

# **Estimation of subgrid scale processes using a cloud-resolving model**

**T.Nasuno**

**Frontier Research System for Global Change**

**T.Kato**

**The Meteorological Research Institute**

**Workshop on The Future of cloud Parametrization**

**May 7-9, 2003, Princeville, Kauai**

At Frontier Research System for Global Change, we are now developing

## **A new Nonhydrostatic Global Circulation Model**

(Dr. Satoh's talk, on Friday)

aiming a breaking through of the cloud parameterization problem by

### ■ **Resolving Clouds**

- horizontal resolution 1 km (in future)

### ■ **Resolve Mesoscale Convective Systems**

- horizontal resolution 5\_30 km (at present)  
search for proper cloud parameterization

horizontal resolution: 5\_30 km

- Scale-sparation : unclear
- Quasi-equilibrium, Small cloud fraction : not proper
- Problem of **Grid-resolved-condensation**

■ Re-examination of subgrid-scale effects

---- especially, to resolve mesoscale systems ----

using an established nonhydrostatic model.

## the Meteorological Research Institute/Numerical Prediction Division Unified Nonhydrostatic Model (MRI/NPD-NHM)

- Fully compressible
- Ice microphysics; Ikawa et al. (1991)
- Turbulence; Deardorff (1980)
- Surface Flux; Kondo (1975)
- Cloud interactive Radiation; Sugi et al. (1990)

**(Dr. Saito's and Mr.Miura's talks on Wednesday)**

Tropical Squall Line

--- GCSS WG4 Case1

Redelsperger et al.(2000)

TOGA COARE (1993/2/22)

Horizontal Resolution:

1.5, 2.5, 3.75, 5, 7.5 km

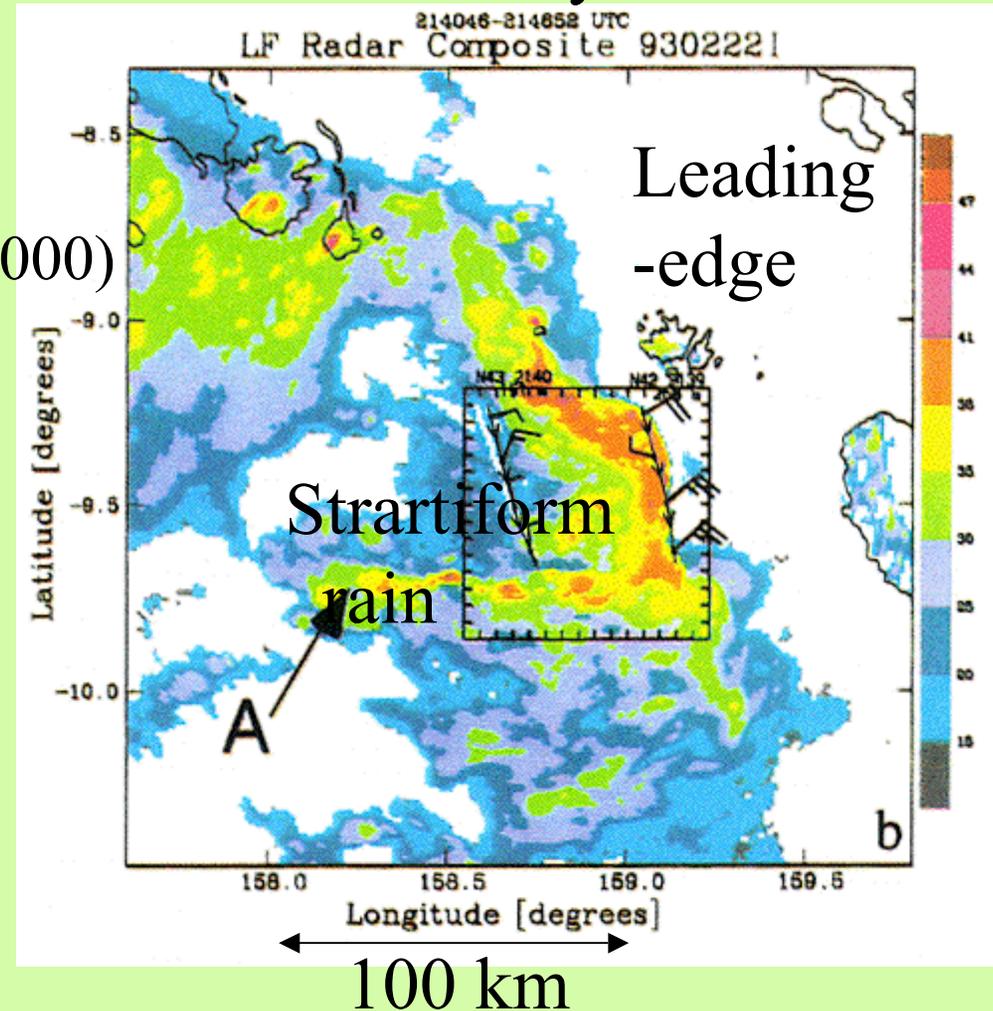

**Comparison of  
Convective Behavior  
to estimate**

**Subgrid-scale Effects**

(Nasuno and Saito, 2003

Submitted to Mon.Wea.Rev.)

fewer clouds

stabilization  
at a local area

over-  
stabilization

## **At a coarse resolution**

### **■ Fewer clouds causes**

- weak cold pool → less organization**
- less heat release**

**→ instability remains in a vast domain**

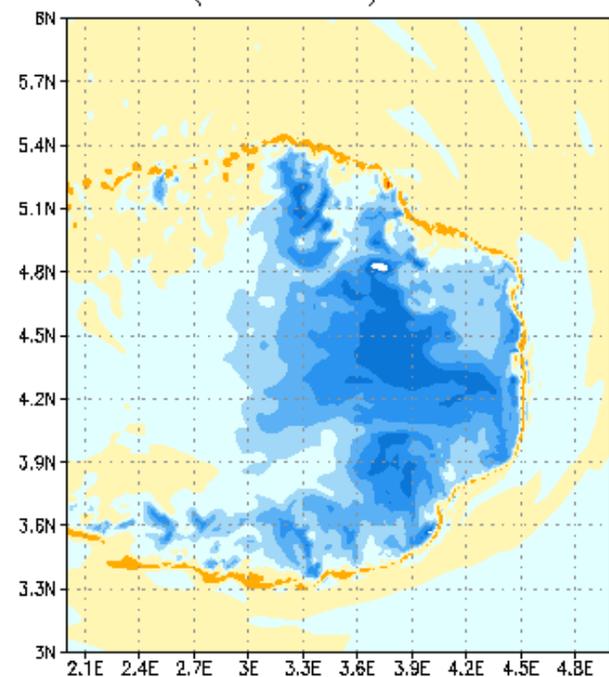

**→ accumulation of moisture in the boundary layer**

**→ when heat release begins, vigorous convection abruptly removes the instability  
(huge mass flux, convective heating)**

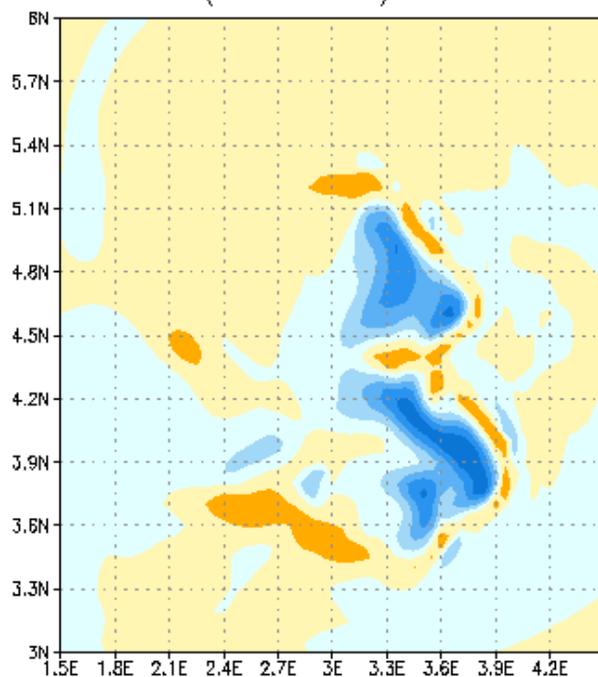

**➤ the range of the variation in stability is larger**

QV-QVB (z=500m) 9h dx=1.5km    QV-QVB (z=500m) 9h dx=5km

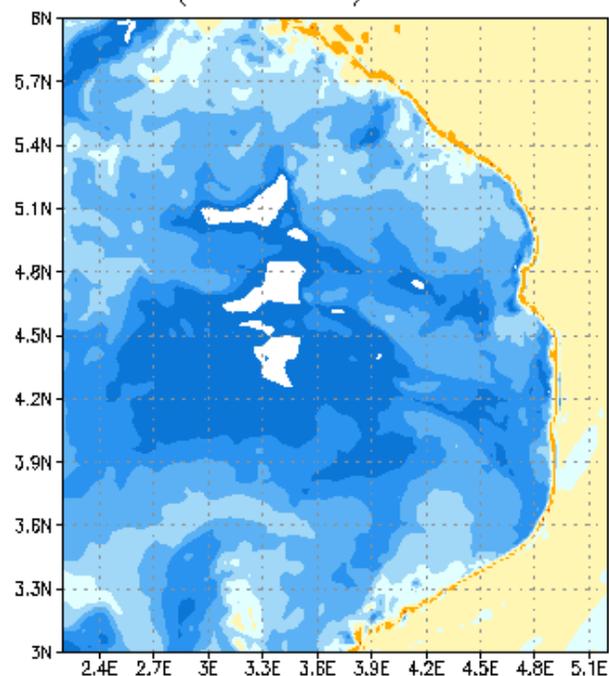

GrADS: COLA/IGES

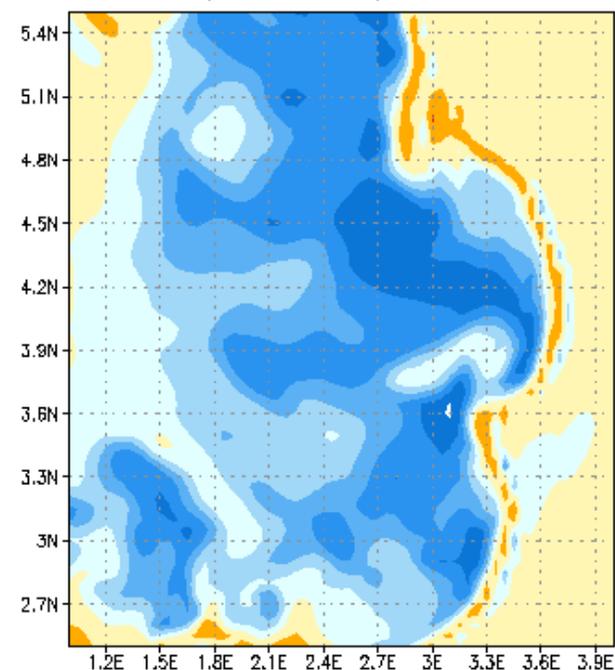

GrADS: COLA/IGES

QV-QVB (z=500m) 18h dx=1.5km QV-QVB (z=500m) 18h dx=5km

GrADS: COLA/IGES

GrADS: COLA/IGES

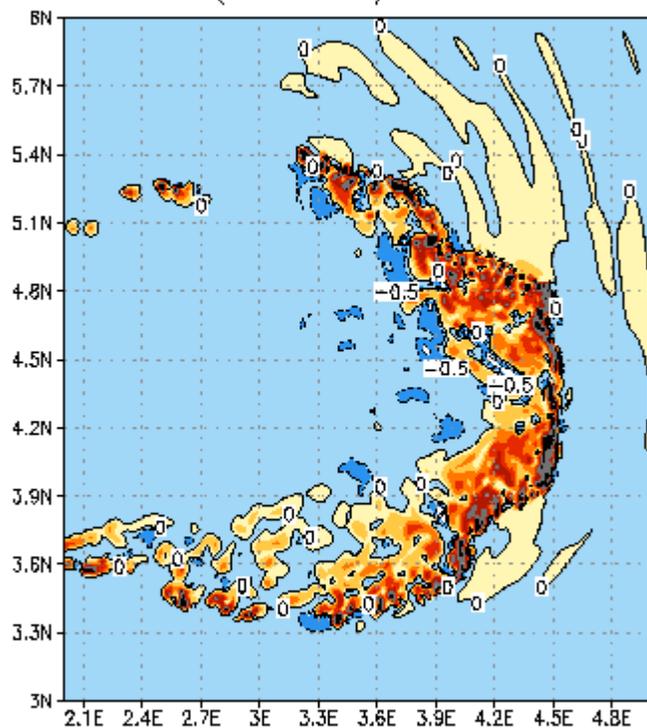

## ■ **Why fewer clouds at a coarse resolution?**

- **No heat release until grid-saturation**
- **Difficulty to get a positive buoyancy (updraft, heating) in the boundary layer to Break CIN**
  - **Adiabatic cooling vs. Convective heating**
- **Inhibition by strong local drying by subsidence**
  
- **Cloud formation processes at a finer resolution (observation)**

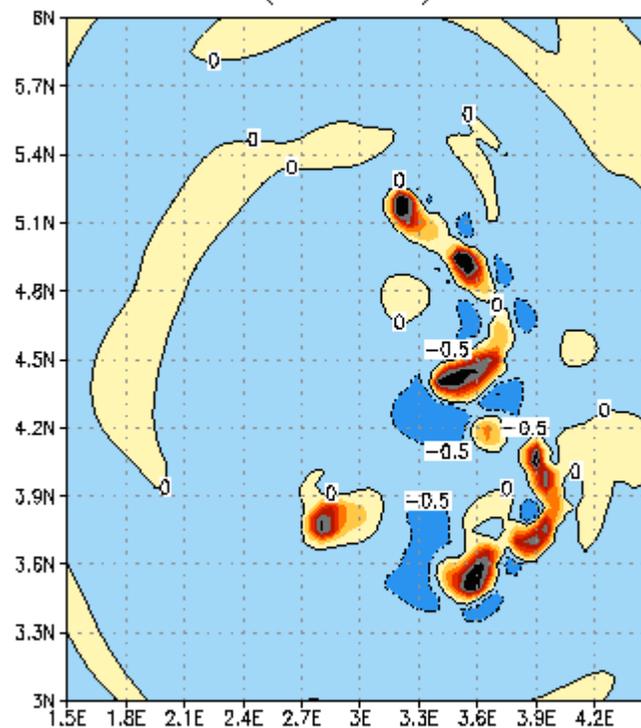

QV-QVB (z=2km) 9h dx=1.5km

GrADS: COLA/IGES

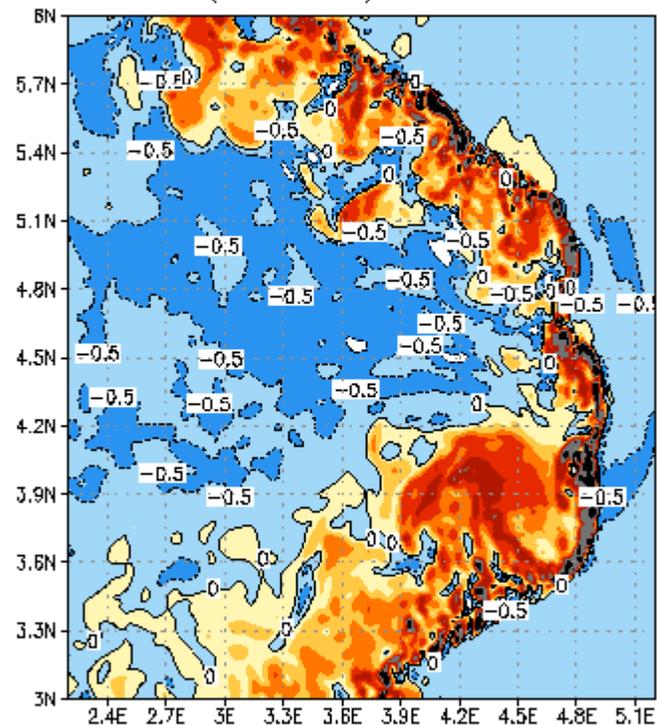

QV-QVB (z=2km) dx=5km

GrADS: COLA/IGES

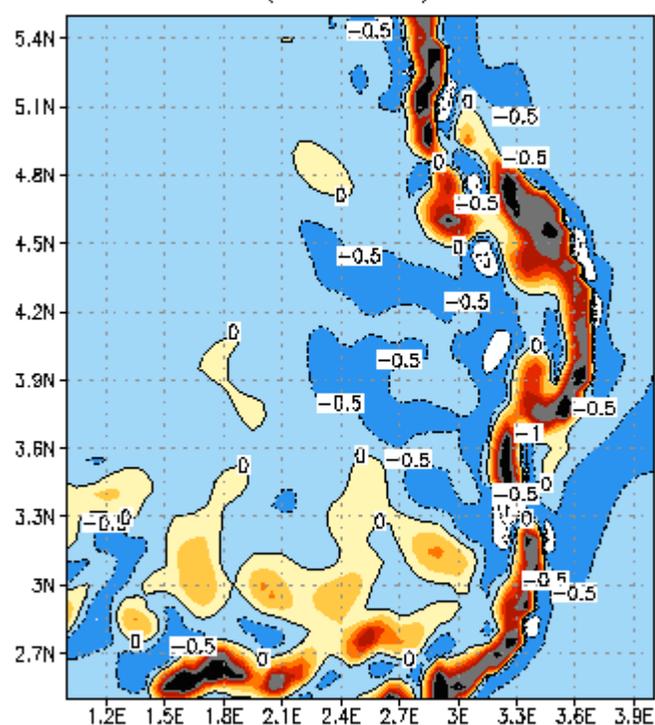

QV-QVB (z=2km) 18h dx=1.5km

GrADS: COLA/IGES

QV-QVB (z=2km) dx=5km

GrADS: COLA/IGES

- **Proper representation of**
  - **subgrid-scale precipitation**
  - **the speed and range of stabilization**
  - **the initiation of convection (Dr.Suzuki's talk)****will surely improve current schemes.**

**cf. Yamasaki (1986, 2001)**

- **prediction of cloud water and rainwater**
- **control heating rate and vertical profile  
as a function of low-level instability**

■ How the current cloud schemes represent the effects of subgrid-scale clouds ?

---- more proper assumption/concepts ?----

■ Kain-Fritsch, Yamasaki, etc. : mesoscale model

■ Arakawa-Schubert, Emanuel, etc.: large-scale model

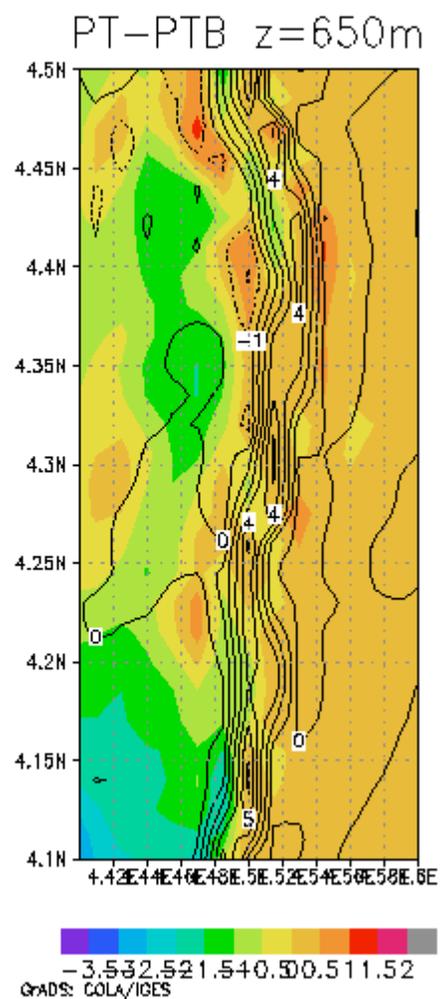

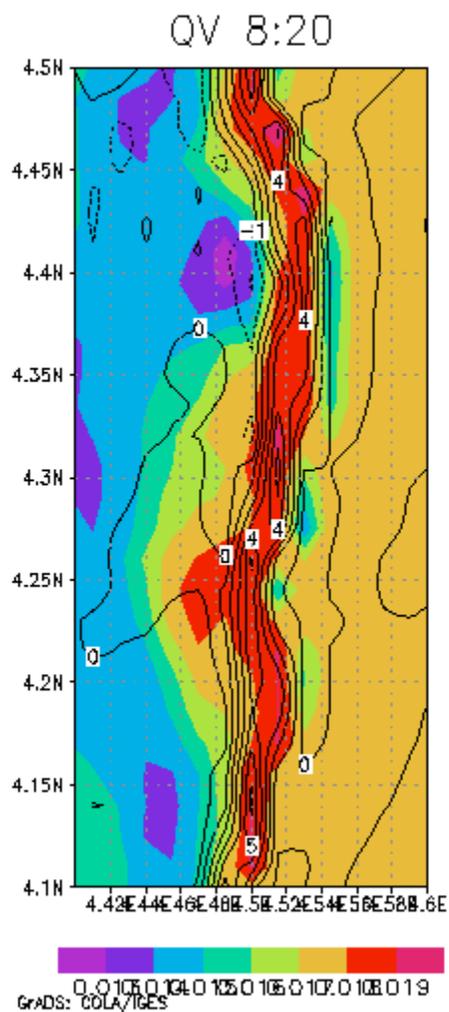

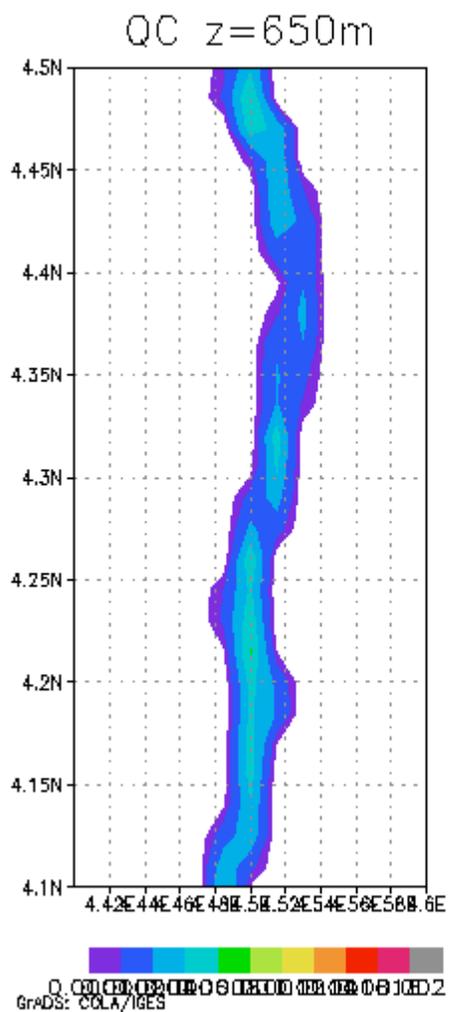

■ Concerns on the use of CRM to this problem

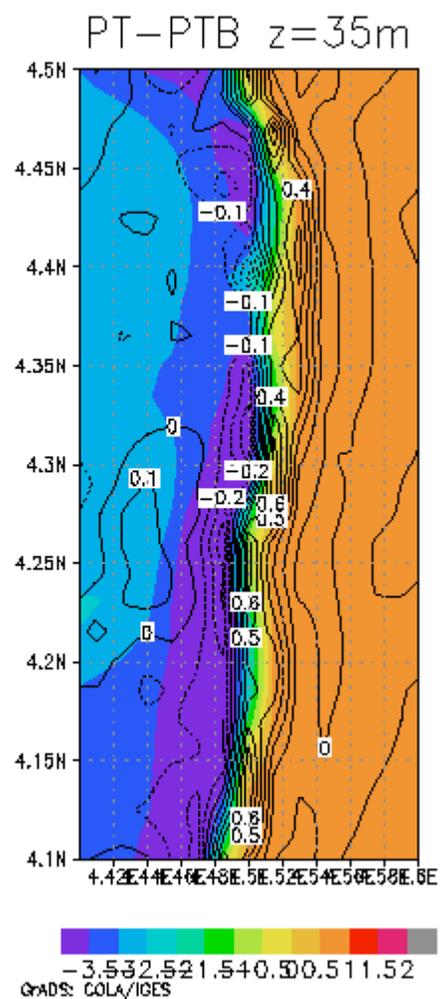

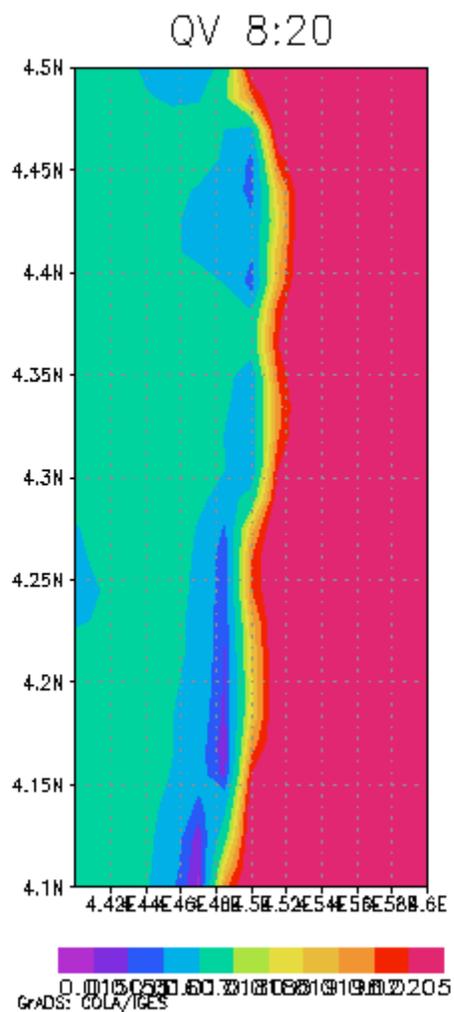

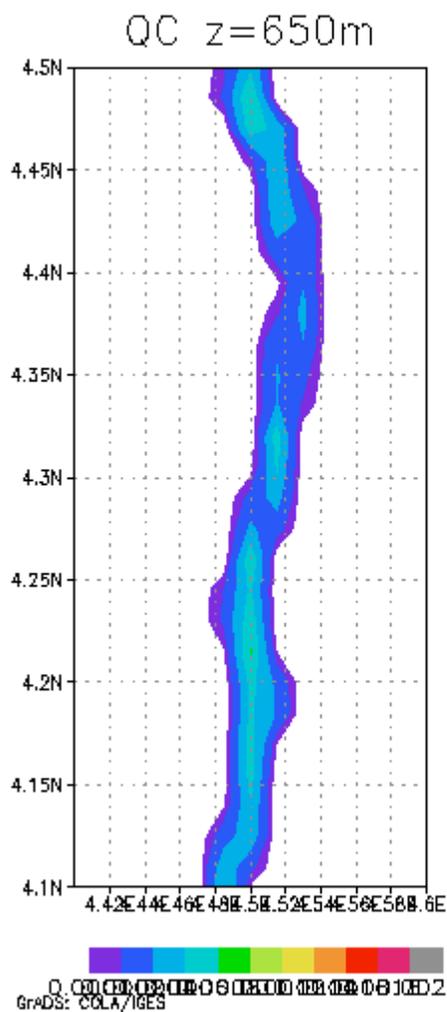

■ Dependence on numerical diffusion

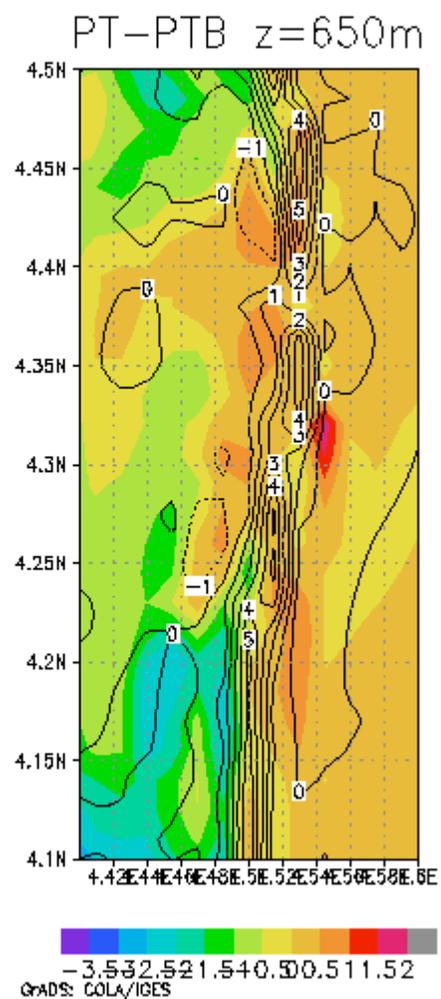

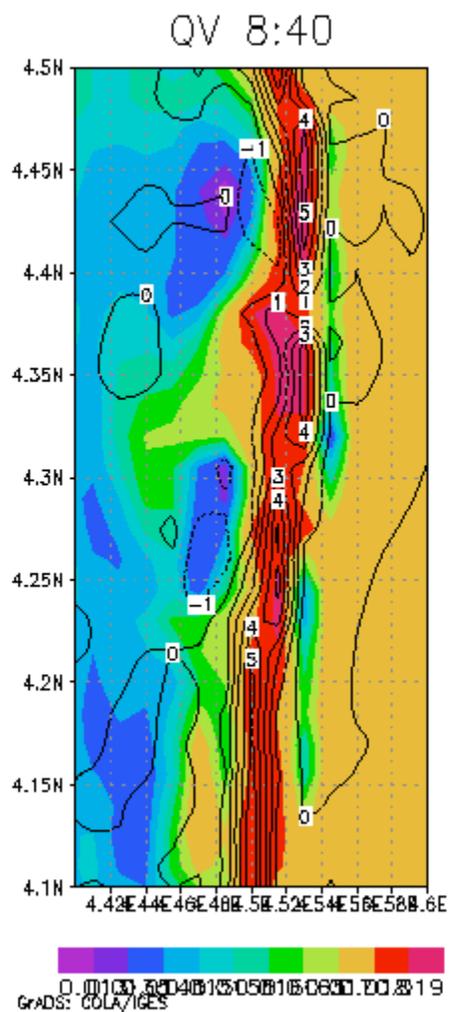

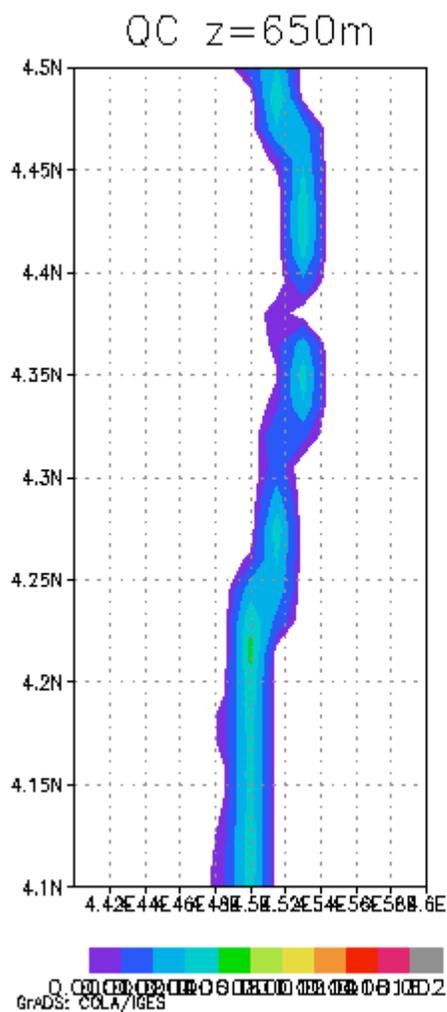

■ Sensitivity to physical schemes

(cloud microphysics, surface fluxes, etc)
