STORM MORPHOLOGY AND RAINFALL CHARACTERISTICS OF TRMM PRECIPITATION FEATURES

Stephen W. Nesbitt, Robert Cifelli, and Steven A. Rutledge
Radar Meteorology Group - Department of Atmospheric Science
Colorado State University

TRMM AS A CLOUD MODEL VALIDATOR

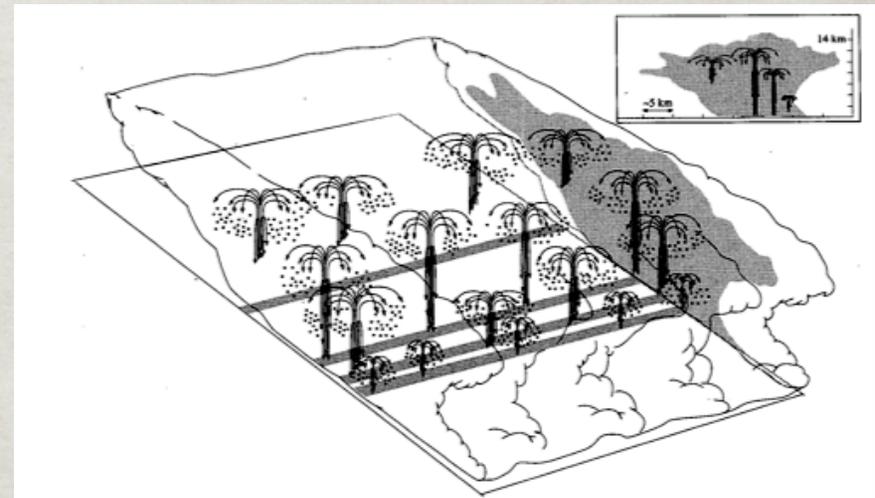

- ✿ In the past...
 - ✿ “Scale separation” in traditional GCM convective parameterizations make it difficult to compare model and observations (Grabowski 2004)
- ✿ But now...
 - ✿ Global CRM's and MMF's exist which resolve convective systems, and can generate statistics of “observable” quantities for evaluation of cloud structures in both the horizontal and vertical
 - ✿ TRMM can provide statistical validation of CRM simulations of the horizontal and vertical structure of precipitation, especially for deep convective systems

MOTIVATION

- ✿ Many previous studies have examined the horizontal structure of storms:
 - ✿ IR cloud clusters regionally (e.g., Williams and Houze 1987, Mapes and Houze 1993) and globally (e.g., Machado and Rossow 1998)
 - ✿ Radar echoes regionally using ground based radar (López 1977, Rickenbach and Rutledge 1998) and the TRMM PR (Nesbitt et al. 2000)
 - ✿ With TRMM, we can examine the spatial variation of *rainfall* Tropics-wide and obtain “climatological” averages of storm characteristics

FACTORS INFLUENCING RAINFALL SYSTEMS' HORIZONTAL STRUCTURE

- ☼ Convective Forcing
- ☼ Convective and Mesoscale Dynamics
- ☼ Microphysics, Rainfall
- ☼ Convective system- Large Scale Feedbacks

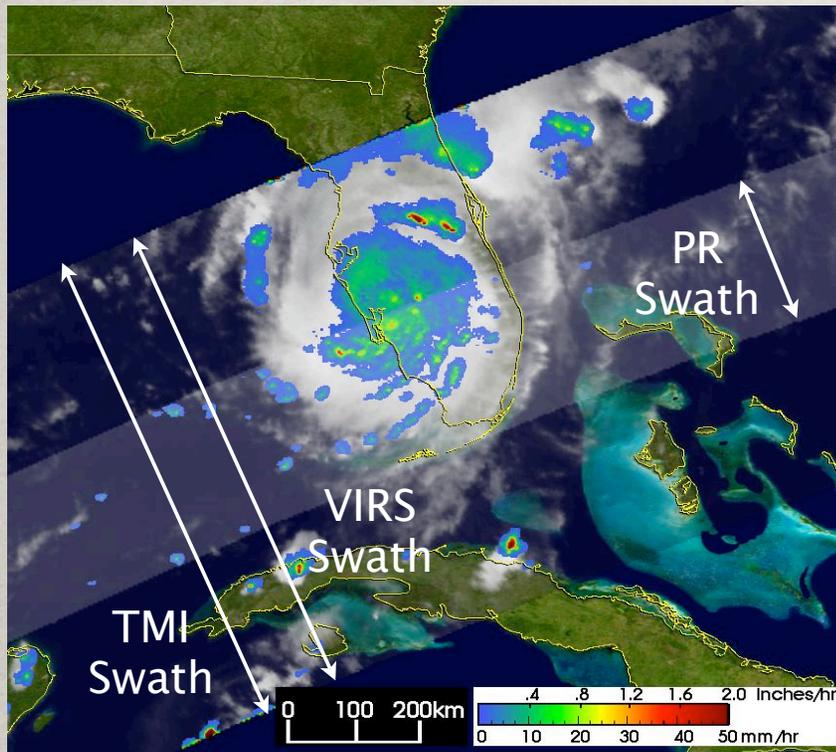

Yuter and Houze (1995)

GOALS OF THIS STUDY

- ✿ What is the parameter space of the precipitating features' echo horizontal dimension?
- ✿ How do features of various horizontal scales contribute to rainfall in a given region?
- ✿ What is the relationship between vertical and horizontal structure of these systems?
- ✿ How do storms of different types scale in rainfall contribution as a function of total rainfall?

TRMM INSTRUMENTS

<http://trmm.gsfc.nasa.gov>

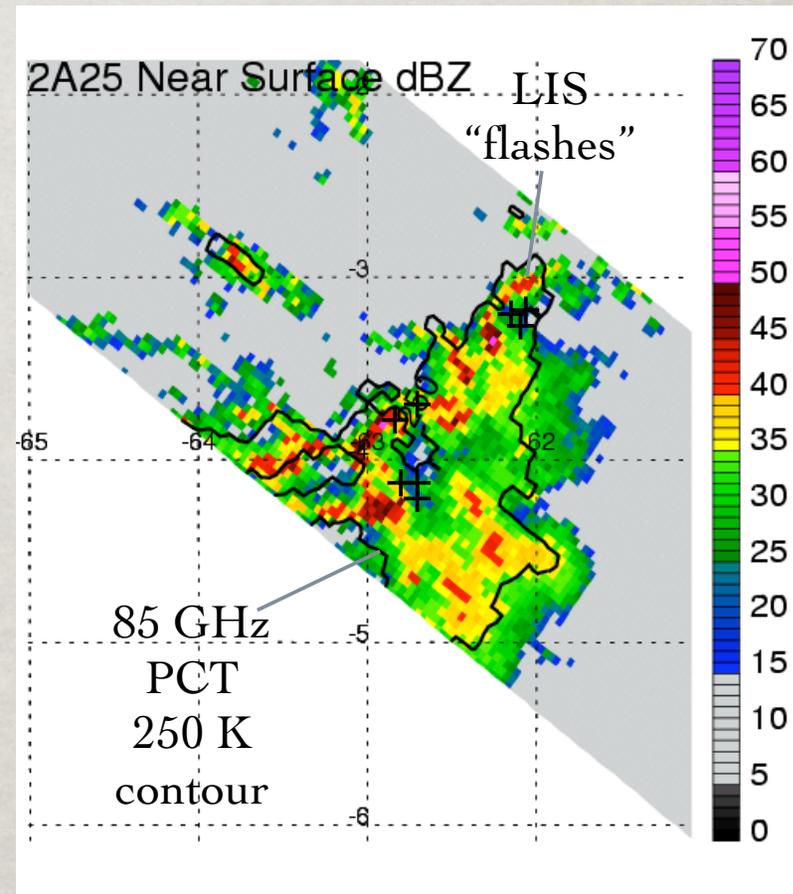

- ✧ Precipitation Radar (PR)
 - ✧ 215 km swath
 - ✧ Ka Band - 14 GHz - 2.2 cm
 - ✧ 17 dBZ minimum detectable signal
 - ✧ 4 x 4 x 0.25-1.5 km resolution
 - ✧ Calibrated to within ± 1 dBZ
- ✧ TRMM Microwave Imager (TMI)
 - ✧ 759 km swath
 - ✧ 9 channels, 10 - 85 GHz, dual polarization, elliptically-scanning
 - ✧ Resolution varies from 5 x 7 km at 85 GHz to 60 x 60 km at 10 GHz
 - ✧ Rainfall retrievals based on different physics over land and ocean
- ✧ Visible and Infrared Scanner (VIRS)
 - ✧ 720 km swath
 - ✧ Measures radiances at 5 channels from 0.6-12 μm

THE PRECIPITATION FEATURE DATABASE

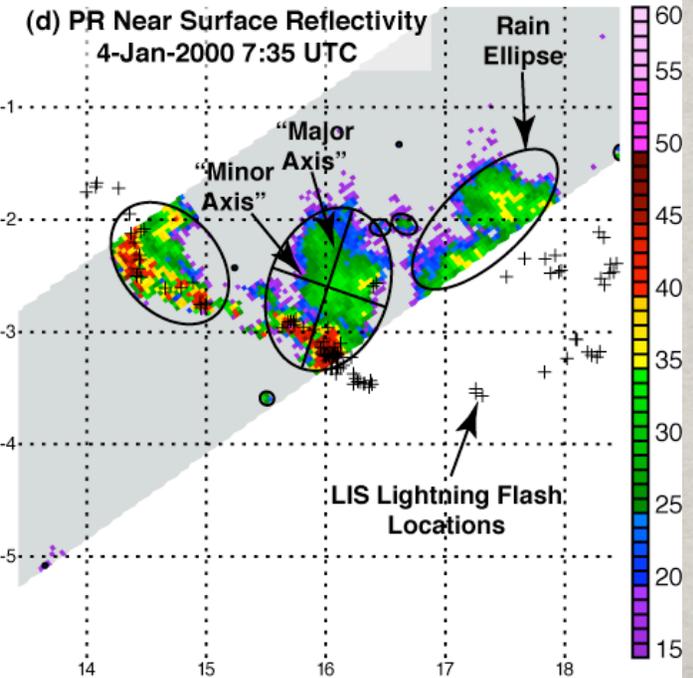

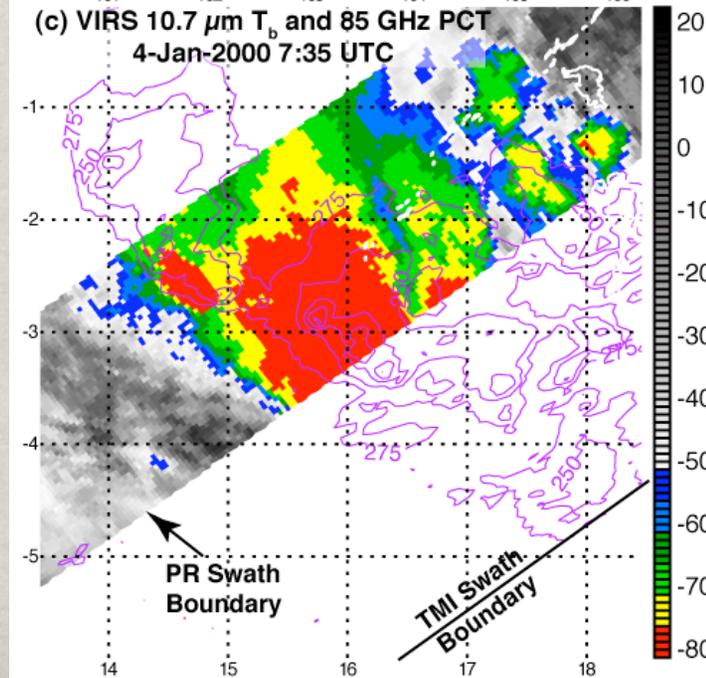

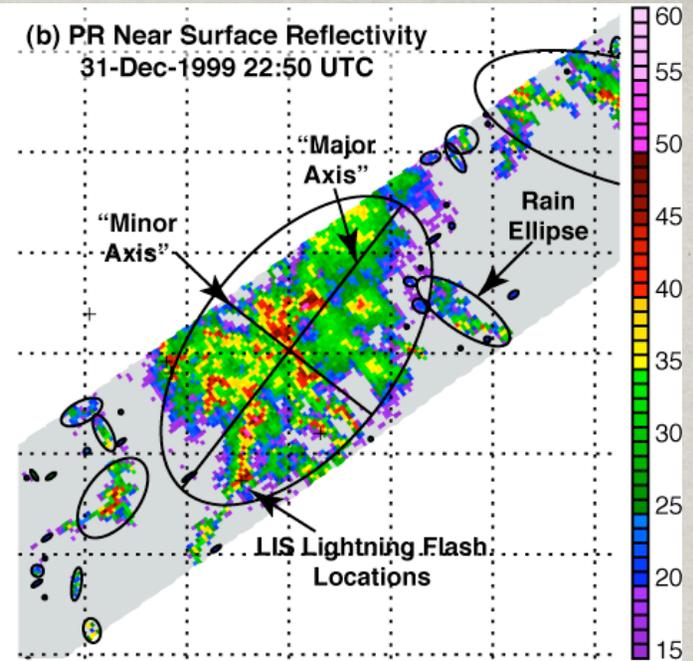

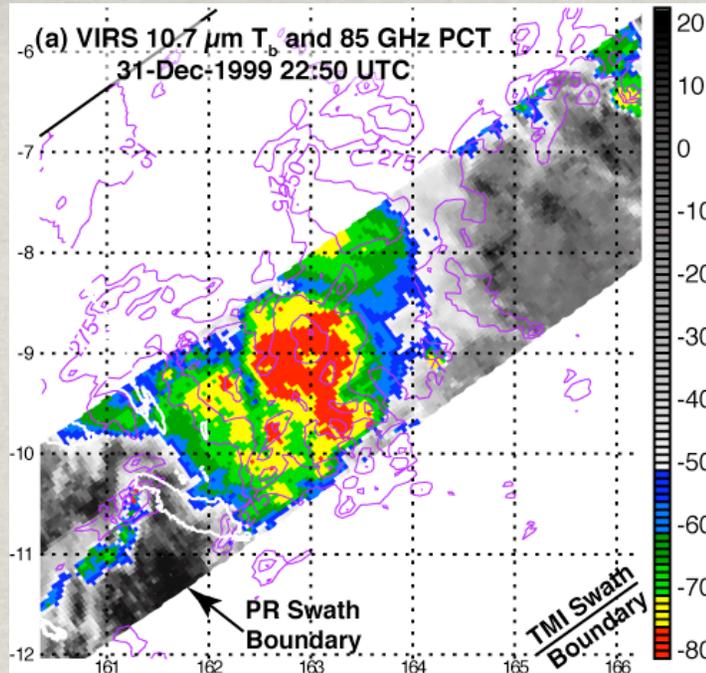

- ✿ Joint effort among University of Utah, Colorado State University, University of Alabama at Huntsville, NASA GSFC/TSDIS
- ✿ Brought forth a massive meteorological “data mining” effort to identify and classify rain systems within the TRMM PR and TMI swaths
- ✿ With “version 6” reprocessing, we have transitioned processing to GSFC
 - ✿ Level 1: PR/TMI/VIRS/LIS data compressed by a factor of 40
 - ✿ Level 2: Statistics calculated for PR-only, PR/TMI, and TMI-only identified precipitation features
- ✿ Roughly 36 million PR-defined PFs identified between 1998-2004

METHODOLOGY

- ✿ A PF is defined as an area of contiguous pixels with PR reflectivity ≥ 20 dBZ
- ✿ For this study, we analyzed 3 years of version 6 PFs (1998-2000)
- ✿ Ellipses are fitted to the perimeter of each PF using a least squares technique to estimate maximum dimension

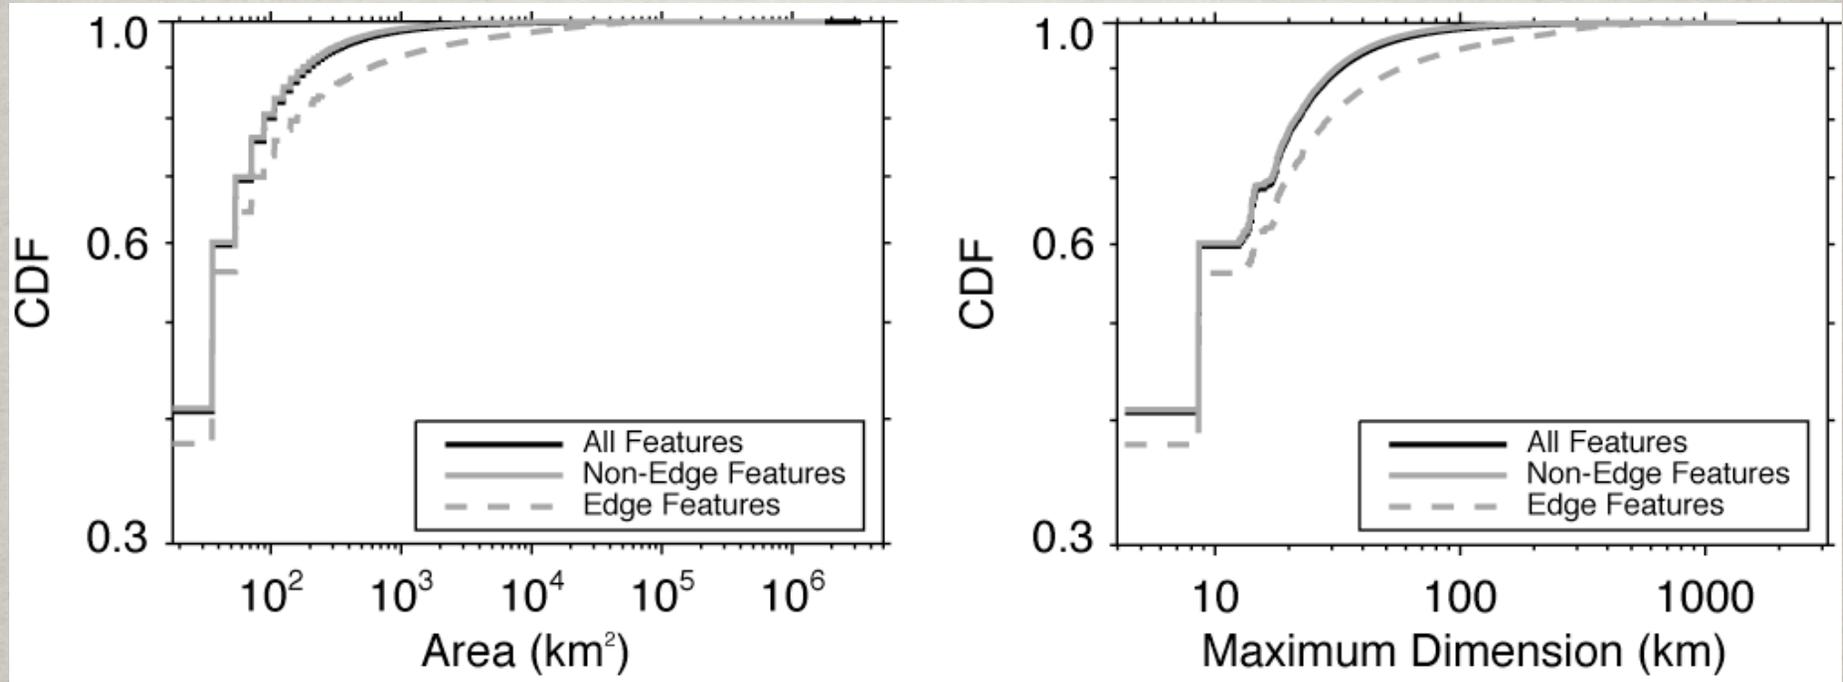

Tropical West Pacific

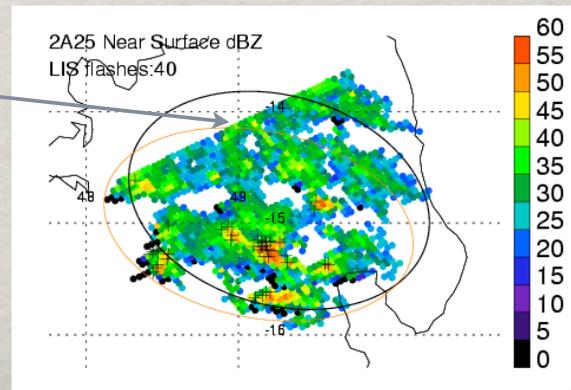

Congo Basin

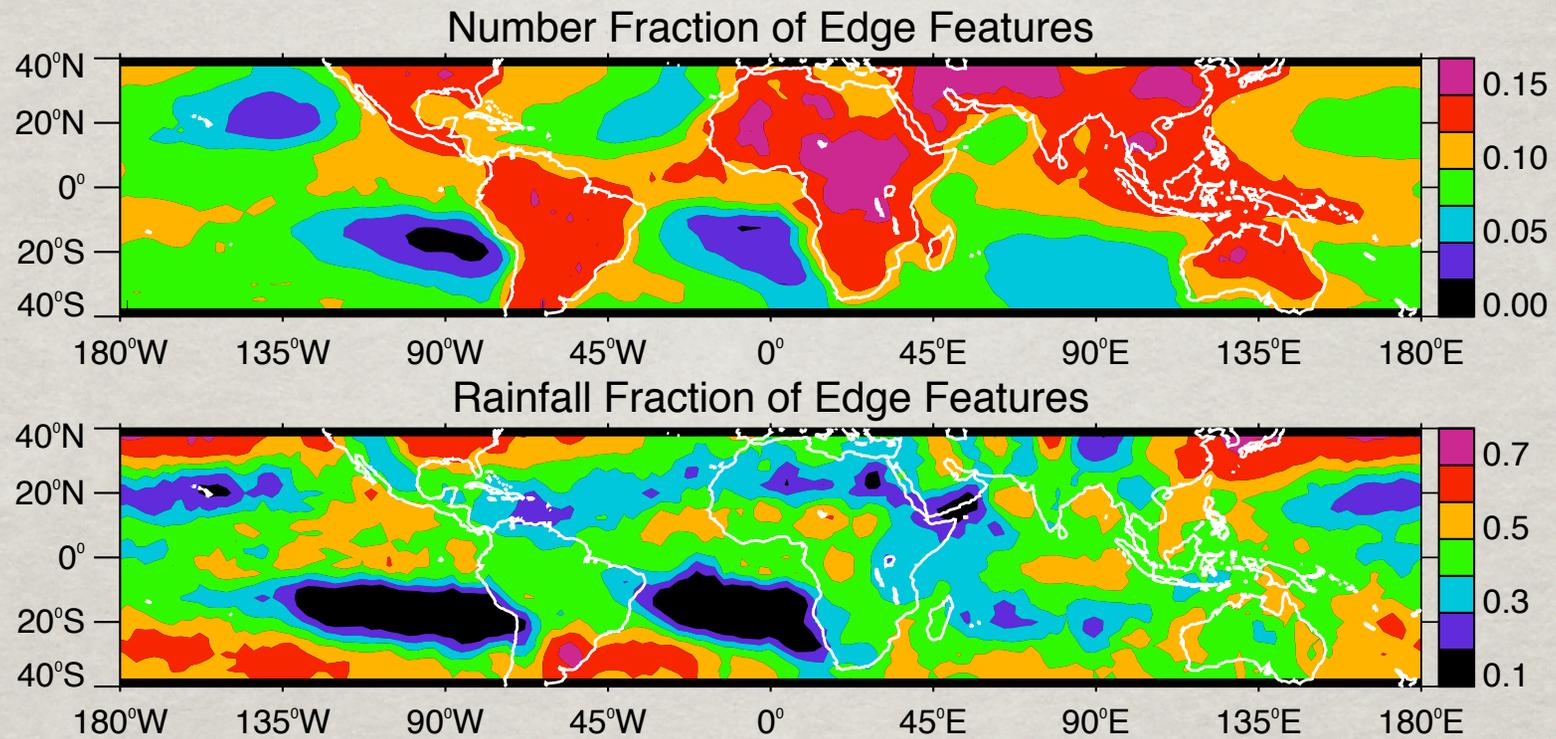

CDF of feature area for those hitting and not hitting the edge of the PR swath

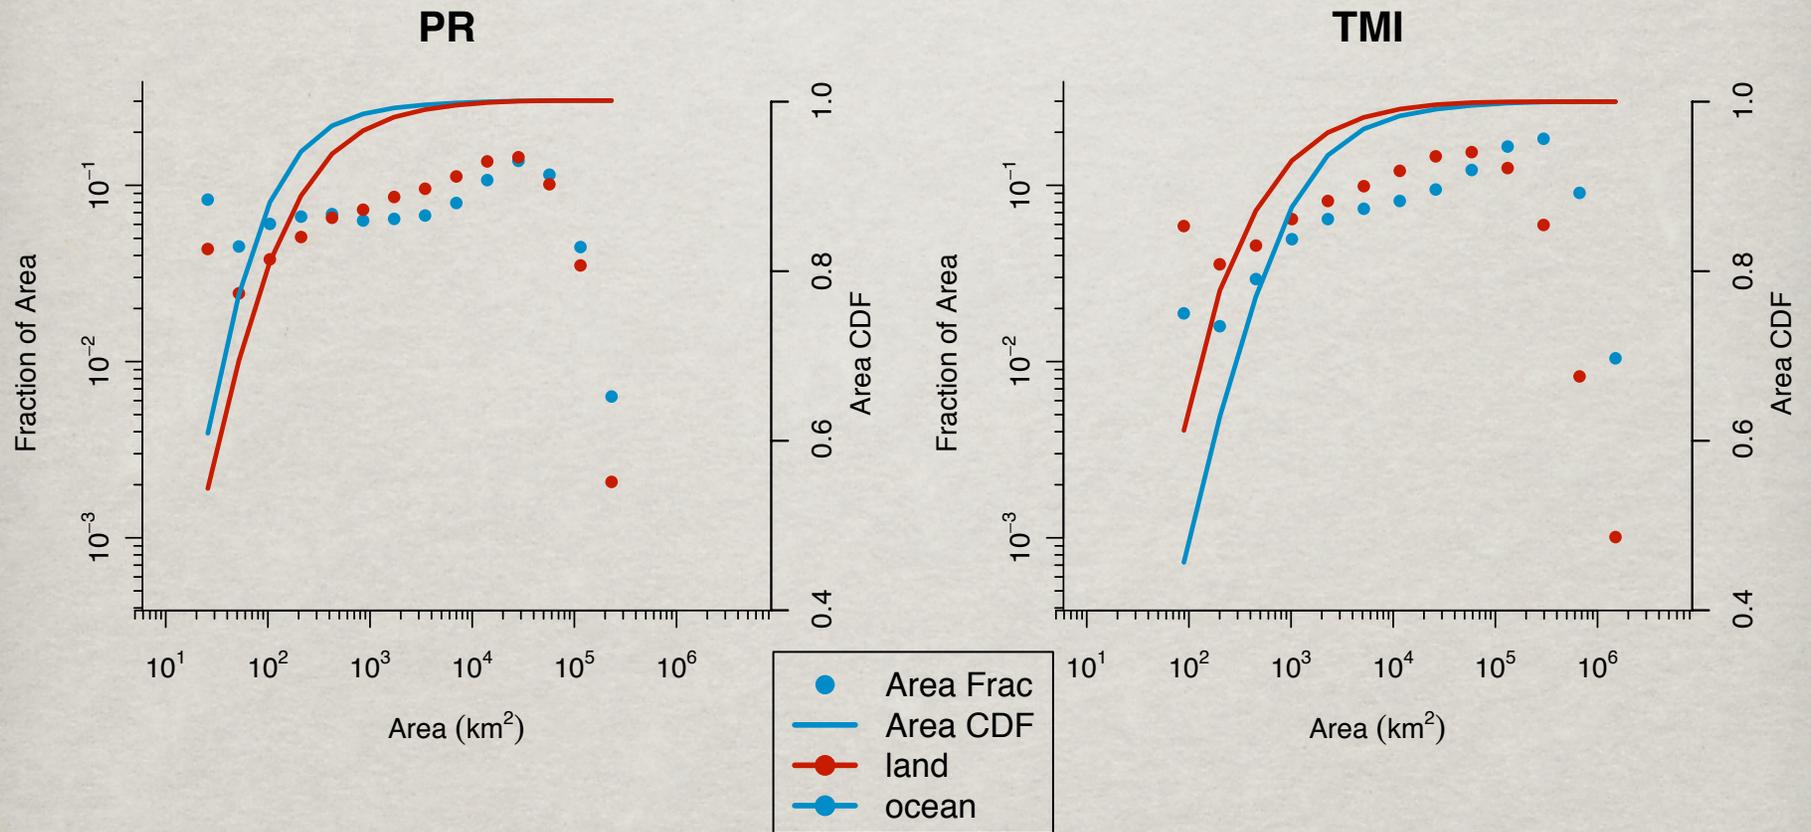

Edge of PR swath

Population and rainfall of PR edge features

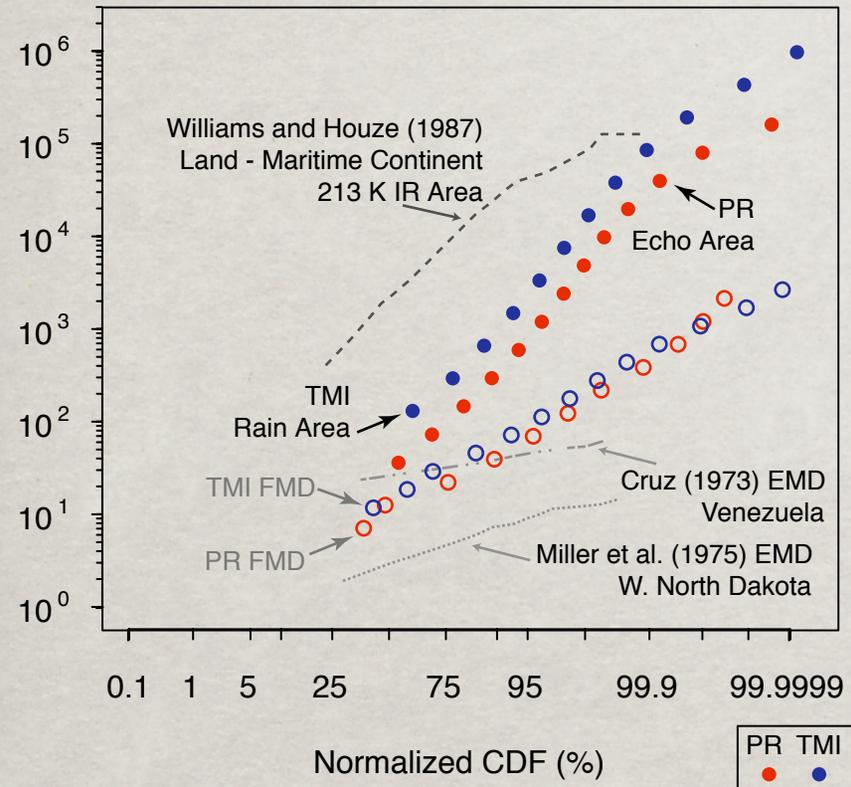

Distributions of feature area over land and ocean comparing PR 2A25 and TMI 2A12 near surface rain

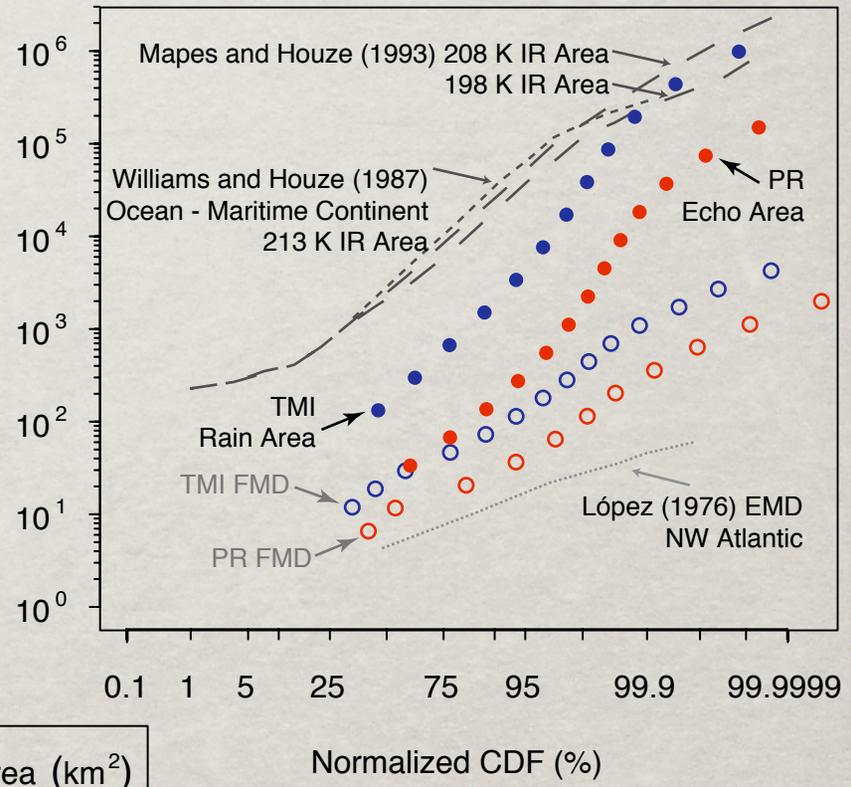

Feature size distributions on log-normal paper

PF Type	FMD criteria	ETH criteria
Shallow (S)	-	ETH \leq 4.5 km (MSL)
Small "Cold" (SC)	FMD $<$ 100 km	ETH $>$ 4.5 km
Large "Mid-level" (LM)	FMD \geq 100 km	4.5 $>$ ETH $>$ 9.5 km
MCS	FMD \geq 100 km	ETH \geq 9.5 km

Fraction of rainfall

Rainfall fraction by feature type

Examination of rainfall budgets

number of features
mean feature area

Total rain volume

$$\sum R_{\text{vol}} = A_r \overline{RR}_{\text{cond}} = n_f \overline{ARR}_{\text{cond}}$$

raining area

mean conditional rain rate

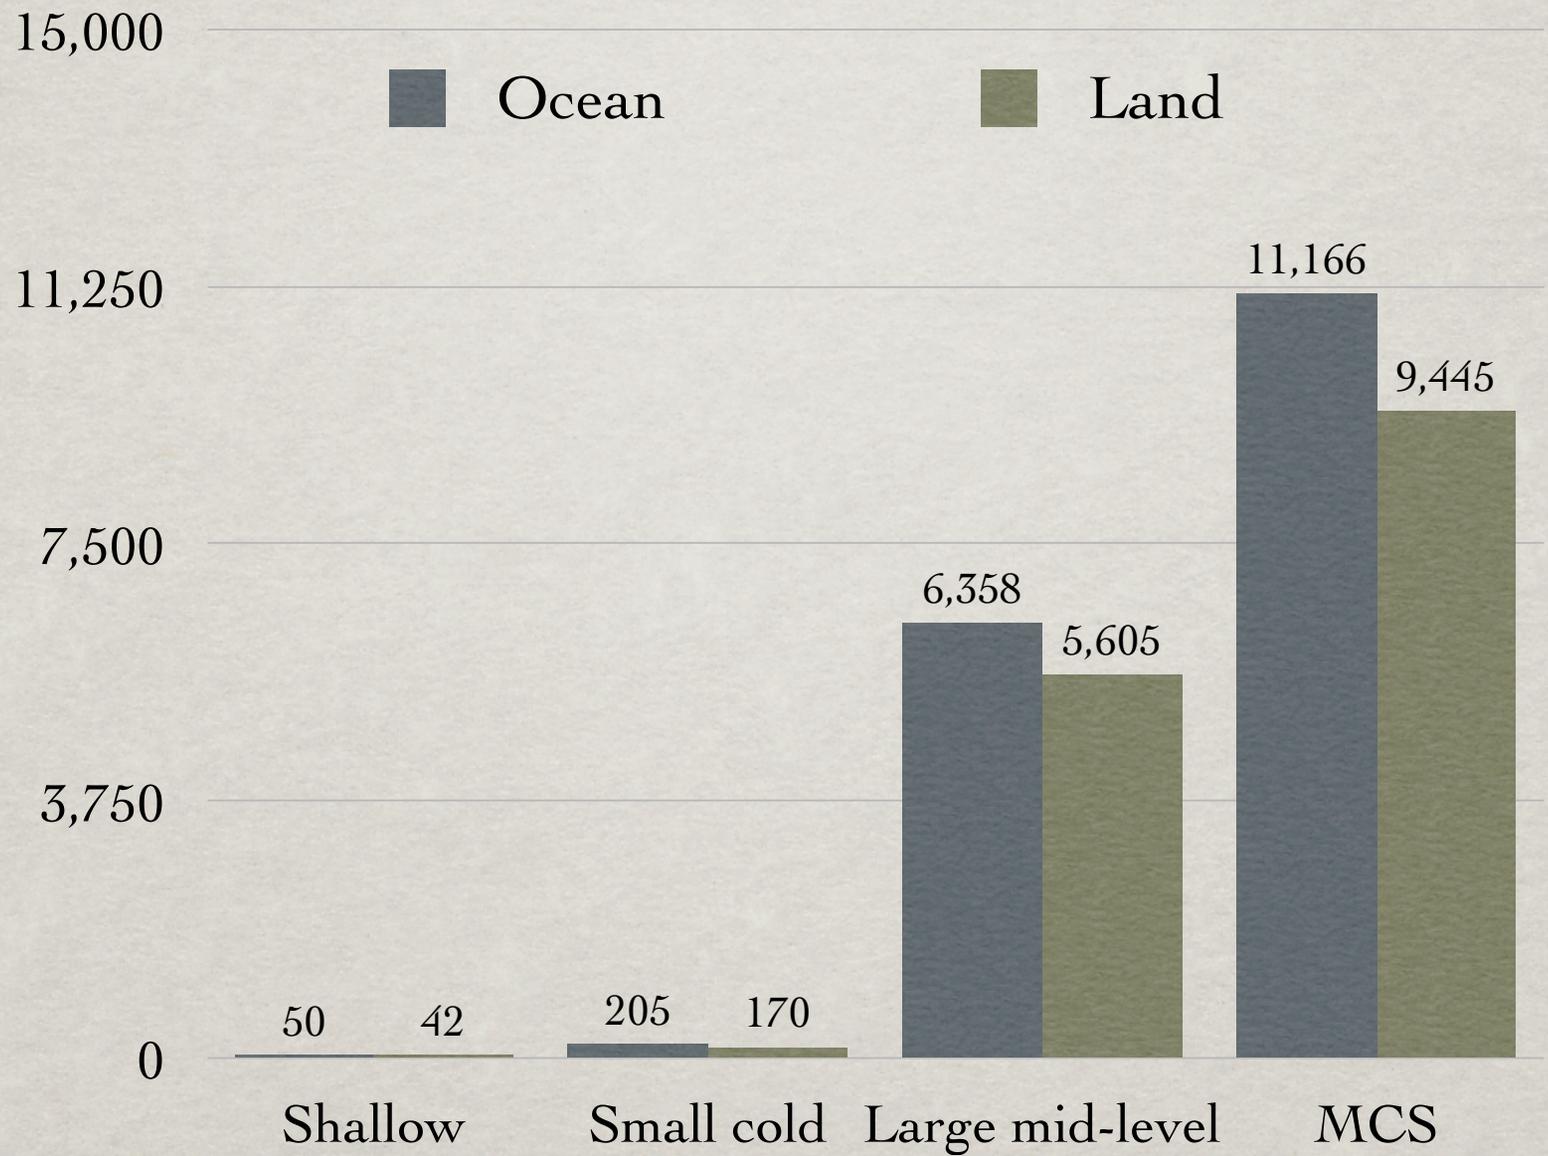

$$= n_f \overline{A} \left[f_{a_s} \overline{RR}_{\text{cond}_s} + (1 - f_{a_s}) \overline{RR}_{\text{cond}_c} \right]$$

fraction of area stratiform

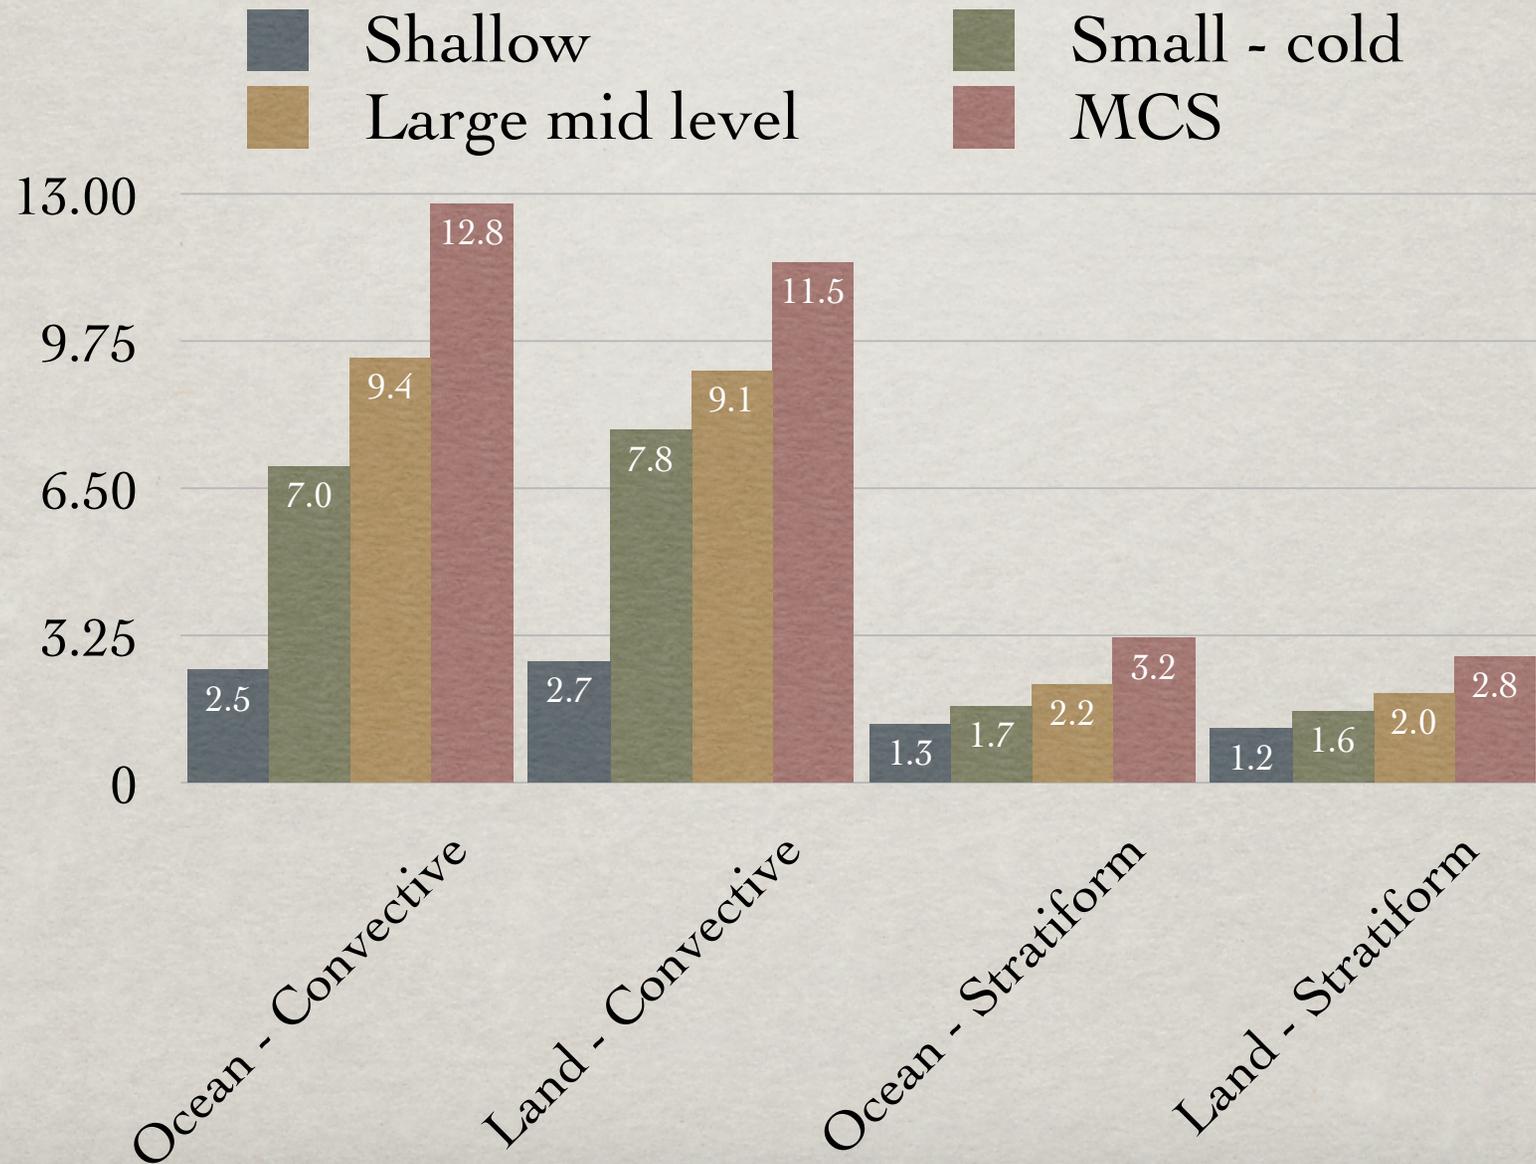

mean stratiform conditional rain rate

mean convective conditional rain rate

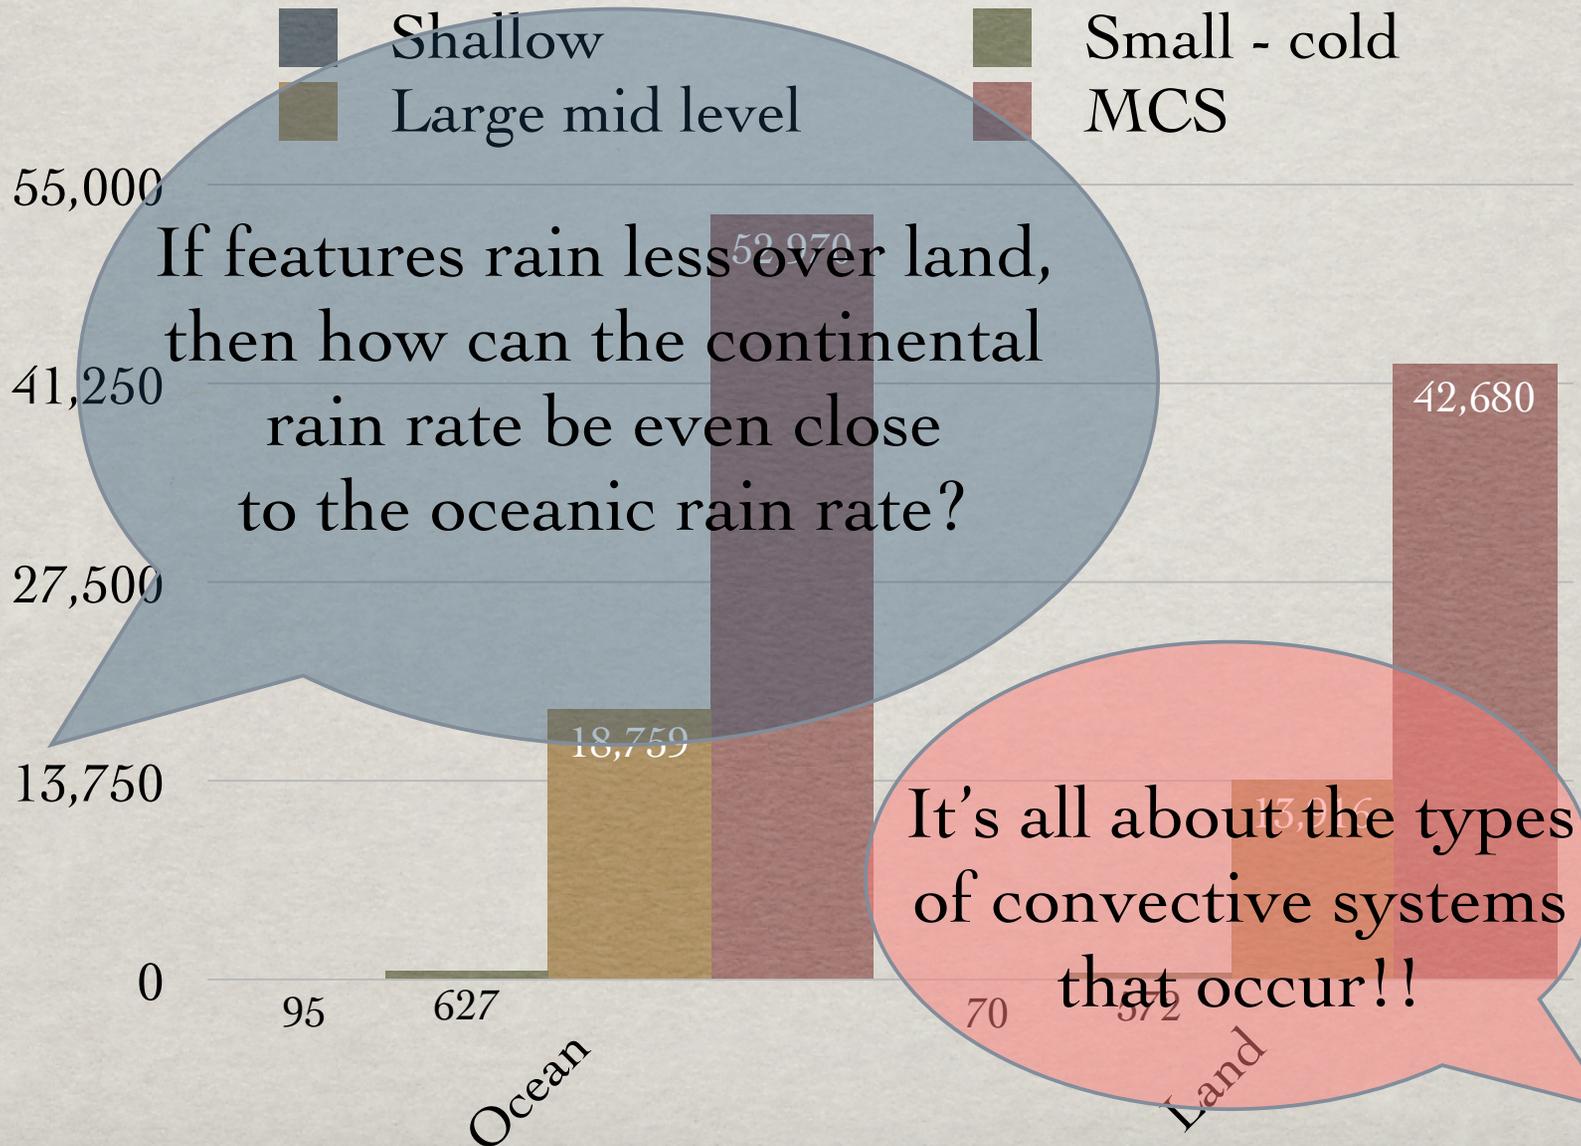

Mean feature area (km²)

Conditional rain rate (mm hr⁻¹)

Rain volume per feature (mm hr⁻¹ km²)

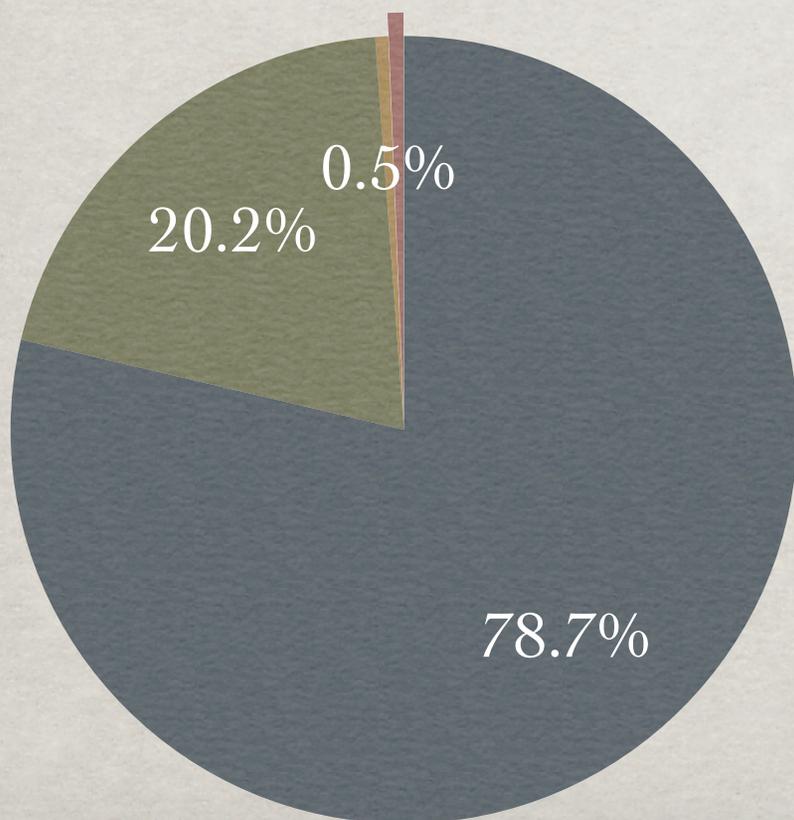

Fraction of number of features

- Shallow
- Small cold
- Large mid-level
- MCS

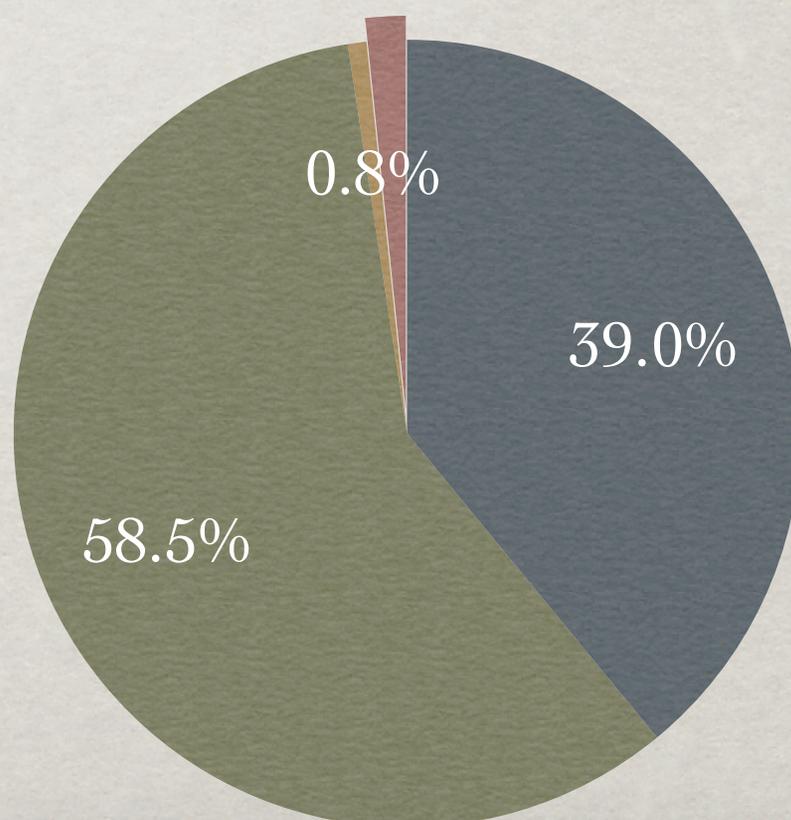

Ocean

0.6%

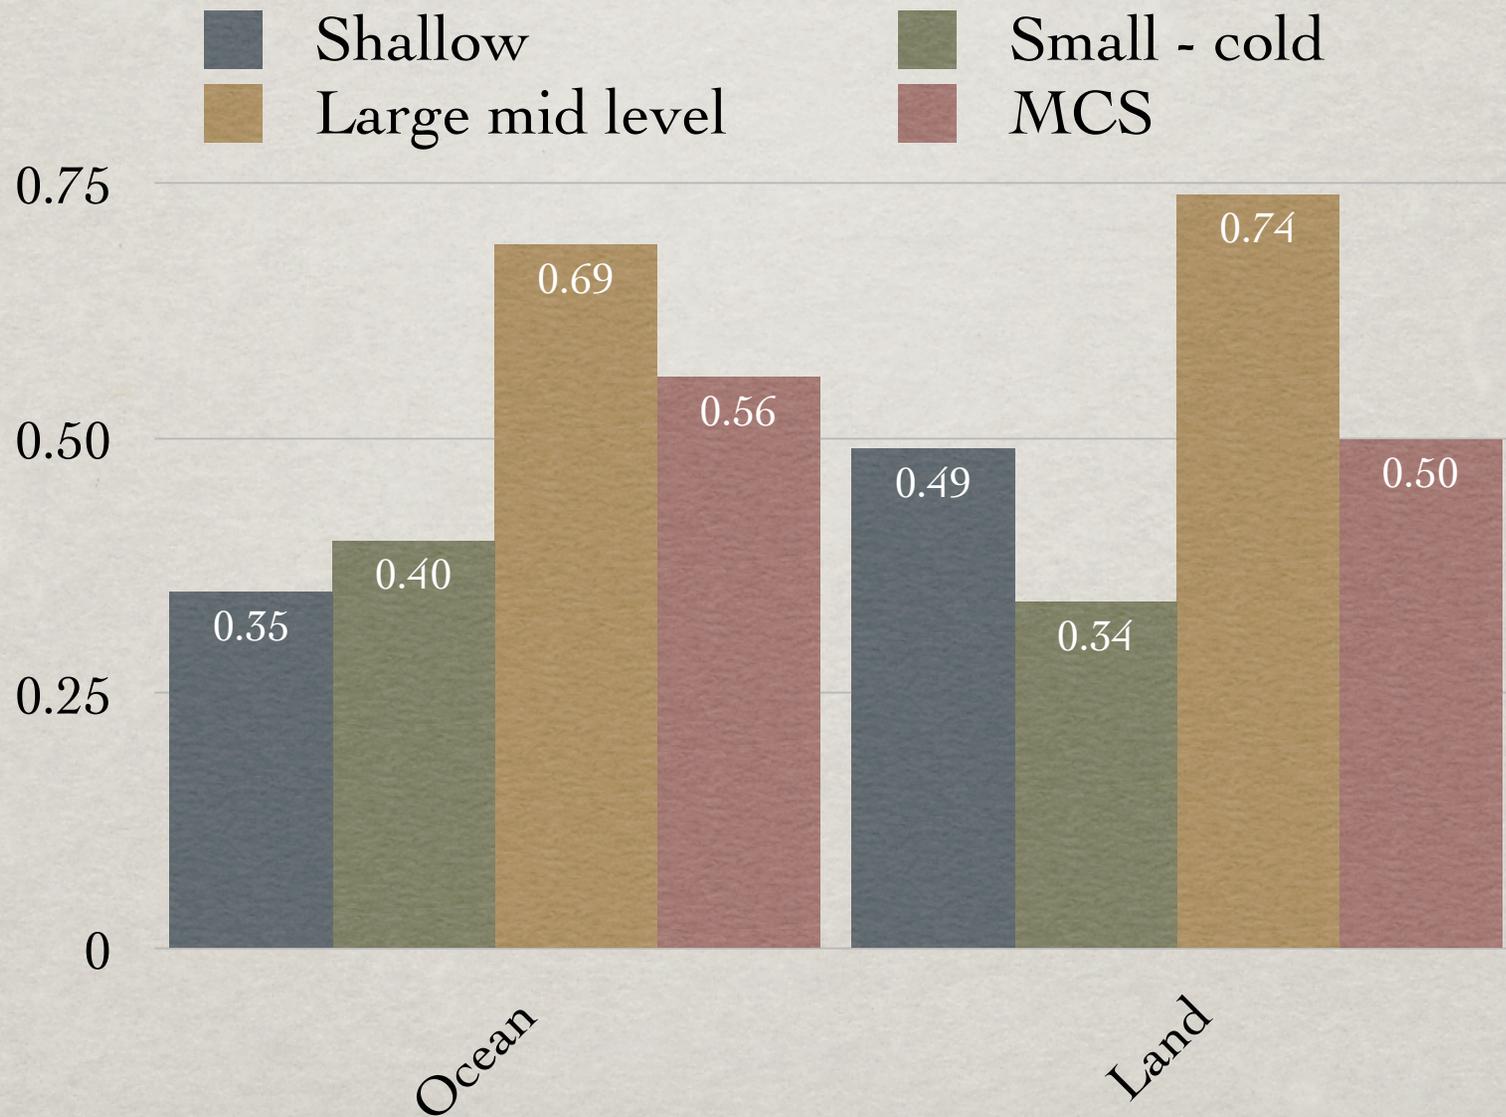

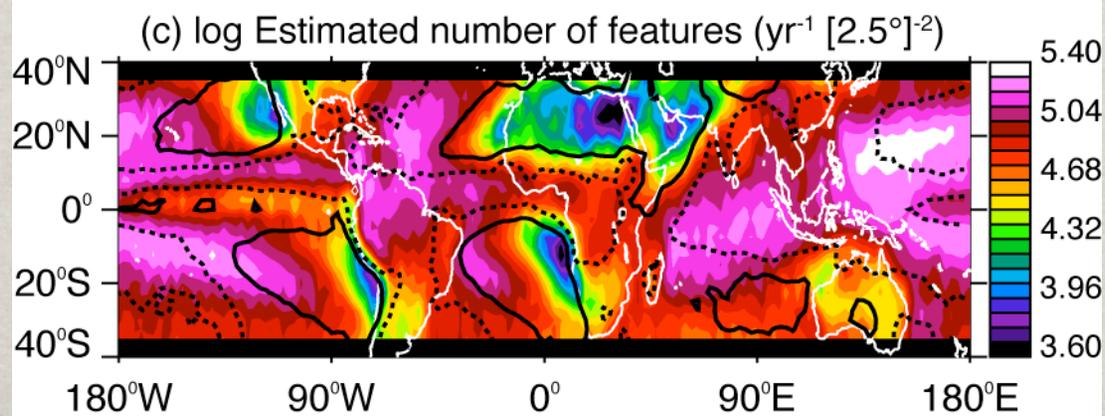

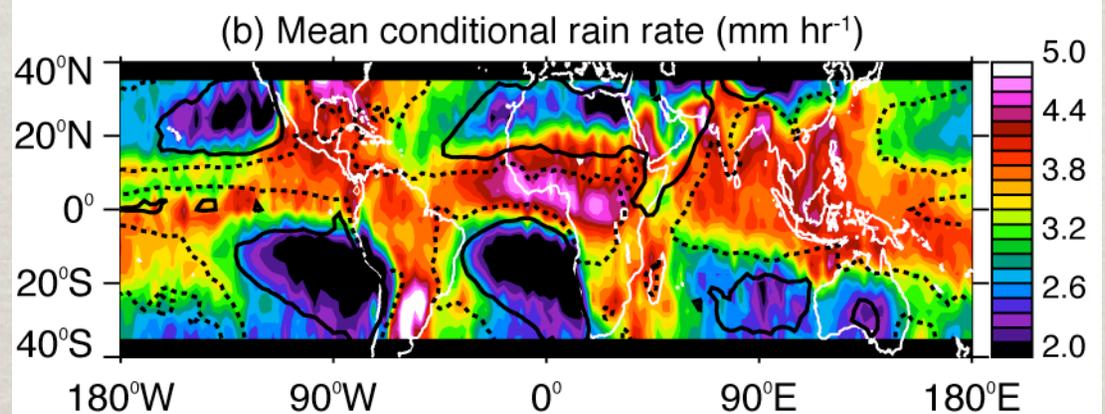

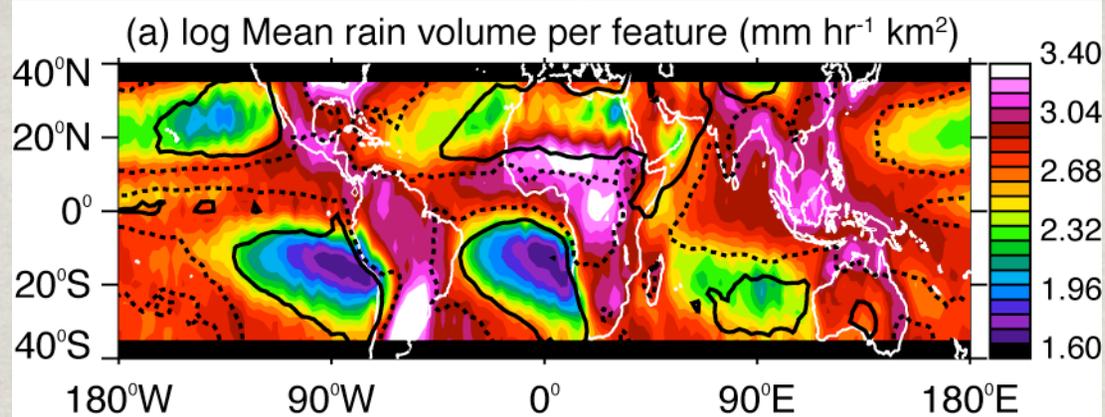

Land

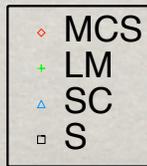

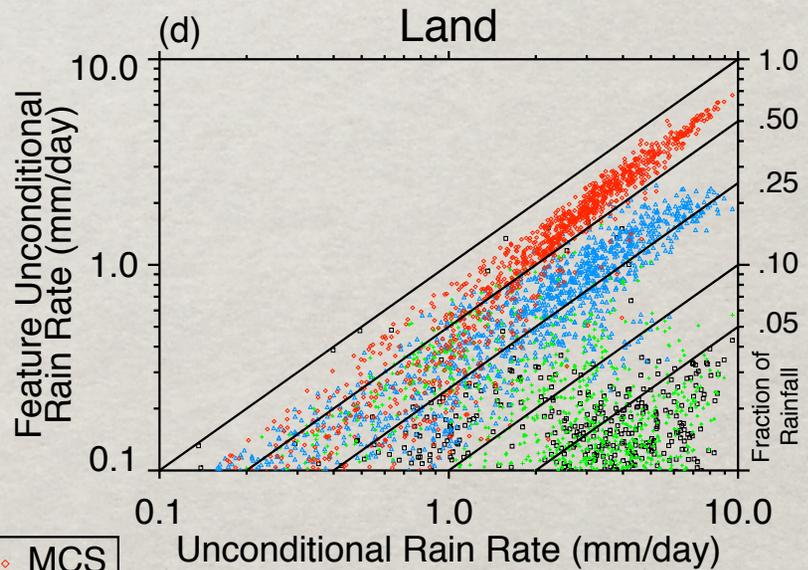

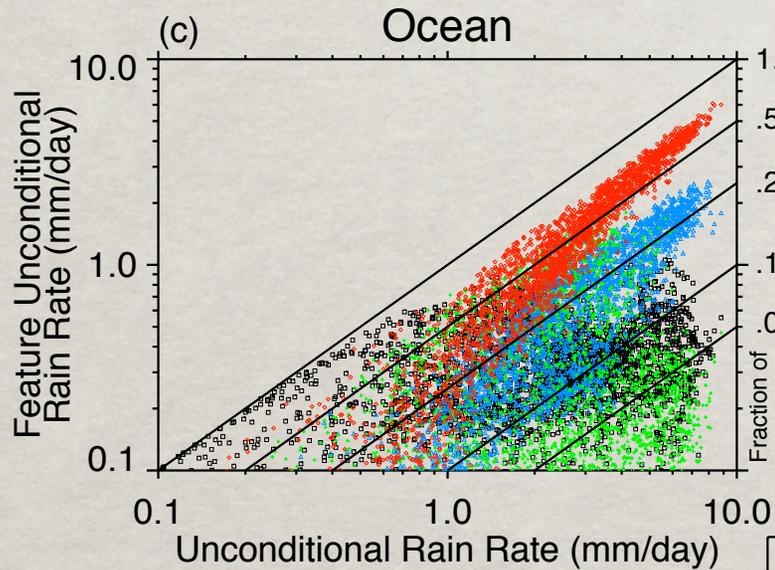

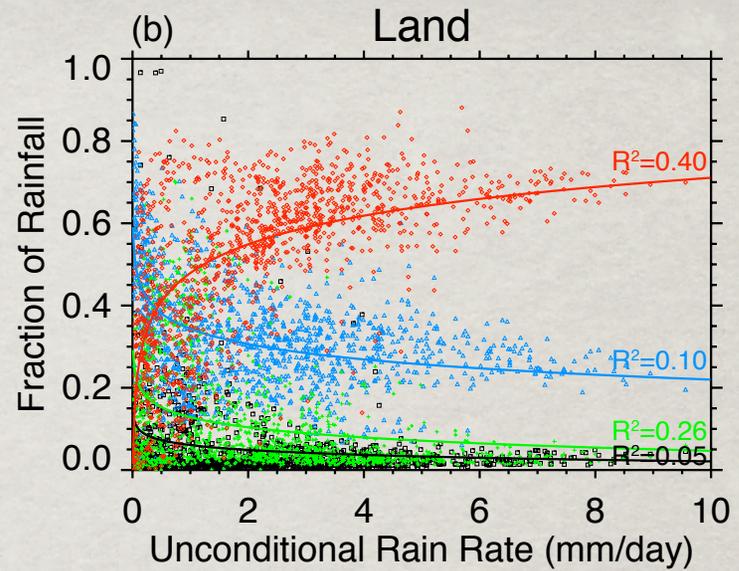

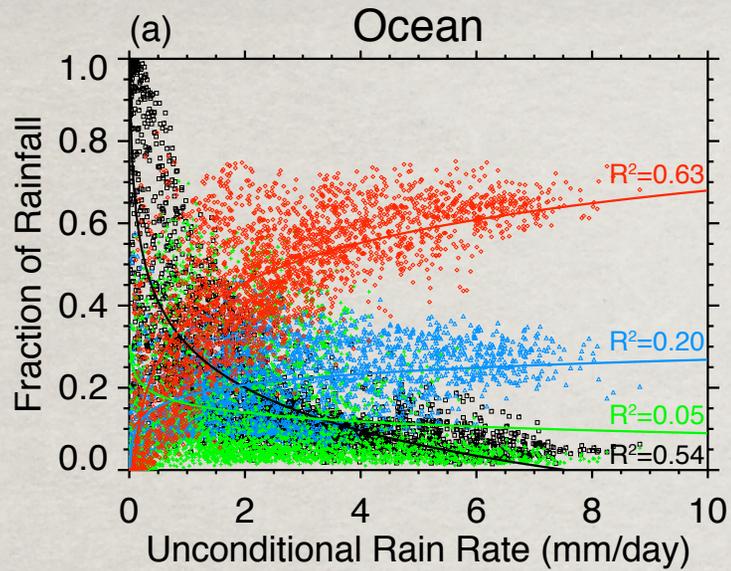

1.6%

Fraction of rainfall stratiform

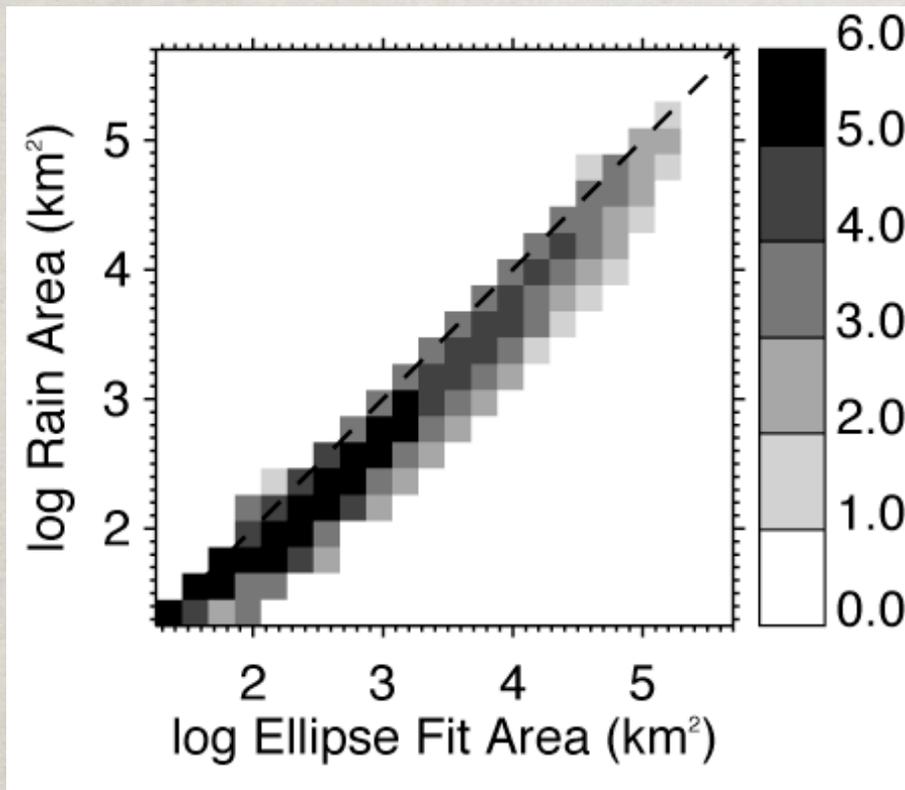

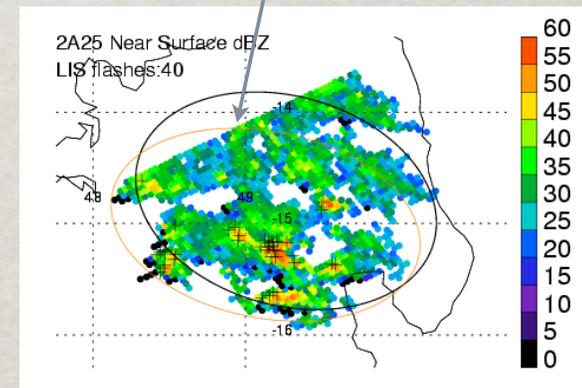

SUMMARY

- ✿ TRMM precipitation feature database provides an excellent test bed for comparing with statistics from CRM and MMF-climate simulations
- ✿ Land-ocean differences in convective system populations and characteristics important in controlling rainfall rates and amounts
 - ✿ More convective rainfall, higher relative occurrence of heavier raining but less frequent features over land
- ✿ This study provides the framework to quantitatively compare observations and CRMs

RAIN AREA VS. ELLIPSE FIT AREA

Edge of PR swath

Fraction of features hitting the edge of the PR swath
