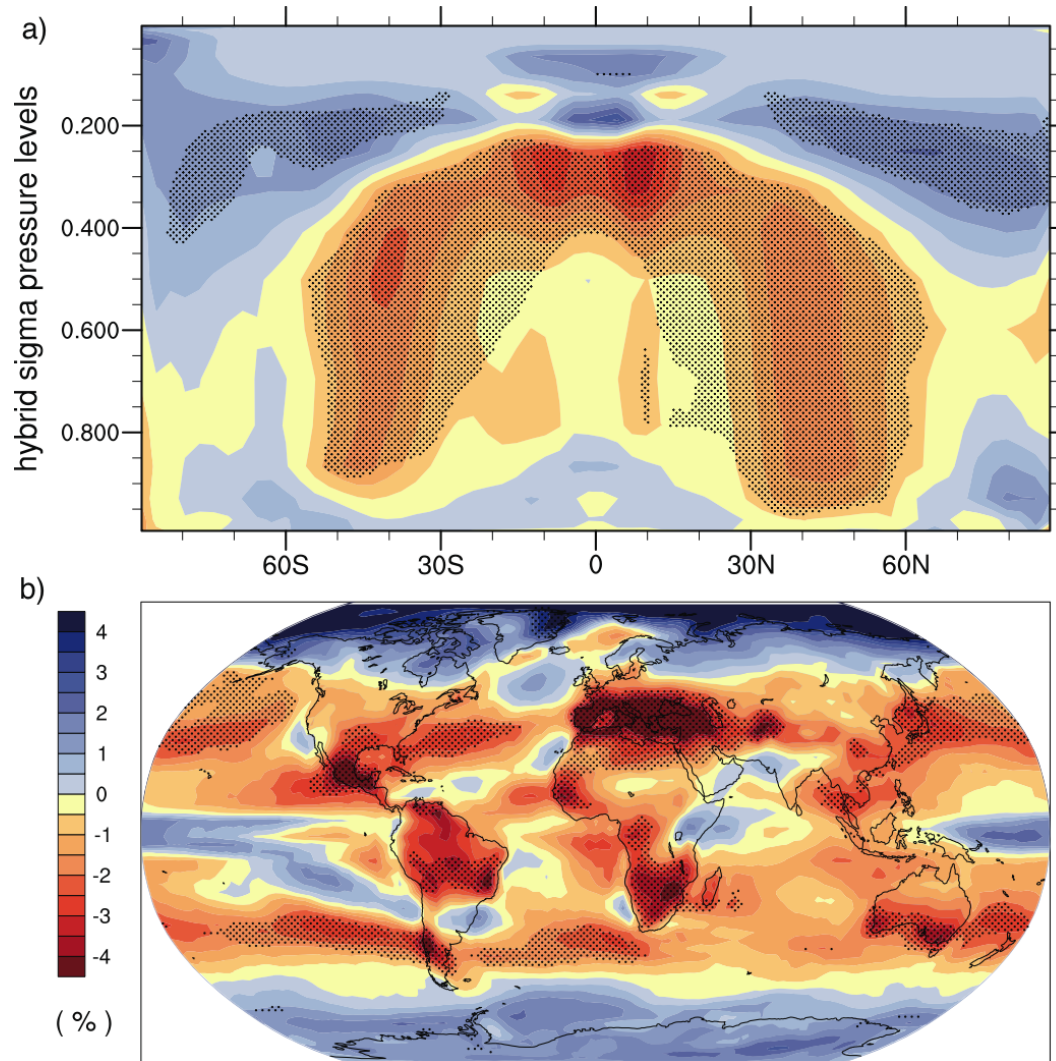

**H** indicates locations of annual mean subtropical anticyclone centers

Increased trade winds in eastern subtropical regions  
other than NE Pacific

More evaporation, reduced SST warming, stronger EIS

More cloud cover?

# Multimodel Trend in Total Cloud

Low-latitude trends dominated by high-level cloud changes

Not really consistent with EIS and circulation trends

Adapted from Fig. 10.10 of IPCC AR4, courtesy of Steve Klein

# Hypotheses

# “Tropical Mean” Cloud Hypotheses

- Changes in moist adiabatic lapse rate will have little impact on EIS and thus little impact on low-level cloud cover (*no negative feedback*)
- Weaker tropical mean subsidence with unchanged EIS will promote a deeper BL and less low-level cloud cover (*positive feedback*)
- Warmer tropical mean SST and reduced cloud top radiative cooling will promote decoupling and less cloud cover (*positive feedback*)

# Regional Cloud Hypotheses

- Regional circulation trends will have a bigger impact on low-level clouds than tropical mean trends (*varying regional cloud changes*)
- Circulation changes may offset warmer SST effects on clouds
- Clouds exert a positive feedback on regional SST and circulation (*we will do modeling experiments*)

# Conclusions

- Regional circulation has a large impact on subtropical low-level cloud variability
- Clouds appear to exert a positive feedback on regional circulation and SST on decadal and probably longer time scales
- Models should reproduce multiple observed relationships between meteorology and cloud as a necessary (but not sufficient) condition for a credible subtropical cloud feedback
