- Helena Schlüter, Univ of Utah
- Hermann Gerber, Reston, VA

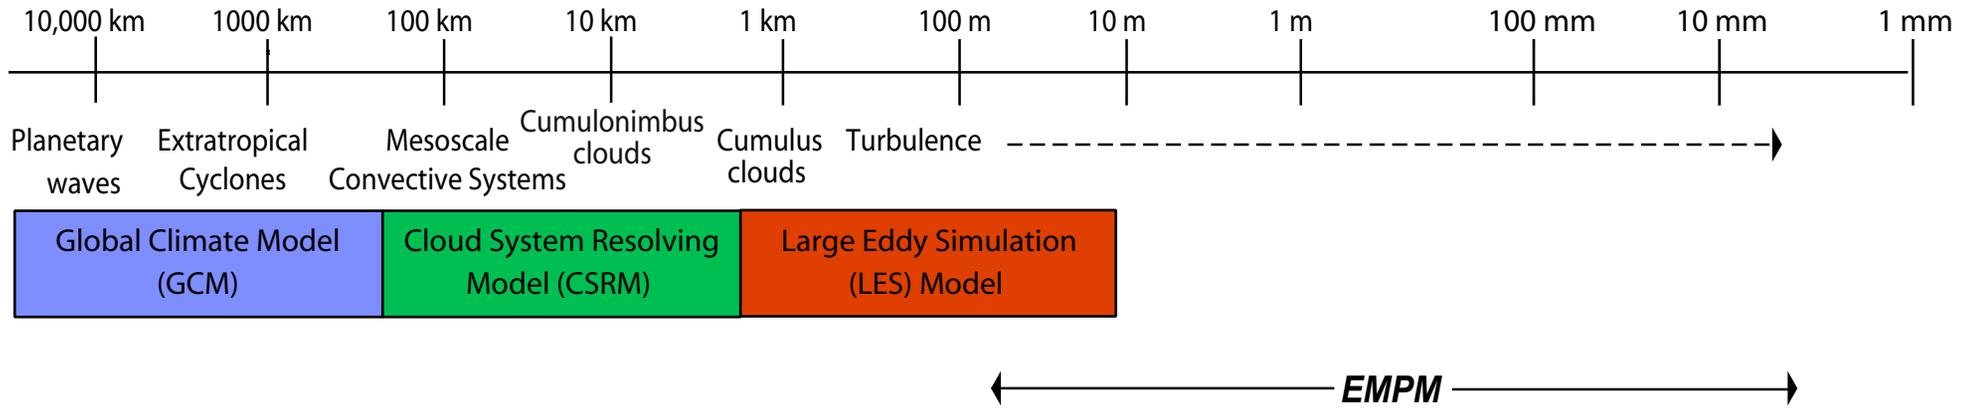

Motivation

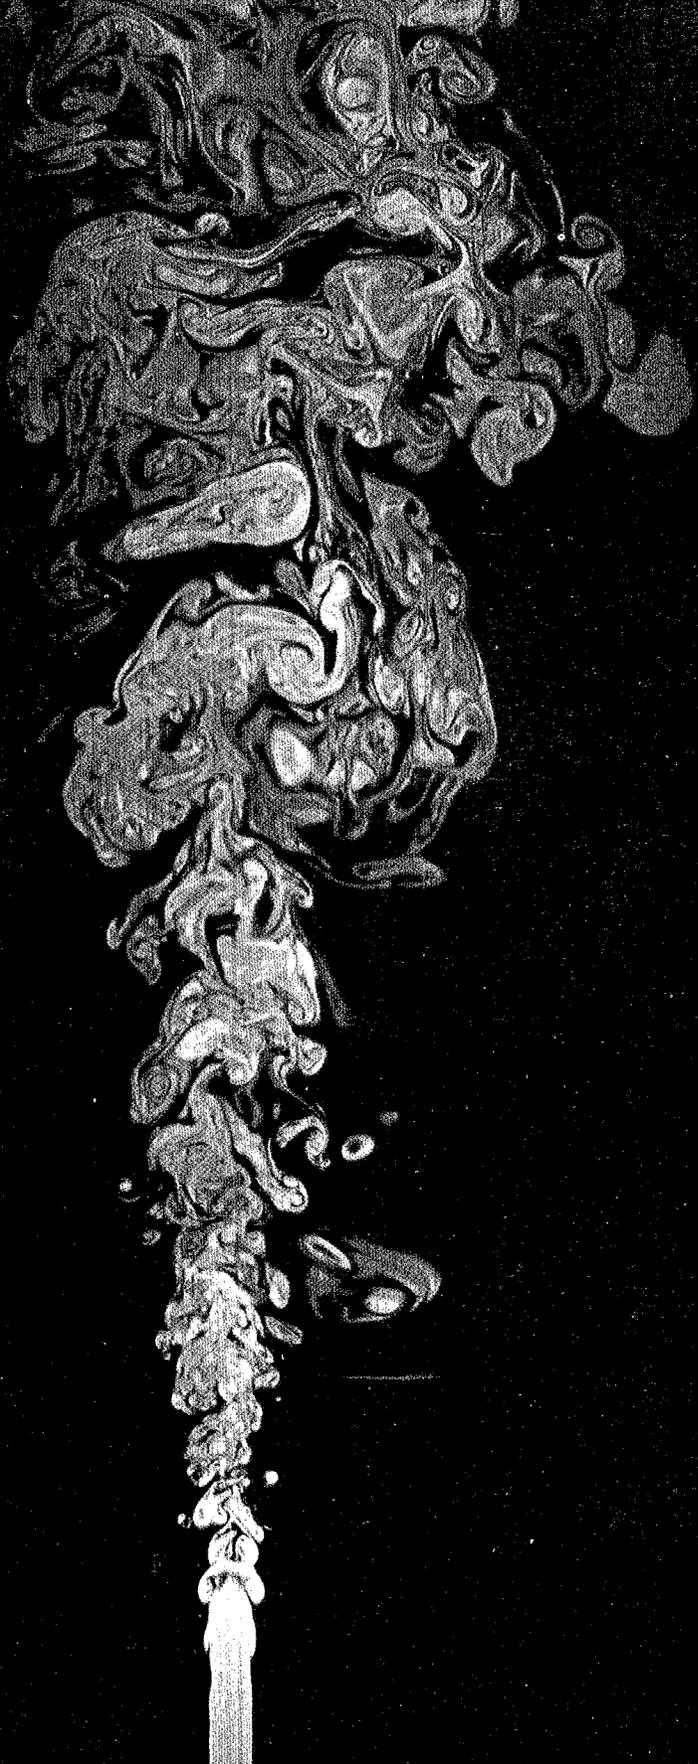

- Our overall goal is to use the Explicit Mixing Parcel Model (EMPM) with droplet growth to study the relative importance of several physical mechanisms that have been proposed to explain droplet spectral broadening and rain initiation in warm cumulus clouds.
- The mechanisms that we are investigating are
 - entrainment and mixing,
 - droplet clustering due to turbulence, and
 - ultrafine cloud condensation nuclei.

Explicit Mixing Parcel Model (EMPM)

- The EMPM predicts the evolving in-cloud variability due to entrainment and finite-rate turbulent mixing using a 1D representation of a rising cloudy parcel.
- The 1D formulation allows the model to resolve fine-scale variability down to the smallest turbulent scales (~ 1 mm).
- The EMPM can calculate the growth of several thousand individual cloud droplets based on each droplet's local environment.

Scales of Atmospheric Motion

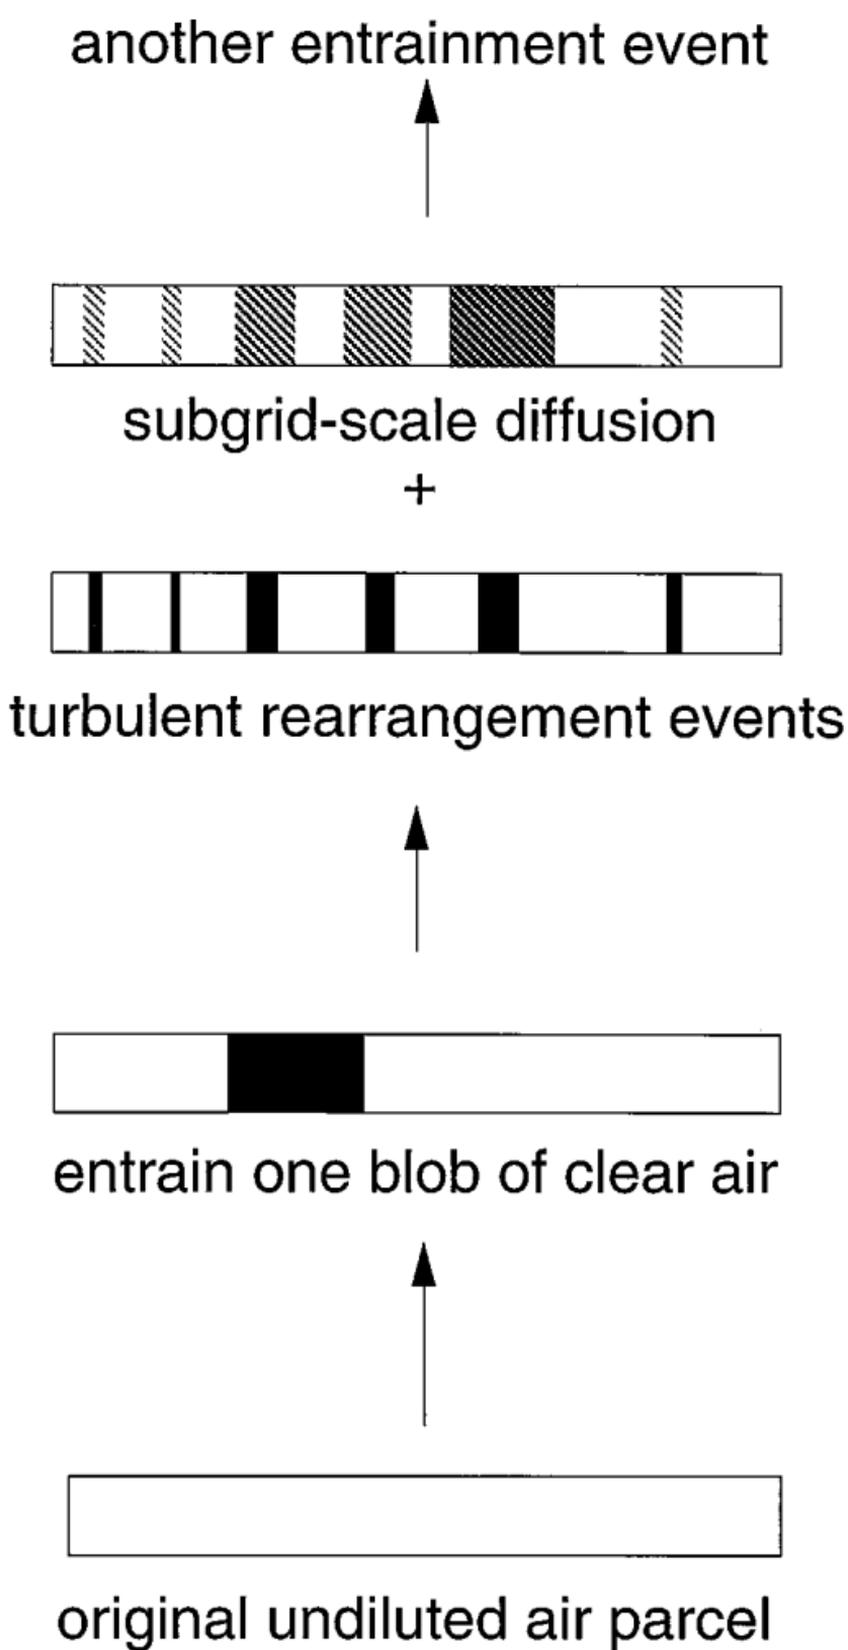

FIG. 3. A parcel is represented by a 1D domain in the EMPM. The parcel's internal structure evolves due to discrete entrainment events and turbulent mixing (rearrangement events and subgrid-scale diffusion).

EMPM Required Inputs

- Required for a classical (instant mixing) parcel model calculation:

Thermodynamic properties of cloud-base air

Updraft speed

Entrainment rate

Thermodynamic properties of entrained air

Aerosol properties

- In addition, the EMPM requires:

Parcel size

Entrained blob size, d

Turbulence intensity (e.g., dissipation rate, ϵ)

Mixing Time Scale

$$\tau = \left(\frac{d^2}{\epsilon} \right)^{1/3},$$

d is blob size, ϵ is dissipation rate of turbulence kinetic energy:

$$\epsilon \sim \frac{U^3}{L} = \frac{u(l)^3}{l} = \frac{u(d)^3}{d},$$

U is velocity scale for largest eddies (of size L); $u(l)$ is same for size l eddies. Therefore,

$$\tau = \left(\frac{d^2}{\epsilon} \right)^{1/3} \sim \left(\frac{d^3}{u(d)^3} \right)^{1/3} = \frac{d}{u(d)},$$

which is the eddy turnover time for an eddy of size d .

Cumulus cloud: $U \sim 2$ m/s, $L \sim 1000$ m, so $\epsilon \sim 10^{-2}$ m²/s³.

For $d = 100$ m, $\tau \sim 100$ s.

Classic (instant mixing) parcel model is recovered when

- Mixing time scale $\rightarrow 0$
- This occurs when
 - Entrained blob size $\rightarrow 0$, or
 - Turbulence intensity $\rightarrow \infty$

Comparison to Measurements

EMPM results can be directly compared to high-rate [1 Hz (100 m) to 1000 Hz (10 cm)] aircraft measurements of temperature, water vapor, liquid water content, and droplet size spectra.

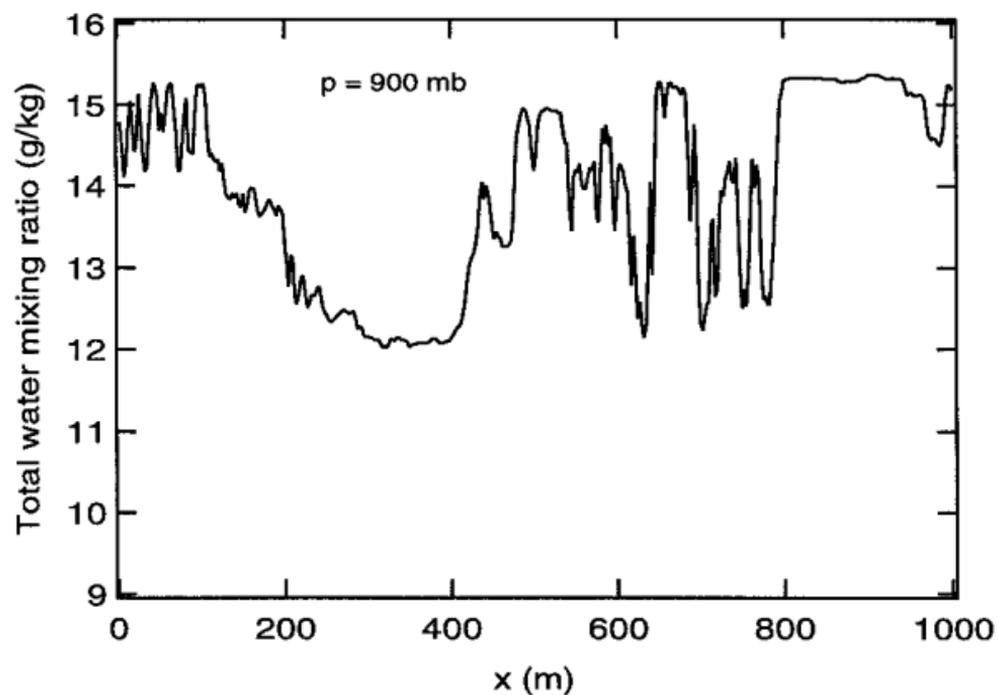

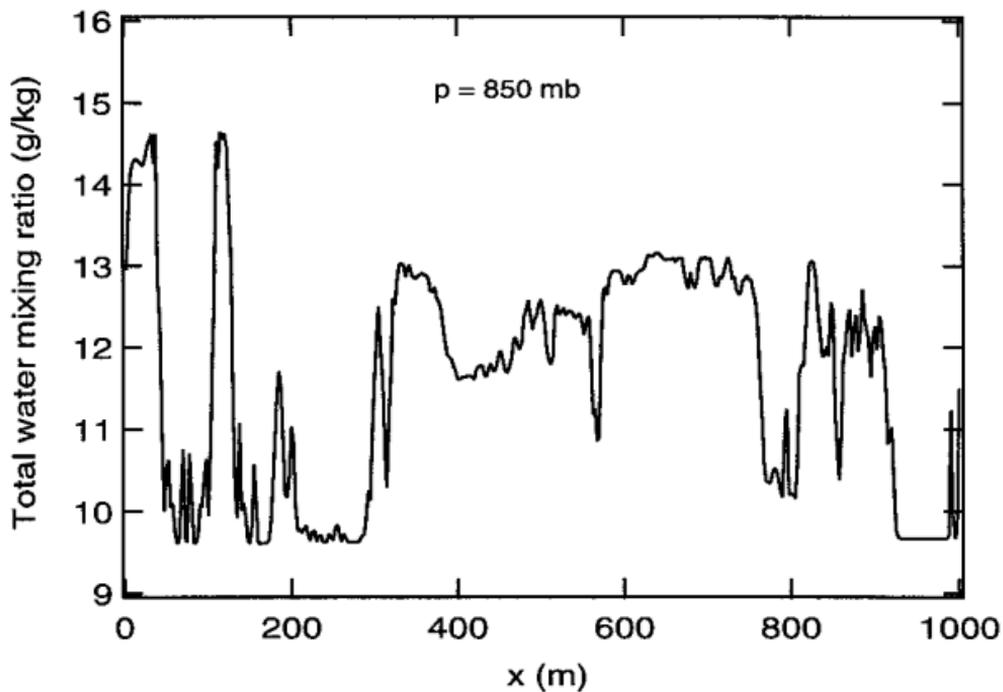

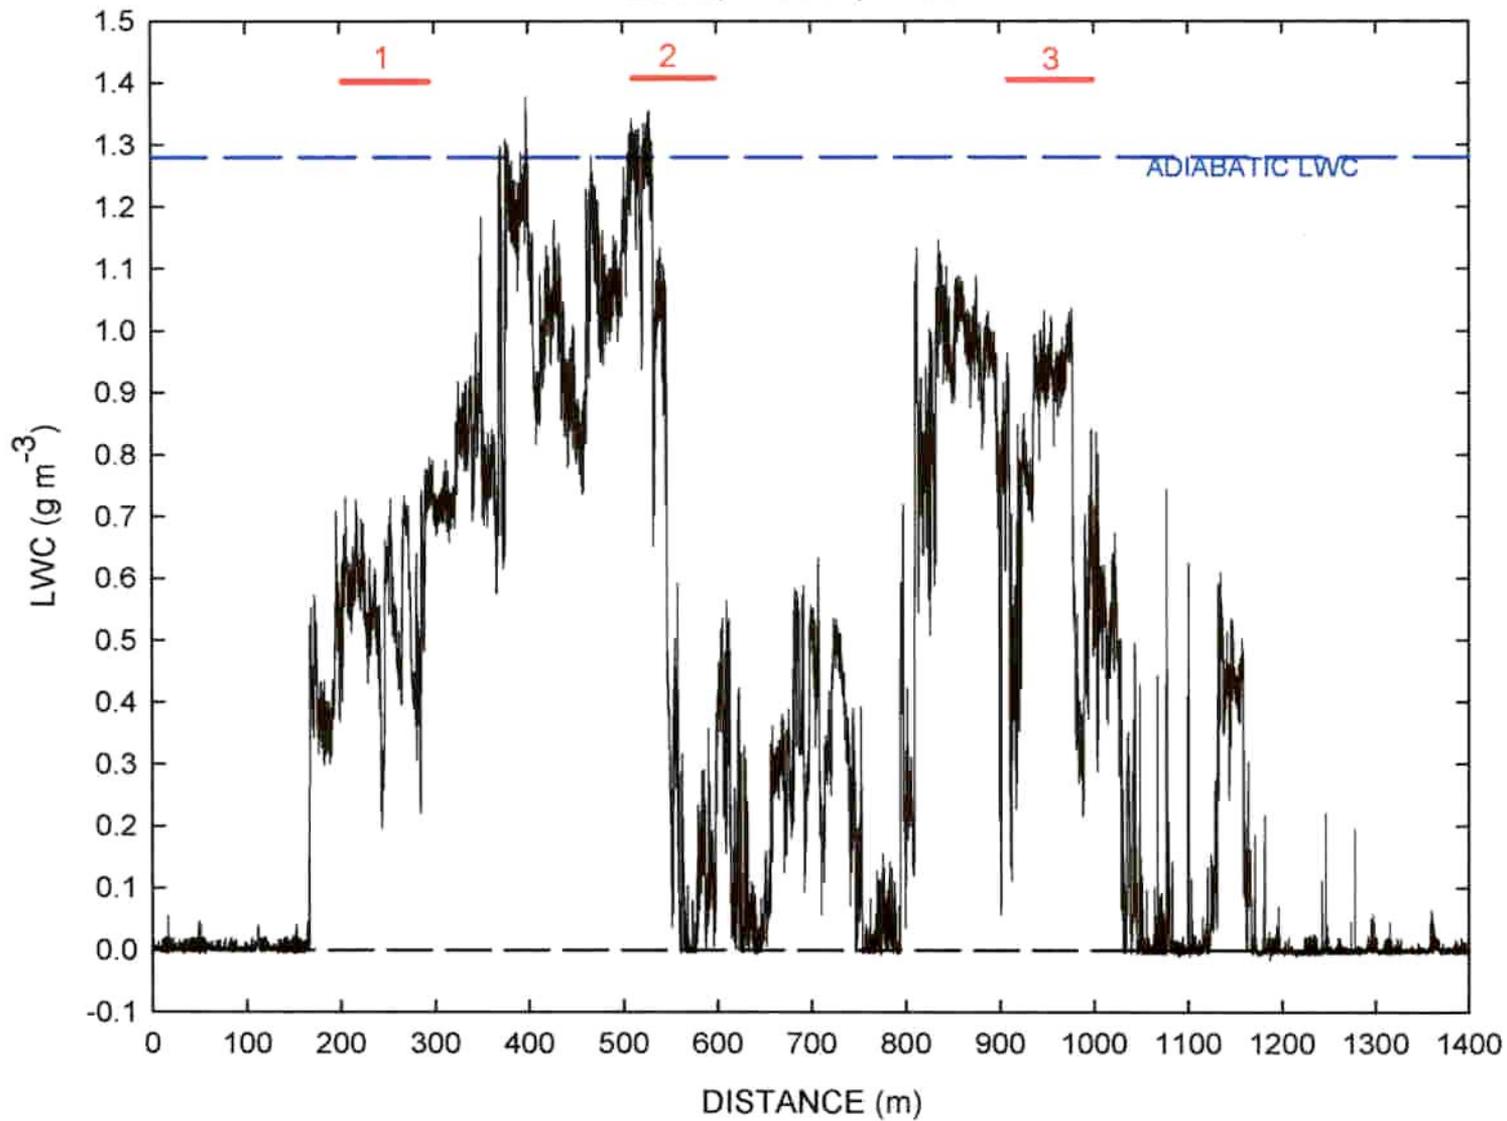

FIG. 4. "Snapshots" from the EMPM of $q_w(x)$ at $p = 900$ mb (top) and $p = 850$ mb (bottom) during one realization.

SCMS; 19 JULY, PASS #7

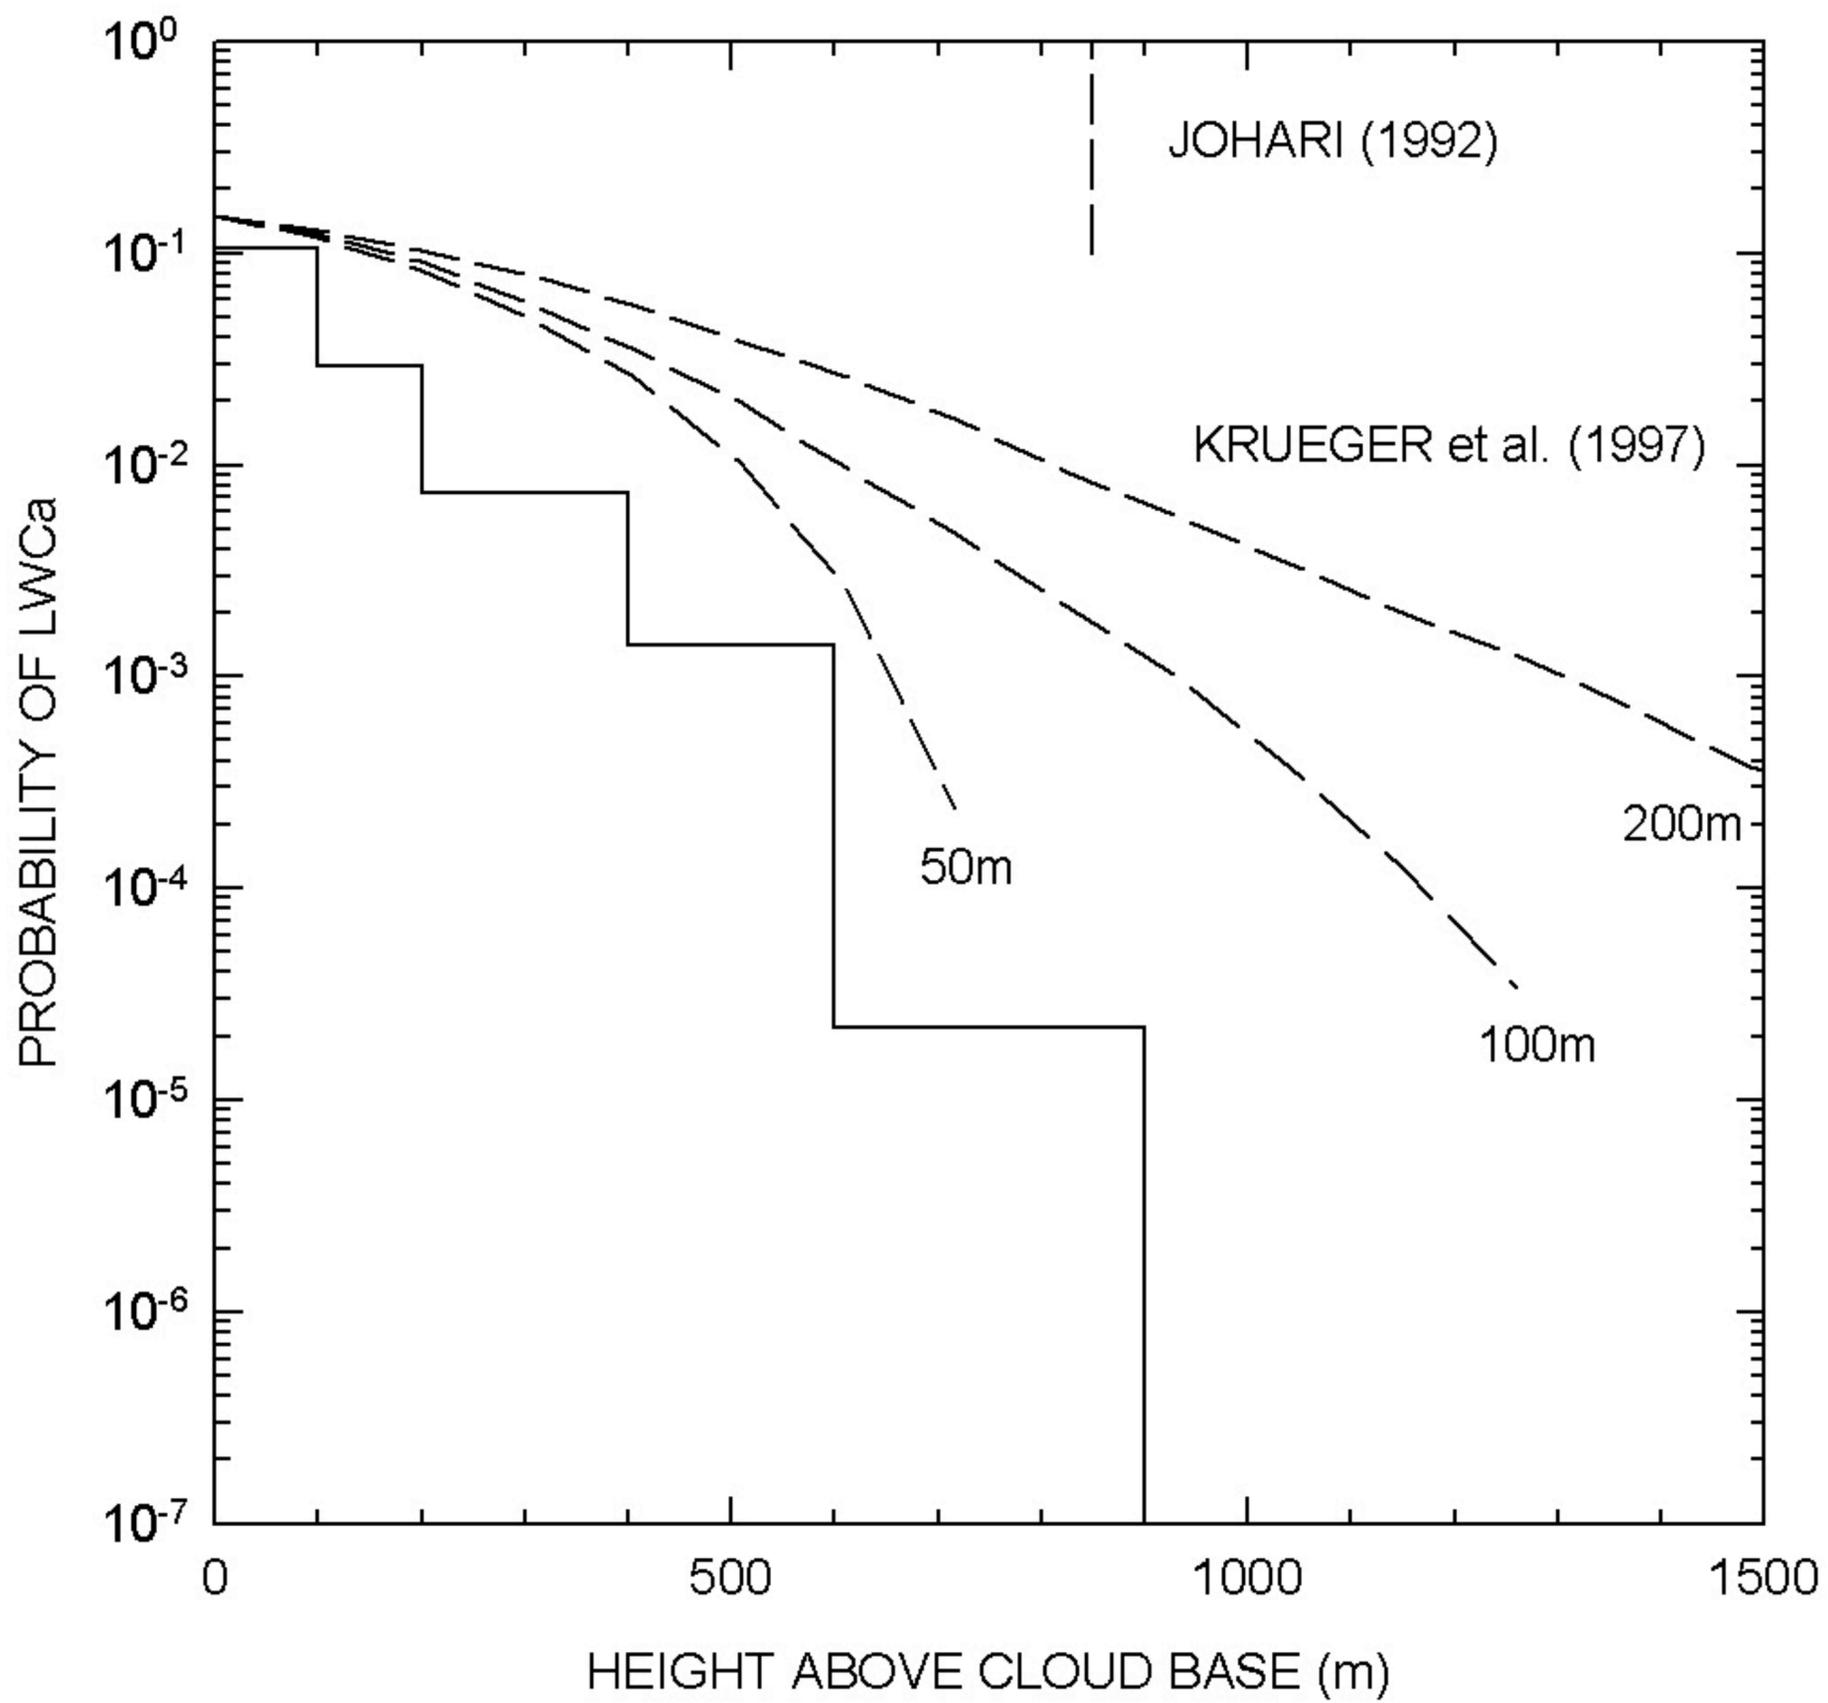

FIG. 13. Illustration of entrainment and mixing in small cumulus clouds. Key characteristics: initial entrainment and mixing near edges, simultaneous but discrete large-scale entrainment events due to cloud-scale eddies, subsequent homogenization of regions 10–100 m in length.

Applying the EMPM to Hawaiian Cumuli

Results

- Based on composited measurements of active cloud turrets (Raga et al. 1990)
- **Macrophysics:** in-cloud profiles (data: G. Raga)
- **Microphysics:** droplet spectra (data: C. Pontikis)
- **Large-droplet production**

Applying the EMPM to Hawaiian Cumuli

Macrophysics: in-cloud profiles

Microphysics: droplet spectra

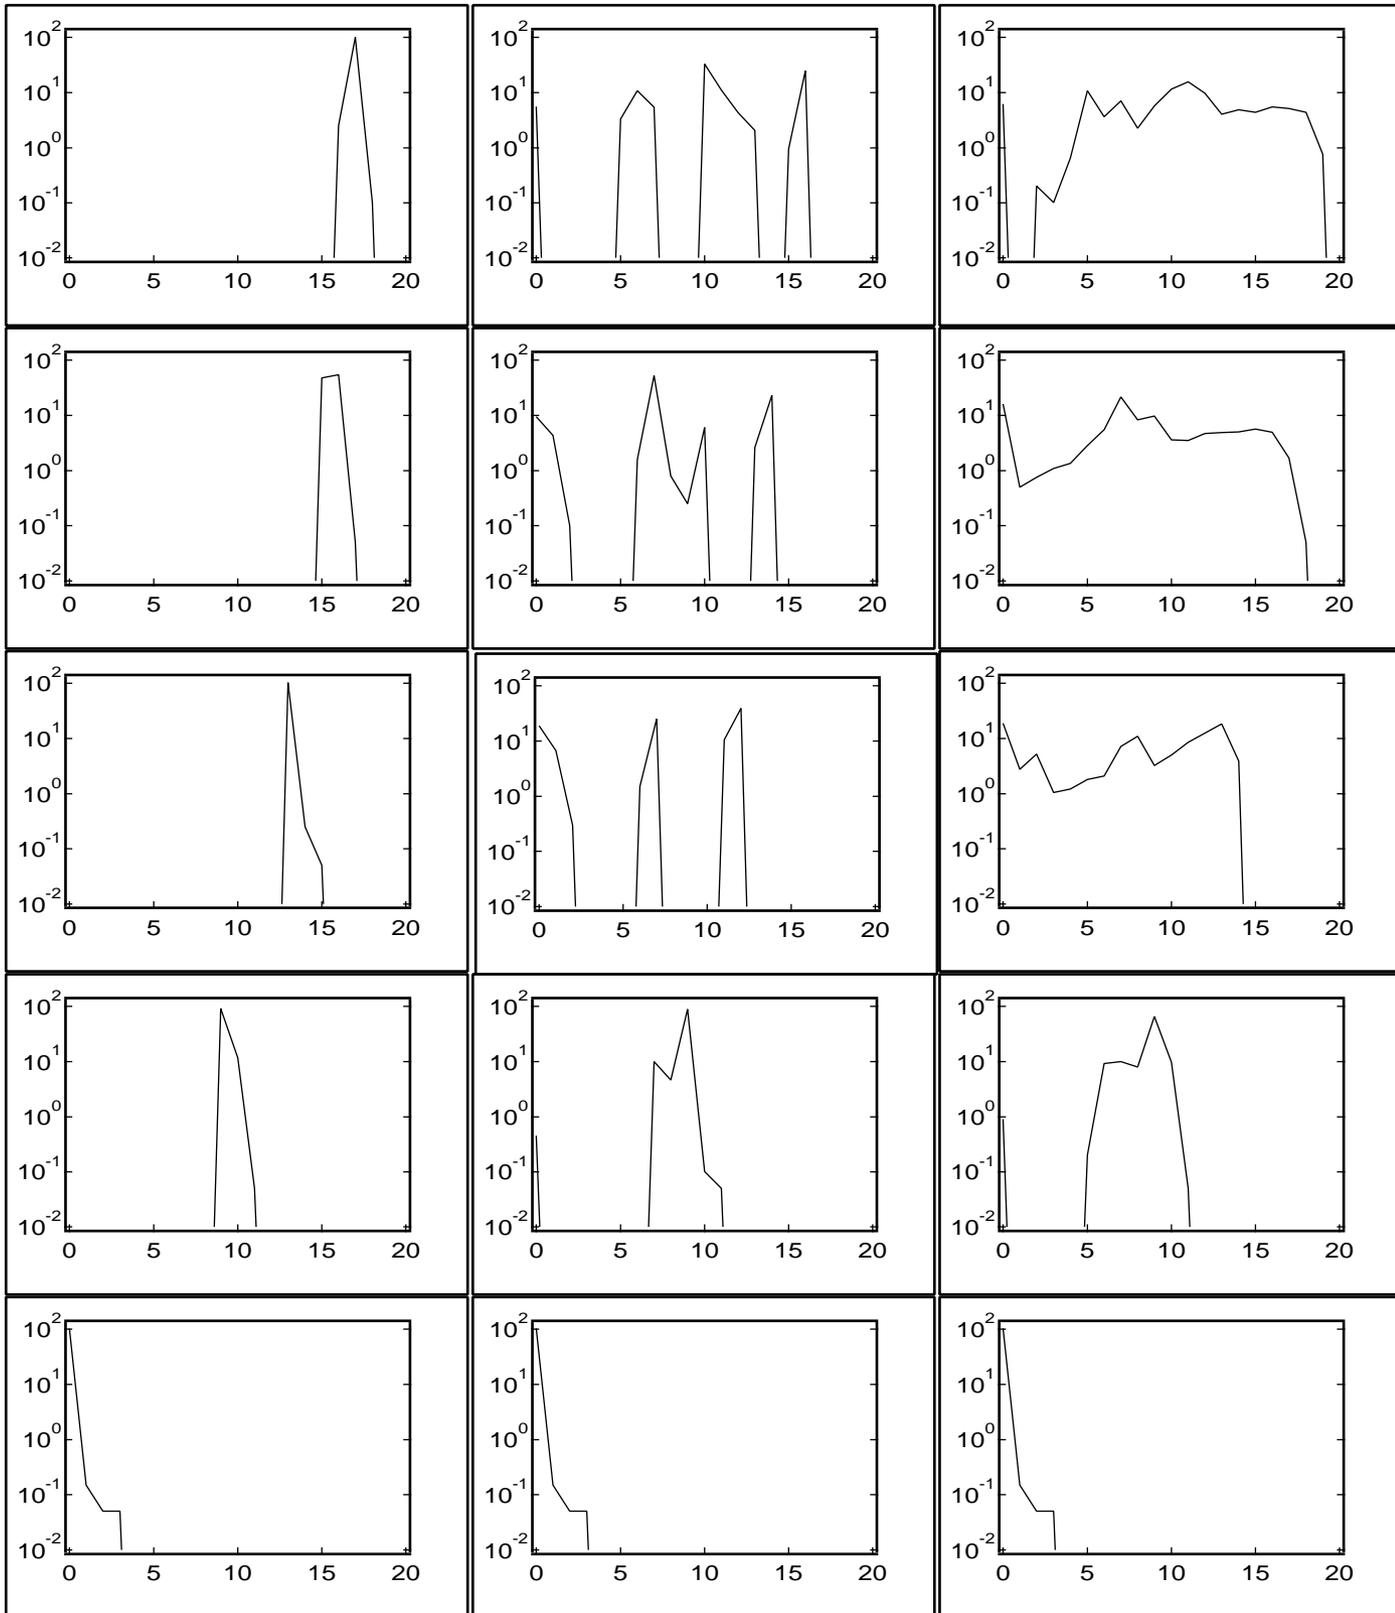

droplet radius (μm)

no entrainment +
finite-rate mixing

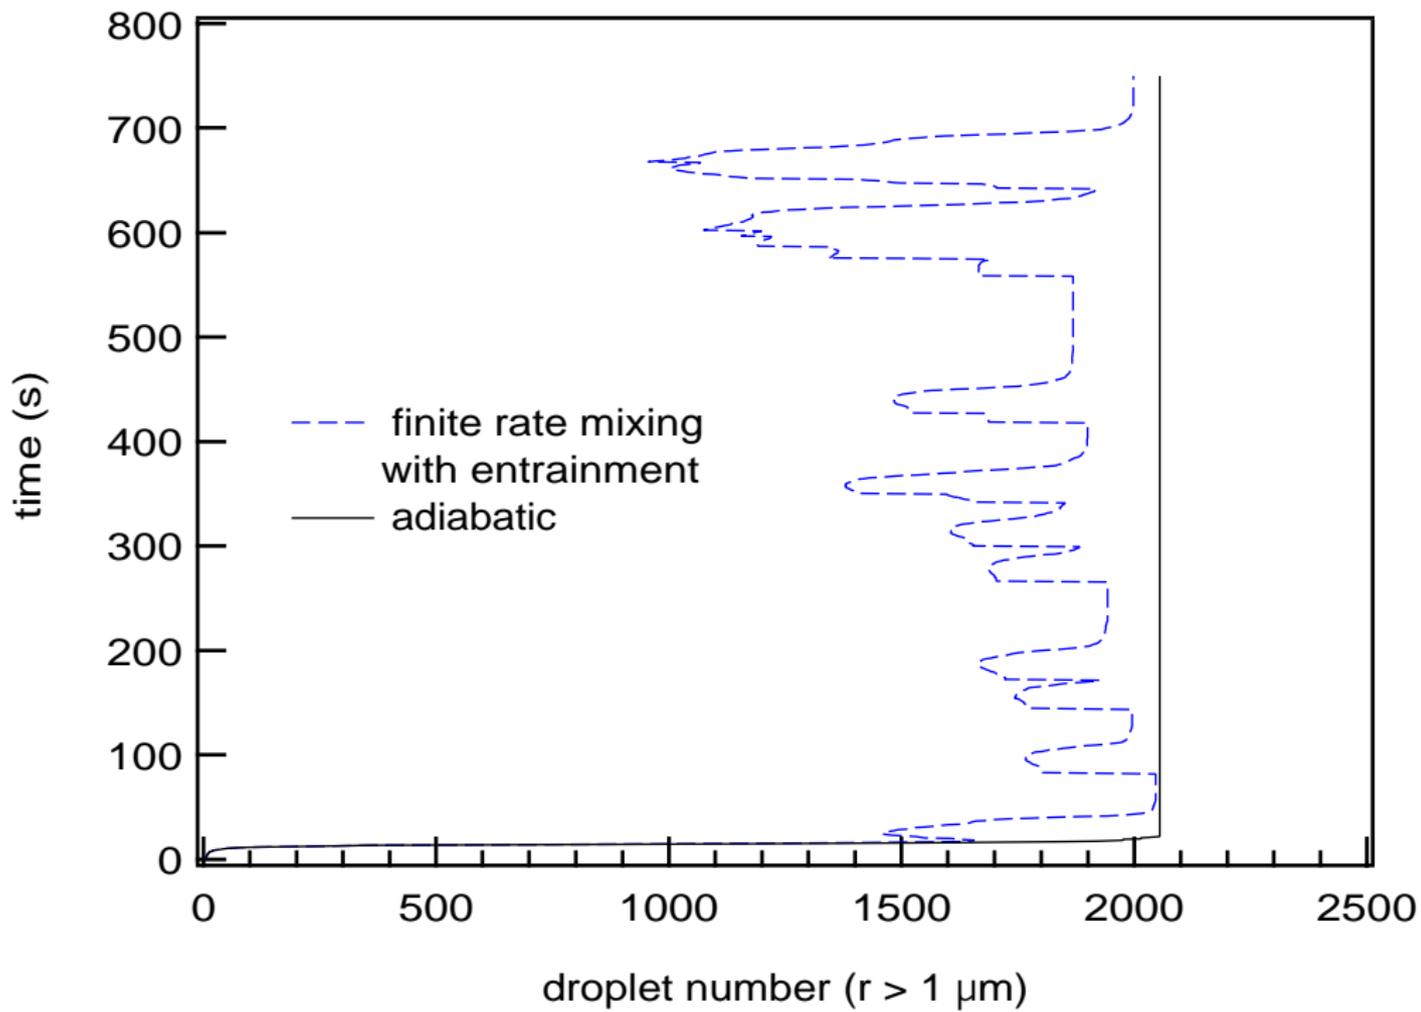

entrainment +
instant mixing

entrainment +
finite rate mixing

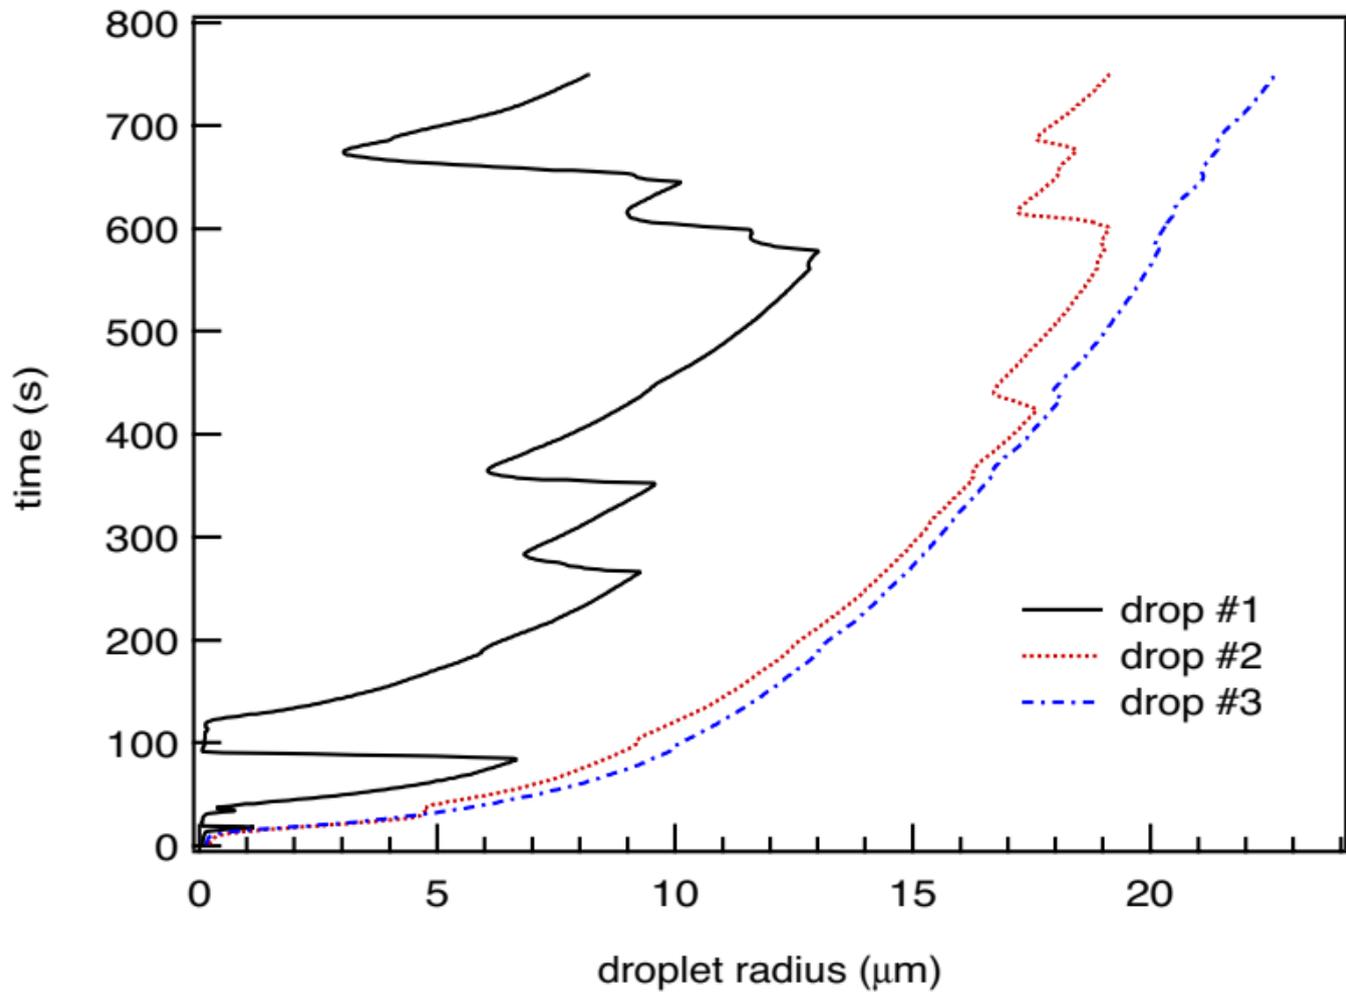

droplet concentration ($\text{cm}^{-3} \mu\text{m}^{-1}$)

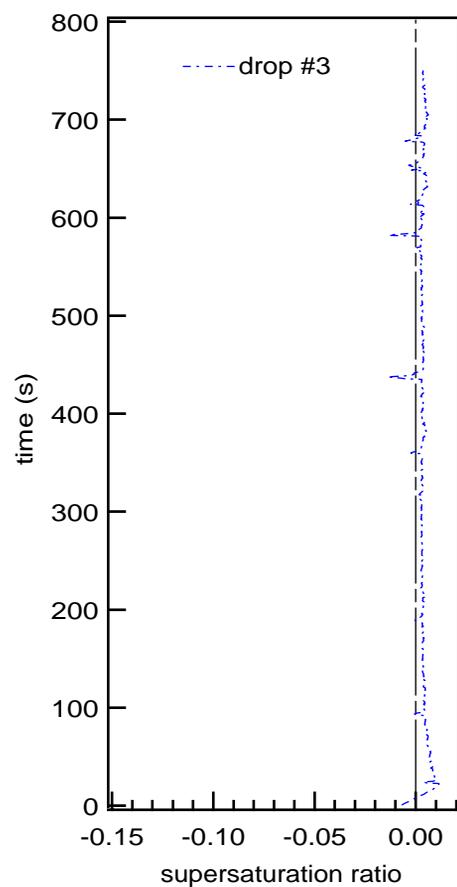

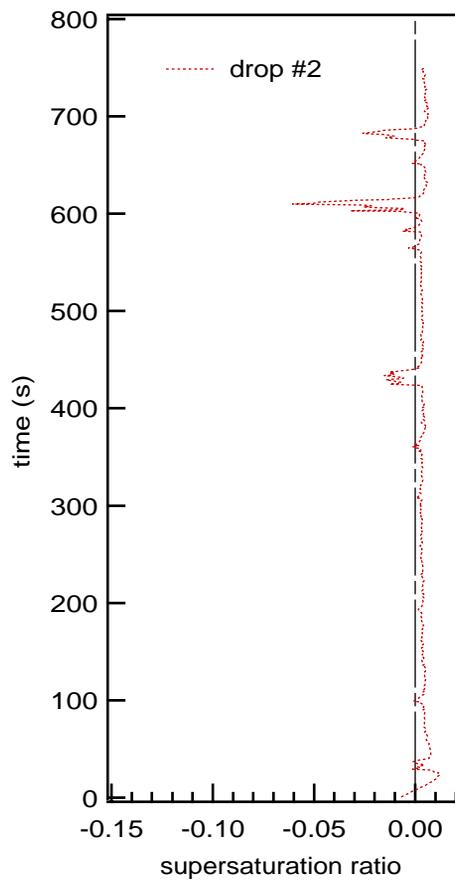

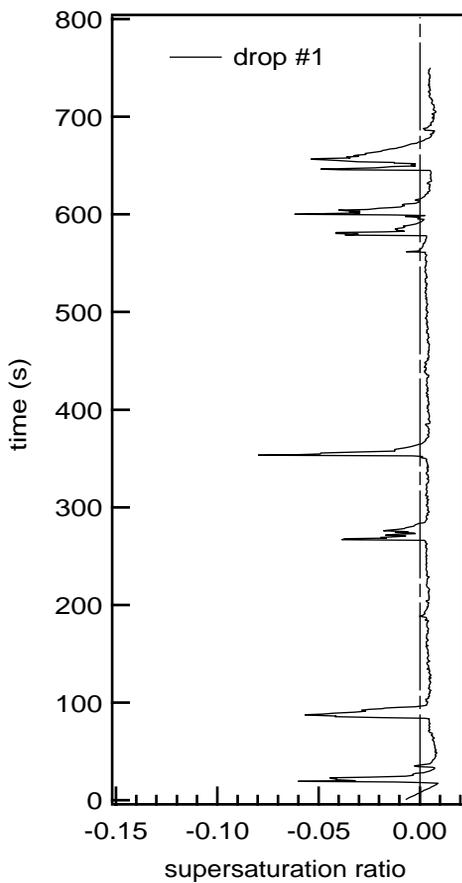

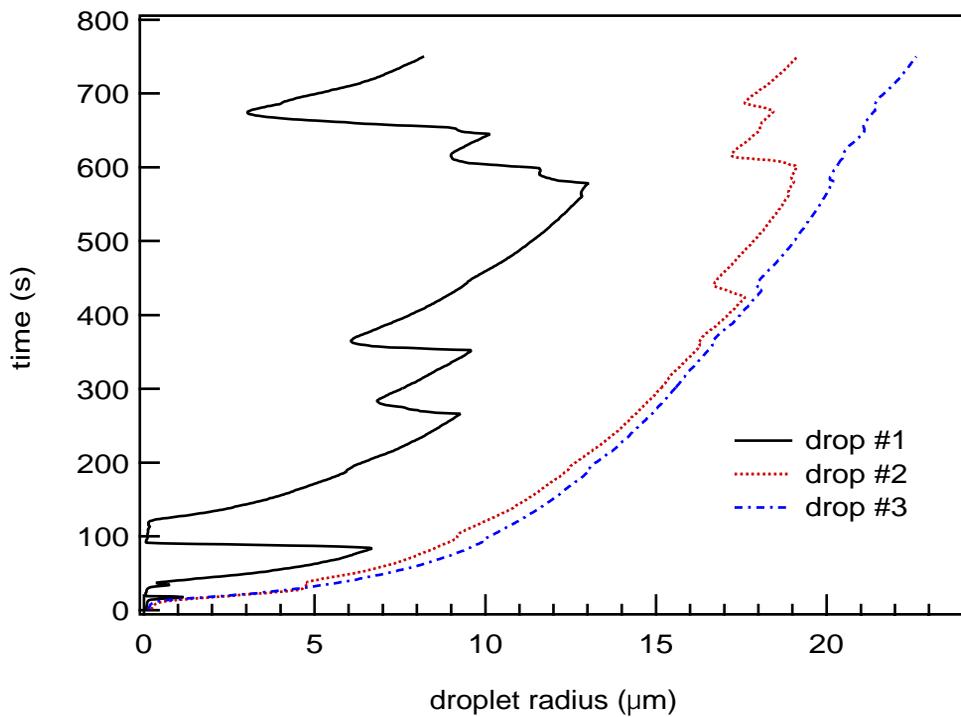

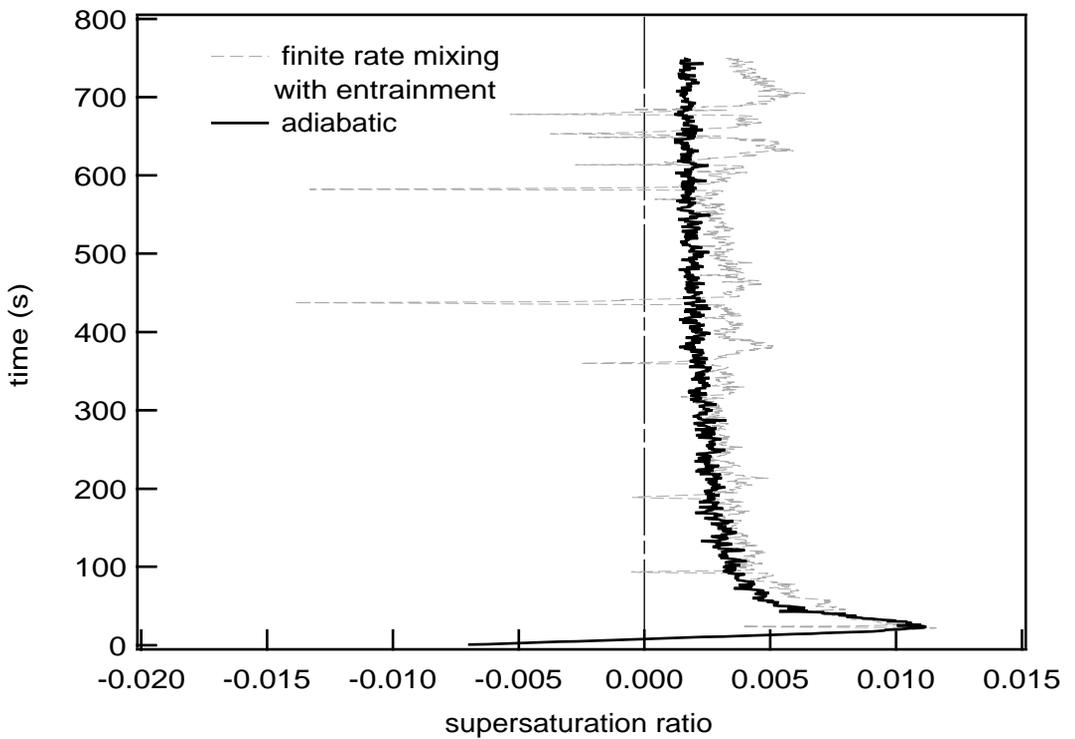

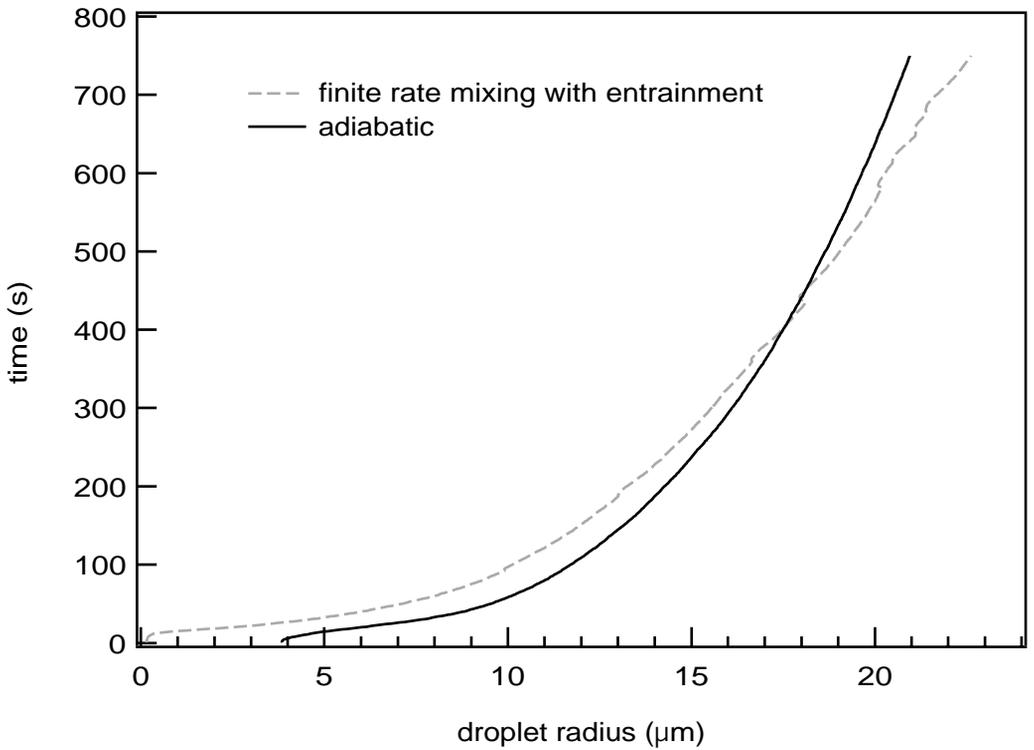

droplet radius (μm)

Large-droplet production

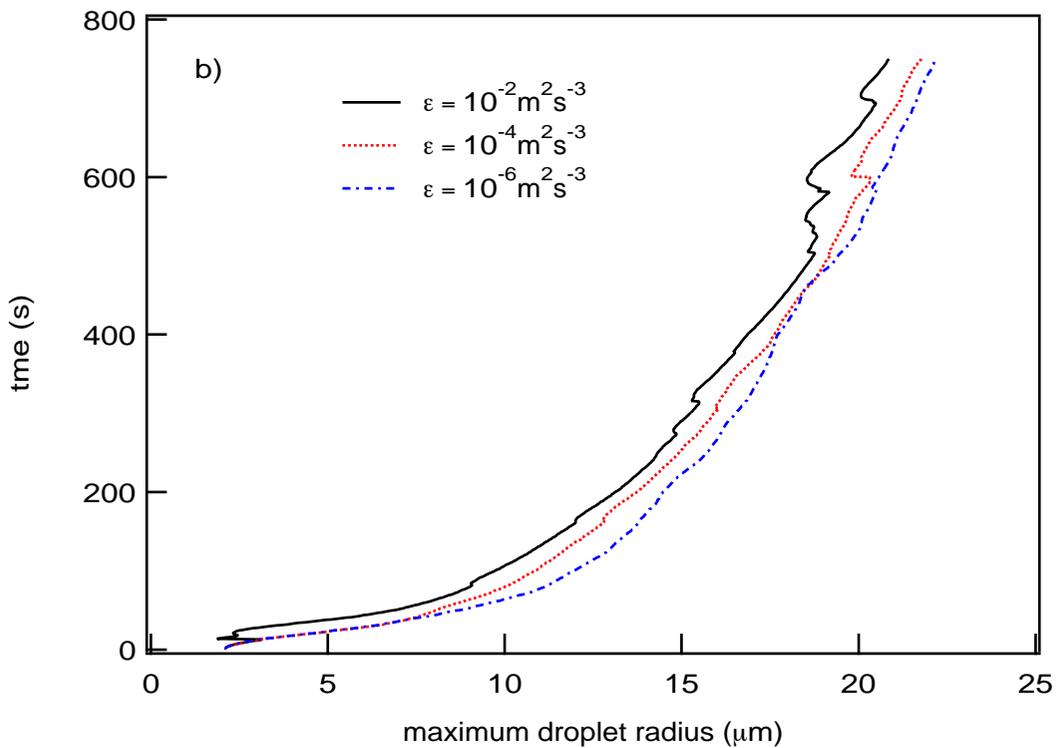

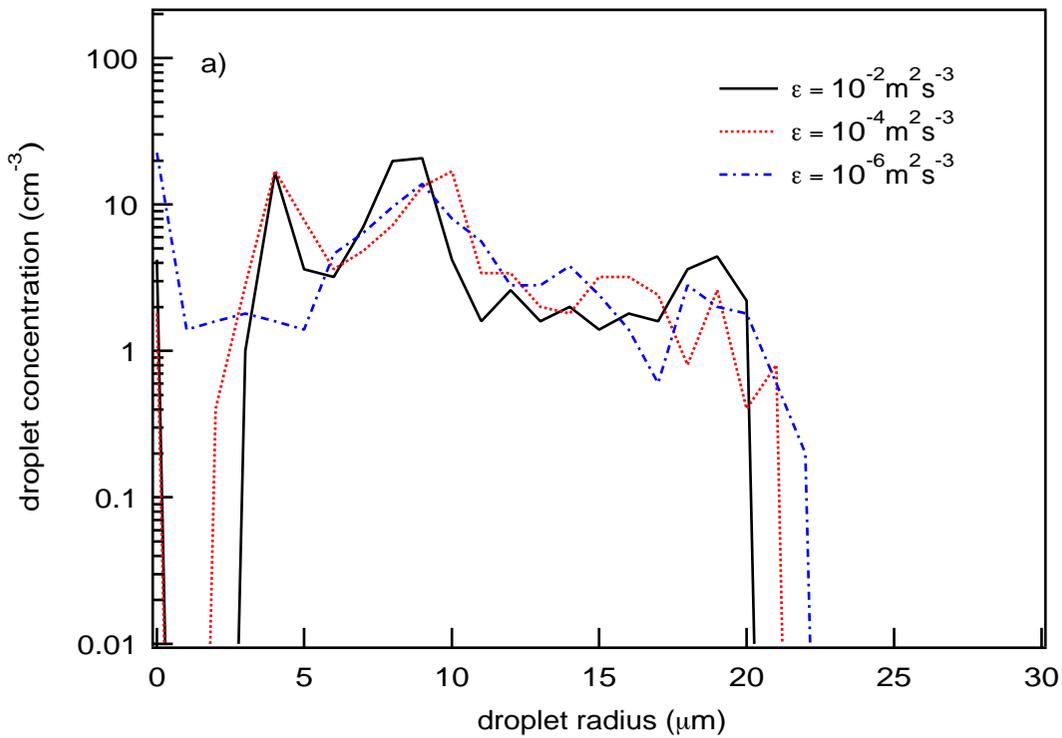

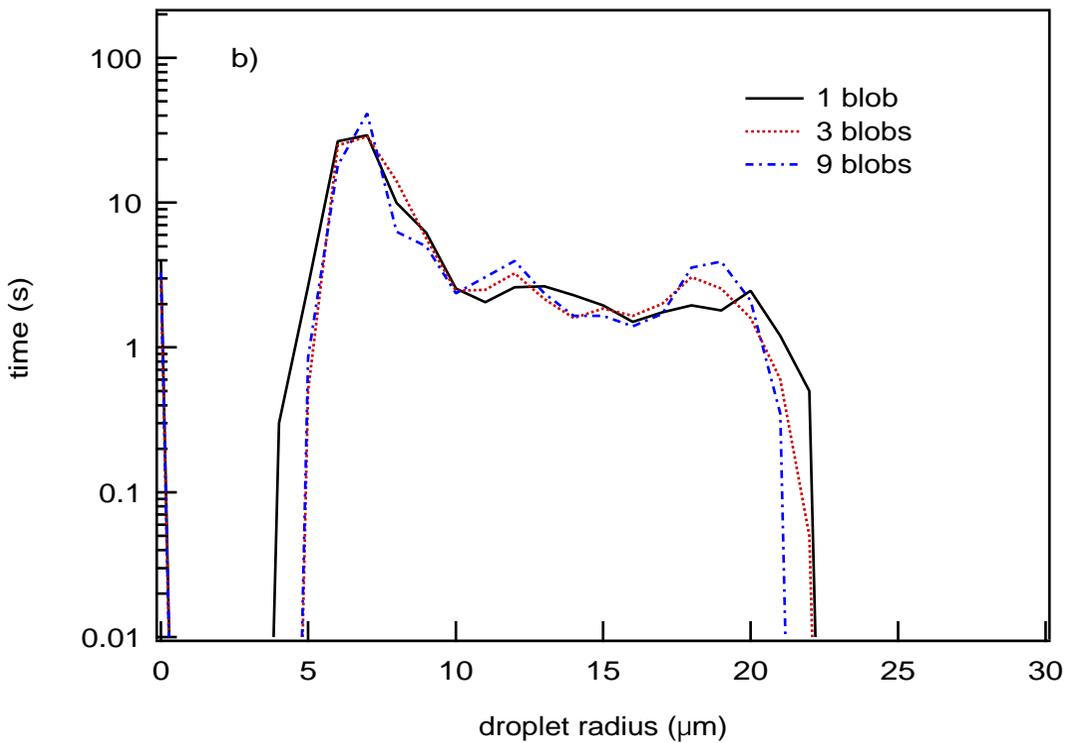

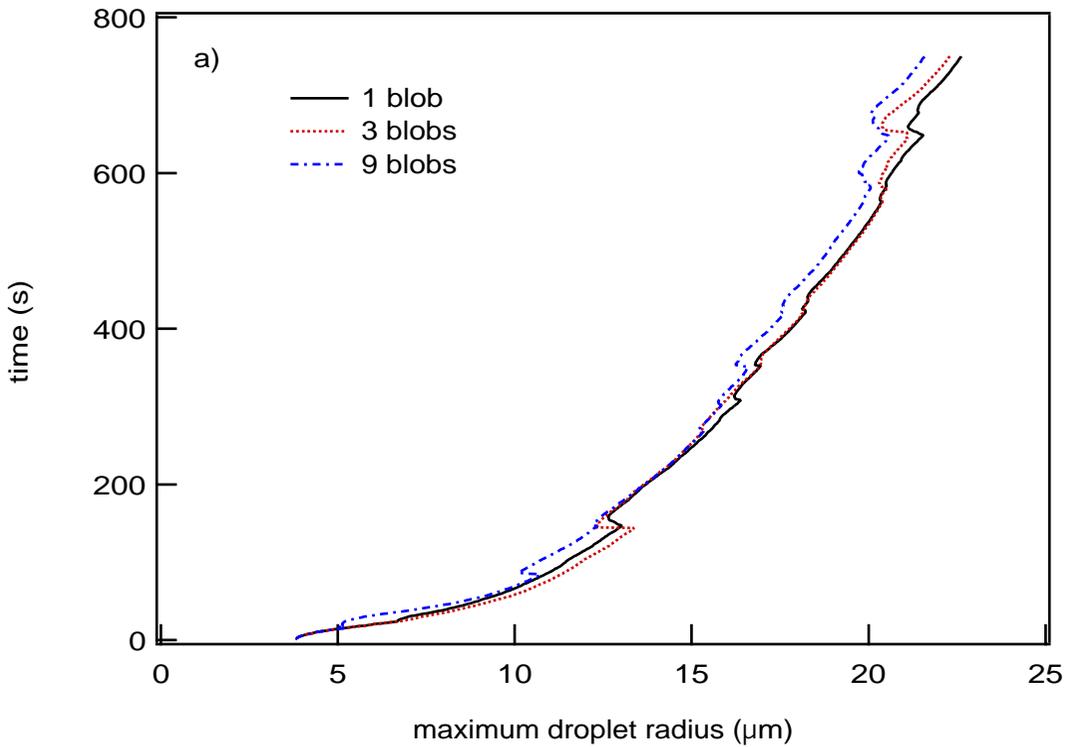

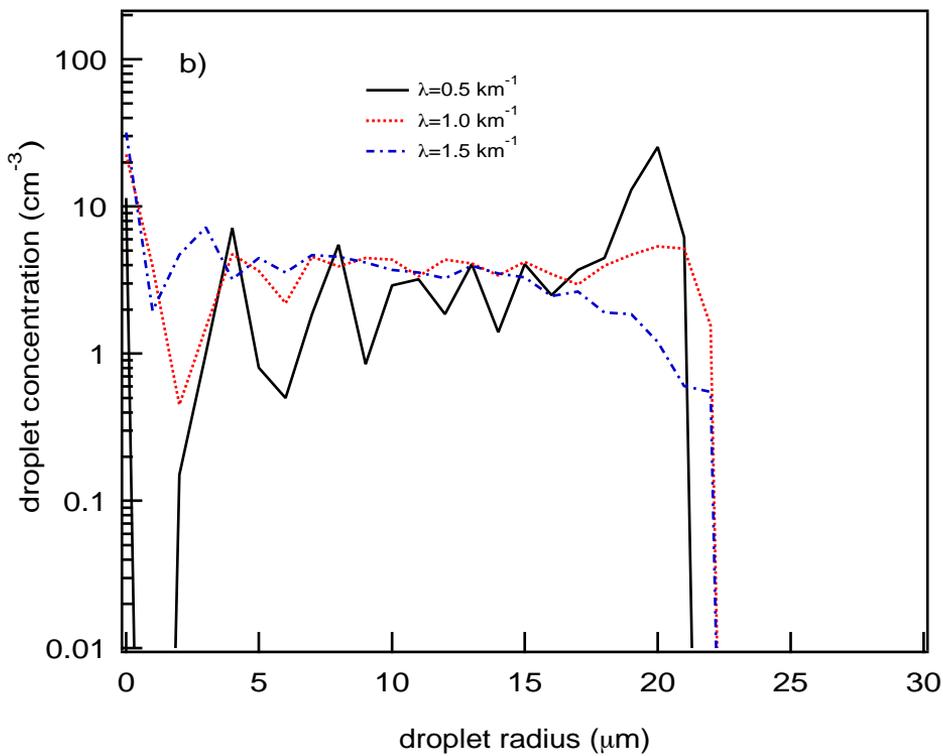

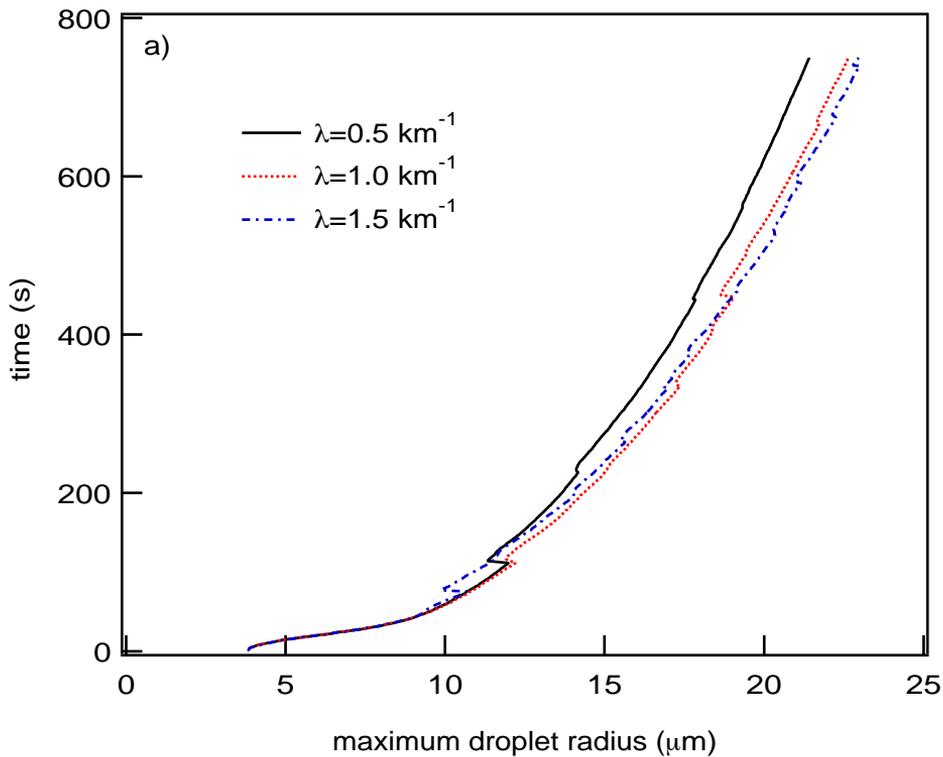

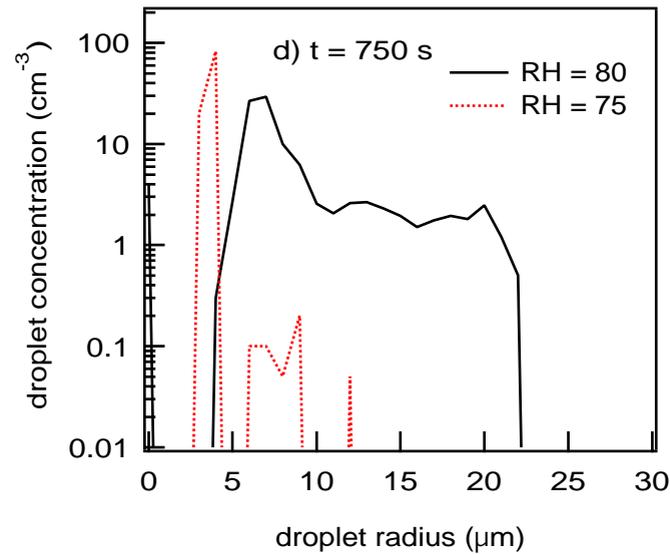

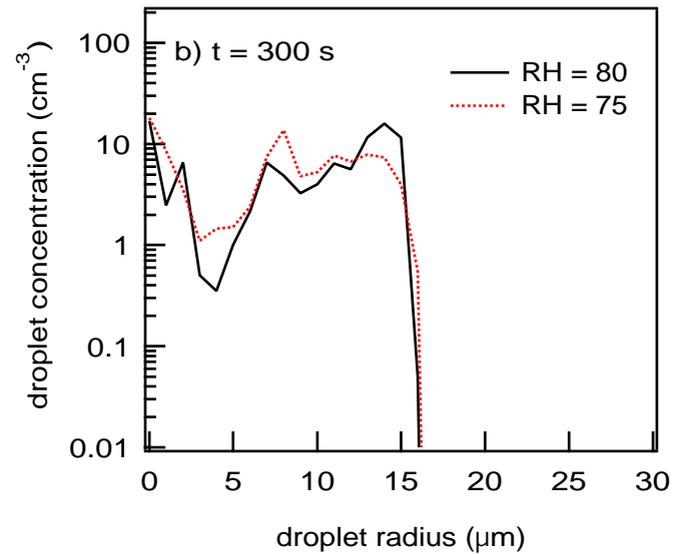

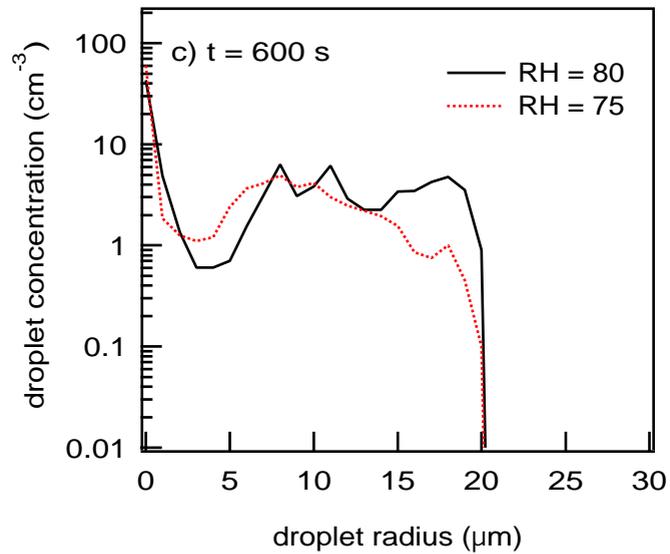

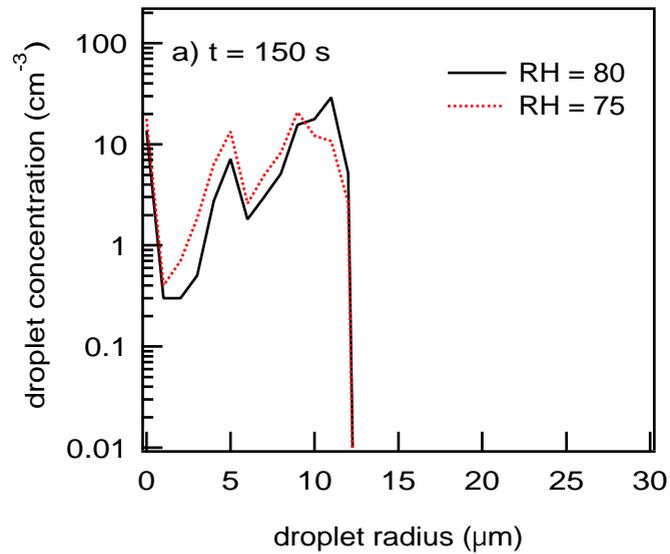

Some factors that affect large droplet production

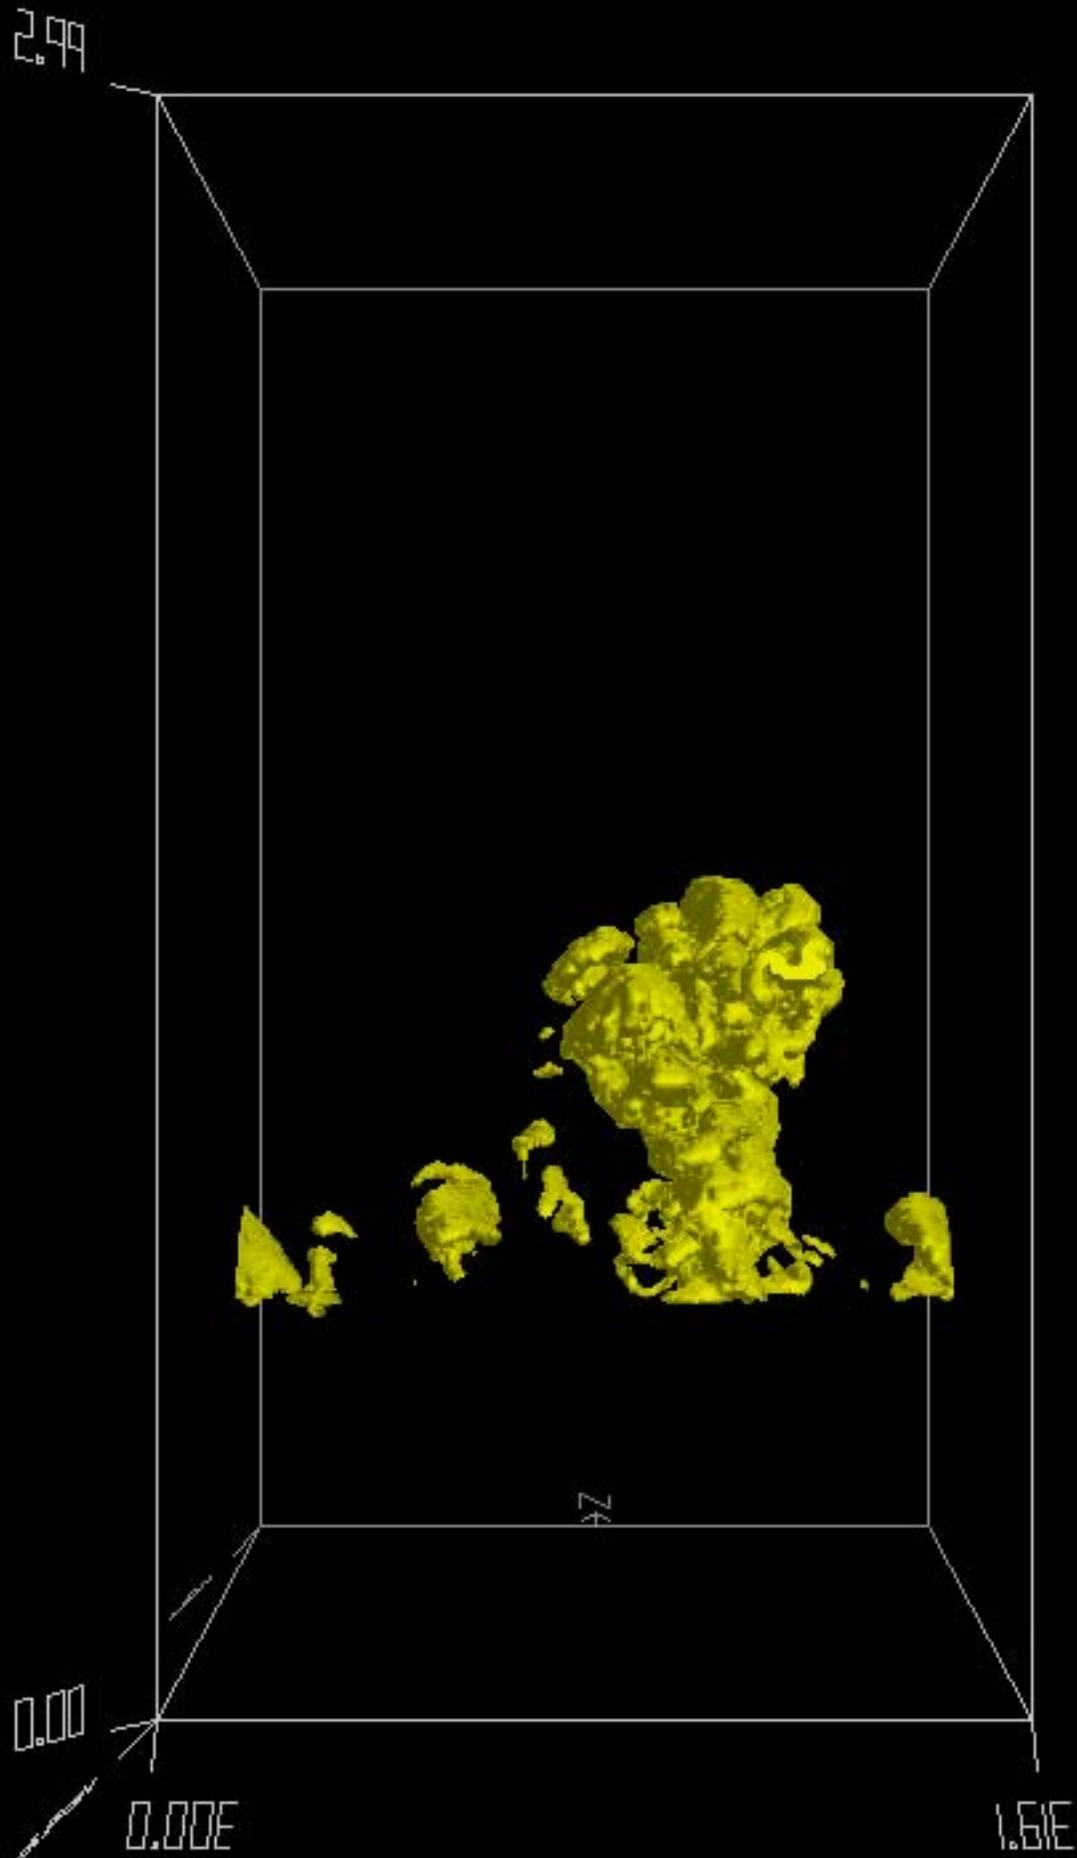

- Turbulence intensity (dissipation rate)
- Entrained blob size
- Entrainment rate
- Relative humidity of entrained air

Coupling EMPM and 3D large-eddy simulations (LES)

- We will better resolve the SGS structure in 3D LES by implementing a 1D subgrid-scale (SGS) mixing model with a grid size of about 10 cm---a scale of variability that is measurable by aircraft.
- The CPU time required for a LES with a grid size of 0.1 m is 10^8 more than one with a grid size of 10 m.

Coupling EMPM and 3D LES

CPU times for ODT grid size = 0.1 m with different $(\Delta x)_{LES}$:

$(\Delta x)_{LES}$	Relative CPU time	CPU hours	GAUs
10 (no ODT)	1	800	200
5	9	7200	1800
40 (with ODT)	2	1600	400
20	7	5600	1400
10	28	22,400	5600

Multiscale Modeling Framework

Stand-alone Averaged	Stand-alone Reduced dimensionality	Coupled MMF
1D Cu par 0D parcel model	2D CRM 1D EMPM	3D GCM + 2D CRM 3D LES + 1D ODT

Conclusions

- Stand-alone and coupled ODT-based models are promising for studying fundamental physics of cloud-turbulence-microphysics-radiation interactions.
- MMF approach is viable for cloud-turbulence scale interactions as well as for synoptic-meso-cloud scale interactions.
- Cross-fertilization of ideas & techniques should be beneficial to further development of both approaches.
- Perhaps coupling GCM, CRM, and ODT will be useful for certain problems, such as aerosol-microphysics-climate interactions. . .

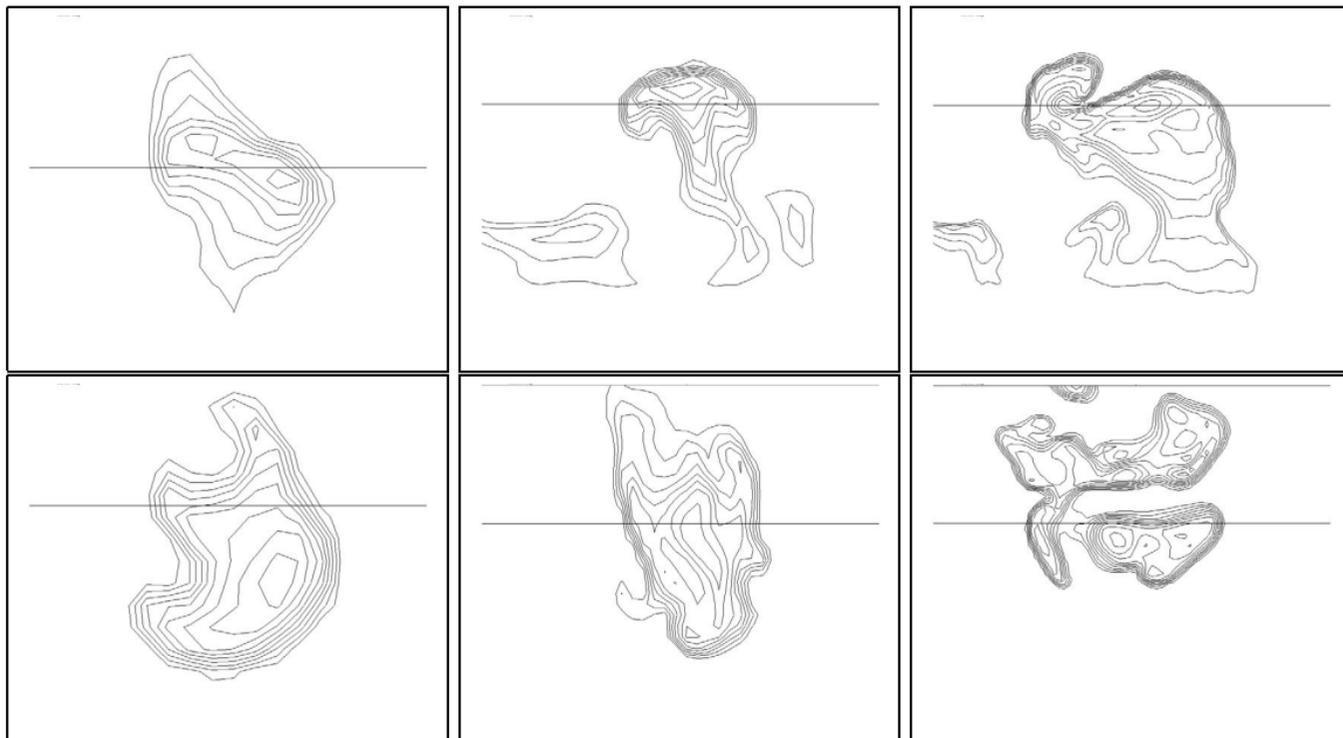

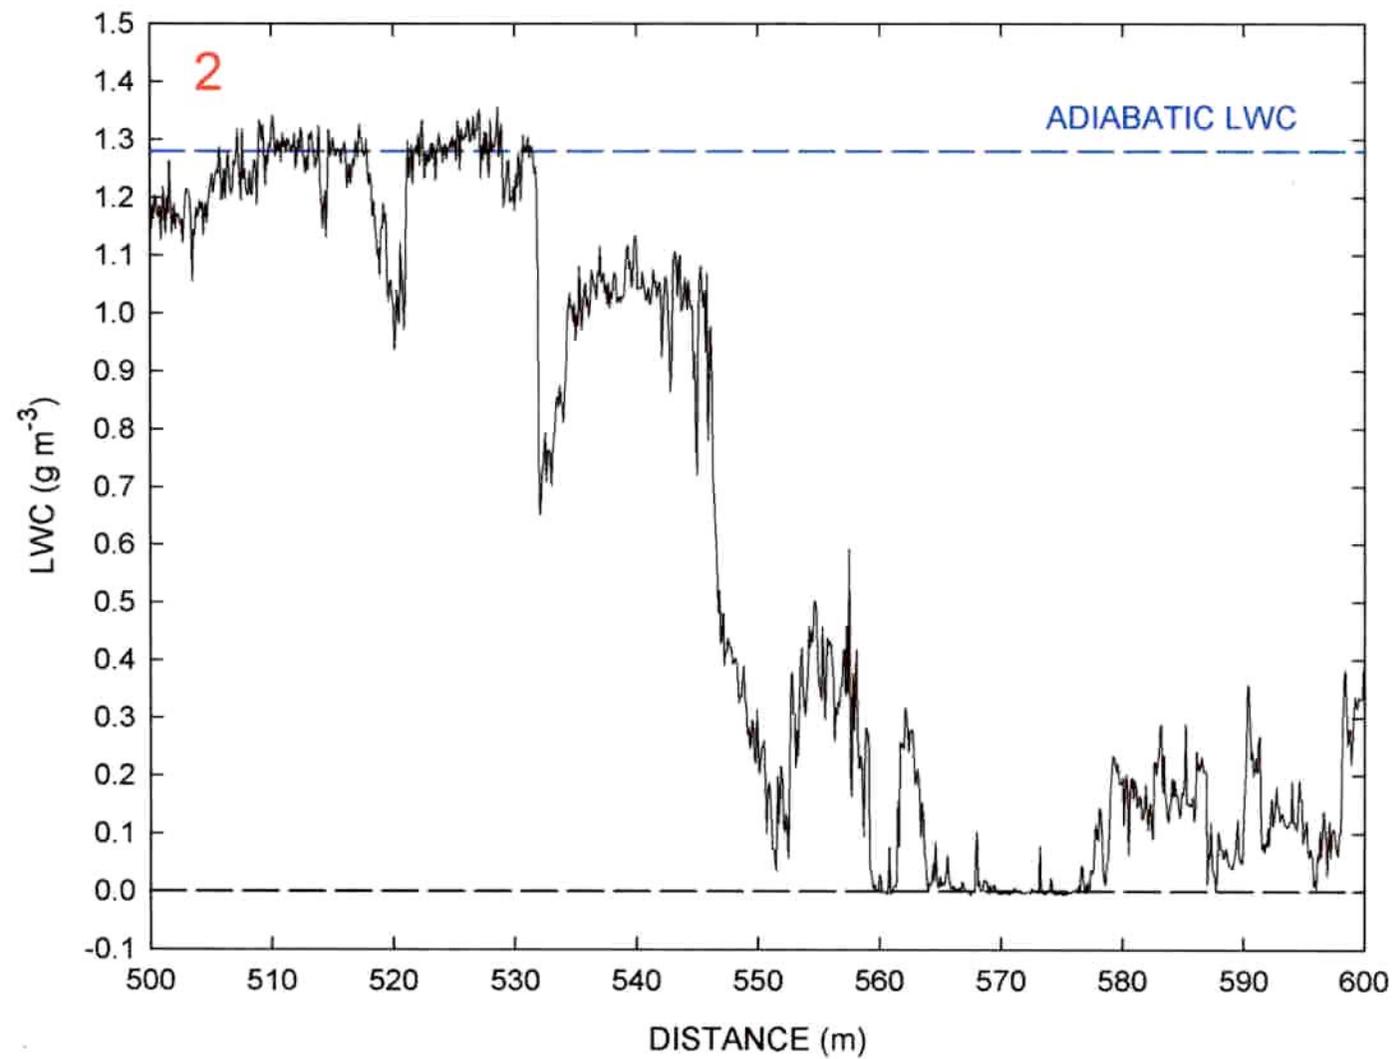

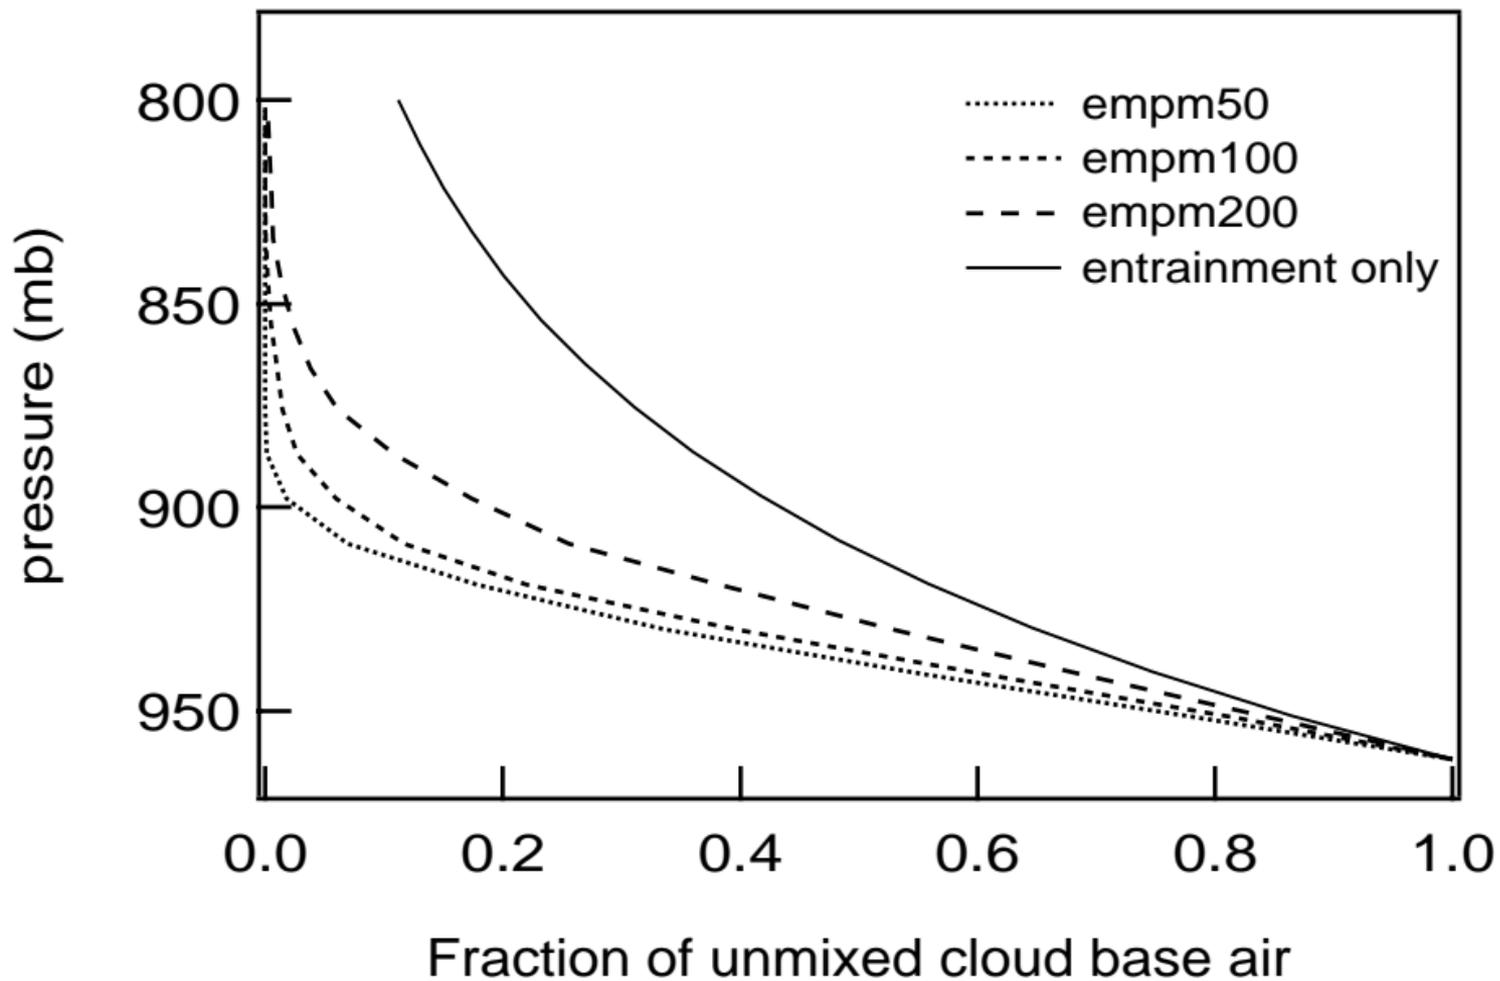

Figure 5: Vertical (top) and horizontal (bottom) cross-sections of liquid water mixing ratio for BOMEX trade cumulus simulations with resolutions of 40 m (left), 20 m (center), and 10 m (right). The horizontal cross sections are located at $z = 1000$ m. The contour interval is 0.1 g kg^{-1} . The line through each cross-section indicates its intersection with the accompanying perpendicular cross-section. Each cross section displays an area 590 m by 725 m.

Planned EMPM Improvements

- Additional physics:

 - Collision and coalescence growth of cloud droplets

 - Turbulence effects on droplet clustering

- Better representation of entrainment:

 - Use realistic trajectories obtained from a 3D Large-Eddy Simulation Model (LES_M).

 - Analyze entrainment in the LES_M.

 - Compare relevant EMPM and aircraft statistics.
