

Rainfall Monitoring

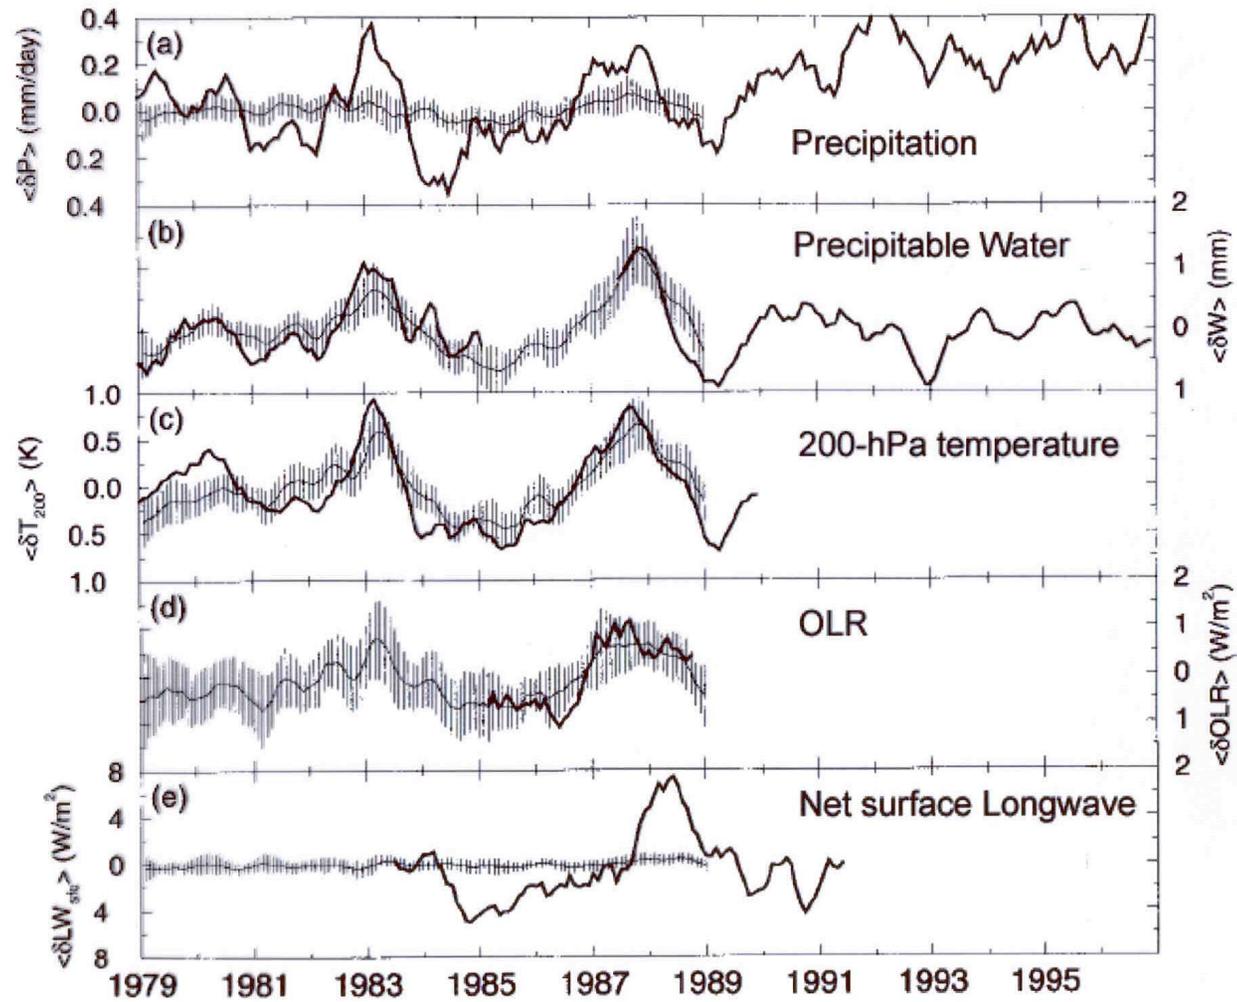

Prospects for a synergistic approach
between models and observations

Christian Kummerow

Climate Models

Soden, 2000

JOURNAL OF CLIMATE

The Problem(s)

- Rainfall Measurements - how accurate are they ?

It is hard to find decent validation data to compare to

When we find data, it is hard to do intelligent comparisons

When we do the intelligent comparisons, we still can't get uncertainties

- Cloud Resolving Models

It is hard to find decent validation data to compare to

When we find data, it is hard to do intelligent comparisons

When we do the intelligent comparisons, it is not clear what we do

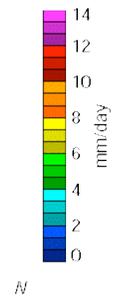

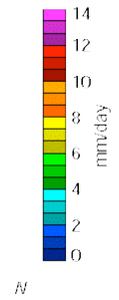

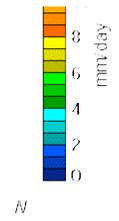

with the results except to tell the model developers about

the differences. They ignore us because of (a) & (b) and

because the differences may not be systemic but merely an

issue with the realization, and besides, they have plenty to do.

GPI/MSU/SSM/I

Tropical Rainfall Measuring Mission (TRMM)

NASDA
NATIONAL SPACE DEVELOPMENT AGENCY OF JAPAN

TRMM Sensors

Precipitation radar (PR):

- 13.8 GHz
- 4.3 km footprint
- 0.25 km vertical res.
- 215 km swath

Microwave radiometer (TMI):

- 10.7, 19.3, 21.3, 37.0
- 85.5 GHz (dual polarized except for 21.3 V-only)
- 10x7 km FOV at 37 GHz
- 760 km swath

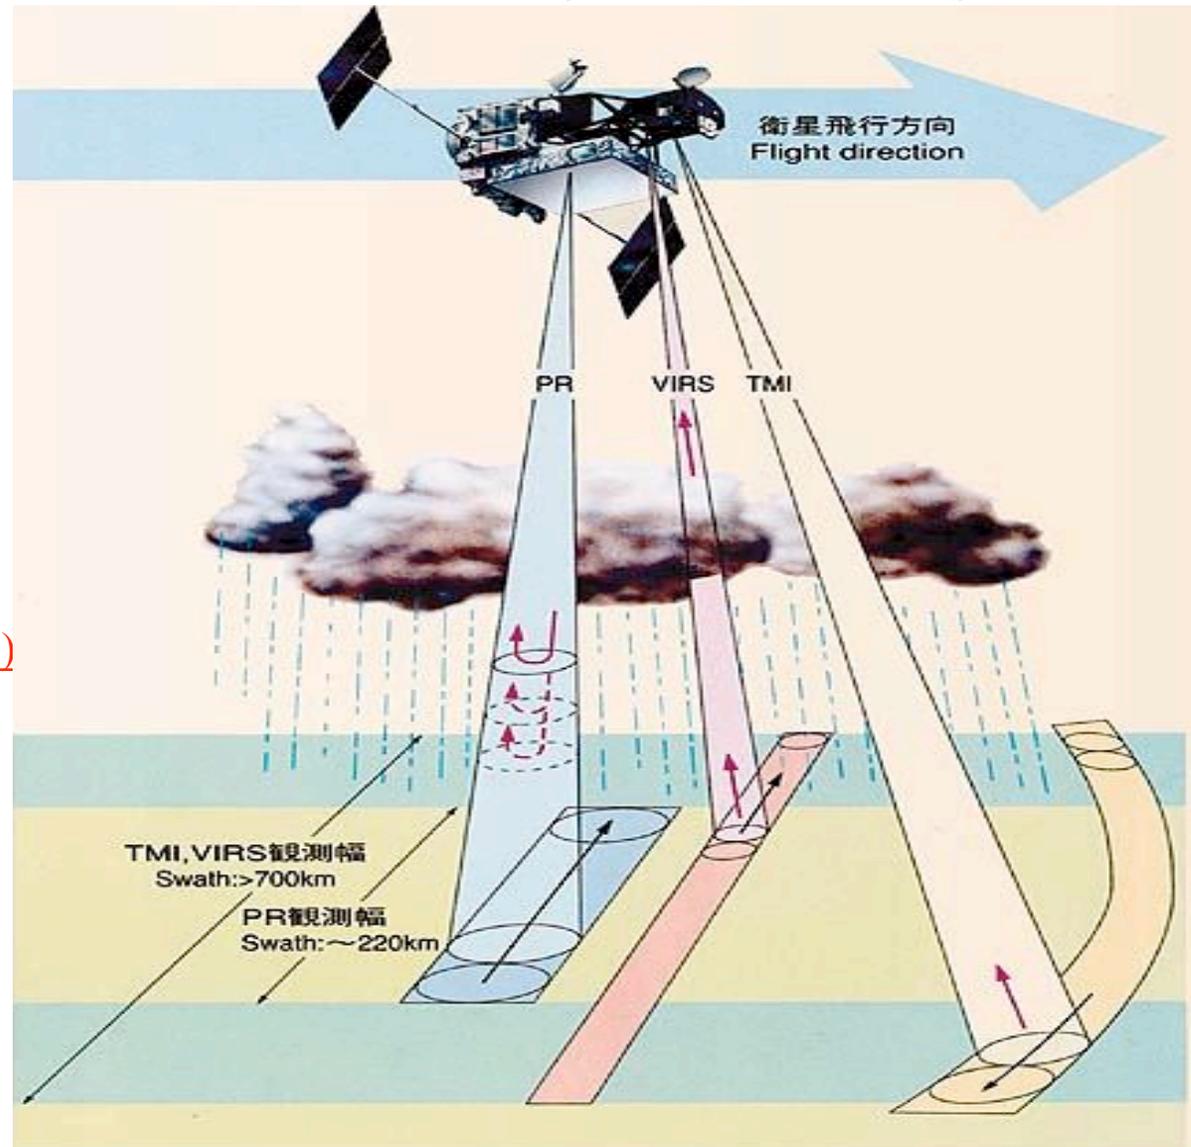

Visible/infrared radiometer (VIRS)

- 0.63, 1.61, 3.75, 10.8, and 12 :m
- at 2.2 km resolution

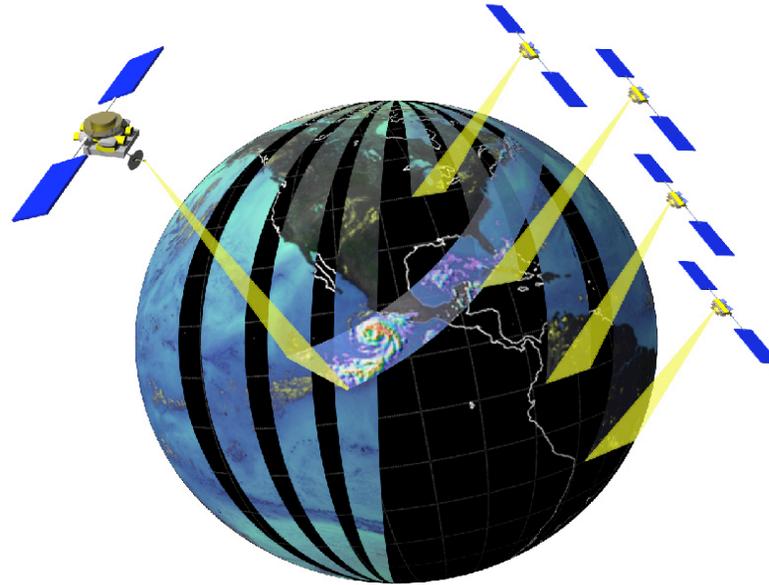

Lightning Imaging Sensor (LIS)

Cloud & Earth Radiant Energy System (CERES)

Nov. 1997 launch, 35° inclination; 402 km

The Global Precipitation Mission (~2008)

CORE SATELLITE

- Dual frequency radar
- Multifrequency radiometer
- Non-sun synchronous orbit
- ~ 70° inclination
- ~ 400 - 500 km altitude
- ~ 4 km horizontal resolution
- 250 m vertical resolution

MISSION: Understand the horizontal and vertical structure of rainfall and its microphysical elements. Provide training for constellation radiometers.

CONSTELLATION SATELLITES

- 8 small satellites with microwave radiometer only*
- 3 hr revisit time
- Sun-synchronous polar orbit
- ~ 600 km altitude

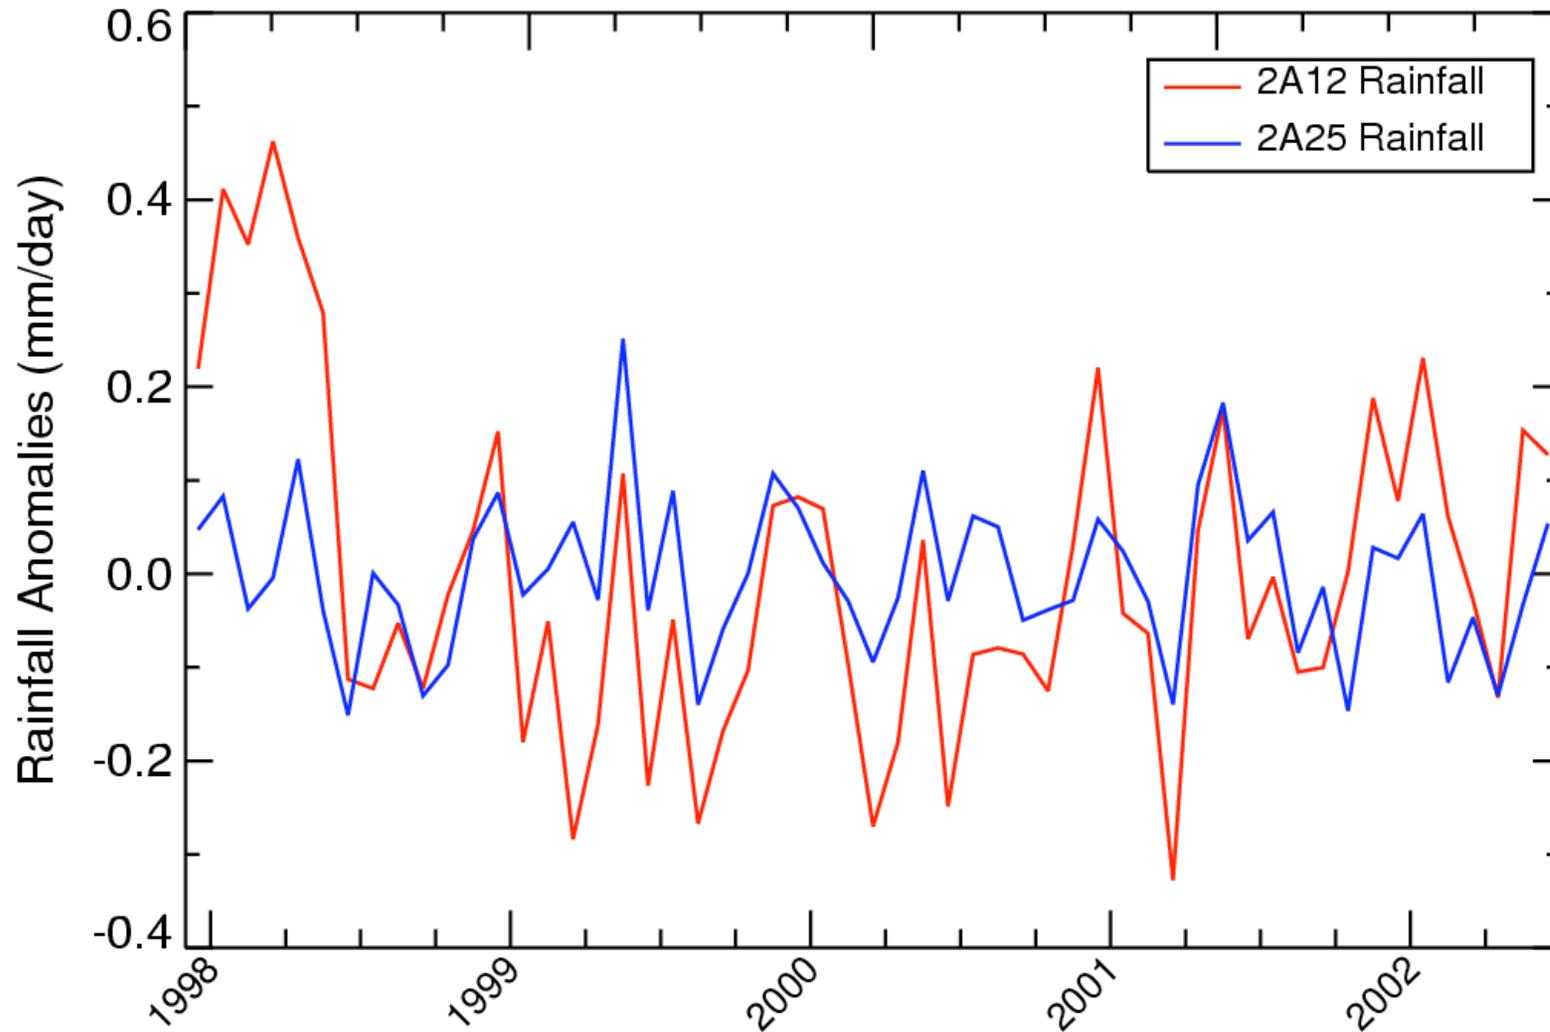

*Some of the 8 small satellites may be replaced by existing radiometers (e.g., SSM/Is, AMSR, etc.)

MISSION: Provide enough sampling to reduce uncertainty in short-term rainfall accumulations. Extend scientific and societal applications.

Tropical Rainfall Anomalies

(TRMM Ocean Retrievals)

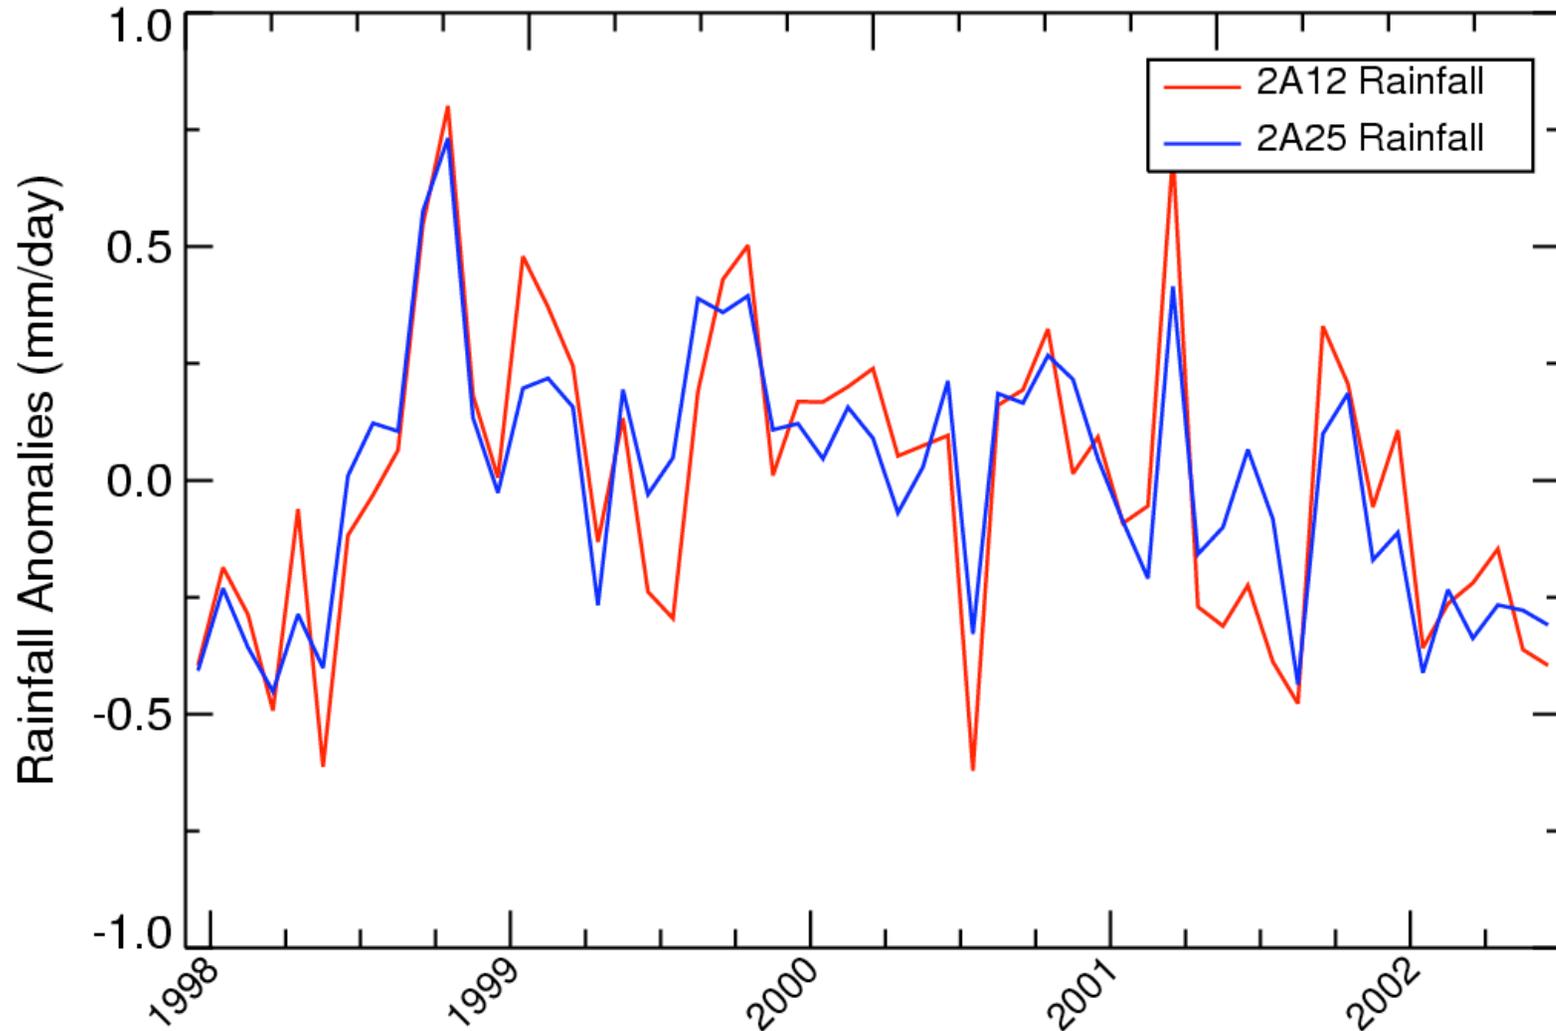

Monthly Mean Rainfall (ocean only)
(Selected Region: 30S-30N, 0-360E)

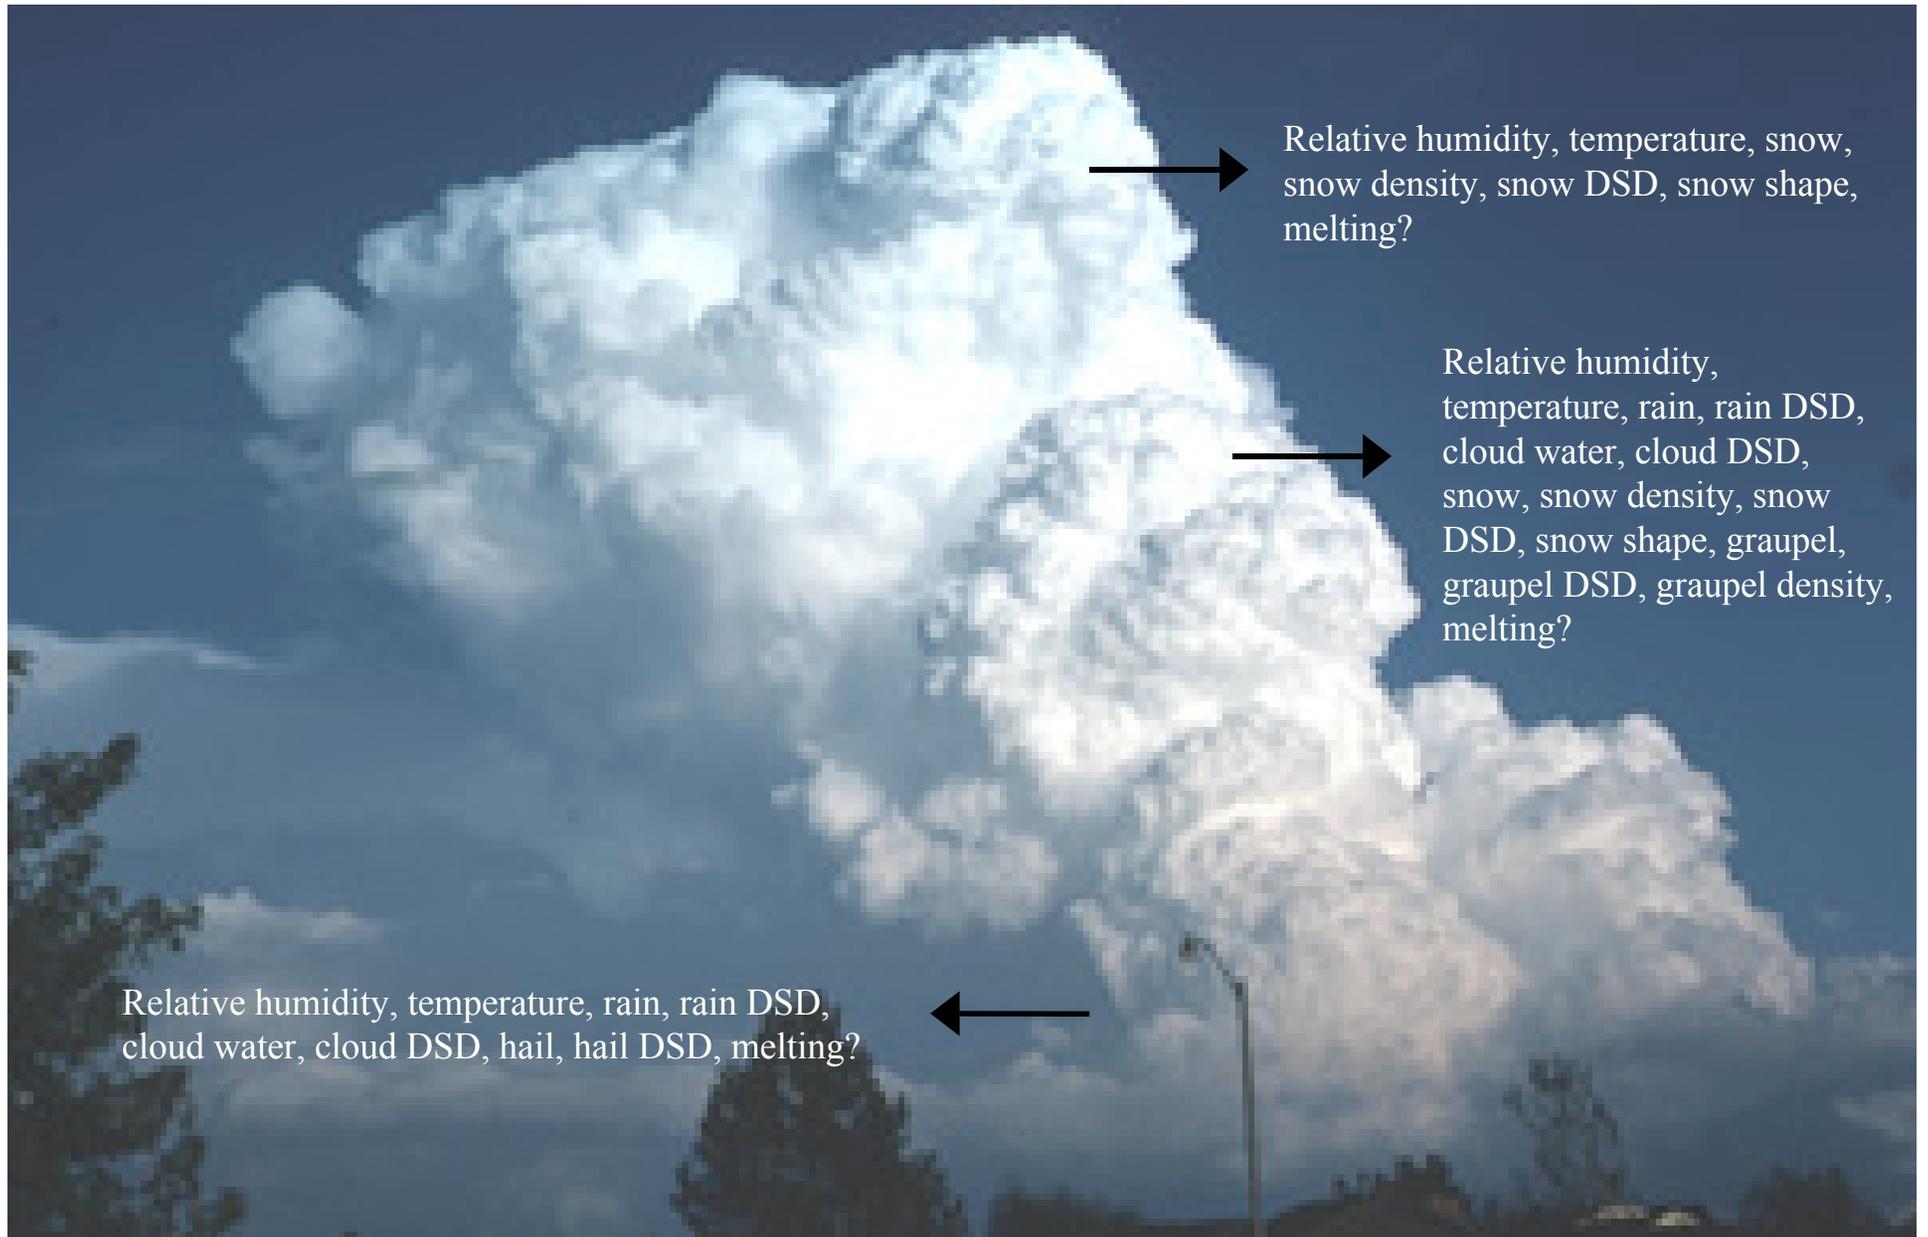

Tropical Rainfall Anomalies

(TRMM Land Retrievals)

Monthly Mean Rainfall (land only)
(Selected Region: 30S-30N, 0-360E)

Real Clouds are Complicated

Relative humidity, temperature, snow, snow density, snow DSD, snow shape, melting?

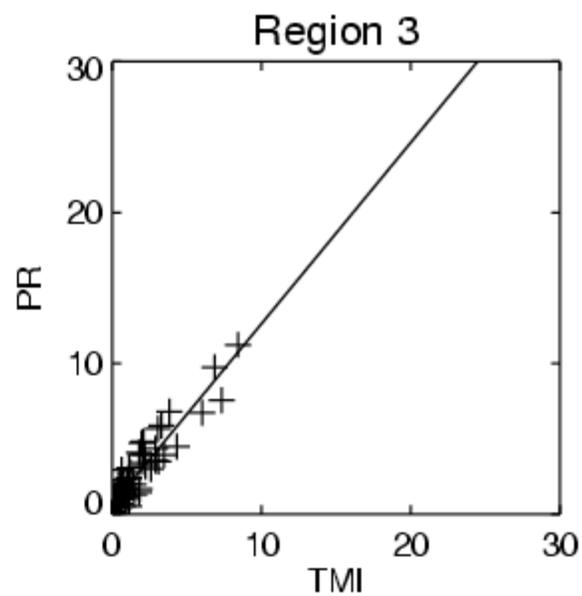

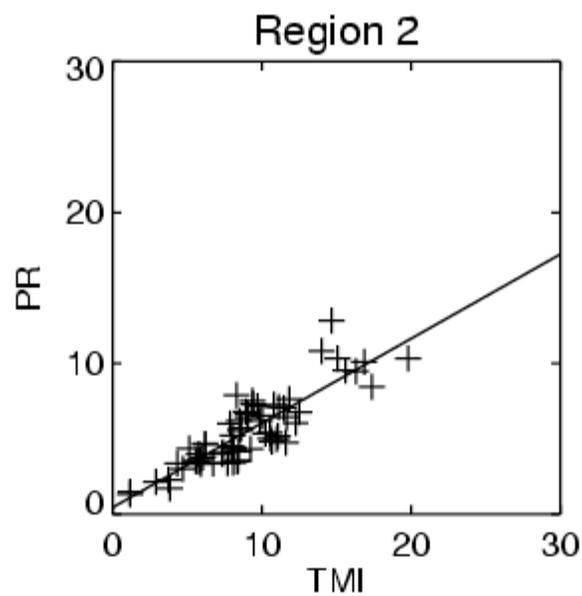

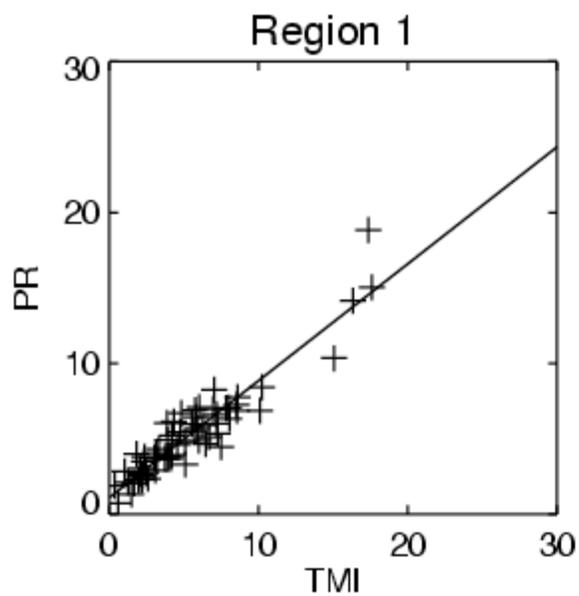

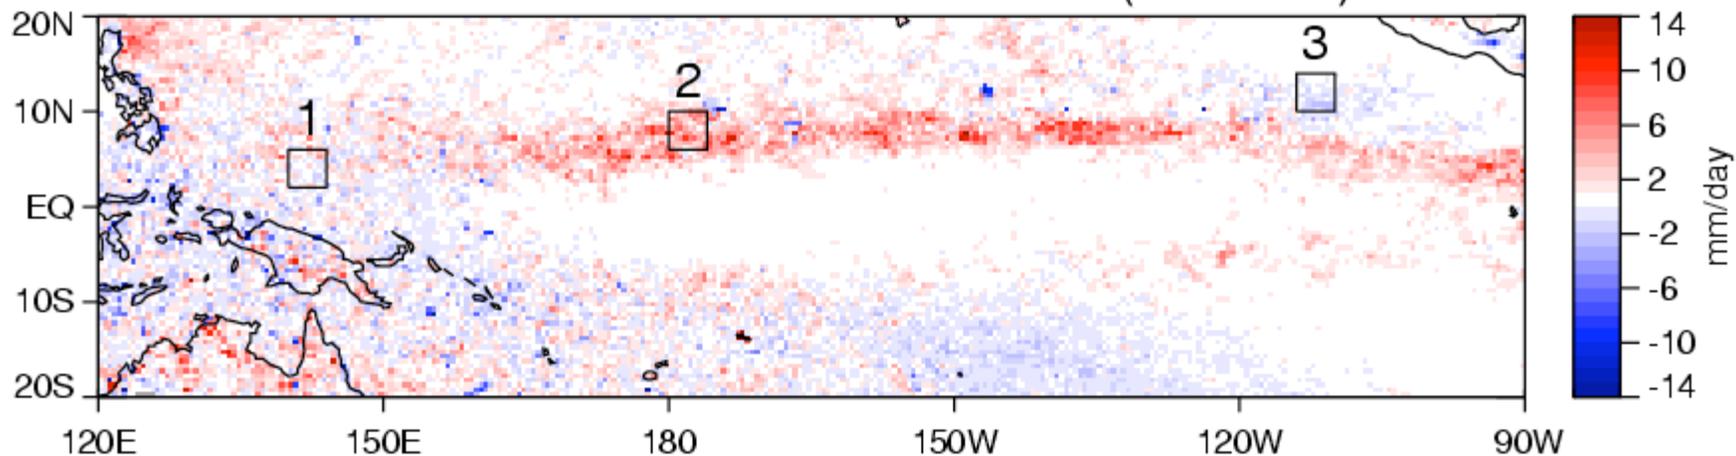

Relative humidity, temperature, rain, rain DSD, cloud water, cloud DSD, snow, snow density, snow DSD, snow shape, graupel, graupel DSD, graupel density, melting?

Relative humidity, temperature, rain, rain DSD, cloud water, cloud DSD, hail, hail DSD, melting?

Rainfall Retrievals

- A cloud resolving model (1.5 km resolution) provides **7840** parameters that affect the upwelling Tb in a typical radiometer FOV (30km).
- Retrievals must make “reasonable” assumptions about some of these parameters, any cross correlations between them, and what sorts of clouds occur in nature. Can use conceptual models or 3-D **C**loud **R**esolving **M**odels. These assumptions can have significant impacts on the retrieved results.
- It has taken the community ~15 years to get these mean assumptions into place such that different sensors (somewhat different assumptions) now agree reasonably well for global scale averages.
- If these mean assumed cloud properties change regionally, or with climate, then the retrievals will differ regionally and over time.
- **Given the significant number of assumptions in the CRMs, one expects them to behave the same way.**

Dec-Jan-Feb 1999/2000 Rainfall Bias (TMI - PR)

The Validation Problem

- Biases at any one site are fairly meaningless because they represent largely random errors when viewed from a global perspective.
- Aggregate statistics (standard error of the mean and confidence intervals) are treated as independent samples from a population which do not consider the behavior of the “system” as a whole. This causes aggregate statistics to overestimate actual uncertainty at the global (or large regional) scales.

Baroque validation activities have occasionally revealed procedural errors but have been unable to quantify uncertainties needed for climate studies.

CRM validation is currently centered around procedural issues only. Are climate change issues properly accounted for ? (e.g upper level humidity changes the rain efficiency in most CRMs - fact or fiction ?)

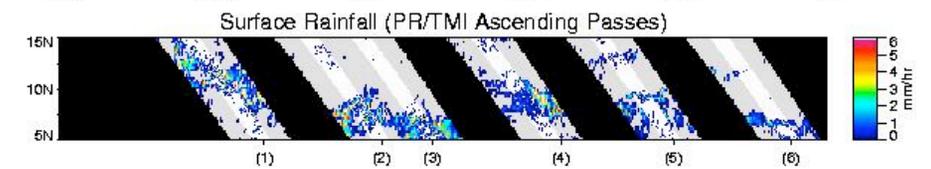

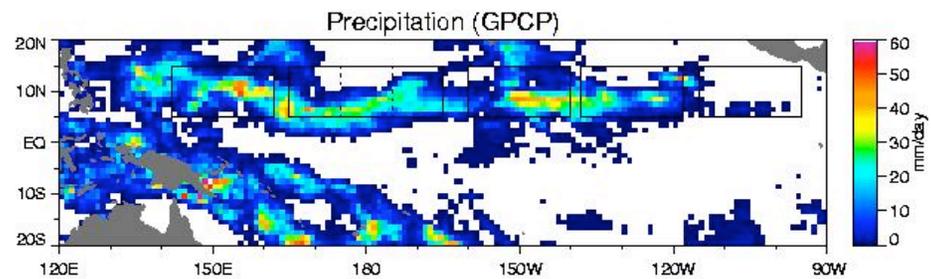

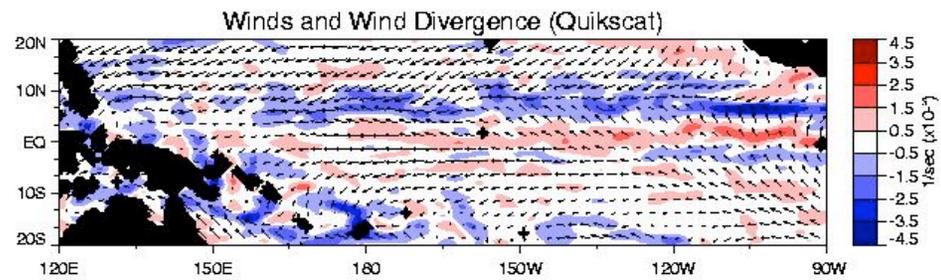

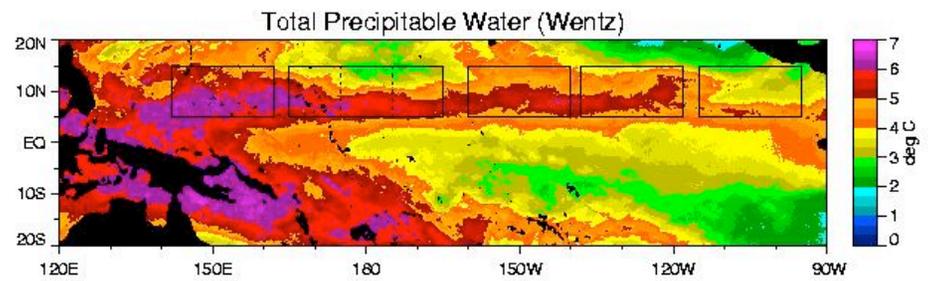

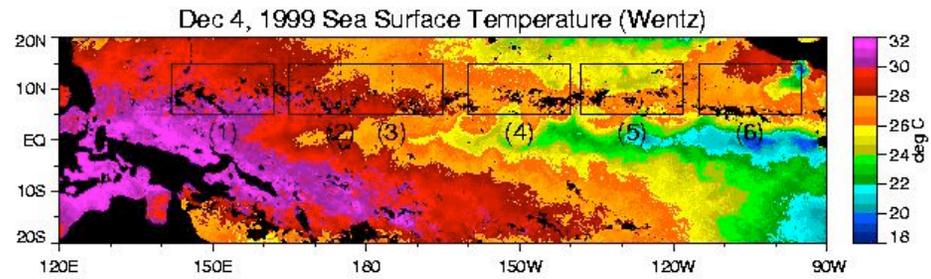

Rainfall Validation by Climate Regime

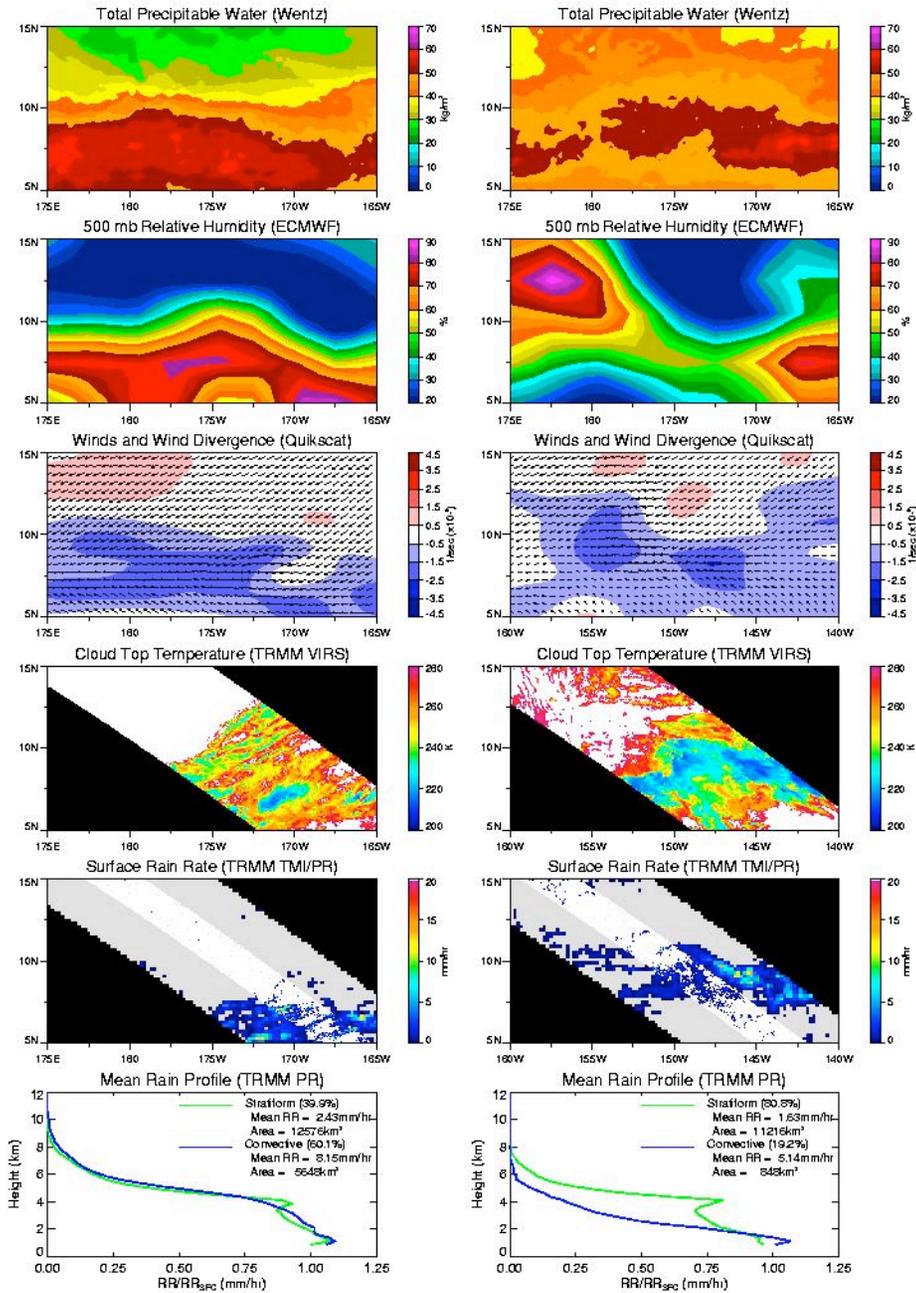

- We have substantial evidence from Field Experiments that cloud structures are consistent within climate regimes
- We have less quantitative but substantial anecdotal evidence that algorithm biases are consistent within climate regimes.

..... but we're not sure how to define these climate regimes.

- By defining climate regimes based upon globally observed atmospheric state parameters, we expect rainfall statistics to show consistent behavior that does not confuse a regional variability with a systematic problem.

..... Quantifying rainfall properties as a function of robust atmospheric state parameters can also lead to the validation of the physical processes of the Cloud Models that do not depend on latitude & longitude.

Conclusions

Rainfall to rainfall comparisons by Lat, Lon & Time got us nowhere in validating global satellite rainfall products.

By changing rainfall validation and Cloud Resolving Model assessments to a more physically based parameter space (the atmospheric state parameters) we can make progress on both fronts

A lot of work remains to find what these optimal atmospheric state parameters are.
