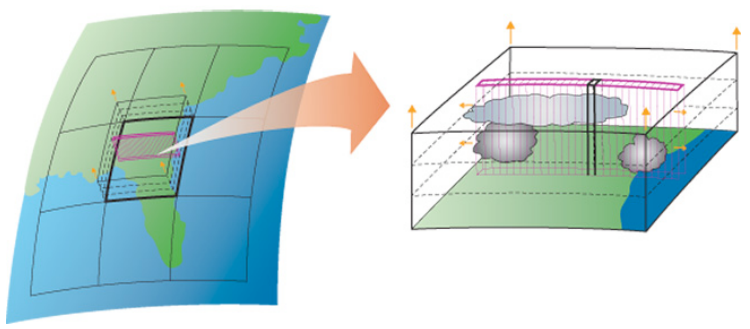
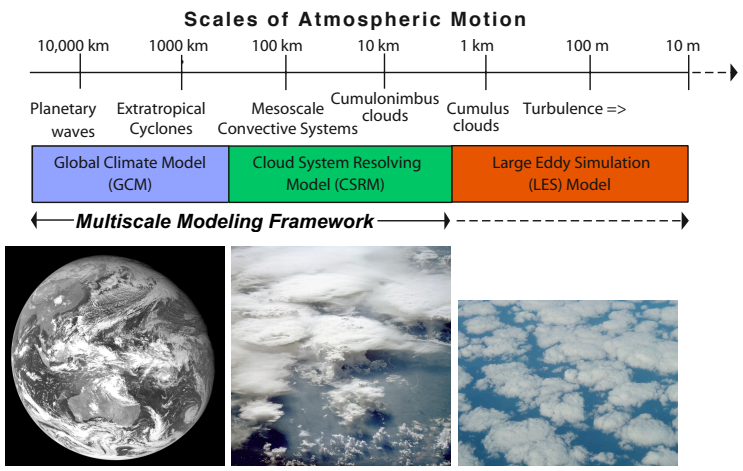
Multiscale Modeling Framework





Boundary layer clouds and turbulence in deep-convection-resolving models (DCRMs)

- DCRMs are CRMs with horizontal grid sizes of 4 km or more.
- Used in MMF, GCRMs (global CRMs), and tropical cyclone models.
- In MMF and GCRMs, DCRMs are expected to represent all types of cloud systems.
- However, many cloud-scale circulations are not resolved by DCRMs.
- Representations of SGS circulations currently used in DCRMs can be improved.

Our PDF-based parameterization

- We have constructed a 1D parameterization (Golaz et al. 2002b).
- It parameterizes layer clouds and turbulence in a unified way.
- Initially it was developed for boundary layers. It is being generalized further.
- It is based on the Assumed PDF Method.

Our PDF includes several variables

We use a three-dimensional PDF of vertical velocity, w, total water (vapor + liquid) mixing ratio, q_t, and liquid water potential temperature, θ_l :

$$P = P(w, q_t, \theta_l)$$

This allows us to couple subgrid interactions of vertical motions and buoyancy.

Randall et al. (1992)

Steps in the Assumed PDF Method

The Assumed PDF Method contains 3 main steps that must be carried out for each grid box and time step:

(1) Prognose means and various higher-order moments.

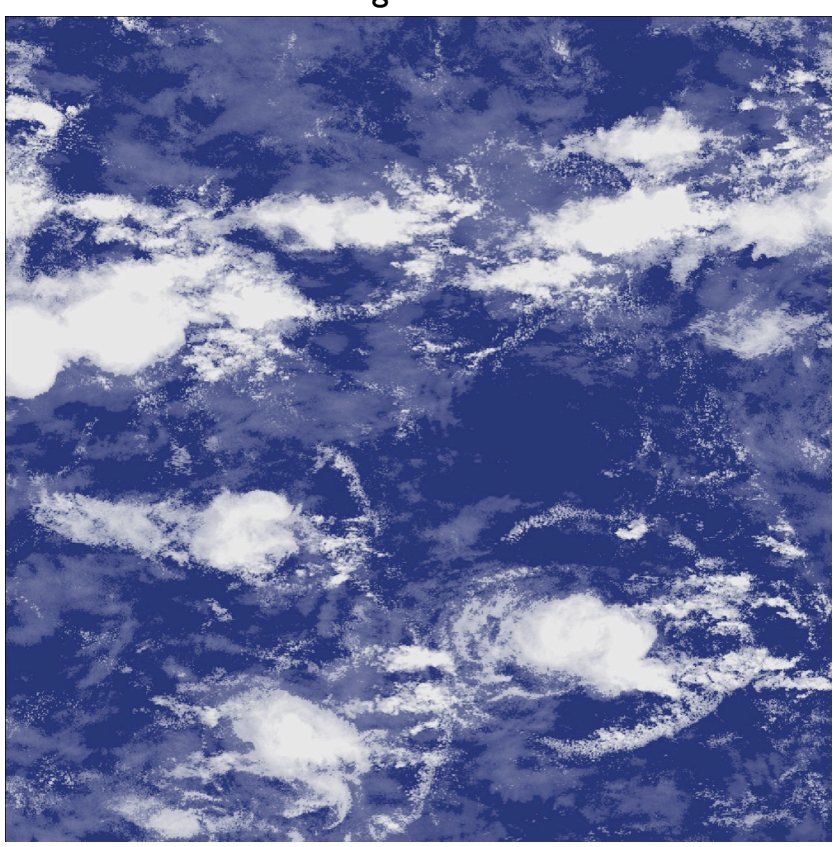
(2) Use these moments to select a particular PDF member from the assumed functional form.

(3) Use the selected PDF to compute many higher-order terms that need to be closed, e.g. buoyancy flux, cloud fraction, etc.

Use results from a large-domain LES of deep convection to test the assumed PDF method

- Idealized GATE simulation with shear.
- Used SAM with 2048 x 2048 x 256 grid points and 100-m grid size for a 24-h LES.
- Equivalent to 1024 6.4-km x 6.4-km LESs.
- Collected statistics for calculating the moments needed to specify assumed PDFs for grid sizes of 800 m x 800 m x 100 m and multiples thereof.
- The statistics also include cloud fraction, liquid water mixing ratio, and its vertical flux, that can be compared to those obtained from the PDF.

LES "visible image" 180 km x 180 km



MISR visible image 380 km x 345 km (west of Marshall Is., 11 March 2002)

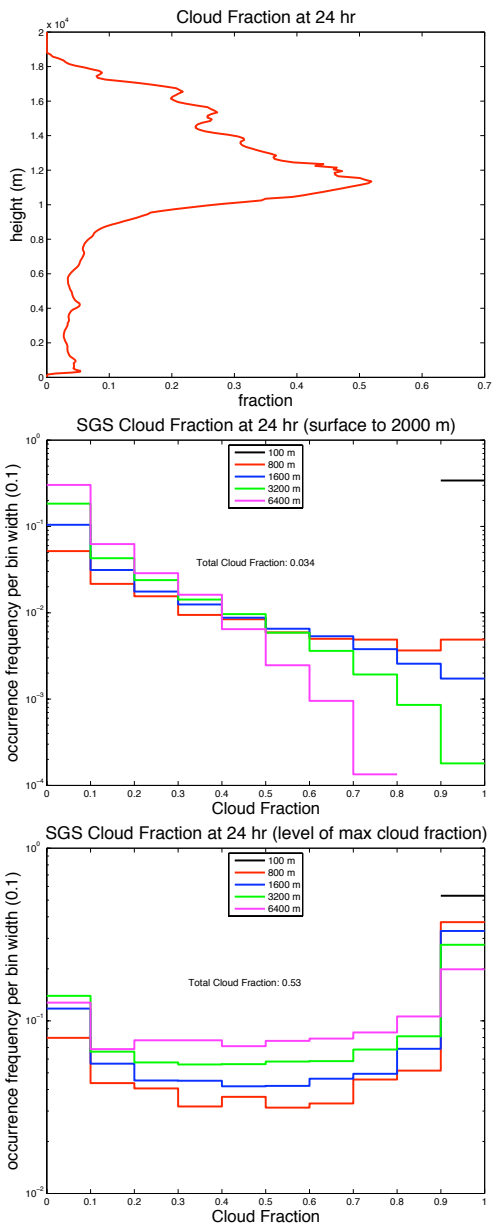
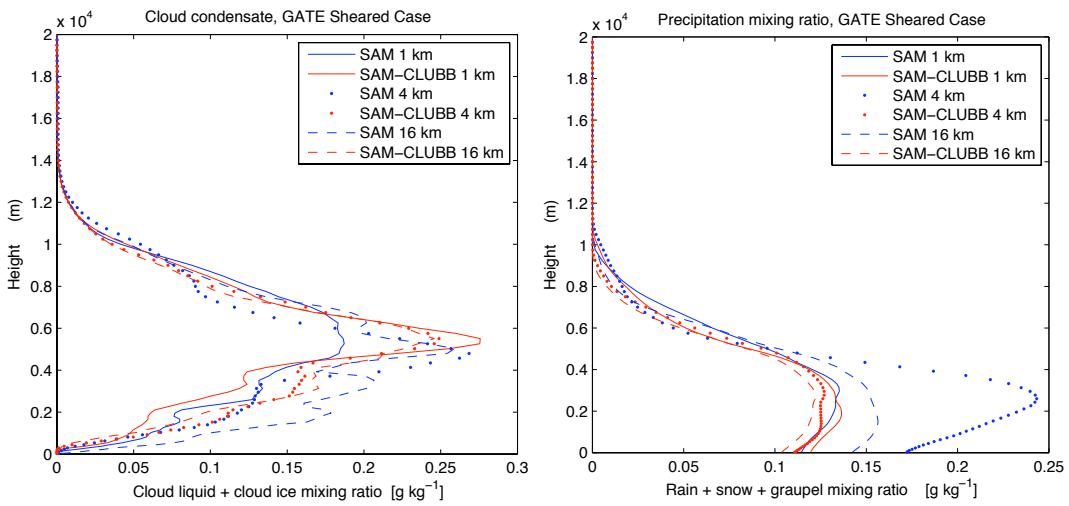
PDFs of SGS cloud fraction for various horizontal grid sizes for low clouds and high clouds obtained from the large-domain LES of deep convection



SAM & SAM-CLUBB (SAM + assumed PDF): 2D, 64-km domain, 128 levels (large-scale forcing is 6x super run)



Summary

- We will use the "benchmark" results from a large-domain LES of deep convection to test the assumed PDF method for various horizontal grid sizes.
- We will also use the "benchmark" results to evaluate DCRMs with various configurations (SGS parameterization, grid size, domain size, and dimensionality).
- Large-domain LES of deep convection can be used to study many multiscale phenomena, such as triggering of new convection, entrainment, gust fronts, and even waterspouts.
